tCG TORSION PAIRS

DANIEL BRAVO AND CARLOS E. PARRA

Abstract. We investigate conditions for when the t-structure of Happel-Reiten-Smalø associated to a torsion pair is a compactly generated t-structure. The concept of a tCG torsion pair is introduced and for any ring R, we prove that t = (T, F) is a tCG torsion pair in R-Mod if, and only if, there exists, {T_λ} a set of finitely presented R-modules in T, such that F = \bigcap \text{Ker}(\text{Hom}_R(T_λ, ?)). We also show that every tCG torsion pair is of finite type, and show that the reciprocal is not true. Finally, we give a precise description of the tCG torsion pairs over Noetherian rings and von Neumann regular rings.

1. INTRODUCTION

The notion of a torsion pair was introduced in the sixties by Dickson (see [Dic66]) in the setting of abelian categories, generalizing the classical notions for abelian groups. Since then, torsion pairs have found many applications in the study of localizations, tilting theory, category theory, etc. Indeed, an important class of examples of torsion pairs in triangulated categories is provided by the concept of t-structure introduced by Beilinson, Bernstein and Deligne [BBD82], in their study of the perverse sheaves over an analytic or algebraic variety stratified by some closed subsets. This notion allows us to associate, to an object of an arbitrary triangulated category, its corresponding “objects of homology”, which belong to some abelian subcategory of such triangulated category. Such subcategory is called the heart of the t-structure.

In the nineties, Happel, Reiten and Smalø observed that there is a natural way to associate a t-structure to the derived category of a given abelian category endowed with a torsion pair (see [HRS96]). The Happel-Reiten-Smalø t-structure is

perhaps the most well known \( t \)-structure for triangulated categories. Nevertheless, other \( t \)-structures, such as the compactly generated \( t \)-structures, have also been well documented in the literature (see [ATJLS10], [ATJLSS03], [PS17]). Some of these compactly generated \( t \)-structures, when certain conditions on the ambient triangulated category are imposed, have an explicit description for the co-aisle (see [ATJLSS03]). For these two types of \( t \)-structures, several authors have investigated conditions for when the heart of such \( t \)-structures is a Grothendieck category or a module category (see [CGM07], [CMT11], [HKM02], [MT12], [PS15], [PS16a], [PS16b], [PS17]).

In particular, [PS17] shows that over a commutative Noetherian ring \( R \), the heart of almost every compactly generated \( t \)-structure in \( D(R) \), the derived category of the ring \( R \), is a Grothendieck category. On the other hand, Theorem 3.7 in [PS15] shows that a countable direct limit of exact sequences in the heart of a compactly generated \( t \)-structure is always exact. Recall that over a Grothendieck category, direct limits of exact sequences are exact.

Hence, given any ring \( R \), the following question seems natural to ask: is the heart of a compactly generated \( t \)-structure in \( D(R) \) an AB5 category? We tackle this question for the \( t \)-structure of Happel-Reiten-Smalø. The main goal of this article is to provide a positive answer to this question, through the concept of \( tCG \) torsion pairs (see Definition 3.1), and to study the relation of torsion pairs of finite type and the \( tCG \) torsion pairs.

The organization of this paper is as follows. In Section 2 we give all the preliminaries and terminology needed in the rest of the paper. Section 3 introduces the reader to the notion of a \( tCG \) torsion pair, and contains the main result of this article, namely Theorem 3.3, which gives a characterization of the \( tCG \) torsion pairs. This characterization result, then allows us to describe the \( tCG \) torsion pairs over Noetherian rings (see Theorem 3.10). For coherent rings, we establish an injective function between the set of the torsion pairs in \( fp(R\Mod) \) and the set of the \( tCG \) torsion pairs (see Theorem 3.12). In Section 4, we study the relation between the \( tCG \) torsion pair and the left constituent pair of a TTF triple in \( R\Mod \). In this direction, we obtain an example of a torsion pair of finite type that is not a \( tCG \) torsion pair. Finally, over a von Neumann regular ring, we show that the only \( tCG \) torsion pairs are left constituent pairs of a TTF-triple.

2. Preliminaries and terminology

The concepts that we shall introduce in this section are applied in the case of module categories, but sometimes we will use them in the more general context of Abelian categories and it is in this context that we define them. Hence in what follows, \( \mathcal{A} \) will denote an AB3 abelian category, that is, \( \mathcal{A} \) is an abelian category with coproducts. Let \( X \) and \( V \) be objects of \( \mathcal{A} \). We say that \( X \) is \( V \)-generated when there is an epimorphism \( V(I) \to X \), for some set \( I \). We will denote by \( \text{Gen}(V) \) the class of \( V \)-generated objects. For a class of objects \( S \) in \( \mathcal{A} \), we will use the following notation \( S^{\perp} := \{ X \in \mathcal{A} : \text{Hom}_{\mathcal{A}}(S, X) = 0, \text{for all } S \in S \} \) and \( ^{\perp} S := \{ X \in \mathcal{A} : \text{Hom}_{\mathcal{A}}(X, S) = 0, \text{for all } S \in S \} \).

A torsion pair in \( \mathcal{A} \) is a pair \( \mathcal{t} = (T, F) \) of full subcategories of \( \mathcal{A} \) satisfying the following two conditions:

1. \( T =^{\perp} F; \)
(2) For each object $X$ of $\mathcal{A}$, there is an exact sequence

$$0 \rightarrow T_X \rightarrow X \rightarrow F_X \rightarrow 0$$

where $T_X \in \mathcal{T}$ and $F_X \in \mathcal{F}$. The objects $T_X$ and $F_X$ in the previous exact sequence are uniquely determined, up to isomorphism, and the assignment $X \mapsto T_X$ (resp. $X \mapsto F_X$) underlies a functor $t : \mathcal{A} \rightarrow \mathcal{T}$ (resp. $(1 : t) : \mathcal{A} \rightarrow \mathcal{F}$), which is right (resp. left) adjoint to the inclusion functor $\mathcal{T} \hookrightarrow \mathcal{A}$ (resp. $\mathcal{F} \hookrightarrow \mathcal{A}$).

The composition $\mathcal{A} \xrightarrow{t} \mathcal{T} \hookrightarrow \mathcal{A}$ (resp. $\mathcal{A} \xrightarrow{(1 : t)} \mathcal{F} \hookrightarrow \mathcal{A}$), which we will still denote by $t$ (resp. $(1 : t)$), is called the torsion radical (resp. torsion coradical) associated to $t$. The torsion pair $t = (\mathcal{T}, \mathcal{F})$ is called hereditary when $\mathcal{T}$ is closed under taking subobjects in $\mathcal{A}$.

