Abstract

While Shannon’s mutual information has wide spread applications in many disciplines, for practical applications it is often difficult to calculate its value accurately for high-dimensional variables because of the curse of dimensionality. This paper is focused on effective approximation methods for evaluating mutual information in the context of neural population coding. For large but finite neural populations, we derive several information-theoretic asymptotic bounds and approximation formulas that remain valid in high-dimensional spaces. We prove that optimizing the population density distribution based on these approximation formulas is a convex optimization problem which allows efficient numerical solutions. Numerical simulation results confirmed that our asymptotic formulas were highly accurate for approximating mutual information for large neural populations. In special cases, the approximation formulas are exactly equal to the true
mutual information. We also discuss techniques of variable transformation and dimensionality reduction to facilitate computation of the approximations.

1 Introduction

Shannon’s mutual information (MI) provides a quantitative characterization of the association between two random variables by measuring how much knowing one of the variables reduces uncertainty about the other (Shannon, 1948). Information theory has become a useful tool for neuroscience research (Rieke et al., 1997; Borst & Theunissen, 1999; Pouget et al., 2000; Laughlin & Sejnowski, 2003; Brown et al., 2004; Quiroga & Panzeri, 2009), with applications to various problems such as sensory coding problems in the visual systems (Eckhorn & Pöpel, 1975; Optican & Richmond, 1987; Atick & Redlich, 1990; McClurkin et al., 1991; Atick et al., 1992; Becker & Hinton, 1992; Van Hateren, 1992; Gawne & Richmond, 1993; Tovee et al., 1993; Bell & Seinowski, 1997; Lewis & Zhaoping, 2006) and the auditory systems (Chechik et al., 2006; Gourévitch & Eggermont, 2007; Chase & Young, 2005).

One major problem encountered in practical applications of information theory is that the exact value of mutual information is often hard to compute in high-dimensional spaces. For example, suppose we want to calculate the mutual information between a random stimulus variable that requires many parameters to specify and the elicited noisy responses of a large population of neurons. In order to accurately evaluate the mutual information between the stimuli and the responses, one has to average over all possible stimulus patterns and over all possible response patterns of the whole population. This averaging quickly leads to a combinatorial explosion as either the stimulus dimension or the population size increases. This problem occurs not only when one computes MI numerically for a given theoretical model but also when one estimates MI empirically from experimental data.

Even when the input and output dimensions are not that high, MI estimate from experimental data tends to have a positive bias due to limited sample size (Miller, 1955; Treves & Panzeri, 1995). For example, a perfectly flat joint probability distribution implies zero MI, but an empirical joint distribution with fluctuations due to finite data size
appears to suggest a positive MI. The error may get much worse as the input and output dimensions increase because a reliable estimate of MI may require exponentially more data points to fill the space of the joint distribution. Various asymptotic expansion methods have been proposed to reduce the bias in MI estimate (Miller, 1955; Carlton, 1969; Treves & Panzeri, 1995; Victor, 2000; Paninski, 2003). Other estimators of MI have also been studied, such as those based on $k$-nearest neighbor (Kraskov et al., 2004) and minimal spanning trees (Khan et al., 2007). However, it is not easy for these methods to handle the general situation with high-dimensional inputs and high-dimensional outputs.

For numerical computation of MI for a given theoretical model, one useful approach is Monte Carlo sampling, a convergent method that may potentially reaches arbitrary accuracy (Yarrow et al., 2012). However, its stochastic and inefficient computational scheme makes it unsuitable for many applications. For instance, to optimize the distribution of a neural population for a given set of stimuli, one may want to slightly alter the population parameters and see how the perturbation affects the MI, but a tiny change of MI can be easily drowned out by the inherent noise in the Monte Carlo method.

An alternative approach is to use information-theoretic bounds and approximations to simplify calculations. For example, the Cramér-Rao lower bound (Rao, 1945) tell us that the inverse of Fisher information (FI) is a lower bound to the mean square decoding error of any unbiased decoder. Fisher information is useful for many applications partly because it is often much easier to calculate than MI (see e.g., Zhang et al., 1998; Zhang & Seinowski, 1999; Abbott & Dayan, 1999; Bethge et al., 2002; Harper & McAlpine, 2004; Toyoizumi et al., 2006).

A link between MI and FI has been studied by several researchers (Clarke & Barron, 1990; Rissanen, 1996; Brunel & Nadal, 1998; Sompolinsky et al., 2001). Clarke & Barron (1990) first derived an asymptotic formula between the relative entropy and FI for parameter estimation from independent and identically distributed (i.i.d.) observations with suitable smoothness conditions. Rissanen (1996) generalized it in the framework of stochastic complexity for model selection. Brunel & Nadal (1998) presented an asymptotic relationship between the MI and FI in the limit of a large number of neurons. The method was extended to discrete inputs by Kang & Sompolinsky (2001). More
general discussions about this also appeared in other papers (e.g. Ganguli & Simoncelli, 2014; Wei & Stocker, 2015). However, for finite population size, the asymptotic formula may lead to large errors, especially for high-dimensional inputs as detailed in sections 2.2 and 4.1.

In this paper, our main goal is to improve FI approximations to MI for finite neural populations especially for high-dimensional inputs. Another goal is to discuss how to use these approximations to optimize neural population coding. We will present several information-theoretic bounds and approximation formulas and discuss the conditions under which they are established in section 2 with detailed proofs given in Appendix. We also discuss how our approximation formulas are related to other statistical estimators and information-theoretic bounds, such as Cramér-Rao bound and van Trees’ Bayesian Cramér-Rao bound (section 3). In order to better apply the approximation formulas in high-dimensional input space, we propose some useful techniques in section 4 including variable transformation and dimensionality reduction, which may greatly reduce the computational complexity for practical applications. Finally, in section 5 we discuss how to use the approximation formulas for the optimization of information transfer for neural population coding.

2 Bounds and Approximations for Mutual Information in Neural Population Coding

2.1 Mutual Information and Notations

Suppose the input $x$ is a $K$-dimensional vector, $x = (x_1, x_2, \cdots, x_K)^T$, the outputs of $N$ neurons are denoted by a vector, $r = (r_1, r_2, \cdots, r_N)^T$. In this paper we denote random variables by upper case letters, e.g., random variables $X$ and $R$, in contrast to their vector values $x$ and $r$. The MI $I(X; R)$ (denoted as $I$ below) between $X$ and $R$ is defined by (Cover & Thomas, 2006)

$$I = \int_{\mathcal{X}} \int_{\mathcal{R}} p(r|x)p(x) \ln \frac{p(r|x)}{p(r)} dr dx,$$

(2.1)
where $x \in \mathcal{X} \subseteq \mathbb{R}^K$, $r \in \mathcal{R} \subseteq \mathbb{R}^N$, $dx = \prod_{k=1}^{K} dx_k$, $dr = \prod_{n=1}^{N} dr_n$, and the integration symbol $\int$ is for the continuous variables and can be replaced by summation symbol $\sum$ for discrete variables. The probability density function (p.d.f.) of $r$, $p(r)$, satisfies

$$p(r) = \int_{\mathcal{X}} p(r|x)p(x)dx. \tag{2.2}$$

The MI $I$ in (2.1) may also be expressed equivalently as

$$I = H(X) - \langle \ln \frac{p(r)}{p(r|x)p(x)} \rangle_{r,x} = H(X) - H(X|R), \tag{2.3}$$

where $H(X)$ is the entropy of random variable $X$:

$$H(X) = -\langle \ln p(x) \rangle_x, H(X|R) = -\langle \ln p(x|r) \rangle_{r,x}, \tag{2.4}$$

and $\langle \cdot \rangle$ denotes expectation:

$$\langle \cdot \rangle_x = \int_{\mathcal{X}} p(x)(\cdot)dx, \tag{2.5}$$

$$\langle \cdot \rangle_{r|x} = \int_{\mathcal{R}} p(r|x)(\cdot)dr, \tag{2.6}$$

$$\langle \cdot \rangle_{r,x} = \int_{\mathcal{X}} \int_{\mathcal{R}} p(r,x)(\cdot)drdx. \tag{2.7}$$

Next, we introduce the following notations,

$$l(r|x) = \ln p(r|x), \tag{2.8}$$

$$L(r|x) = \ln \left( \frac{p(r|x)p(x)}{p(x)} \right), \tag{2.9}$$

$$q(x) = \ln p(x), \tag{2.10}$$

and

$$I_F = \frac{1}{2} \langle \ln \left( \det \left( \frac{J(x)}{2\pi e} \right) \right) \rangle_x + H(X), \tag{2.11}$$

$$I_G = \frac{1}{2} \langle \ln \left( \det \left( \frac{G(x)}{2\pi e} \right) \right) \rangle_x + H(X), \tag{2.12}$$

where $\det(\cdot)$ denotes the matrix determinant, and

$$J(x) = \langle l'(r|x)l'(r|x)^T \rangle_{r|x}, \tag{2.13}$$

$$G(x) = J(x) + P(x), \tag{2.14}$$

$$P(x) = -q''(x). \tag{2.15}$$
Here $\mathbf{J}(\mathbf{x})$ is FI matrix, which is symmetric and positive-semidefinite, and $'$ and $''$ denote the first and second derivative for $\mathbf{x}$, respectively; that is, $l'(r|x) = \partial l(r|x)/\partial x$ and $q''(r|x) = \partial^2 \ln p(x)/\partial x\partial x^T$. If $p(r|x)$ is twice differentiable for $\mathbf{x}$, then

$$\mathbf{J}(\mathbf{x}) = \left\langle l'(r|x)l'(r|x)^T \right\rangle_{r|x} = -\left\langle l''(r|x) \right\rangle_{r|x}.$$ (2.16)

We denote the Kullback-Leibler (KL) divergence as

$$D(\mathbf{x}||\hat{\mathbf{x}}) = \int_{\mathcal{R}} p(r|x) \ln \frac{p(r|x)}{p(r|\hat{x})} dr,$$ (2.17)

and define

$$\mathcal{X}_\omega(\mathbf{x}) = \left\{ \hat{\mathbf{x}} \in \mathbb{R}^K : (\hat{\mathbf{x}} - \mathbf{x})^T \mathbf{G}(\mathbf{x}) (\hat{\mathbf{x}} - \mathbf{x}) < N\omega^2 \right\},$$ (2.18)

as the $\omega$ neighborhoods of $\mathbf{x}$, and its complementary set as

$$\bar{\mathcal{X}}_\omega(\mathbf{x}) = \mathcal{X} - \mathcal{X}_\omega(\mathbf{x}),$$ (2.19)

where $\omega$ is a positive number.

### 2.2 Information-Theoretic Asymptotic Bounds and Approximations

In large $N$ limit, Brunel & Nadal (1998) proposed an asymptotic relationship $I \sim I_F$ between MI and FI and gave a proof in the case of one-dimensional input. Another proof is given by Sompolinsky et al. (2001) although there appears to be an error in their proof when replica trick is used (see Eq. (B1) in their paper; their Eq. (B5) does not follow directly from the replica trick). For large but finite $N$, $I \sim I_F$ is usually a good approximation as long as the inputs are low-dimensional. For the high-dimensional inputs, the approximation may no longer be valid. For example, suppose $p(r|x)$ is a normal distribution with mean $\mathbf{A}^T\mathbf{x}$ and covariance matrix $\mathbf{I}_N$ and $p(\mathbf{x})$ is a normal distribution with mean $\mu$ and covariance matrix $\Sigma$.

$$p(r|x) = \mathcal{N}(\mathbf{A}^T\mathbf{x}, \mathbf{I}_N), \quad p(\mathbf{x}) = \mathcal{N}(\mu, \Sigma),$$ (2.20)

where $\mathbf{A} = [\mathbf{a}_1, \mathbf{a}_2, \cdots, \mathbf{a}_N]$ is a deterministic $K \times N$ matrix and $\mathbf{I}_N$ is the $N \times N$ identity matrix. The MI $I$ is given by (see Verdu, 1986; Guo et al., 2005, for details)

$$I = \frac{1}{2} \ln \left( \det \left( \Sigma^{1/2} \mathbf{A} \mathbf{A}^T \Sigma^{1/2} + \mathbf{I}_K \right) \right).$$ (2.21)
If rank \( \text{rank}(J(x)) < K \), then \( I_F = -\infty \). Notice that here \( J(x) = AA^T \). When \( a = a_1 = \cdots = a_N \) and \( \Sigma = I_K \), then by (2.21) and matrix determinant lemma, we have

\[
I = \frac{1}{2} \ln \left( \det \left( Naa^T + I_K \right) \right) = \frac{1}{2} \ln \left( Na^T a + 1 \right) \geq 0, \quad (2.22)
\]

and by (2.11),

\[
I_F = \frac{1}{2} \ln \left( \det \left( Naa^T \right) \right) = -\infty, \quad (2.23)
\]

which is obviously incorrect as an approximation to \( I \). For high-dimensional inputs, the determinant \( \det(J(x)) \) may become close to zero in practical applications. When the FI matrix \( J(x) \) becomes degenerate, the regularity condition ensuring the Cramér-Rao paradigm of statistics is violated (Amari & Nakahara, 2005), in which case using \( I_F \) as a proxy for \( I \) incurs large errors.