In the case of $R$-Mod, where $R$ is a unital associative ring, we are interested in investigating a particular case of hereditary torsion pairs, namely the TTF-triples. A TTF-triple is a triple of classes $(\mathcal{C}, \mathcal{T}, \mathcal{F})$ in $R$-Mod such that $(\mathcal{C}, \mathcal{T})$ and $(\mathcal{T}, \mathcal{F})$ are torsion pairs. In this case [Ste75, Proposition VI.6.12] characterizes the TTF-triples in terms of two-sided idempotent ideal of $R$. More precisely, $(\mathcal{C}, \mathcal{T}, \mathcal{F})$ is a TTF-triple if and only if there exists an $a$, a two-sided idempotent ideal of $R$, such that $\mathcal{C} = \text{Gen}(a) = \{\mathcal{C} \in R$-Mod : $a \mathcal{C} = \mathcal{C}\}$, $\mathcal{T} = \{\mathcal{T} \in R$-Mod : $a \mathcal{T} = 0\}$ and $\mathcal{F} = \text{Ker}(\text{Hom}_R(R/a, ?))$. In reference to the ideal $a$, we will denote such TTF-triple as $(\mathcal{C}_a, \mathcal{T}_a, \mathcal{F}_a)$.

In the sequel, we let $(\mathcal{D}, ?[1])$ be a triangulated category, and denote the triangles in $\mathcal{D}$ by $X \xrightarrow{f} Y \xrightarrow{g} Z \xleftarrow{h}$. An additive functor $H : \mathcal{D} \rightarrow \mathcal{A}$, where $\mathcal{A}$ is an abelian category, is called cohomological, if for any triangle $X \xrightarrow{f} Y \xrightarrow{g} Z \xleftarrow{h}$ in $\mathcal{D}$, we get the following long exact sequence in $\mathcal{A}$:

$$\cdots \rightarrow H^{n-1}(Z) \rightarrow H^n(X) \rightarrow H^n(Y) \rightarrow H^n(Z) \rightarrow \cdots,$$

where $H^n(?) := H \circ (?[n])$, for each integer $n$. A pair $(\mathcal{U}, \mathcal{V})$ of full subcategories in $\mathcal{D}$, is called a $t$-structure, when both class are closed under direct summands, and satisfies the following assertions:

1. $\text{Hom}_\mathcal{D}(U, V[-1]) = 0$, for all $U \in \mathcal{U}$ and for all $V \in \mathcal{V}$.
2. $U[1] \subseteq \mathcal{U}$.
3. For each $X \in \text{Ob}(\mathcal{D})$, there is a triangle $U_X \xrightarrow{f} X \xrightarrow{g} V_X \xleftarrow{h}$ in $\mathcal{D}$, where $U_X \in \mathcal{U}$ and $V_X \in \mathcal{V}[-1]$.

In this case, $\mathcal{U}$ is called the aisle of the $t$-structure, and $\mathcal{V}$ is called the co-aisle of the $t$-structure. Moreover, $\mathcal{V} = \mathcal{U}^\perp[1]$ and $\mathcal{U} = \mathcal{V}[-1] = \mathcal{U}^\perp[1]$, hence we will denoted such $t$-structure by $(\mathcal{U}, \mathcal{U}^\perp[1])$.

If $(\mathcal{U}, \mathcal{U}^\perp[1])$ is a $t$-structure in $\mathcal{D}$, then the full subcategory $\mathcal{H} = \mathcal{U} \cap \mathcal{V} = \mathcal{U} \cap \mathcal{U}^\perp[1]$ is an abelian category, called the heart of the $t$-structure and there is a cohomological functor $H^0_{\mathcal{U}} : \mathcal{D} \rightarrow \mathcal{H}$ (see [BBD82]). If $\mathcal{D} = \mathcal{D}(R)$ and $\mathcal{S}$ is a set of objects in $\mathcal{D}$, the smallest full subcategory of $\mathcal{D}$, containing $\mathcal{S}$, closed under coproducts, extensions and positive shifts is the aisle of a $t$-structure (cf. [ATJLSS03, Proposition 3.2]). In that case, if $(\mathcal{U}, \mathcal{U}^\perp[1])$ denotes such $t$-structure, then $\mathcal{U}^\perp$ consists of the $Y \in \mathcal{D}$ such that $\text{Hom}_\mathcal{D}(\mathcal{S}[n], Y) = 0$, for all $\mathcal{S} \in \mathcal{S}$ and for all integers $n \geq 0$. In this case, we will write that $\mathcal{U} = \text{aisle}(\mathcal{S})$, moreover, the $t$-structure $(\text{aisle}(\mathcal{S}), \text{aisle}(\mathcal{S})^\perp[1])$ is called compactly generated if $\mathcal{S}$ consist of compact objects (i.e. for each $\mathcal{S} \in \mathcal{S}$ the functor $\text{Hom}_\mathcal{D}(\mathcal{S}, ?)$ commutes with coproducts) and we say that $\mathcal{S}$ is a set of compact generators of the aisle. Recall
that the compact objects of $D(R)$ are the complexes which are quasi-isomorphic to bounded complexes of finitely generated projective modules (see [Ric89]).

For the rest of this section, we assume that $R$ is a commutative Noetherian ring and we denote by $\text{Spec}(R)$ its spectrum. A subset $Z$ of $\text{Spec}(R)$ is stable under specialization if, for any pair of prime ideals $p \subseteq q$, with $p \in Z$, it holds that $q \in Z$. Equivalently, $Z$ is a union of closed subsets of $\text{Spec}(R)$, with respect to the Zariski topology of $\text{Spec}(R)$. Such a subset will be called sp-subset in the sequel. The typical example is the support of an $R$-module $N$, denoted by $\text{Supp}(N)$, which consists of the prime ideals $p$ such that $N_p := R_p \otimes_R N \neq 0$. We have the following description for hereditary torsion pairs in $R$-Mod.

**Proposition 2.1.** [Ste75, Chapter VI §5.6] The assignment $Z \mapsto (T_Z, T_Z^\perp)$ defines a bijection between the sp-subsets of $\text{Spec}(R)$ and the hereditary torsion pairs in $R$-Mod, where $T_Z$ is the class of the $R$-modules $T$ such that $\text{Supp}(T) \subseteq Z$. Its inverse takes $(T, T^\perp)$ to the set $Z_T$ of prime ideals $p$ such that $R/p \in T$.