In the following, we will show \( I_G \) is a better approximation of \( I \) for high-dimensional inputs. For instance, for the above example, we can verify that

\[
I_G = \frac{1}{2} \ln \left( \det \left( \frac{1}{2\pi e} (AA^T + \Sigma^{-1}) \right) \right) + \frac{1}{2} \ln \left( \det \left( 2\pi e \Sigma \right) \right) \\
= \frac{1}{2} \ln \left( \det \left( \Sigma^{1/2} AA^T \Sigma^{1/2} + I_K \right) \right) = I, \quad (2.24)
\]

which is exactly equal to the MI \( I \) given in (2.21).

2.2.1 Regularity Conditions

First, we consider the following regularity conditions for \( p(x) \) and \( p(r|x) \):

\textbf{C1:} \( p(x) \) and \( p(r|x) \) are twice continuously differentiable for almost every \( x \in \mathcal{X} \), where \( \mathcal{X} \) is a convex set; \( G(x) \) is positive definite and \( \|G^{-1}(x)\| = O(N^{-1}) \), where \( \|\cdot\| \) denotes the Frobenius norm of a matrix; the following conditions hold

\[
\|q'(x)\| < \infty, \quad (2.25a)
\]

\[
\|q''(x)\| < \infty, \quad (2.25b)
\]

\[
\left\langle \left( N^{-1}l''(r|x)^Tl'(r|x) \right)^2 \right\rangle_{r|x} = O(1), \quad (2.25c)
\]

\[
\left\langle \left\| N^{-1}(l''(r|x) - \langle l''(r|x) \rangle_{r|x}) \right\|^2 \right\rangle_{r|x} = O(N^{-1}), \quad (2.25d)
\]
and there exists an $\omega = \omega(x) > 0$ for $\forall \bar{x} \in \mathcal{X}_\omega(x)$ such that

$$N^{-1} \| l''(\bar{r} | \bar{x}) - l''(r | x) \| = O(1),$$

(2.25e)

where $O$ indicates the big-O notation.

**C2:** The following condition is satisfied:

$$\mathbb{E}_{r|x} \left[ \left\| N^{-1} \left( l''(r | x) - \mathbb{E} l''(r | x) \right) \right\|_{r|x}^{2(m+1)} \right] = O \left( N^{-1} \right),$$

(2.26a)

for $m \in \mathbb{N}$, and there exists $\eta > 1$ such that

$$\mathbb{P}_{r|x} \left\{ \det (G(x))^{1/2} \int_{\mathcal{X}_\omega(x)} p(\hat{x} | r) d\hat{x} > \epsilon p(x | r) \right\} = O \left( N^{-\eta} \right)$$

(2.26b)

for all $\epsilon \in (0, 1/2)$, $\omega \in (0, \omega)$ and $x \in \mathcal{X}$ with $p(x) > 0$, where $\mathbb{P}_{r|x} \{ \cdot \}$ denotes the probability of $r$ given $x$.

The regularity conditions **C1** and **C2** are needed to prove theorems in later sections. They are expressed in mathematical forms that are convenient for our proofs although their meanings may seem opaque at the first glance. In the following, we will examine these conditions more closely. We will use specific examples to make interpretations of these conditions more transparent.

**Remark 2.1.** In this paper we assume that the probability distributions $p(x)$ and $p(r | x)$ are piecewise twice continuously differentiable. This is because we need to use Fisher information to approximate mutual information, and Fisher information requires derivatives that make sense only for continuous variables. Therefore, the methods developed in this paper apply only to continuous input variables or stimulus variables. For discrete input variables, we need alternative methods for approximating MI and we will address this issue in a separate publication.

Conditions (2.25a) and (2.25b) state that the first and the second derivatives of $q(x) = \ln p(x)$ have finite values for any given $x \in \mathcal{X}$. These two conditions are easily satisfied by commonly encountered probability distributions because they only require finite derivatives within $\mathcal{X}$, the set of allowable inputs, and derivatives do not need to be finitely bounded.
Remark 2.2. Conditions (2.25c)–(2.26a) constrain how the first and the second derivatives of \( l(r|x) = \ln p(r|x) \) scale with \( N \), the number of neurons. These conditions are easily met when \( p(r|x) \) is conditionally independent or when the noises of different neurons are independent, i.e., \( p(r|x) = \prod_{n=1}^{N} p(r_n|x) \).

We emphasize that it is possible to satisfy these conditions even when \( p(r|x) \) is not independent or when the noises are correlated, as shown later. Here we first examine these conditions closely assuming independence. For simplicity, our demonstration below is based on a one-dimensional input variable (\( K = 1 \)). The conclusions are readily generalizable to higher dimensional inputs (\( K > 1 \)) because \( K \) is fixed and does not affect the scaling with \( N \).

Assuming independence, we have \( l(r|x) = \sum_{n=1}^{N} l(r_n|x) \) with \( l(r_n|x) = \ln p(r_n|x) \), and the left-hand side of (2.25c) becomes

\[
N^{-2} \left\langle l' (r|x)^4 \right\rangle_{r|x} = N^{-2} \left( \sum_{n \neq m} \left\langle l'(r_n|x)^2 \right\rangle_{r_n|x} \left\langle l'(r_m|x)^2 \right\rangle_{r_m|x} + \sum_{n=1}^{N} \left\langle l'(r_n|x)^4 \right\rangle_{r_n|x} \right),
\]

(2.27)

where the final result contains only two terms with even numbers of duplicated indices while all other terms in the expansion vanish because any unmatched or lone index \( k \) (from \( n_1, n_2, n_3, n_4 \)) should yield a vanishing average:

\[
\left\langle l'(r_k|x) \right\rangle_{r_k|x} = \int_{\mathcal{R}} p(r_k|x) l'(r_k|x) dr_k = \frac{\partial}{\partial x} \left( \int_{\mathcal{R}} p(r_k|x) dr_k \right) = 0.
\]

(2.28)

Thus, condition (2.25c) is satisfied as long as \( \left\langle l'(r_n|x)^2 \right\rangle_{r_n|x} \) and \( \left\langle l'(r_n|x)^4 \right\rangle_{r_n|x} \) are bounded by some finite numbers, say, \( a \) and \( b \), respectively, because now (2.27) should scale as \( N^{-2} (aN(N-1) + bN) = O(1) \). For instance, a Gaussian distribution always meets this requirement because the averages of the second and fourth powers are proportional to the second and fourth moments, which are both finite. Note that the argument above works even if \( \left\langle l'(r_n|x)^4 \right\rangle_{r_n|x} \) is not finitely bounded but scales as \( O(N) \).

Similarly, under the assumption of independence, the left-hand side of (2.25d) be-
comes
\[ N^{-2} \left\langle \left( I''(r|x) - \langle I''(r|x) \rangle_{r|x} \right)^2 \right\rangle_{r|x} \]
\[ = N^{-2} \sum_{n,m=1}^{N} \left\langle \left( I''(r_n|x) - \langle I''(r_n|x) \rangle_{r_n|x} \right) \left( I''(r_m|x) - \langle I''(r_m|x) \rangle_{r_m|x} \right) \right\rangle_{r_n,r_m|x} \]
\[ = N^{-2} \sum_{n=1}^{N} \left\langle \left( I''(r_n|x) - \langle I''(r_n|x) \rangle_{r_n|x} \right)^2 \right\rangle_{r_n|x} \]
\[ = N^{-2} \sum_{n=1}^{N} \left( \left\langle I''(r_n|x)^2 \right\rangle_{r_n|x} - \left\langle I''(r_n|x) \right\rangle_{r_n|x}^2 \right), \quad (2.29) \]

where in the second step, the only remaining terms are the squares while all other terms in the expansion with \( n \neq m \) have vanished because \( \left\langle I''(r_n|x) - \langle I''(r_n|x) \rangle_{r_n|x} \right\rangle_{r_n|x} = 0 \).

Thus, condition (2.25d) is satisfied as long as \( \left\langle I''(r_n|x) \right\rangle_{r_n|x} \) and \( \left\langle I''(r_n|x)^2 \right\rangle_{r_n|x} \) are bounded so that (2.29) scales as \( N^{-2} N = N^{-1} \).

Condition (2.25e) is easily satisfied under the assumption of independence. It is easy to show that this condition holds when \( I''(r_n|x) \) is bounded.

Condition (2.26a) can be examined using similar arguments used for (2.27) and (2.29). Assuming independence, we rewrite the left-hand side of (2.26a) as:
\[ N^{-2z} \left\langle \left( I''(r|x) - \langle I''(r|x) \rangle_{r|x} \right)^{2z} \right\rangle_{r|x} \]
\[ = N^{-2z} \sum_{n_1, \ldots, n_z=1}^{N} \left\langle \left( I''(r_{n_1}|x) - \langle I''(r_{n_1}|x) \rangle_{r_{n_1}|x} \right) \cdots \left( I''(r_{n_z}|x) - \langle I''(r_{n_z}|x) \rangle_{r_{n_z}|x} \right) \right\rangle_{r_{n_1}, \ldots, r_{n_z}|x} \]
\[ = N^{-2z} \sum_{n_1, \ldots, n_{m+1}=1}^{N} \left( \prod_{i=1}^{m+1} \left( I''(r_{n_i}|x) - \langle I''(r_{n_i}|x) \rangle_{r_{n_i}|x} \right)^2 \right)_{r_{n_i}|x} \]
\[ + \cdots \quad (2.30) \]

where \( z = 2(m+1) \geq 4 \) is an even number. Any term in the expansion with an unmatched index \( n_k \) should vanish, as in the cases of (2.27) and (2.29). When \( \langle I''(r_n|x) \rangle_{r_n|x} \) and \( \langle I''(r_n|x)^2 \rangle_{r_n|x} \) are bounded, the leading term with respect to scaling with \( N \) is the product of squares as shown at the end of (2.30) because all the other non-vanishing terms increase more slowly with \( N \). Thus (2.30) should scale as \( N^{-2} N^{m+1} = N^{-m-1} \), which trivially satisfies condition (2.26a).

In summary, conditions (2.25c)-(2.26a) are easy to meet when \( p(r|x) \) is independent. It is sufficient to satisfy these conditions when the averages of the first and second
derivatives of $l(r|x) = \ln p(r|x)$ as well as the averages of their powers are bounded by finite numbers for all the neurons.