A filtration by supports of $\text{Spec}(R)$ is a decreasing map $\phi: Z \to \mathcal{P}(\text{Spec}(R))$, such that $\phi(i)$ is an sp-subset for each $i \in Z$; here $\mathcal{P}(\text{Spec}(R))$ is the power set of $\text{Spec}(R)$. We will refer to a filtration by supports of $\text{Spec}(R)$ simply by an sp-filtration of $\text{Spec}(R)$. In [ATLS10], Alonso, Jeremías and Saorín associated to each sp-filtration $\phi: Z \to \mathcal{P}(\text{Spec}(R))$, the $t$-structure $(\mathcal{U}_\phi, \mathcal{U}_\phi^+ [1])$ in $D(R)$, where $\mathcal{U}_\phi := \text{aisle}(\{R/p[-i] : i \in Z \text{ and } p \in \phi(i)\})$.

3. $t$CG TORSION PAIRS

Throughout this section, $R$-Mod is the category of left $R$-modules and $t = (T, \mathcal{F})$ is a torsion pair in $R$-Mod. The $t$-structure of Happel-Reiten-Smalø in $D(R)$ associated to the torsion pair $t$, is given by $(\mathcal{U}_t, \mathcal{U}_t^+ [1]) := (\mathcal{U}_t, \mathcal{W}_t)$, where:

$$\mathcal{U}_t = \{ X \in D^{\leq 0}(R) : H^0(X) \in T \} \quad \text{and} \quad \mathcal{W}_t = \{ X \in D^{\geq -1}(R) : H^{-1}(X) \in \mathcal{F} \}.$$  

The heart $\mathcal{H}_t$ of this $t$-structure consists of the complexes $M \in D^{[-1,0]}(R)$ such that $H^{-1}(M) \in \mathcal{F}$ and $H^0(M) \in T$.

**Definition 3.1.** Let $t = (T, \mathcal{F})$ be a torsion pair in $R$-Mod. We say that $t$ is a $t$CG torsion pair when $(\mathcal{U}_t, \mathcal{U}_t^+ [1])$ is a compactly generated $t$-structure.

**Example 3.2.** Let $R$ be a commutative Noetherian ring. In $R$-Mod, the $t$CG torsion pairs coincide with the hereditary torsion pairs. Indeed, if $t = (T, \mathcal{F})$ is a hereditary torsion pair, then Proposition 2.1 says that there exists $Z$ an sp-subset of $\text{Spec}(R)$ such that $t = (T, \mathcal{F}) = (T_Z, T_Z^\perp)$. Now, we define an sp-filtration as follows:

$$\phi(n) = \begin{cases} 
\emptyset & \text{if } n > 0 \\
Z & \text{if } n = 0 \\
\text{Spec}(R) & \text{if } n < 0.
\end{cases}$$

By [ATLS10, Theorem 3.11], we obtain that $\mathcal{U}_\phi = \{ X \in D(R) : \text{Supp}(H^j(X)) \subseteq \phi(j) \}$, for all $j \in \mathbb{Z}\} = \mathcal{U}_t$. Now using [ATLS10, Theorem 3.10], we get that $(\mathcal{U}_\phi, \mathcal{U}_\phi^+ [1]) = (\mathcal{U}_t, \mathcal{U}_t^+ [1])$ is a compactly generated $t$-structure.

On the other hand, let $t = (T, \mathcal{F})$ be a $t$CG torsion pair. By [ATLS10, Theorem 3.10], there exists an sp-filtration $\phi: Z \to \mathcal{P}(\text{Spec}(R))$, such that $\mathcal{U}_t = \mathcal{U}_\phi$. From the description of $\mathcal{U}_\phi$, we see that $\phi(k) = \emptyset$, for all integers $k > 0$ and $\phi(k) = \text{Spec}(R)$, for all integers $k \leq -1$. Moreover, $T = T_0$, where $(T_0, \mathcal{F}_0)$ is the hereditary torsion pair associated to the sp-subset $\phi(0)$.
The following result characterizes the tCG torsion pairs in terms of the torsion pair in $R$-$\text{Mod}$. We will use the following notation: for each $M \in R$-$\text{Mod}$, we denote by $M[0]$ the complex concentrated in degree 0 with $M$, and zero everywhere else.

**Theorem 3.3.** Let $t = (T, F)$ be a torsion pair in $R$-$\text{Mod}$. Then, $t$ is a tCG torsion pair, if and only if, there exists a set $\{T_\lambda\}_{\lambda \in \Lambda}$ of finitely presented $R$-modules in $T$, such that $F = \bigcap_{\lambda \in \Lambda} \text{Ker}(\text{Hom}_R(T_\lambda, ?))$.

**Proof.** Let $S = \{S_\lambda\}_{\lambda \in \Lambda}$ be a set of compact generators of the aisle $U_t = \{X \in D^{\leq 0}(R) : H^0(X) \in T\}$. Without loss of generality, we can assume that each $S_\lambda$ is of the form:

$$S_\lambda := \cdots \to 0 \to P^{m_\lambda}_0 \xrightarrow{d^{m_\lambda}_0} \cdots \to P^{m_\lambda}_1 \xrightarrow{d^{m_\lambda}_1} \cdots \to P^{m_\lambda}_{-1} \xrightarrow{d^{m_\lambda}_{-1}} P^{m_\lambda}_0 \to 0 \to \cdots,$$

where each $P^{k}_\lambda$ is a finitely generated projective $R$-module (see [Ric89]). Since each $S_\lambda$ is in $D^{\leq 0}(R)$, we obtain that for $m_\lambda \geq 2$, the following exact sequence is split:

$$0 \to \text{Ker}(d^{m_\lambda-1}_\lambda) = \text{Im}(d^{m_\lambda-2}_\lambda) \to P^{m_\lambda-1}_\lambda \to \text{Im}(d^{m_\lambda-1}_\lambda) = P^{m_\lambda}_\lambda \to 0.$$

Thus $\text{Im}(d^{m_\lambda-2}_\lambda)$ is a finitely generated projective $R$-module. Using this argument in a recursive way, we obtain that $\text{Im}(d^{0}_\lambda)$ is also a finitely generated projective $R$-module and thus, so is $\text{Ker}(d^{0}_\lambda)$. Next, since $\text{Im}(d^{-1}_\lambda)$ is a finitely generated $R$-module, the following exact sequence shows that $H^0(S_\lambda)$ is a finitely presented $R$-module:

$$0 \to \text{Im}(d^{-1}_\lambda) \to \text{Ker}(d^{0}_\lambda) \to H^0(S_\lambda) \to 0.$$