**Remark 2.3.** For neurons with correlated noises, if there exists an invertible transformation that maps $r$ to $\tilde{r}$ such that $p(\tilde{r}|x)$ becomes conditionally independent, then conditions $C1$ and $C2$ are easily met in the space of the new variables by the discussion in Remark 2.2. This situation is best illustrated by the familiar example of a population of neurons with correlated noises that obey a multivariate Gaussian distribution:

$$p(r|x) = \frac{1}{\sqrt{\det(2\pi \Sigma)}} \exp \left( -\frac{1}{2} (r - g)^T \Sigma^{-1} (r - g) \right).$$ (2.31)

where $\Sigma$ is an $N \times N$ invertible covariance matrix and $g = (g_1(x; \theta_1), \cdots, g_N(x; \theta_N))$ describes the mean responses with $\theta_n$ being the parameter vector. Using the following transformation,

$$\tilde{r} = \Sigma^{-1/2} r = (\tilde{r}_1, \tilde{r}_2, \cdots, \tilde{r}_N)^T,$$ (2.32)

$$\tilde{g} = \Sigma^{-1/2} g = (\tilde{g}_1, \tilde{g}_2, \cdots, \tilde{g}_N)^T,$$ (2.33)

we obtain the independent distribution:

$$p(\tilde{r}|x) = \prod_{n=1}^{N} \frac{1}{\sqrt{2\pi}} \exp \left( -\frac{1}{2} (\tilde{r}_n - \tilde{g}_n)^2 \right).$$ (2.34)

In the special case when the correlation coefficient between any pair of neurons is a constant $c$, $-1 < c < 1$, the noise covariance can be written as

$$\Sigma = a \left( (1-c)I_N + cuu^T \right),$$ (2.35)

where $a > 0$ is a constant, $I_N$ is the $N \times N$ identity matrix, $u = (1, 1, \cdots, 1)^T \in \mathbb{R}^{N \times 1}$. The desired transformation in (2.32) and (2.33) is given explicitly by

$$\Sigma^{-1/2} = b_0 \left( I_N - b_1 uu^T \right),$$ (2.36)

where

$$b_0 = \frac{1}{\sqrt{a(1-c)}}, \quad b_1 = \frac{1}{N} \left( 1 \pm \sqrt{\frac{1-c}{(N-1)c+1}} \right).$$ (2.37)
The new response variables defined in (2.32) and (2.33) now read:

\[ \tilde{r}_n = b_0 \left( r_n - b_1 \sum_{m=1}^{N} r_m \right), \]  
(2.38)

\[ \tilde{g}_n = b_0 \left( g_n - b_1 \sum_{m=1}^{N} g_m \right). \]  
(2.39)

Now we have the derivatives:

\[ l'(\tilde{r}_n | x) = (\tilde{r}_n - \tilde{g}_n) \frac{\partial \tilde{g}_n}{\partial x}, \]  
(2.40)

\[ l''(\tilde{r}_n | x) - \langle l''(\tilde{r}_n | x) \rangle_{r_n | x} = (\tilde{r}_n - \tilde{g}_n) \frac{\partial^2 \tilde{g}_n}{\partial x^2}, \]  
(2.41)

where \( \partial \tilde{g}_n / \partial x \) and \( \partial^2 \tilde{g}_n / \partial x^2 \) are finite as long as \( \partial g_n / \partial x \) and \( \partial^2 g_n / \partial x^2 \) are finite. Conditions C1 and C2 are satisfied when the derivatives and their powers are finitely bounded as shown before.

The example above shows explicitly that it is possible to meet conditions C1 and C2 even when the noises of different neurons are correlated. More generally, if a nonlinear transformation exists that maps correlated random variables into independent variables, then by similar argument, conditions C1 and C2 are satisfied when the derivatives of the log likelihood functions and their powers in the new variables are finitely bounded. Even when the desired transformation does not exist or is unknown, it does not necessarily imply that conditions C1 and C2 must be violated.

While the exact mathematical conditions for the existence of the desired transformation are unclear, let us consider a specific example. If a joint probability density function can be morphed smoothly and reversibly into a flat or constant density in a cube (hypercube), which is a special case of an independent distribution, then this morphing is the desired transformation. Here we may replace the flat distribution by any known independent distribution and the argument above should still work. So the desired transformation may exist under rather general conditions.

For correlated random variables, one may use algorithms such as independent component analysis to find an invertible linear mapping that makes the new random variables as independent as possible (Bell & Sejnowski, 1997), or use neural networks to find related nonlinear mappings (Huang & Zhang, 2017). These methods do not directly apply to the problem of testing conditions C1 and C2 because they work for a
given network size $N$ and further development is needed to address the scaling behavior in the large network limit $N \to \infty$.

Finally, we note that the value of the MI of the transformed independent variables is the same as the MI of the original correlated variables because of the invariance of MI under invertible transformation of marginal variables. A related discussion is in Theorem 4.1 which involves a transformation of the input variables rather than a transformation of the output variables as needed here.

**Remark 2.4.** Condition (2.26b) is satisfied if a positive number $\delta$ and a positive integer $m$ exist such that

$$
\det \left( G(x) \right)^{1/2} \int_{\hat{\mathcal{X}}_\omega(x)} \int_{\mathcal{B}_{m,\delta}(x)} p(r|\hat{x}) p(\hat{x}) d\hat{x} d\hat{\mathbf{x}} = O \left( N^{-\eta} \right), \tag{2.42}
$$

for all $\hat{x} \in \hat{\mathcal{X}}_\omega(x)$, where

$$
\mathcal{B}_{m,\delta}(x) = \left\{ r \in \mathcal{R} : -\delta N^{-\frac{1}{2m}} G(x) < l''(r|x) - \langle l''(r|x) \rangle_{r|x} < \delta N^{-\frac{1}{2m}} G(x) \right\}, \tag{2.43}
$$

and $A < B$ means that the matrix $A - B$ is negative definite. A proof is as follows.

First note that in (2.43) if $\eta \to 1$ or $m \to \infty$, then $N^{-\frac{1}{2m}} \to 1$. Following Markov’s inequality, condition C2 and (A.19) in the Appendix, for the complementary set of $\mathcal{B}_{m,\delta}(x)$, $\mathcal{B}_{m,\delta}(x)$, we have

$$
\mathbb{P}_{r|x} \left\{ \bar{B}_{m,\delta}(x) \right\} \leq \mathbb{P}_{r|x} \left\{ \|B_0\|^2 \geq \delta^2 N^{-\frac{\eta-1}{m}} \right\} \leq \delta^{-2m} N^{-(\eta-1)} \langle \|B_0\|^{2m} \rangle_{r|x} = O \left( N^{-\eta} \right), \tag{2.44}
$$

where

$$
B_0 = G^{-1/2}(x) \left( l''(r|x) - \langle l''(r|x) \rangle_{r|x} \right) G^{-1/2}(x). \tag{2.45}
$$

Define the set,

$$
\mathcal{A}_\omega(x) = \left\{ r \in \mathcal{R} : \int_{\hat{\mathcal{X}}_\omega(x)} \frac{p(\hat{x}|r)}{p(x|r)} d\hat{x} > \det \left( G(x) \right)^{-1/2} \epsilon \right\}, \tag{2.46}
$$
then it follows from the Markov’s inequality and (2.42) that

\[
\mathbb{P}_{\mathbf{r}|\mathbf{x}} \{ \mathcal{A}_\omega (\mathbf{x}) \cap \mathcal{B}_{m, \delta} (\mathbf{x}) \} \\
\leq e^{-1} \det (\mathbf{G} (\mathbf{x}))^{1/2} \int_{\mathcal{B}_{m, \delta} (\mathbf{x})} \int_{\mathcal{X}_\omega (\mathbf{x})} \frac{p(\mathbf{r}|\hat{\mathbf{x}})p(\hat{\mathbf{x}})}{p(\mathbf{x})} d\hat{\mathbf{x}} d\mathbf{r} \\
= O \left( N^{-\eta} \right) .
\] (2.47)

Hence, we get

\[
\mathbb{P}_{\mathbf{r}|\mathbf{x}} \{ \mathcal{A}_\omega (\mathbf{x}) \} \leq \mathbb{P}_{\mathbf{r}|\mathbf{x}} \{ \mathcal{A}_\omega (\mathbf{x}) \cap \mathcal{B}_{m, \delta} (\mathbf{x}) \} + \mathbb{P}_{\mathbf{r}|\mathbf{x}} \{ \mathcal{B}_{m, \delta} (\mathbf{x}) \} = O \left( N^{-\eta} \right) ,
\]

which yields the condition (2.26b).

Condition (2.42) is satisfied if there exists a positive number \( \zeta \) such that

\[
\ln \frac{p(\mathbf{r} | \mathbf{x})}{p(\mathbf{r} | \hat{\mathbf{x}})} \geq N \zeta
\]

for all \( \hat{\mathbf{x}} \in \mathcal{X}_\omega (\mathbf{x}) \) and \( \mathbf{r} \in \mathcal{B}_{m, \delta} (\mathbf{x}) \). This is because

\[
\det (\mathbf{G} (\mathbf{x}))^{1/2} \int_{\mathcal{X}_\omega (\mathbf{x})} \int_{\mathcal{B}_{m, \delta} (\mathbf{x})} p(\mathbf{r} | \hat{\mathbf{x}})p(\hat{\mathbf{x}}) d\mathbf{r} d\hat{\mathbf{x}} \\
= \det (\mathbf{G} (\mathbf{x}))^{1/2} \int_{\mathcal{X}_\omega (\mathbf{x})} \int_{\mathcal{B}_{m, \delta} (\mathbf{x})} p(\mathbf{r} | \mathbf{x}) \exp \left( - \ln \frac{p(\mathbf{r} | \mathbf{x})}{p(\mathbf{r} | \hat{\mathbf{x}})} \right) d\mathbf{r} d\hat{\mathbf{x}} \\
\leq \det (\mathbf{G} (\mathbf{x}))^{1/2} \exp (-N \zeta) = O \left( N^{K/2} e^{-N \zeta} \right) .
\] (2.49)

Here notice that \( \det (\mathbf{G} (\mathbf{x}))^{1/2} = O \left( N^{K/2} \right) \) (see Eq. A.23).

Inequality (2.48) holds if \( p(\mathbf{r} | \mathbf{x}) \) is conditionally independent, namely, \( p(\mathbf{r} | \mathbf{x}) = \prod_{n=1}^{N} p(\mathbf{r}_n | \mathbf{x}) \), with

\[
\ln \frac{p(\mathbf{r}_n | \mathbf{x})}{p(\mathbf{r}_n | \hat{\mathbf{x}})} \geq \zeta, \forall n = 1, 2, \cdots, N,
\]

for all \( \hat{\mathbf{x}} \in \mathcal{X}_\omega (\mathbf{x}) \) and \( \mathbf{r} \in \mathcal{B}_{m, \delta} (\mathbf{x}) \). Consider the inequality \( \langle \ln p(\mathbf{r}_n | \mathbf{x}) / p(\mathbf{r}_n | \hat{\mathbf{x}}) \rangle_{\mathbf{r}_n | \mathbf{x}} \geq 0 \) where the equality holds when \( \mathbf{x} = \hat{\mathbf{x}} \). If there is only one extreme point at \( \hat{\mathbf{x}} = \mathbf{x} \) for \( \hat{\mathbf{x}} \in \mathcal{X}_\omega (\mathbf{x}) \), then generally it is easy to find a set \( \mathcal{B}_{m, \delta} (\mathbf{x}) \) that satisfies (2.50), so that (2.26b) holds.

### 2.2.2 Asymptotic Bounds and Approximations for Mutual Information

Let

\[
\xi = N^{-1} \left\langle \left\| \left( l''(\mathbf{r} | \mathbf{x}) - \langle l''(\mathbf{r} | \mathbf{x}) \rangle_{\mathbf{r} | \mathbf{x}} \right) \mathbf{G}^{-1}(\mathbf{x}) l'(\mathbf{r} | \mathbf{x}) \right\|^2 \right\rangle_{\mathbf{r} | \mathbf{x}} ,
\]

(2.51)
and it follows from conditions $C_1$ and $C_2$ that

$$\xi \leq \left\| N G^{-1} (x) \right\|^2 \left\langle \left\| N^{-1} \left( l''(r|x) - \langle l''(r|x) \rangle_{r|x} \right) \right\|_{r|x}^4 \right\rangle_{r|x}^{1/2} \times \left\langle \left( N^{-1} l'(r|x)^T l'(r|x) \right)^2 \right\rangle_{r|x}^{1/2} \times \left\langle \left( N^{-1} l''(r|x) - \langle l''(r|x) \rangle_{r|x} \right) \right\|_{r|x}^2 \right\rangle_{r|x} = O \left( N^{-1/2} \right). \quad (2.52)$$

Moreover, if $p(r|x)$ is conditionally independent, then by an argument similar to the discussion in Remark 2.2, we can verify that the condition $\xi = O \left( N^{-1} \right)$ is easily met.

In the following we state several conclusions about the MI, and their proofs are given in Appendix.