We now check that $F = \bigcap_{\lambda \in \Lambda} \text{Ker}(\text{Hom}_R(H^0(S_\lambda), ?))$. Indeed, if we fix an $R$-module $M$ in $\bigcap_{\lambda \in \Lambda} \text{Ker}(\text{Hom}_R(H^0(S_\lambda), ?))$, then it is clear that $t(M)$ also is in $\bigcap_{\lambda \in \Lambda} \text{Ker}(\text{Hom}_R(H^0(S_\lambda), ?))$. Therefore:

$$0 = \text{Hom}_R(H^0(S_\lambda), t(M))
= \text{Hom}_{D(R)}(H^0(S_\lambda)[0], t(M)[0])
\cong \text{Hom}_{D(R)}(S_\lambda, t(M)[0]),$$

where the last isomorphism follows by applying the contravariant cohomological functor $\text{Hom}_{D(R)}(?, t(M)[0])$ to the canonical triangle obtained from the $t$-structure $(D^{\leq 1}(R), D^{\geq 1}(R))$:

$$\tau^{\leq -1}(S_\lambda) \to S_\lambda \to H^0(S_\lambda)[0] \xrightarrow{\pm}.$$

It follows that $\text{Hom}_{D(R)}(S_\lambda[n], t(M)[0]) = 0$ for all $S_\lambda \in S$ and integers $n \geq 0$. This implies that $t(M)[0] \in U_t \cap U_t^\perp = \{0\}$ and therefore $M \in F$.

Conversely, for each $\lambda$, we will denoted by, $S_\lambda$, the complex:

$$S_\lambda := \cdots \to 0 \to R(m_\lambda) \xrightarrow{d_\lambda} R(m_\lambda) \to 0 \to \cdots,$$

where $m_\lambda, n_\lambda$ are positive integers, $R(m_\lambda)$ is in degree 0, and $K_\lambda$ is the finitely generated $R$-module given by the kernel of the epimorphism $R(m_\lambda) \to T_\lambda$. Note that $S_0 := \{S_\lambda\} \cup \{R[1]\}$ is a set of compact complexes in $U_t$, and therefore aisle($S_0$) $\subseteq U_t$. On the other hand, let $X$ be a complex in aisle($S_0$)$^\perp$. Then we obtain that:

$$0 = \text{Hom}_{D(R)}((R[1])[n], X) = \text{Hom}_{D(R)}(R, X[-1 - n]) = H^{1 - n}(X),$$

where $H^{1 - n}(X)$ is the complex concentrated in degree 0 with $X$, and zero everywhere else.

Therefore, for each $\lambda$, $S_\lambda$ is a $t$-complex in $T$, and therefore $S_\lambda$ is a set of compact generators of the aisle $U_t$. 

Therefore, we have shown that $t$ is a tCG torsion pair if and only if there exists a set of finitely presented $R$-modules $\{T_\lambda\}_{\lambda \in \Lambda}$ in $T$ such that $F = \bigcap_{\lambda \in \Lambda} \text{Ker}(\text{Hom}_R(T_\lambda, ?))$. This completes the proof.
for all integers \( n \geq 0 \), showing that \( X \in \mathcal{D}^{2n}(R) \).

Now, applying the cohomological functor \( \text{Hom}_{\mathcal{D}(R)}(S_\lambda, ?) \) to the triangle

\[
H^0(\mathcal{X})[0] \to X \to \tau^{-0}(X) \xrightarrow{\perp},
\]
gives that \( \text{Hom}_{\mathcal{D}(R)}(S_\lambda, X) \cong \text{Hom}_{\mathcal{D}(R)}(S_\lambda, H^0(\mathcal{X})[0]) \). But,

\[
0 = \text{Hom}_{\mathcal{D}(R)}(S_\lambda, X) \\
\cong \text{Hom}_{\mathcal{D}(R)}(S_\lambda, H^0(\mathcal{X})[0]) \\
\cong \text{Hom}_{\mathcal{D}(R)}(H^0(S_\lambda)[0], H^0(\mathcal{X})[0]) \\
= \text{Hom}_R(T_\lambda, H^0(\mathcal{X})).
\]

Since \( \mathcal{F} = \bigcap_{\lambda \in \Lambda} \text{Ker}(\text{Hom}_R(T_\lambda, ?)) \), it follows that \( H^0(\mathcal{X}) \in \mathcal{F} \). Therefore, aisle\( (S_0)^\perp \subseteq \mathcal{U}_t^\perp \), and since \( \mathcal{U}_t^\perp \subseteq \text{aisle}(S_0)^\perp \), then we obtain that \( (\mathcal{U}_t, \mathcal{U}_t^\perp[1]) = (\text{aisle}(S_0), \text{aisle}(S_0)^\perp[1]) \) is a compactly generated \( t \)-structure. \( \square \)

**Remark 3.4.** Using the fact that the isomorphism classes of finitely presented modules form a set, along with Theorem 3.3, we get that the collection of the \( \text{tCG} \) torsion pairs actually form a set, that we denote by \( \text{tCG}(R) \).

The simplest version of Theorem 3.3 is when the set \( \{ T_\lambda \}_{\lambda \in \Lambda} \) is a singleton. In such case \( \mathcal{F} = \text{Ker}(\text{Hom}_R(T_\lambda, ?)) \). One way to obtain this condition over \( \mathcal{F} \) is when \( \mathcal{T} = \text{Gen}(T_\lambda) \), for some finitely presented \( T_\lambda \); for example if \( \mathcal{H}_t \) is a module category (see [PS16b, Lemma 3.2]).

**Corollary 3.5.** Let \( R \) be a ring. Then, every torsion pair \( \mathbf{t} = (\mathcal{T}, \mathcal{F}) \) in \( R\text{-Mod} \) such that \( \mathcal{T} = \text{Gen}(V) \), for some finitely presented \( R\)-module \( V \), is a \( \text{tCG} \) torsion pair.

However, the reciprocal of the previous result is not true; see Remark 3.13.

**Corollary 3.6.** Let \( R \) be a ring and \( \mathbf{t} = (\mathcal{T}, \mathcal{F}) \) be a torsion pair in \( R\text{-Mod} \). If \( \mathbf{t} \) is a \( \text{tCG} \) torsion pair, then \( \mathcal{H}_t \) is a Grothendieck category.