**Lemma 2.1.** If condition $C_1$ holds, then the MI $I$ has an asymptotic upper bound for integer $N$,

$$I \leq I_G + O \left( N^{-1} \right). \quad (2.53)$$

Moreover, if Eqs. (2.25c) and (2.25d) are replaced by

$$\left\langle \left\| N^{-1} l''(r|x)^T l''(r|x) \right\|_{r|x}^{1+\tau} \right\rangle_{r|x} = O \left( 1 \right), \quad (2.54a)$$

$$\left\langle \left\| N^{-1} \left( l''(r|x) - \langle l''(r|x) \rangle_{r|x} \right) \right\|^2 \right\rangle_{r|x} = o \left( 1 \right). \quad (2.54b)$$

for some $\tau \in (0, 1)$, where $o$ indicates the Little-O notation, then the MI has the following asymptotic upper bound for integer $N$,

$$I \leq I_G + o \left( 1 \right). \quad (2.55)$$

**Lemma 2.2.** If conditions $C_1$ and $C_2$ hold, $\xi = O \left( N^{-1} \right)$, then the MI has an asymptotic lower bound for integer $N$,

$$I \geq I_G + O \left( N^{-1} \right). \quad (2.56)$$

Moreover, if condition $C_1$ holds but Eqs. (2.25c) and (2.25d) are replaced by (2.54a) and (2.54b), and inequality (2.26b) in $C_2$ also holds for $\eta > 0$, then the MI has the following asymptotic lower bound for integer $N$,

$$I \geq I_G + o \left( 1 \right). \quad (2.57)$$
**Theorem 2.1.** If conditions C1 and C2 hold, \( \xi = O\left( N^{-1} \right) \), then the MI has the following asymptotic equality for integer \( N \),

\[
I = I_G + O\left( N^{-1} \right).
\]  

(2.58)

For more relaxed conditions, suppose condition C1 holds but Eqs. (2.25c) and (2.25d) are replaced by (2.54a) and (2.54b), and inequality (2.26b) in C2 also holds for \( \eta > 0 \), then the MI has an asymptotic equality for integer \( N \),

\[
I = I_G + o\left( 1 \right).
\]  

(2.59)

**Theorem 2.2.** Suppose \( J(x) \) and \( G(x) \) are symmetric and positive-definite. Let

\[
\xi = \langle \text{Tr}(\Psi(x)) \rangle_x,
\]  

(2.60)

\[
\Psi(x) = J^{-1/2}(x)P(x)J^{-1/2}(x),
\]  

(2.61)

then

\[
I_G \leq I_F + \frac{\xi}{2},
\]  

(2.62)

where \( \text{Tr}(\cdot) \) indicating matrix trace; moreover, if \( P(x) \) is positive-semidefinite, then

\[
0 \leq I_G - I_F \leq \frac{\xi}{2}.
\]  

(2.63)

On the other hand, if

\[
\xi_1 = \langle \|\Psi(x)\| \rangle_x = O(N^{-\beta})
\]  

(2.64)

for some \( \beta > 0 \), then

\[
I_G = I_F + O(N^{-\beta}).
\]  

(2.65)

**Remark 2.5.** In general, we only need to assume that \( p(x) \) and \( p(r|x) \) are piecewise twice continuously differentiable for \( x \in X \). In this case, Lemma 2.1 Lemma 2.2 and Theorem 2.1 can still be established. For more general cases, such as discrete or continuous inputs, we have also derived a general approximation formula for MI from which we can easily derive formula for \( I_G \) and which will be discussed in separate paper. \( \Box \)
2.3 Approximations of Mutual Information in Neural Populations with Finite Size

In the preceding section we have provided several bounds, including both lower and upper bounds, and asymptotic relationships for the true MI in the large $N$ (network size) limit. In the following, we will discuss effective approximations to the true MI in the case of finite $N$. Here we only consider the case of continuous inputs and will discuss the case of discrete inputs in another paper.

Theorem 2.1 tells us that under suitable conditions, we can use $I_G$ to approximate $I$ for a large but finite $N$ (e.g. $N \gg K$); that is

$$I \simeq I_G. \quad (2.66)$$

Moreover, by Theorem 2.2, we know that if $\varsigma \approx 0$ with positive-semidefinite $P(x)$ or $\varsigma_1 \approx 0$ holds (see Eqs. 2.60 and 2.64), then by (2.63), (2.65) and (2.66) we have

$$I \simeq I_G \simeq I_F. \quad (2.67)$$

Define

$$\tilde{G}(x) = J(x) + P(x) + Q(x),$$

$$\tilde{I}_G = \frac{1}{2} \left< \ln \left( \det \left( \frac{\tilde{G}(x)}{2\pi e} \right) \right) \right>_x + H(X), \quad (2.69)$$

where $\tilde{G}(x)$ is positive-definite, $Q(x)$ is a symmetric matrix depending on $x$ and $\|Q(x)\| = O(1)$. Suppose $\|\tilde{G}^{-1}(x)\| = O(N^{-1})$, if we replace $I_G$ by $\tilde{I}_G$ in Theorem 2.1, then we can prove equations (2.58) and (2.59) in a manner similar to the proof of Theorem 2.1 Considering a special case where $\|P(x)\| \to 0$, $\det(J(x)) = O(1)$ (e.g. rank $(J(x)) \leq K$) and $\|G^{-1}(x)\| \neq O(N^{-1})$, then we can no longer use the asymptotic formulas in Theorem 2.1 However, if we substitute $\tilde{G}(x)$ for $G(x)$ by choosing an appropriate $Q(x)$ such that $\tilde{G}(x)$ is positive-definite and $\|\tilde{G}^{-1}(x)\| = O(N^{-1})$, then we can use (2.58) or (2.59) as the asymptotic formulas.

If we assume $G(x)$ and $\tilde{G}(x)$ are positive-definite and

$$\varsigma = \left< \|Q(x)\tilde{G}^{-1}(x)\| \right>_x = O(N^{-\beta}), \beta > 0, \quad (2.70)$$
then similar to the proof of Theorem 2.2, we have

\[
\langle \ln (\det (G(x))) \rangle_x = \langle \ln (\det (\tilde{G}(x))) \rangle_x + \langle \ln \left( \det \left( I_K - Q(x)\tilde{G}^{-1}(x) \right) \right) \rangle_x = \langle \ln (\det (\tilde{G}(x))) \rangle_x + O(N^{-\beta})
\]

and

\[
\tilde{I}_G = I_G + O(N^{-\beta}).
\]

For large \( N \), we usually have \( \tilde{I}_G \simeq I_G \).

It is more convenient to redefine the following quantities:

\[
Q(x) = P_+ - P(x), \tag{2.72}
\]

\[
P_+ = \left\langle \frac{\partial \ln p(x)}{\partial x} \frac{\partial \ln p(x)}{\partial x^T} \right\rangle_x, \tag{2.73}
\]

\[
G_+(x) = \tilde{G}(x) = J(x) + P_+, \tag{2.74}
\]

and

\[
I_{G_+} = I_G = \frac{1}{2} \left\langle \ln \left( \det \left( \frac{G_+(x)}{2\pi e} \right) \right) \right\rangle_x + H(X). \tag{2.75}
\]

Notice that if \( p(x) \) is twice differentiable for \( x \) and

\[
\int_X \frac{\partial^2 p(x)}{\partial x \partial x^T} dx = 0, \tag{2.76}
\]

then

\[
P_+ = \langle P(x) \rangle_x = \left\langle \frac{1}{p(x)} \frac{\partial^2 p(x)}{\partial x \partial x^T} \right\rangle_x - \left\langle \frac{\partial^2 \ln p(x)}{\partial x \partial x^T} \right\rangle_x. \tag{2.77}
\]

For example, if \( p(x) \) is a normal distribution, \( p(x) = N(\mu, \Sigma) \), then

\[
P(x) = P_+ = \Sigma^{-1}. \tag{2.78}
\]

Similar to the proof of Theorem 2.2, we can prove that

\[
0 \leq I_{G_+} - I_F \leq \zeta_+ \tag{2.79}
\]

where

\[
\zeta_+ = \left\langle \text{Tr} \left( P_+ J^{-1}(x) \right) \right\rangle_x. \tag{2.80}
\]
We find that $I_G$ is often a good approximation of MI $I$ even for relatively small $N$. However, we cannot guarantee that $P(x)$ is always positive-semidefinite in Eqs. (2.14), and as a consequence, it may happen that $\det(G(x))$ is very small for small $N$, $G(x)$ is not positive-definite and $\ln(\det(G(x)))$ is not a real number. In this case, $I_G$ is not a good approximation to $I$ but $I_{G+}$ is still a good approximation. Generally, if $P(x)$ is always positive-semidefinite, then $I_G$ or $I_{G+}$ is a better approximation than $I_F$, especially when $p(x)$ be close to a normal distribution.

In the following we will give an example of 1-D inputs. High-dimensional inputs will be discussed in section 4.1.

### 2.3.1 A Numerical Comparison for 1-D Stimuli

Considering the Poisson neuron model (see Eq. 5.7 in section 5.1 for details), the tuning curve of the $n$-th neuron, $f(x; \theta_n)$, takes the form of circular normal or von Mises distribution

$$f(x; \theta_n) = A \exp\left(-\left(\frac{T}{2\pi\sigma_f}\right)^2 \left(1 - \cos\left(\frac{2\pi}{T} (x - \theta_n)\right)\right)\right),$$  \hspace{1cm} (2.81)

where $x \in [-T/2, T/2)$, $\theta_n \in [-T_\theta/2, T_\theta/2]$, $n \in \{1, 2, \cdots, N\}$, with $T = \pi$, $T_\theta = 1$, $\sigma_f = 0.5$ and $A = 20$, and the centers $\theta_1, \theta_2, \cdots, \theta_N$ of the $N$ neurons are uniformly distributed on interval $[-T_\theta/2, T_\theta/2]$, i.e., $\theta_n = (n - 1) d_\theta - T_\theta/2$, with $d_\theta = T_\theta/(N - 1)$ and $N \geq 2$. Suppose the distribution of 1-D continuous input $x$ ($K = 1$) $p(x)$ has the form

$$p(x) = Z^{-1} \exp\left(-\left(\frac{T}{2\pi\sigma_p}\right)^2 \left(1 - \cos\left(\frac{2\pi}{T} x\right)\right)\right),$$  \hspace{1cm} (2.82)

where $\sigma_p$ is a constant set to $\pi/4$, and $Z$ is the normalization constant. Figure 1A shows graphs of the input distribution $p(x)$ and the tuning curves $f(x; \theta)$ with different centers $\theta = -\pi/4, 0, \pi/4$.

To evaluate the precision of the approximation formulas, we use Monte Carlo (MC) simulation to approximate MI $I$. For MC simulation, we first sample an input $x_j$ by the distribution $p(x)$, then generate the neural response $r_j$ by the conditional distribution $p(r_j|x_j)$, where $j = 1, 2, \cdots, j_{\text{max}}$. The value of MI by MC simulation is calculated by

$$I^*_{MC} = \frac{1}{j_{\text{max}}} \sum_{j=1}^{j_{\text{max}}} \ln \left(\frac{p(r_j|x_j)}{p(r_j)}\right),$$  \hspace{1cm} (2.83)
where $p(r_j)$ is given by
\[ p(r_j) = \sum_{m=1}^{M} p(r_j|x_m)p(x_m), \quad (2.84) \]
and $x_m = (m - 1) T/M - T/2$ for $m \in \{1, 2, \cdots, M\}$.

To evaluate the accuracy of MC simulation, we compute the standard deviation
\[ I_{std} = \sqrt{\frac{1}{i_{\max}} \sum_{i=1}^{i_{\max}} (I_{i_{MC}}^i - I_{MC})^2}, \quad (2.85) \]
where
\[ I_{i_{MC}}^j = \frac{1}{j_{\max}} \sum_{j=1}^{j_{\max}} \ln \left( \frac{p(r_{j_{\Gamma_{ji}}}|x_{\Gamma_{ji}})}{p(r_{j_{\Gamma_{ji}}})} \right), \quad (2.86) \]
\[ I_{MC} = \frac{1}{i_{\max}} \sum_{i=1}^{i_{\max}} I_{i_{MC}}^i, \quad (2.87) \]
and $\Gamma_{ji} \in \{1, 2, \cdots, j_{\max}\}$ is the $(j, i)$-th entry of the matrix $\Gamma \in \mathbb{N}^{j_{\max} \times i_{\max}}$ with samples taken randomly from the integer set $\{1, 2, \cdots, j_{\max}\}$ by a uniform distribution. Here we set $j_{\max} = 5 \times 10^5$, $i_{\max} = 100$ and $M = 10^3$.

For different $N \in \{2, 3, 4, 6, 10, 14, 20, 30, 50, 100, 200, 400, 700, 1000\}$, we compare $I_{MC}$ with $I_G$, $I_{G+}$ and $I_F$, which are illustrated in Figure 1B–D. Here we define the relative error of approximation, e.g., for $I_G$, as
\[ DI_G = \frac{I_G - I_{MC}}{I_{MC}}, \quad (2.88) \]
and the relative standard deviation
\[ DI_{std} = \frac{I_{std}}{I_{MC}}. \quad (2.89) \]
Figure 1B shows how the values of $I_{MC}$, $I_G$, $I_{G+}$ and $I_F$ change with neuron number $N$, and Figure 1C and 1D show their relative errors and the absolute values of the relative errors with respect to $I_{MC}$. From Figure 1B–D we can see that the values of $I_G$, $I_{G+}$ and $I_F$ are all very close to one another and the absolute values of their relative errors are all very small. The absolute values are less than 1% when $N \geq 10$ and less than 0.1% when $N \geq 100$. However, for the high-dimensional inputs, there will be a big difference between $I_G$, $I_{G+}$ and $I_F$ in many cases (see section 4.1 for more details).
Figure 1: A comparison of approximations $I_{MC}$, $I_G$, $I_{G+}$ and $I_F$ for one-dimensional input stimuli. All of them were almost equally good, even for small population size $N$. (A) The stimulus distribution $p(x)$ and tuning curves $f(x; \theta)$ with different centers $\theta = -\pi/4, 0, \pi/4$. (B) The values of $I_{MC}$, $I_G$, $I_{G+}$ and $I_F$ all increase with neuron number $N$. (C) The relative errors $DI_G$, $DI_{G+}$ and $DI_F$ for the results in panel B. (D) The absolute values of the relative errors $|DI_G|$, $|DI_{G+}|$, and $|DI_F|$, with error bars showing standard deviations of repeated trials.
3 Statistical Estimators and Neural Population Decoding

Given the neural response \( r \) elicited by the input \( x \), we may infer or estimate the input \( x \) from the response. This procedure is sometimes referred to as decoding from the response. We need to choose an efficient estimator, or a function \( \hat{x} = \hat{x}(r) \) that maps the response \( r \) to an estimate \( \hat{x} \) of the true stimulus \( x \). The Maximum Likelihood (ML) estimator defined by

\[
\hat{x}(r) = \arg \max_x p(r|x) = \arg \max_x l(r|x)
\]  

(3.1)
is known to be efficient in large \( N \) limit. According to the Cramér-Rao lower bound (Rao, 1945), we have the following relationship between the covariance matrix of any unbiased estimator, \( \Sigma_{\hat{x}} \), and the FI matrix \( J(x) \),

\[
\Sigma_{\hat{x}} = \left\langle (\hat{x}(r) - x)(\hat{x}(r) - x)^T \right\rangle_r |_x \geq J^{-1}(x),
\]

(3.2)

where \( \hat{x}(r) \) is an unbiased estimation of \( x \) from the response \( r \), and \( A \geq B \) means that matrix \( A - B \) is positive-semidefinite. Thus

\[
I_F = \frac{1}{2} \left\langle \ln \left( \det \left( \frac{J(x)}{2\pi e} \right) \right) \right\rangle_x + H(X)
\]

\[
\geq \frac{1}{2} \left\langle \ln \left( \det \left( \frac{\Sigma_{\hat{x}}^{-1}}{2\pi e} \right) \right) \right\rangle_x + H(X) = \hat{I}_{\text{var}}.
\]

(3.3)

On the other hand, the MI between \( X \) and \( \hat{X} \) is given by

\[
\hat{I} = H(\hat{X}) - \left\langle H(\hat{X}|X) \right\rangle_{\hat{x},x},
\]

(3.4)

where \( H(\hat{X}) \) is the entropy of random variable \( \hat{X} \) and \( H(\hat{X}|X) \) is its conditional entropy of random variable \( \hat{X} \) given \( X \). Since the maximum entropy probability distribution is Gaussian, \( H(\hat{X}|X) \) satisfies

\[
H(\hat{X}|X) \leq \frac{1}{2} \ln \left( \det \left( 2\pi e \Sigma_{\hat{x}} \right) \right).
\]

(3.5)

Therefore, from (3.4) and (3.5), we get

\[
\hat{I} \geq \frac{1}{2} \left\langle \ln \left( \det \left( \frac{\Sigma_{\hat{x}}^{-1}}{2\pi e} \right) \right) \right\rangle_x + H(\hat{X}) = \hat{I}_{\text{var}}.
\]

(3.6)
The data processing inequality (Cover & Thomas, 2006) states that post-processing cannot increase information, so that we have

\[ I \geq \hat{I} \geq \hat{I}_{\text{var}}. \]  

(3.7)

Here we can not directly obtain \( I \geq I_F \) as in Brunel & Nadal (1998) when \( H(\hat{X}) = H(X) \) and \( I_{\text{var}} = \hat{I}_{\text{var}} \). The simulation results in Figure 1 also show that \( I_F \) is not a lower bound of \( I \).

For biased estimators, the van Trees’ Bayesian Cramér-Rao bound (Van Trees & Bell, 2007) provides a lower bound:

\[
\langle \Sigma_{\hat{x}} \rangle_x = \left\langle \left( (\hat{x}(r) - x)(\hat{x}(r) - x)^T \right)_{r|x} \right\rangle_x \geq \left( \langle J(x) \rangle_x + P_+ \right)^{-1} = \langle G_+(x) \rangle_x^{-1}.
\]

(3.8)

It follows from (2.75), (3.6) and (3.8) that

\[
I_{G_+} \leq \frac{1}{2} \ln \left( \det \left( \frac{\langle G_+(x) \rangle_x}{2\pi e} \right) \right) + H(X) = I_{VT},
\]

(3.9)

\[
I_{VT} \geq \frac{1}{2} \ln \left( \det \left( \frac{\langle \Sigma_{\hat{x}} \rangle_x^{-1}}{2\pi e} \right) \right) + H(X) = \tilde{I}_{var},
\]

(3.10)

\[
I_{\text{var}} \geq \tilde{I}_{\text{var}}.
\]

(3.11)

We may also regard decoding as Bayesian inference. By Bayes’ rule,

\[
p(x|r) = \frac{p(r|x)p(x)}{p(r)}.
\]

(3.12)

According to the Bayesian decision theory, if we know the response \( r \), from the prior \( p(x) \) and the likelihood \( p(r|x) \), we can infer an estimation of the true stimulus \( x \), \( \hat{x}(r) \), for example,

\[
\hat{x}(r) = \arg \max_x p(x|r) = \arg \max_x L(r|x),
\]

(3.13)

which is also called Maximum A Posteriori (MAP) estimation.

Consider a loss function \( \varphi(\hat{x}(r)|x) \) for estimation,

\[
\varphi(\hat{x}(r)|x) = -\ln p(x|r),
\]

(3.14)

which is minimized when \( p(x|r) \) reaches its maximum. Now the conditional risk is

\[
R(\hat{x}(r)|r) = \left\langle \varphi(\hat{x}(r)|x) \right\rangle_{x|r},
\]

(3.15)
and the overall risk is

\[ R_o = \langle R(\hat{x}(r)|r) \rangle_r = \left\langle \langle \varphi(\hat{x}(r)|x) \rangle_{x|r} \right\rangle_r = -\langle \ln p(x|r) \rangle_{x,r}. \] (3.16)

Then it follows from (2.3) and (3.16) that

\[ I = \langle \ln p(x|r) \rangle_{r,x} + H(X) = -R_o + H(X). \] (3.17)

Comparing (2.12), (2.66) and (3.17), we find

\[ R_o \simeq -\frac{1}{2} \left\langle \ln \left( \det \left( \frac{G(x)}{2\pi e} \right) \right) \right\rangle_x. \] (3.18)

Hence, maximizing MI \( I \) (or \( I_G \)) means minimizing the overall risk \( R_o \) for a determinate \( H(X) \). Therefore, we can get the optimal Bayesian inference via optimizing MI \( I \) (or \( I_G \)).

By the Cramér-Rao lower bound, we know that the inverse of FI matrix \( J^{-1}(x) \) reflects the accuracy of decoding (see Eq. 3.2). \( P(x) \) provides some knowledge about the prior distribution \( p(x) \); for example, \( P^{-1}(x) \) is the covariance matrix of input \( x \) when \( p(x) \) is a normal distribution. \( \|P(x)\| \) is small for a flat prior (poor prior) and large for a sharp prior (good prior). Hence, if the prior \( p(x) \) is flat or poor and the knowledge about model is rich, then the MI \( I \) is governed by the knowledge of model, which results in a small \( \varsigma_1 \) (Eq. 2.64) and \( I \simeq I_G \simeq I_F \). Otherwise, the prior knowledge has a great influence on MI \( I \), which results in a large \( \varsigma_1 \) and \( I \simeq I_G \not\simeq I_F \).

4 Variable Transformation and Dimensionality Reduction in Neural Population Coding

For low-dimensional input \( x \) and large \( N \), both \( I_G \) are \( I_F \) are good approximations of MI \( I \), but for high-dimensional input \( x \), a large value of \( \varsigma_1 \) may lead to a large error of \( I_F \), in which case \( I_G \) (or \( I_{G+,} \)) is a better approximation. It is difficult to directly apply the approximation formula \( I \simeq I_G \) when we do not have an explicit expression of \( p(x) \) or \( P(x) \). For many applications, we do not need to know the exact value of \( I_G \) and only care about the value of \( \langle \ln (\det(G(x))) \rangle_x \) (see section 5). From (2.12),
and (2.78), we know that if \( p(x) \) is close to a normal distribution, we can easily approximate \( P(x) \) and \( H(X) \) to obtain \( \langle \ln (\det (G(x))) \rangle_x \) and \( I_G \). When \( p(x) \) is not a normal distribution, we can employ a technique of variable transformation to make it closer to a normal distribution, as discussed below.

4.1 Variable Transformation

Suppose \( T: \mathcal{X} \to \tilde{\mathcal{X}} \) is an invertible and differentiable mapping:

\[
\tilde{x} = T(x) = (T_1(x), T_2(x), \ldots, T_K(x))^T, \tag{4.1}
\]

\( x = T^{-1}(\tilde{x}) \) and \( \tilde{x} \in \tilde{\mathcal{X}} \subseteq \mathbb{R}^K \). Let \( p(\tilde{x}) \) denotes the p.d.f. of random variable \( \tilde{X} \) and

\[
p(r|\tilde{x}) = p(r|x)|_{x = T^{-1}(\tilde{x})}. \tag{4.2}
\]

Then we have the following conclusions, the proofs of which are given in Appendix.