**Proof.** Note that \( \mathcal{F} \) is closed under direct limits if \( \mathbf{t} \) is a \( \text{tCG} \) torsion pair. The result now follows from [PS16a, Theorem 1.2]. \( \square \)

**Definition 3.7.** A torsion pair \( \mathbf{t} = (\mathcal{T}, \mathcal{F}) \) in \( \text{R-Mod} \) is said to be of finite type, if \( \mathcal{F} = \text{lim} \mathcal{F} \).

**Corollary 3.8.** Let \( R \) be a ring and let \( \mathbf{t} = (\mathcal{T}, \mathcal{F}) \) be a hereditary torsion pair in \( \text{R-Mod} \). Then, \( \mathbf{t} \) is a \( \text{tCG} \) torsion pair if, and only if, \( \mathbf{t} \) is of finite type.

**Proof.** Suppose that \( \mathbf{t} \) is of finite type. From [Hrb16, Lemma 2.4] and its proof, there exists \( \{ T_\lambda \}_{\lambda \in \Lambda} \), a set of finitely presented \( R \)-modules in \( \mathcal{T} \), such that \( \mathcal{F} = \{ T_\lambda : \lambda \in \Lambda \}^\perp \). The result now follows from Theorem 3.3. \( \square \)

The following corollary, relaxes the condition in Theorem 3.3 when the torsion pair is of finite type.

**Corollary 3.9.** Let \( \mathbf{t} = (\mathcal{T}, \mathcal{F}) \) be a torsion pair in \( \text{R-Mod} \) of finite type. The following assertions are equivalent.

1. \( \mathbf{t} \) is a \( \text{tCG} \) torsion pair.
2. There exists a set \( \{ T_\lambda \}_{\lambda \in \Lambda} \) of finitely presented \( R \)-modules in \( \mathcal{T} \), such that \( \mathcal{F} = \bigcap_{\lambda \in \Lambda} \text{Ker}(\text{Hom}_R(T_\lambda, ?)) \).
(3) There exists a set \( \{ T_\lambda \}_{\lambda \in \Lambda} \) of finitely generated \( R \)-modules in \( \mathcal{T} \), such that \( \mathcal{F} = \bigcap_{\lambda \in \Lambda} \text{Ker}(\text{Hom}_R(T_\lambda, ?)) \).

Proof. Theorem 3.3 says that (1) \( \iff \) (2), and since that (2) \( \implies \) (3) is trivial, we just need to prove (3) \( \implies \) (2). This last implication follows directly from the proof of [Hrb16, Lemma 2.4], nevertheless, for clarity, we include some details of the proof. Let \( \{ T_\lambda \}_{\lambda \in \Lambda} \) be a set of finitely generated \( R \)-modules in \( \mathcal{T} \), such that \( \mathcal{F} = \bigcap_{\lambda \in \Lambda} \text{Ker}(\text{Hom}_R(T_\lambda, ?)) \). For each \( \lambda \), we consider the following exact sequence in \( R\text{-Mod} \): 

\[
0 \to K \to R^{(n_\lambda)} \to T_\lambda \to 0,
\]

where \( n_\lambda \) is a natural number. Now, we fix a direct system \( (K_i)_{i \in I} \) of finitely generated submodules of \( K \) such that \( K = \bigcup_{i \in I} K_i \). Note that for each \( i \), we have the following commutative diagram:

\[
\begin{array}{ccc}
0 & \to & K_i \\
\downarrow & & \downarrow \\
0 & \to & K \\
\end{array}
\]

\[
\begin{array}{ccc}
K_i & \to & R^{(n_\lambda)}/K_i \\
\downarrow & & \downarrow \\
0 & \to & T_\lambda \\
\end{array}
\]

It follows that \( T_\lambda \cong \lim_{\to} R^{(n_\lambda)}/K_i \), where all morphisms of this direct system are projections. Since \( \mathcal{F} = \lim_{\to} \mathcal{F} \), we obtain that \( T_\lambda = \lim_{\to} t(R^{(n_\lambda)}/K_i) \).

Next, for each \( i \in I \), we consider the following commutative diagram:

\[
\begin{array}{ccc}
0 & \to & K_i \\
\downarrow & & \downarrow \\
0 & \to & R^{(n_\lambda)} \\
\downarrow & & \downarrow \\
R^{(n_\lambda)}/J_i & \sim & (1 : t)(R^{(n_\lambda)}/J_i).
\end{array}
\]

Where the top right square of this diagram is the pullback square obtained from \( R^{(n_\lambda)} \to R^{(n_\lambda)}/K_i \) and \( t(R^{(n_\lambda)}/K_i) \to R^{(n_\lambda)}/K_i \).

Given that \( \lim_{i \in I} R^{(n_\lambda)}/J_i \cong \lim_{i \in I} (1 : t)(R^{(n_\lambda)}/K_i) = 0 \), it follows that \( (J_i)_{i \in I} \) is a directed union such that \( \bigcup_{i \in I} J_i = R^{(n_\lambda)} \). Since \( R^{(n_\lambda)} \) is a finitely generated \( R \)-module, there is \( k \in I \) such that \( J_i = R^{(n_\lambda)} \), for all \( i \geq k \). Hence \( R^{(n_\lambda)}/K_i \) is a finitely presented \( R \)-module which is in \( \mathcal{T} \), for all \( i \geq k \). If we let \( S_\lambda := \{ R^{(n_\lambda)}/K_i : i \geq k \} \), then we obtain that \( \mathcal{F} = \bigcap_{S \in \bigcup S_\lambda} \text{Ker}(\text{Hom}_R(S, ?)) \). \( \square \)

**Theorem 3.10.** Let \( R \) be a left Noetherian ring and let \( t = (\mathcal{T}, \mathcal{F}) \) be a torsion pair in \( R\text{-Mod} \). The following assertions are equivalent:

1. \( t \) is a \( tCG \) torsion pair.
2. \( t \) is of finite type.
3. \( \mathcal{H}_t \) is a Grothendieck category.

Proof. By [PS16a, Theorem 1.2] and Corollary 3.6, we just need to prove (2) \( \implies \) (1). From [PS15, Lemma 4.6], we can assume that \( \mathcal{T} = \text{Gen}(V) \), for some \( R \)-module \( V \). Now, we fix a direct system \( (V_\lambda)_{\lambda \in \Lambda} \) of finitely generated submodules of \( V \), such
that \( \lim V_\lambda = V \). By hypothesis, \( F = \lim F \), and so we get that \( \lim t(V_\lambda) \cong V \). Furthermore, each \( t(V_\lambda) \) is a finitely presented \( R \)-module, since \( R \) is a left Noetherian ring. Note that \( F = \ker(\text{Hom}_R(V, ?)) = \ker(\text{Hom}_R(\lim t(V_\lambda), ?)) \). Therefore \( F = \bigcap_{\lambda \in \Lambda} \ker(\text{Hom}_R(t(V_\lambda), ?)) \), and hence the result follows from Theorem 3.3. \( \square \)

The next result is a surprising result to the authors that can be obtained as an immediate corollary of Theorem 3.10 and [ATJLS10, Theorem 3.10]. However, this result is also given in [AHH17, Lemma 4.2], but from a different point of view, namely the theory of the silting modules.

**Corollary 3.11.** Let \( R \) be a commutative Noetherian ring and \( t = (\mathcal{T}, F) \) be a torsion pair in \( R \text{-Mod} \). Then \( t = (\mathcal{T}, F) \) is a hereditary torsion pair if, and only if, \( F \) is closed under direct limits.

**Proof.** This follows from Theorem 3.10 and Example 3.2. Nevertheless, for the benefit of the reader, we make one of the implications explicit.

If \( t = (\mathcal{T}, F) \) is a hereditary torsion pair in \( R \text{-Mod} \), then we have that \( F = \bigcap_{a \in F_a} \ker(\text{Hom}_R(R/a, ?)) \), where \( F_a \) is the Gabriel filter associated to the torsion pair \( t \) (see [Ste75]). Since \( R \) is a Noetherian ring, then \( R/a \) is finitely presented as an \( R \)-module and so \( F \) is closed under direct limits.

Recall that a ring \( R \) is called left coherent ring if each finitely generated left ideal of \( R \) is a finitely presented \( R \)-module. It is a well known fact that if \( R \) is a left coherent ring, then the subcategory \( fp(R \text{-Mod}) \) of finitely presented \( R \)-modules, is an abelian category. Again, using the fact that isomorphism classes of finitely presented modules form a set, we get that all torsion pairs in \( fp(R \text{-Mod}) \) form a set, which we will denote by \( t(fp(R)). \)

The following result shows us a way to get a \( tCG \) torsion pair, for left coherent rings, from a torsion pair in \( t(fp(R)). \) However there are \( tCG \) torsion pairs that cannot be obtained in this way. First we recall that a ring \( R \) is called von Neumann regular ring (VNR), if for every \( a \) in \( R \), there exists \( x \) in \( R \) such that \( a = axa \). It is well known that over a VNR ring every finitely presented \( R \)-module is a projective \( R \)-module, hence every VNR ring is also coherent.

**Theorem 3.12.** Let \( R \) be a left coherent ring. The assignment \( t = (\mathcal{X}, \mathcal{Y}) \mapsto \tilde{t} := (\lim \mathcal{X}, \lim \mathcal{Y}) \) defines an injective function \( \phi : t(fp(R)) \rightarrow tCG(R). \)

Moreover, the following assertions hold:

1. If \( R \) is a Noetherian ring, then \( \phi \) is a bijective function.
2. Let \( R := \prod_{N} \mathbb{Z}/2\mathbb{Z} \) with addition and multiplication defined componentwise. For this coherent ring, \( \phi \) is not bijective.

**Proof.** Let \( t = (\mathcal{X}, \mathcal{Y}) \) be a torsion pair in \( fp(R \text{-Mod}) \). By [CB94, Lemma 4.4], we know that the torsion pair in \( R \text{-Mod} \) generated by \( \mathcal{X} \) is \( \tilde{t} := (\mathcal{T}, F) = (\lim \mathcal{X}, \lim \mathcal{Y}) \).

In other words, \( F = \lim \mathcal{Y} \) consists of the \( R \)-modules \( F \) such that \( \text{Hom}_R(X, F) = 0 \), for all \( X \in \mathcal{X} \). Thus, \( F = \bigcap_{X \in \mathcal{X}} \ker(\text{Hom}_R(X, ?)) \) and therefore \( \tilde{t} = (\mathcal{T}, F) = (\lim \mathcal{X}, \lim \mathcal{Y}) \) is a \( tCG \) torsion pair.

On the other hand, if \( t_1 = (\mathcal{X}_1, \mathcal{Y}_1) \) is a torsion pair in \( fp(R \text{-Mod}) \) such that \( t_1 = (\lim \mathcal{X}_1, \lim \mathcal{Y}_1) = (\lim \mathcal{X}, \lim \mathcal{Y}) = \tilde{t} \). Then, for each \( X_1 \in \mathcal{X}_1 \), we have that \( (1 : t)(X_1) \in \mathcal{X}_1 \cap \mathcal{Y} \subseteq \lim \mathcal{X}_1 \cap \lim \mathcal{Y} = \lim \mathcal{X} \cap \lim \mathcal{Y} = 0 \), hence \( X_1 \in \mathcal{X} \) and therefore \( \tilde{t} = t = t_1 \).
This shows that φ is an injective function, thus completing the first part of the theorem.

We now suppose that R is a Noetherian ring. Let t = (T, F) be a tCG torsion pair in R-Mod. We will show that there is t_1 ∈ tfp(R), such that φ(t_1) = t. If P ∈ fp(R-Mod), then we have the following exact sequence in R-Mod:

$$0 \rightarrow t(P) \rightarrow P \rightarrow (1 : t)(P) \rightarrow 0.$$ 

Note that t(P) is a finitely generated R-module, which in this case is also a finitely presented R-module. Therefore, the previous exact sequence is also in fp(R-Mod). This shows that t_1 := (T ∩ fp(R-Mod), F ∩ fp(R-Mod)) is a torsion pair in fp(R-Mod). Since F is closed under direct limits, we obtain that \( \lim(T ∩ fp(R-Mod)) \subseteq T \) and that \( \lim(F ∩ fp(R-Mod)) \subseteq F \), and hence φ(t_1) = t.

For the final statement of the theorem, let R := \( \prod_{\mathbb{N}} \mathbb{Z}/2\mathbb{Z} \) and let \( a := \bigoplus_{\mathbb{N}} \mathbb{Z}/2\mathbb{Z} \).

It is clear that a is a two-sided idempotent ideal of R and we consider the TTF triple \( (C_a, T_a, F_a) \) in R-Mod associated to the ideal a. Next, for each \( n \in \mathbb{N} \), we consider \( \bigoplus_{n=1}^{\infty} \mathbb{Z}/2\mathbb{Z} \) the canonical inclusion, and let \( I_n := \text{Im}(\iota_n) \).