**Theorem 4.1.** The MI is equivariant under the invertible transformations. More specifically, for the above invertible transformation \( T \), the MI \( I(X; R) \) in (2.7) is equal to

\[
I(\tilde{X}; R) = \left\langle \ln \frac{p(r|\tilde{x})}{p(r)} \right\rangle_{r, \tilde{x}}. \tag{4.3}
\]

Furthermore, suppose \( p(\tilde{x}) \) and \( p(r|\tilde{x}) \) fulfill the conditions \( C1, C2 \) and \( \xi = O(N^{-1}) \), then we have

\[
I(\tilde{X}; R) = \tilde{I}_G + O(N^{-1}), \tag{4.4}
\]

\[
\tilde{I}_G = \frac{1}{2} \left\langle \ln \left( \det \left( \frac{G(\tilde{x})}{2\pi e} \right) \right) \right\rangle_{\tilde{x}} + H(\tilde{X})
\]

\[
= \frac{1}{2} \left\langle \ln \left( \det \left( \frac{G(x)}{2\pi e} \right) \right) \right\rangle_x + H(X)
\]

\[
= I_G, \tag{4.5}
\]

where \( H(\tilde{X}) \) is the entropy of random variable \( \tilde{X} \) and satisfies

\[
H(\tilde{X}) = -\langle \ln p(\tilde{x}) \rangle_{\tilde{x}} = H(X) + \langle \ln |\det (DT(x))| \rangle_x, \tag{4.6}
\]

and \( DT(x) \) denotes the Jacobian matrix of \( T(x) \).

\[
(DT(x))_{i,j} = \frac{\partial T_i(x)}{\partial x_j}, \quad \forall i, j = 1, 2, \ldots, K. \tag{4.7}
\]
Corollary 4.1. Suppose $p(r|x)$ is a normal distribution,

$$p(r|x) = \mathcal{N} \left( A^T y, I_N \right),$$  \hspace{1cm} (4.8)

where $y = f \left( B^T x \right) = (y_1, y_2, \cdots, y_K)^T$, $y_k = f_k(b_k^T x)$ for $k = 1, 2, \cdots, K$, $A$ is a deterministic $K \times N$ matrix, $B = [b_1, b_2, \cdots, b_K]$ is a deterministic invertible matrix and $f_k$ is an invertible and differentiable function. If $Y$ has also a normal distribution, $p(y) = \mathcal{N} \left( \mu_f, \Sigma_f \right)$, then

$$I_G = I_{G+} = I(X; R) = I(Y; R)$$

$$= \frac{1}{2} \ln \left( \det \left( \frac{1}{2\pi e} \left( AA^T + \Sigma_f^{-1} \right) \right) \right) + H(Y)$$

$$= \frac{1}{2} \left\langle \ln \left( \det \left( \frac{1}{2\pi e} \left( J(x) + P(x) \right) \right) \right) \right\rangle_x + H(X),$$ \hspace{1cm} (4.9)

where

$$H(Y) = \frac{1}{2} \ln \left( \det \left( 2\pi e \Sigma_f \right) \right) = H(X) + \left\langle \ln \left| \det \left( D(x) \right) \right| \right\rangle_x,$$ \hspace{1cm} (4.10)

$$D(x) = \left( f'_1(b_1^T x)b_1, f'_2(b_2^T x)b_2, \cdots, f'_K(b_K^T x)b_K \right)^T,$$ \hspace{1cm} (4.11)

$$f'_k(b_k^T x) = \left. \frac{\partial f_k(y_k)}{\partial y_k} \right|_{y_k = b_k^T x}, \quad \forall k = 1, 2, \cdots, K.$$ \hspace{1cm} (4.12)

Remark 4.1. From Corollary 4.1 and Eq. (2.78) we know that the approximation accuracy for $I_G \simeq I(X; R)$ is improved when we employ an invertible transformation on the input random variable $X$ to make the new random variable $Y$ closer to a normal distribution (see section 4.3). \hspace{1cm} $\square$

Consider the eigendecompositions of $AA^T$ and $\Sigma_f$ as given by

$$AA^T = U_A \hat{\Sigma} U_A^T.$$ \hspace{1cm} (4.13)

$$\Sigma_f = U_f \tilde{\Sigma} U_f^T,$$ \hspace{1cm} (4.14)

where $U_A$ and $U_f$ are $K \times K$ orthogonal matrices; $\hat{\Sigma} = \text{diag} (\hat{\sigma}_1^2, \hat{\sigma}_2^2, \cdots, \hat{\sigma}_K^2)$ and $\tilde{\Sigma} = \text{diag} (\tilde{\sigma}_1^2, \tilde{\sigma}_2^2, \cdots, \tilde{\sigma}_K^2)$ are $K \times K$ eigenvalue matrices, $\hat{\sigma}_1 \geq \hat{\sigma}_2 \geq \cdots \geq \hat{\sigma}_K > 0$ and $\tilde{\sigma}_1 \geq \tilde{\sigma}_2 \geq \cdots \geq \tilde{\sigma}_K > 0$. \hspace{1cm} $\square$
and $\bar{\sigma}_1 \geq \bar{\sigma}_2 \geq \cdots \geq \bar{\sigma}_K > 0$. Then by (2.11) and (4.9) we have

$$I_G = I_{G_x} = I(X; R) = I(Y; R)$$
$$= \frac{1}{2} \ln \left( \det \left( \frac{1}{2\pi e} \left( \mathbf{U}_A \hat{\Sigma} \mathbf{U}_A^T + \mathbf{U}_f \hat{\Sigma}^{-1} \mathbf{U}_f^T \right) \right) \right) + H(Y), \quad (4.15)$$

$$I_F = \frac{1}{2} \ln \left( \det \left( \frac{\hat{\Sigma}}{2\pi e} \right) \right) + H(Y), \quad (4.16)$$

and

$$I_F - I_G = -\frac{1}{2} \ln \left( \det \left( \mathbf{I}_K + \hat{\Sigma}^{-1/2} \mathbf{U}_A \Sigma^{-1} \mathbf{U}_f^T \mathbf{U}_A \hat{\Sigma}^{-1/2} \right) \right). \quad (4.17)$$

Now consider two special cases. If $\hat{\Sigma} = \mathbf{I}_K$, then by (4.17) we get

$$I_F - I_G = -\frac{1}{2} \ln \left( 1 + \hat{\sigma}_K^{-2} \right). \quad (4.18)$$

If $\mathbf{U}_A = \mathbf{U}_f$, then

$$I_F - I_G = -\frac{1}{2} \sum_{k=1}^{K} \ln \left( 1 + \hat{\sigma}_K^{-2} \hat{\sigma}_K^{-2} \right). \quad (4.19)$$

Here $\mathbf{J}(\mathbf{x}) = \mathbf{U}_A \hat{\Sigma} \mathbf{U}_A^T$, $\mathbf{P}^{-1}(\mathbf{x}) = \mathbf{U}_f \hat{\Sigma} \mathbf{U}_f^T$. The FI matrix $\mathbf{J}(\mathbf{x})$ and $\mathbf{P}^{-1}(\mathbf{x})$ become degenerate when $\hat{\sigma}_K^2 \to 0$ and $\hat{\sigma}_K^2 \to 0$.

From (4.18) and (4.19) we see that if either $\mathbf{J}(\mathbf{x})$ or $\mathbf{P}^{-1}(\mathbf{x})$ becomes degenerate, then $(I_F - I_G) \to -\infty$. This may happen for high-dimensional stimuli. For a specific example, consider a random matrix $\mathbf{A}$ defined as follows. Here we first generate $K \times N$ elements $A_{k,n}$, $(k = 1, 2, \cdots, K; n = 1, 2, \cdots, N)$ from a normal distribution $\mathcal{N}(0, 1)$. Then each column of matrix $\mathbf{A}$ is normalized by $A_{k,n} \leftarrow A_{k,n} / \sqrt{\sum_{k=1}^{K} A_{k,n}^2}$. We randomly sample $M$ (set to $2 \times 10^4$) image patches with size $w \times w$ from Olshausen’s nature image dataset (Olshausen & Field, 1996) as the inputs. Each input image patch was centered by subtracting its mean, i.e., $\mathbf{x}_m \leftarrow \mathbf{x}_m - \frac{1}{K} \sum_{k=1}^{K} x_{k,m}$, then let $\mathbf{x}_m \leftarrow \mathbf{x}_m - \frac{1}{M} \sum_{m'=1}^{M} x_{m'}$ for $\forall m \in \{1, 2, \cdots, M\}$. Define matrix $\mathbf{X} = [\mathbf{x}_1, \mathbf{x}_2, \cdots, \mathbf{x}_M]$ and compute eigendecomposition

$$\frac{1}{M} \mathbf{X} \mathbf{X}^T = \mathbf{U}_x \hat{\Sigma}_x \mathbf{U}_x^T, \quad (4.20)$$

where $\mathbf{U}_x$ is a $K \times K$ orthogonal matrix and $\hat{\Sigma} = \text{diag}(\hat{\sigma}_1^2, \hat{\sigma}_2^2, \cdots, \hat{\sigma}_K^2)$ is a $K \times K$ eigenvalue matrix with $\hat{\sigma}_1 \geq \hat{\sigma}_2 \geq \cdots \geq \hat{\sigma}_K > 0$. Define

$$\mathbf{y} = \mathbf{U}_x^T \mathbf{x}, \quad (4.21)$$
then
\[
\frac{1}{M} \sum_{m=1}^{M} y_m y_m^T = \tilde{\Sigma}.
\] (4.22)

The distribution of random variable $Y$ can be approximated by a normal distribution (see section 4.3 for more details). When $p(y) = \mathcal{N}(\mu, \Sigma)$, we have

\[
I_G = I_{G+} = I(X; R) = I(Y; R),
\] (4.23)

\[
I_G = \frac{1}{2} \ln \left( \det \left( \frac{1}{2\pi e} \left( \Sigma + \tilde{\Sigma}^{-1} \right) \right) \right) + H(Y)
= \frac{1}{2} \ln \left( \det \left( \frac{1}{2\pi e} \left( \tilde{\Sigma}^{1/2} \Sigma^{1/2} + \mathbf{I}_K \right) \right) \right),
\] (4.24)

\[
I_F = \frac{1}{2} \ln \left( \det \left( \frac{\mathbf{A} \mathbf{A}^T}{2\pi e} \right) \right) + H(Y).
\] (4.25)

The error of approximation $I_F$ is given by

\[
dI_F = I_F - I(X; R) = I_F - I_G
= -\frac{1}{2} \ln \left( \det \left( \mathbf{I}_K + (\mathbf{A} \mathbf{A}^T)^{-1} \tilde{\Sigma}^{-1} \right) \right),
\] (4.26)

and the relative error for $I_F$ is

\[
DI_F = \frac{dI_F}{I_G}.
\] (4.27)

Figure 2A shows how the values of $I_G$ and $I_F$ vary with the input dimension $K = w \times w$ and the number of neurons $N$ (with $w = 2, 4, 6, \cdots, 30$ and $N = 10^4, 2 \times 10^4, 5 \times 10^4, 10^5$). The relative error $DI_F$ is shown in Figure 2B. The absolute value of the relative error tends to decrease with $N$ but may grow quite large as $K$ increases. In Figure 2B, the largest absolute value of relative error $|DI_F|$ is greater than 5000%, which occurs when $K = 900$ and $N = 10^4$. Even the smallest $|DI_F|$ is still greater than 80%, which occurs when $K = 100$ and $N = 10^5$. In this example, $I_F$ is a bad approximation of MI $I$ whereas $I_G$ and $I_{G+}$ are strictly equal to the true MI $I$ across all parameters.
Figure 2: A comparison of approximations $I_G$ and $I_F$ for different input dimensions. Here $I_G$ is always equal to the true MI with $I_G = I_{G+} = I(X; R)$, whereas $I_F$ always has nonzero errors. (A) The value $I_G$ and $I_F$ vary with input dimension $K = \omega^2$ with $\omega = 2, 4, 6, \ldots, 30$, and the number of neurons $N = N_i$ with $N_1 = 10^4$, $N_2 = 2 \times 10^4$, $N_3 = 5 \times 10^4$, $N_4 = 10^5$. (B) The relative error $DI_F$ changes with input dimension $K$ for different $N$.

4.2 Dimensionality Reduction for Asymptotic Approximations

Suppose $\mathbf{x} = (x_1, \ldots, x_K)^T$ is partitioned into two sets of components, $\mathbf{x} = (\mathbf{x}_1^T, \mathbf{x}_2^T)^T$ with

$$\mathbf{x}_1 = (x_1, x_2, \ldots, x_{K_1})^T,$$

$$\mathbf{x}_2 = (x_{K_1+1}, x_{K_1+2}, \ldots, x_K)^T,$$

where $\mathbf{x}_1 \in \mathcal{X}_1 \subseteq \mathbb{R}^{K_1}$, $\mathbf{x}_2 \in \mathcal{X}_2 \subseteq \mathbb{R}^{K_2}$, $K_1 + K_2 = K$, $K \geq 2$, $K_1 \geq 1$ and $K_2 \geq 1$.

Then, by Fubini’s theorem, the MI $I$ in (2.1) can be written as

$$I = \int_{\mathcal{X}_2} \int_{\mathcal{X}_1} \int_{\mathcal{R}} p(r|\mathbf{x}_1, \mathbf{x}_2)p(\mathbf{x}_1, \mathbf{x}_2) \ln \frac{p(r|\mathbf{x}_1, \mathbf{x}_2)}{p(r)} d\mathbf{r} d\mathbf{x}_1 d\mathbf{x}_2,$$

where $p(\mathbf{x}_1, \mathbf{x}_2) = p(\mathbf{x})$ and $p(r|\mathbf{x}_1, \mathbf{x}_2) = p(r|\mathbf{x})$.