Note that a is the directed union of the \( I_n \), and that every \( I_n \) is a finitely presented R-module such that \( aI_n = I_n \).

Since \( T_a = \text{Ker}(\text{Hom}_R(a, ?)) = \text{Ker}(\text{Hom}_R(\bigcup_{n \in \mathbb{N}} I_n, ?)) \) and that each \( I_n \in C_a \), it follows that \( T_a = \bigcap_{n \in \mathbb{N}} \text{Ker}(\text{Hom}_R(I_n, ?)) \). By Theorem 3.3, we obtain that this torsion pair is a tCG torsion pair.

We claim that \( (C_a, T_a) \notin \text{Im}(\phi) \). Indeed, suppose that there exists \( t = (\mathcal{X}, \mathcal{Y}) \) a torsion pair in fp(R-Mod) such that \( \phi(t) = (C_a, T_a) \). Now, we consider the following exact sequence in fp(R-Mod):

$$0 \rightarrow t(R) \rightarrow R \rightarrow (1 : t)(R) \rightarrow 0.$$ 

Since \( t(R) \in \mathcal{X} \subseteq \lim_{\rightarrow} \mathcal{X} = C_a \) and that \( (1 : t)(R) \in \mathcal{Y} \subseteq \lim_{\rightarrow} \mathcal{Y} = T_a \), we obtain that \( t(R) = a \) and that \( (1 : t)(R) = R/a \), but a is not finitely generated. This is a contradiction.

\[ \square \]

**Remark 3.13.** For the pair \( (C_a, T_a) \) in the proof of the previous theorem, there is no finitely presented module M, such that Gen(M) = C_a. Indeed, if such finitely presented module M exists, then it is a direct summand of a finitely generated free module, given that R is a VNR ring. Furthermore, the fact that \( aM = M \), implies that there is an integer \( n \) such that \( e_n M = 0 \), where \( e_n \) is the ring element with 1 in the n-th component and 0 everywhere else. Hence \( R e_n \notin \text{Gen}(M) \) and \( R e_n \in C_a \).

4. Construction of tCG torsion pairs and torsion pairs of finite type

In this section we will present an explicit example of a torsion pair of finite type that is not a tCG torsion pair. The usual example of a finite type torsion pair is the left constituent pair of a TTF-triple. The following result characterizes which of these left constituent pairs are tCG torsion pairs. If \( N \) is a finitely generated submodule of \( M \), then we will write \( N \subseteq_{fg} M \).

**Theorem 4.1.** Let a be a two-sided idempotent ideal of R and consider the set \( S_a = \{a(n)/(K ∩ a(n)) : n \in \mathbb{N}, K \subseteq_{fg} R^{(n)} \text{ such that } K + a(n) = R^{(n)}\} \).

Then the torsion pair \( (C_a, T_a) \) is a tCG torsion pair if and only if the class \( T_a = \bigcap_{S \in S_a} \text{Ker}(\text{Hom}(S, ?)) \).
Proof. We will begin by showing that if $S \in \mathcal{S}_a$, then $S \in \mathcal{C}_a \cap fp(R\text{-Mod})$. Indeed, if $K \subseteq_{fg} R(n)$, with $n \in \mathbb{N}$, such that $K + a(n) = R(n)$, then

$$\frac{R(n)}{K} = \frac{K + a(n)}{K} \cong \frac{a(n)}{K \cap a(n)}.$$  

Since $K$ is finitely generated, then $a(n)/K \cap a(n)$ is finitely presented and it is also in $\text{Gen}(a) = \mathcal{C}_a$. Hence, if $\mathcal{T}_a = \bigcap_{S \in \mathcal{S}_a} \text{Ker}(\text{Hom}(S, ?))$, then by Theorem 3.3, the pair $(\mathcal{C}_a, \mathcal{T}_a)$ is a tCG torsion pair.

For the converse, let’s assume that the pair $(\mathcal{C}_a, \mathcal{T}_a)$ is a tCG torsion pair. Again by Theorem 3.3 there exists a set $\{C_\lambda\}_{\lambda \in \Lambda}$ in $\mathcal{C}_a \cap fp(R\text{-Mod})$, such that $\mathcal{T}_a = \bigcap_{\lambda \in \Lambda} \text{Ker}(\text{Hom}(C_\lambda, ?))$. Then for each $\lambda$ we have the following commutative diagram:

$$
\begin{array}{ccccccccc}
0 & \rightarrow & \tilde{K}_\lambda & \rightarrow & a(n_\lambda) & \rightarrow & C_\lambda & \rightarrow & 0 \\
 & & \downarrow \cong & & \downarrow \cong & & \downarrow \cong & & \\
0 & \rightarrow & K_\lambda & \rightarrow & R(n_\lambda) & \rightarrow & C_\lambda & \rightarrow & 0,
\end{array}
$$

where $q_\lambda$ is the canonical epimorphism and $\iota_{n_\lambda}$ is the canonical inclusion, for some $n_\lambda \in \mathbb{N}$. Note that $q_\lambda$ is an epimorphism, since $aC_\lambda = C_\lambda$, and it follows that $K_\lambda + a(n_\lambda) = R(n_\lambda)$. So $C_\lambda \in \mathcal{S}_a$, for each $\lambda \in \Lambda$. To complete the proof we observe that:

$$\mathcal{T}_a \subseteq \bigcap_{S \in \mathcal{S}_a} \text{Ker}(\text{Hom}(S, ?)) \subseteq \bigcap_{\lambda \in \Lambda} \text{Ker}(\text{Hom}(C_\lambda, ?)) = \mathcal{T}_a.$$

\[\square\]

Given that in the previous result we are dealing with the following module identity $K + a(n) = R(n)$, it seems unavoidable to investigate the relation of $a$ with superfluous ideals. Recall, that an ideal $I$ of a ring $R$ is said to be superfluous if $I + J = R$, for any other ideal $J$, then $J = R$. Indeed, we have the following result, which also provides an example of a torsion pair of finite type that is not a tCG torsion pair.

**Corollary 4.2.** Let $a$ be a two-sided idempotent ideal of a ring $R$. If $a$ is not finitely generated and contained in the Jacobson radical of $R$, then $\mathcal{C}_a \cap fp(R\text{-Mod}) = 0$. This implies that $(\mathcal{C}_a, \mathcal{T}_a)$ is not a tCG torsion pair.

**Proof.** Given that $a$ is contained in the Jacobson radical, then Nakayama’s lemma tells us that if $a$ is finitely generated, then $a = 0$. So suppose $a$ is not finitely generated, which implies that the torsion pair $(\mathcal{C}_a, \mathcal{T}_a)$ is not trivial.