First define

$$\mathbf{G} (\mathbf{x}) = \begin{pmatrix} \mathbf{G}_{1,1} (\mathbf{x}) & \mathbf{G}_{1,2} (\mathbf{x}) \\ \mathbf{G}_{2,1} (\mathbf{x}) & \mathbf{G}_{2,2} (\mathbf{x}) \end{pmatrix},$$

$$\mathbf{G}_{i,j} (\mathbf{x}) = \mathbf{J}_{i,j} (\mathbf{x}) + \mathbf{P}_{i,j} (\mathbf{x}).$$
where $i, j \in \{1, 2\}$, and

$$ J_{i,j}(x) = \left\langle \frac{\partial \ln p(r|x)}{\partial x_i} \frac{\partial \ln p(r|x)}{\partial x_j^T} \right\rangle_{r|x}, \tag{4.32a} $$

$$ P_{i,j}(x) = -\frac{\partial^2 \ln p(x)}{\partial x_i \partial x_j^T}. \tag{4.32b} $$

Then we have the following results and their proofs are given in Appendix.

**Theorem 4.2.** Suppose matrices $G(x)$, $G_{1,1}(x)$ and $G_{2,2}(x)$ are positive-definite. If the matrix $A_x \in \mathbb{R}^{K \times K}$ satisfies

$$ |\text{Tr}(\langle A_x \rangle_x)| \ll 1 \tag{4.33} $$

with

$$ A_x = G_{2,2}^{-1/2}(x) G_{2,1}(x) G_{1,1}^{-1}(x) G_{1,2}(x) G_{2,2}^{-1/2}, \tag{4.34} $$

then we have

$$ I_G \simeq I_{G_1}, \tag{4.35} $$

with strict equality if and only if

$$ G_{2,1}(x) G_{1,1}^{-1}(x) G_{1,2}(x) = 0, \tag{4.36} $$

where

$$ I_{G_1} = \frac{1}{2} \left\langle \ln \left( \det \left( \frac{G_{1,1}(x)}{2\pi e} \right) \right) \right\rangle_x + \frac{1}{2} \left\langle \ln \left( \det \left( \frac{G_{2,2}(x)}{2\pi e} \right) \right) \right\rangle_x + H(X). \tag{4.37} $$

**Theorem 4.3.** Suppose matrices $G(x)$, $G_{1,1}(x)$ and $P_{2,2}(x)$ are positive-definite. If the matrix $B_x \in \mathbb{R}^{K_2 \times K_2}$ is positive-semidefinite and satisfies

$$ 0 \leq \text{Tr}(\langle B_x \rangle_x) \ll 1 \tag{4.38} $$

with

$$ B_x = P_{2,2}^{-1/2}(x) C_x P_{2,2}^{-1/2}(x), \tag{4.39} $$

$$ C_x = J_{2,2}(x) - G_{2,1}(x) G_{1,1}^{-1}(x) G_{1,2}(x), \tag{4.40} $$
then we have
\[ I_G \simeq I_{G_2}, \tag{4.41} \]
with strict equality if and only if
\[ C_x = 0, \tag{4.42} \]
where
\[ I_{G_2} = \frac{1}{2} \left\langle \ln \left( \det \left( \frac{G_{1,1}(x)}{2\pi e} \right) \right) \right\rangle_x + \frac{1}{2} \left\langle \ln \left( \det \left( \frac{P_{2,2}(x)}{2\pi e} \right) \right) \right\rangle_x + H(X). \tag{4.43} \]

**Corollary 4.2.** If the random variables \( X_1 \) and \( X_2 \) are independent so that \( p(x) = p(x_1) p(x_2) \), \( p(x_2) = N(\mu_2, \Sigma_{x_2}) \) is a normal distribution, and \( G(x) \), \( G_{1,1}(x) \), \( P_{1,1}(x) \) and \( P_{2,2}(x) \) are all positive-definite and satisfy (4.38), then we have
\[ I_G \simeq I_{G_1'}, \tag{4.44} \]
\[ I_{G_1'} = \frac{1}{2} \left\langle \ln \left( \det \left( \frac{G_{1,1}(x)}{2\pi e} \right) \right) \right\rangle_x + H(X_1). \tag{4.45} \]
with strict equality if and only if
\[ C_x = J_{2,2}(x) - J_{2,1}(x) G_{1,1}^{-1}(x) J_{1,2}(x) = 0, \tag{4.46} \]
where
\[ H(X_1) = - \left\langle \ln p(x_1) \right\rangle_{x_1}, \tag{4.47a} \]
\[ G_{1,1}(x) = J_{1,1}(x) + P_{1,1}(x), \tag{4.47b} \]
\[ P_{1,1}(x) = - \frac{\partial^2 \ln p(x_1)}{\partial x_1 \partial x_1^T}. \tag{4.47c} \]

**Remark 4.2.** Sometimes we are concerned only with calculating the determinant of matrix \( G(x) \) with a given \( p(x) \). **Theorem 4.2** and **Theorem 4.3** provide a dimensionality reduction method for computing \( G(x) \) or \( \det (G(x)) \), by which we only need to compute \( G_{1,1}(x) \) and \( G_{2,2}(x) \) separately. To apply the approximation (4.35), we do not need to strictly require \( |\text{Tr} (\left\langle A_x \right\rangle_x)| \ll 1 \); instead we only need to require
\[ |\text{Tr} (\left\langle A_x \right\rangle_x)| \ll \left| \left\langle \ln (\det (G_{1,1}(x)) \det (G_{2,2}(x))) \right\rangle_x \right|. \tag{4.48} \]
Similarly, the inequality $|\text{Tr} (\langle B_x \rangle_x)| \ll 1$ can be substituted by
\[
|\text{Tr} (\langle B_x \rangle_x)| \ll |\langle \ln(\det(G_{1,1}(x)) \det(P_{2,2}(x))) \rangle_x|.
\] (4.49)

By (4.44) and the second mean value theorem for integrals, we get
\[
I_{G_1} = \frac{1}{2} \left\langle \ln \left( \frac{\det(G_{1,1}(x_1, \bar{x}_2))}{2\pi e} \right) \right\rangle_{x_1} + H(X_1)
\] (4.50)
for some fixed $\bar{x}_2 \in \mathcal{X}_2$. When $\|\Sigma_{x_2}\|$ is small, $\bar{x}_2$ should be close to the mean: $\bar{x}_2 \approx \mu_2$. It follows from Theorem 2.1 and Corollary 4.2 that the approximate relationship $I \approx I_{G_1}$ holds. However, Eq. (4.50) implies that $I_{G_1}$ is determined only by the first component $x_1$. Hence, there is little impact on information transfer by the minor component (i.e. $x_2$) for the high-dimensional input $x$. In other words, the information transfer is mainly determined by the first component $x_1$ and we can omit the minor component $x_2$. □

4.3 Further Discussion

Suppose $x$ is a zero-mean vector, and if it is not, then let $x \leftarrow x - \langle x \rangle_x$. The covariance matrix of $x$ is given by
\[
\Sigma_x = \left\langle xx^T \right\rangle_x = U\Sigma U^T,
\] (4.51)
where $U$ is a $K \times K$ orthogonal matrix whose $k$-th column is the eigenvector $u_k$ of $\Sigma_x$, and $\Sigma$ is diagonal matrix whose diagonal elements are the corresponding eigenvalues, i.e., $\Sigma = \text{diag}(\sigma_1^2, \sigma_2^2, \ldots, \sigma_K^2)$ with $\sigma_1 \geq \sigma_2 \geq \cdots \geq \sigma_K > 0$. With the whitening transformation,
\[
\tilde{x} = \Sigma^{-1/2}U^Tx,
\] (4.52)
the covariance matrix of $\tilde{x}$ becomes an identity matrix:
\[
\Sigma_{\tilde{x}} = \left\langle \tilde{x}\tilde{x}^T \right\rangle_{\tilde{x}} = \Sigma^{-1/2}U^T \left\langle xx^T \right\rangle_x U\Sigma^{-1/2} = I_K.
\] (4.53)

By the central limit theorem, the distribution of random variable $\tilde{X}$ should be closer to a normal distribution than the distribution of the original random variable $X$; that is, $p(\tilde{x}) \simeq \mathcal{N}(0, I_K)$. Using Laplace’s method asymptotic expansion (MacKay, 2003),
we get
\[
P(\tilde{x}) = -\frac{\partial^2 \ln p(\tilde{x})}{\partial \tilde{x} \partial \tilde{x}^T} \simeq \Sigma_{\tilde{x}}^{-1} = I_K, \tag{4.54}
\]
\[
P_+ = \langle P(\tilde{x}) \rangle_{\tilde{x}} \simeq \Sigma_{\tilde{x}}^{-1} = I_K. \tag{4.55}
\]

In principal component analysis (PCA), the dataset is modeled by a multivariate gaussian. By a PCA-like whitening transformation (4.52) we can use the approximation (4.55) with Laplace’s method, which only requires that the peak be close to the mean and the random variable \( \tilde{X} \) does not need to be an exact Gaussian distribution.

By Theorem 4.1 we have
\[
I(\tilde{X}; R) \simeq I_G = \frac{1}{2} \left\langle \ln \left( \det \left( \frac{G(\tilde{x})}{2\pi e} \right) \right) \right\rangle_{\tilde{x}} + H(\tilde{X}), \tag{4.56}
\]
where
\[
G(\tilde{x}) = J(\tilde{x}) + I_K, \tag{4.57}
\]
\[
J(\tilde{x}) = \left\langle \frac{\partial \ln p(r|\tilde{x}) \partial \ln p(r|\tilde{x})}{\partial \tilde{x} \partial \tilde{x}^T} \right\rangle_{r|\tilde{x}} \tag{4.58}
\]
\[
= \Sigma^{1/2} U^T \left\langle \frac{\partial \ln p(r|x) \partial \ln p(r|x)}{\partial x \partial x^T} \right\rangle_{r|x} U \Sigma^{1/2} \tag{4.59}
\]
\[
= \Sigma^{1/2} U^T J(x) U \Sigma^{1/2}, \tag{4.60}
\]
\[
H(\tilde{X}) = -\langle \ln p(\tilde{x}) \rangle_{\tilde{x}} = H(X) - \frac{1}{2} \ln (\det(S)). \tag{4.61}
\]

Given a \( K \times K \) orthogonal matrix \( B \in \mathbb{R}^{K \times K} \), we define
\[
y = B^T \tilde{x}. \tag{4.62}
\]

Then it follows from (4.56)–(4.62) that
\[
I(Y; R) \simeq I_G = \frac{1}{2} \left\langle \ln \left( \det \left( \frac{G(y)}{2\pi e} \right) \right) \right\rangle_y + H(Y), \tag{4.63}
\]
where
\[
G(y) = J(y) + I_K, \tag{4.64}
\]
\[
J(y) = B^T J(\tilde{x}) B, \tag{4.65}
\]
\[
H(Y) = H(\tilde{X}). \tag{4.66}
\]
Suppose $y$ is partitioned into two sets of components, $y = (y_1^T, y_2^T)^T$ and

$$y_1 = (y_1, y_2, \ldots, y_{K_1})^T,$$

$$y_2 = (y_{K_1+1}, y_{K_1+2}, \ldots, y_K)^T,$$  \hspace{1cm} (4.67)

$$y_2 = (y_{K_1+1}, y_{K_1+2}, \ldots, y_K)^T,$$  \hspace{1cm} (4.68)

where $K_1 + K_2 = K$, $K \geq 2$, $K_1 \geq 1$ and $K_2 \geq 1$. Let

$$G(y) = \begin{pmatrix}
J_{1,1}(y) + I_{K_1} & J_{1,2}(y) \\
J_{2,1}(y) & J_{2,2}(y) + I_{K_2}
\end{pmatrix},$$  \hspace{1cm} (4.69)

where

$$J_{i,j}(y) = \left\langle \frac{\partial \ln p(r|y)}{\partial y_i} \frac{\partial \ln p(r|y)}{\partial y_j^T} \right\rangle_{r|y}, \hspace{1cm} \forall i, j = 1, 2.$$  \hspace{1cm} (4.70)

When $K \gg 1$, suppose we can find an orthogonal matrix $B$ and $K_1$ that satisfy the condition (4.38) in Theorem 4.3 or condition (4.49), i.e.