Let $S \in \mathcal{C}_a \cap fp(R\text{-Mod})$, then by the proof of the previous theorem, we have that:

$$S \cong \frac{a(n)}{K \cap a(n)},$$

for some $n \in \mathbb{N}$ and some $K \subseteq_{fg} R(n)$, such that $K + a(n) = R(n)$. This last equality shows that $\pi_n(K) + a = R$, where $\pi_n$ denotes the $n$-th projection. Since, by assumption, $a$ is a superflous ideal of $R$, we have that $\pi_n(K) = R$ and the following commutative diagram:
Since $aS = S$, we deduce that $K_{n-1} + a^{(n-1)} = R^{(n-1)}$. Using this argument in a recursive manner, we obtain that $K_1 + a = R$ and that $R/K_1 \cong S$. Once again, the ideal $a$ is superfluous, hence $K_1 = R$, which in turn gives us that $S = 0$. The final statement of the corollary follows from Theorem 3.3.

\[\square\]

Example 4.3. Consider, $R = C([0,1])$, the commutative ring of continuous real valued functions over the unit interval. For $x \in [0,1]$ we consider a maximal ideal $M_x$ given by the functions in $R$ such that its value at $x$ is 0. Now localize $R$ at $M_x$, and let $a = M_xM_x$, which is an idempotent, two-sided, not finitely generated ideal, and observe that the Jacobson radical of $R_{M_x}$ is precisely $M_xM_x$. Applying the previous corollary, we get that the torsion pair $(C_a, T_a)$ is not a $tCG$ torsion pair in $R_{M_x}$-Mod.

Lemma 4.4. Let $R$ be a VNR ring. If $a$ is a two-sided ideal of $R$, then for each $a \in a$, we get $a(Ra) = Ra$.

Proof. Note that $a(Ra) = (aR)a = aa$. On the other hand, there exists $x \in R$, such that $axa = a$. Thus, for every $r \in R$, we get $ra = (rax)a$ and since $a$ is a two-sided ideal of $R$, we obtain that $ra \in aa$, so that $Ra \subseteq Ra$. This shows that $Ra \subseteq aa = a(Ra) \subseteq Ra$. \[\square\]

The following result gives us an explicit description of $tCG$ torsion pairs over a VNR ring.

Theorem 4.5. Let $R$ be a VNR ring and let $t = (T, F)$ be a torsion pair in $R$-Mod. The following assertions are equivalent:

1. $t$ is a $tCG$ torsion pair;
2. There exists $\{T_\lambda\}_{\lambda \in \Lambda}$, a set of finitely generated projective $R$-modules such that $T = \text{Gen}(\bigsqcup T_\lambda)$;
3. There exists a unique idempotent two-sided ideal $a$ of $R$ such that $T = C_a = \text{Gen}(a) = \{T \in R$-Mod : $aT = T\}$;
4. $t$ is the left constituent pair of a TTF triple in $R$-Mod.

Proof. (1) $\implies$ (2). By Theorem 3.3, there exists $\{T_\lambda\}_{\lambda \in \Lambda}$, a set of finitely presented $R$-modules in $T$, such that $F = \bigcap_{\lambda \in \Lambda} \ker(Hom_R(T_\lambda, ?))$. Since $R$ is a VNR ring, we get that each $T_\lambda$ is a finitely generated projective $R$-module. Therefore, $\bigsqcup T_\lambda$ is also a projective $R$-module and hence $\text{Gen}(\bigsqcup T_\lambda)$ is a torsion class in $R$-Mod. In this case, the equality $F = \bigcap_{\lambda \in \Lambda} \ker(Hom_R(T_\lambda, ?))$, implies $T = \text{Gen}(\bigsqcup T_\lambda)$.

(2) $\implies$ (3). It follows from [Ste75, Proposition VI.9.4] and [Ste75, Corollary VI.9.5].

(3) $\implies$ (4). It follows from [Ste75, Chapter VI, Section 8].
(4) $\implies$ (1). We suppose that there exists a TTF triple in $R$-Mod of the form $(\mathcal{T}, \mathcal{F}, \mathcal{F}^\perp)$. Hence, $\mathfrak{t} = (\mathcal{T}, \mathcal{F})$ is a torsion pair of finite type, and there exists a unique idempotent two-sided ideal $a$ of $R$, such that $\mathcal{T} = \mathcal{C}_a = \text{Gen}(a) = \{T \in R$-Mod : $aT = T\}$. Now, we fix a direct system $(I_i)_{i \in I}$ of finitely generated submodules of $a$ such that $a = \bigcup_{i \in I} I_i$. By Lemma 4.4, we have $a I_i = I_i$, for all $i \in I$, hence each $I_i$ is in $\mathcal{T} = \mathcal{C}_a$. The result follows from Corollary 3.9, since $\mathcal{F} = \text{Ker}(\text{Hom}_R(a, ?)) = \text{Ker}(\text{Hom}_R(\bigcup_{i \in I} I_i, ?)) = \bigcap_{i \in I} \text{Ker}(\text{Hom}_R(I_i, ?))$. $\square$

Given a torsion pair in $R$-Mod of the form $(\text{Gen}(V), \text{Ker}(\text{Hom}_R(V, ?)))$ and a direct system of finitely presented modules $\{V_\lambda\}_{\lambda \in \Lambda}$ with $V = \varinjlim V_\lambda$, we get from [Ste75, Example VI.2.3] that the pair $(\varprojlim (\bigcap \text{Ker}(\text{Hom}_R(V_\lambda, ?))), \bigcap \text{Ker}(\text{Hom}_R(V_\lambda, ?)))$ is a torsion pair. From Theorem 3.3 we get that this last torsion pair is a tCG torsion pair; furthermore, we get that $\text{Gen}(V) \subseteq (\bigcap \text{Ker}(\text{Hom}_R(V_\lambda, ?)))$. This fact motivates the following question.

**Question 4.6.** Given $R$ a ring and $\mathfrak{t} = (\mathcal{T}, \mathcal{F})$ a torsion pair in $R$-Mod, such that $\mathcal{T} = \text{Gen}(V)$ for some $R$-module $V$. Is there a minimal torsion class $\mathcal{T}'$ of a tCG torsion pair, such that $\mathcal{T} \subseteq \mathcal{T}'$?

**Acknowledgements**

The authors thank Manuel Saorín for several helpful discussions, and the comments of the referee which certainly have improved the quality of this paper.