$$0 \leq \left\langle \text{Tr} \left( B_y \right) \right\rangle_y \ll \gamma,$$  \hspace{1cm} (4.71)

$$B_y = J_{2,2}(y) - J_{2,1}(y) (J_{1,1}(y) + I_{K_1})^{-1} J_{1,2}(y),$$  \hspace{1cm} (4.72)

$$\gamma = \left\langle \ln \left( \det (J_{1,1}(y) + I_{K_1}) \right) \right\rangle_y.$$  \hspace{1cm} (4.73)

Here matrix $B_y$ is positive-semidefinite because

$$J_{2,2}(y) - J_{2,1}(y) (J_{1,1}(y) + I_{K_1})^{-1} J_{1,2}(y) = \left\langle \rho(r|y) \rho(r|y)^T \right\rangle_{r|y},$$  \hspace{1cm} (4.74)

where

$$\rho(r|y) = \frac{\partial \ln p(r|y)}{\partial y_2} - J_{2,1}(y) (J_{1,1}(y) + I_{K_1})^{-1} \left( \frac{\partial \ln p(r|y)}{\partial y_1} + a(r) \right),$$  \hspace{1cm} (4.75)

and $a(r)$ is a $K_1$-dimensional random vector that satisfies

$$\left\langle \frac{\partial \ln p(r|y)}{\partial y_2} a(r)^T \right\rangle_{r|y} = \left\langle \frac{\partial \ln p(r|y)}{\partial y_2} \right\rangle_{r|y} \left\langle a(r)^T \right\rangle_{r|y} = 0,$$  \hspace{1cm} (4.76)

$$\left\langle a(r) a(r)^T \right\rangle_{r|y} = I_{K_1}. $$  \hspace{1cm} (4.77)

Assuming that $J_{1,1}(y)$ is positive-definite, $\left\| J_{1,1}^{-1}(y) \right\| = O(N^{-1})$ and $\left\| J_{1,2}(y) \right\| = \left\| J_{2,1}(y) \right\| = O(N)$, we have

$$(J_{1,1}(y) + I_{K_1})^{-1} = J_{1,1}^{-1}(y) - J_{1,1}^{-2}(y) + O(J_{1,1}^{-3}(y))$$  \hspace{1cm} (4.78)
and

\[
\text{Tr} (C_x) = \text{Tr} \left( J_{2,2}(y) - J_{2,1}(y)J_{1,1}^{-1}(y)J_{1,2}(y) \right) \\
+ \text{Tr} \left( J_{2,1}(y)J_{1,1}^{-2}(y)J_{1,2}(y) \right) + O \left( N^{-1} \right).
\]

(4.79)

Hence, if

\[
\left| \text{Tr} \left( J_{2,2}(y) - J_{2,1}(y)J_{1,1}^{-1}(y)J_{1,2}(y) \right) \right| \ll \gamma, \quad (4.80)
\]

and

\[
\left| \text{Tr} \left( J_{2,1}(y)J_{1,1}^{-2}(y)J_{1,2}(y) \right) \right| \ll \gamma, \quad (4.81)
\]

then (4.71) holds. Notice that the matrix \( \left( J_{2,2}(y) - J_{2,1}(y)J_{1,1}^{-1}(y)J_{1,2}(y) \right) \) is positive-semidefinite which is similar to (4.74) and \( 0 \leq \text{Tr} \left( J_{2,1}(y)J_{1,1}^{-1}(y)J_{1,2}(y) \right) \leq \text{Tr} (J_{2,2}(y)) \).

Hence, if

\[
\text{Tr} (J_{2,2}(y)) \ll \gamma, \quad (4.82)
\]

then (4.80) and (4.81) hold and (4.71) holds.

5 Optimization of Information Transfer in Neural Population Coding

5.1 Population Density Distribution of Parameters in Neural Populations

If \( p(r|x) \) is conditional independent, we can write

\[
p(r|x) = \prod_{n=1}^{N} p(r_n|x; \theta_n),
\]

(5.1)

where \( \theta_n \in \mathbb{R}^{\tilde{K}} \) denotes a \( \tilde{K} \)-dimensional vector for parameters of the \( n \)-th neuron, and \( p(r_n|x; \theta_n) \) is the conditional p.d.f. of the output \( r_n \) given \( x \). With the definition in (2.13), we have following proposition.

**Proposition 5.1.** If \( p(r|x) \) is conditional independent as in Eq. (5.1), we have

\[
J(x) = N \int_{\Theta} p(\theta)S(x; \theta)d\theta,
\]

(5.2)

where

\[
S(x; \theta) = \int_{\mathcal{R}} p(r|x; \theta) \frac{\partial \ln p(r|x; \theta)}{\partial x} \frac{\partial \ln p(r|x; \theta)}{\partial x^T} dr,
\]

(5.3)

35
\( r \in \mathcal{R} \subseteq \mathbb{R}, \theta \in \Theta \subseteq \mathbb{R}^k, \) and \( p(\theta) \) is the population density function of parameter vector \( \theta \):

\[
p(\theta) = \frac{1}{N} \sum_{n=1}^{N} \delta(\theta - \theta_n),
\]

with \( \delta(\cdot) \) being the Dirac delta function.

**Proof.**

\[
J(x) = \int_{\mathbb{R}} p(r|x) \frac{\partial \ln p(r|x)}{\partial x} \frac{\partial \ln p(r|x)}{\partial x^T} dr
\]

\[
= \sum_{n=1}^{N} \int_{\mathbb{R}} p(r_n|x; \theta_n) \frac{\partial \ln p(r_n|x; \theta_n)}{\partial x} \frac{\partial \ln p(r_n|x; \theta_n)}{\partial x^T} dr_n
\]

\[
= \int_{\Theta} \sum_{n=1}^{N} \delta(\theta - \theta_n) \left( \int_{\mathbb{R}} p(r|x; \theta) \frac{\partial \ln p(r|x; \theta)}{\partial x} \frac{\partial \ln p(r|x; \theta)}{\partial x^T} dr \right) d\theta
\]

\[
= N \int_{\Theta} p(\theta) S(x; \theta) d\theta.
\]

**Remark 5.1.** Proposition 5.1 shows that \( J(x) \) can be regarded as a function of the population density of parameters, \( p(\theta) \). If the p.d.f. of the input \( p(x) \) is given, we can find an appropriate \( p(\theta) \) to maximize MI

\[
S(x; \theta) = \int_{\mathbb{R}} p(r|x; \theta) \frac{\partial \ln p(r|x; \theta)}{\partial x} \frac{\partial \ln p(r|x; \theta)}{\partial x^T} dr
\]

\[
= \frac{1}{f(x; \theta)} \frac{\partial f(x; \theta)}{\partial x} \frac{\partial f(x; \theta)}{\partial x^T}
\]

\[
= \frac{\partial g(x; \theta)}{\partial x} \frac{\partial g(x; \theta)}{\partial x^T},
\]

\[
g(x; \theta) = 2 \sqrt{f(x; \theta)}.
\]
Similarly, for neuron response model with Gaussian noise, we have

\[
p(r|x) = \prod_{n=1}^{N} p(r_n|x; \theta_n),
\]

\[
p(r_n|x; \theta_n) = \frac{1}{\sigma\sqrt{2\pi}} \exp \left( -\frac{(r_n - f(x; \theta_n))^2}{2\sigma^2} \right),
\]

where \(\sigma\) is a constant standard deviation. Now we get

\[
S(x; \theta) = \frac{1}{\sigma^2} \frac{\partial f(x; \theta)}{\partial x} \frac{\partial f(x; \theta)}{\partial x^T}.
\]

### 5.2 Optimal Population Distribution for Neural Population Coding

Suppose \(p(x)\) and \(p(r|x)\) fulfill conditions C1 and C2 and Eq. (5.1). Following the discussion of section 2.2, we define the following objective for maximizing MI \(I\),

\[
\text{maximize } I_G[p(\theta)] = \frac{1}{2} \left\langle \ln \left( \det \left( \frac{G(x)}{2\pi e} \right) \right) \right\rangle_x + H(X),
\]

or equivalently,

\[
\text{minimize } Q_G[p(\theta)] = -\frac{1}{2} \left\langle \ln \left( \det \left( \mathbf{J}(x) \right) \right) \right\rangle_x,
\]

where

\[
G(x) = \mathbf{J}(x) + \mathbf{P}(x),\]

\[
\mathbf{J}(x) = N \int_{\Theta} p(\theta) \mathbf{S}(x; \theta) d\theta,
\]

\[
\mathbf{S}(x; \theta) = \left\langle \frac{\partial \ln p(r|x; \theta)}{\partial x} \frac{\partial \ln p(r|x; \theta)}{\partial x^T} \right\rangle_{r|x; \theta}.
\]

Here \(\mathbf{P}(x)\) is given in (2.15) and it generally can be substituted by \(\mathbf{P}_+\) (see Eq. 2.78).

When \(\varsigma_1 \approx 0\) (see Eq. 2.64), the object function (5.13) can be reduced to

\[
\text{maximize } I_F[p(\theta)] = \frac{1}{2} \left\langle \ln \left( \det \left( \frac{\mathbf{J}(x)}{2\pi e} \right) \right) \right\rangle_x + H(X),
\]

or equivalently,

\[
\text{minimize } Q_F[p(\theta)] = -\frac{1}{2} \left\langle \ln \left( \det \left( \mathbf{J}(x) \right) \right) \right\rangle_x.
\]

The constraint condition for \(p(\theta)\) is given by

\[
\text{subject to } \int_{\Theta} p(\theta) d\theta = 1, \quad p(\theta) \geq 0.
\]
However, without further constraints on the neural populations, especially a limit on the peak firing rate, the capacity of the system may grow indefinitely, i.e. \( I(X; R) \rightarrow \infty \). The most common limitation on neural populations is the energy or power constraint. For neuron models with Poisson noise or Gaussian noise, a useful constraint is a limitation on the peak power,

\[
|f(x; \theta_n)| \leq E_{\text{max}}, \quad \forall x \in \mathcal{X} \quad \text{and} \quad \forall n = 1, 2, \cdots, N. \tag{5.21}
\]

where \( E_{\text{max}} > 0 \) is the peak power. Under this constraint, maximizing \( I_G[p(\theta)] \) or \( I_F[p(\theta)] \) for independent neurons will result in \( \max_x |f(x; \theta_n)| = E_{\text{max}} \) for \( \forall n = 1, 2, \cdots, N \).

Another constraint is a limitation on average power. For Poisson neurons given in Eq. (5.7),

\[
\frac{1}{N} \sum_{n=1}^{N} \left\langle r_n p(r_n|x; \theta_n) \right\rangle_{r_n|x} \leq E_{\text{avg}}, \tag{5.22}
\]

which can also be written as

\[
\left\langle \left\langle f(x; \theta) \right\rangle_x \right\rangle_{\theta} \leq E_{\text{avg}}, \tag{5.23}
\]

and for Gaussian noise neurons given in Eq. (5.11),

\[
\left\langle \left\langle (f(x; \theta))^2 \right\rangle_x \right\rangle_{\theta} \leq E_{\text{avg}}, \tag{5.24}
\]

where \( E_{\text{avg}} > 0 \) is the maximum average energy cost.

In Eq. (5.15), we can approximate the continuous integral by a discrete summation for numerical computation,

\[
J(x) = N \sum_{k=1}^{K_1} \alpha_k S(x; \theta_k), \tag{5.25}
\]

where the positive integer \( K_1 \leq N \) denotes the number of subclasses in the neural population, and

\[
\sum_{k=1}^{K_1} \alpha_k = 1, \quad \alpha_k > 0, \forall k = 1, 2, \cdots, K_1. \tag{5.26}
\]

If we do not know the specific form of \( p(x) \) but have \( M \) samples, \( x_1, x_2, \cdots, x_M \), which are i.i.d. samples drawn from the distribution \( p(x) \), then we can approximate the
integral in (5.13) by the sample average:

$$\langle \ln (\det(G(x))) \rangle_x \approx \frac{1}{M} \sum_{m=1}^{M} \ln (\det(G(x_m))).$$  \hspace{1cm} (5.27)\]

Optimizing the objective (5.13) or (5.18) is a convex optimization problem (see Appendix for a proof).

**Proposition 5.2.** The functions $I_G[p(\theta)]$ and $I_F[p(\theta)]$ are concave about $p(\theta)$.

**Remark 5.2.** For a low-dimensional input $x$, we may use (5.18) or (5.19) as the objective. Since $I_G[p(\theta)]$ and $I_F[p(\theta)]$ are concave functions of $p(\theta)$, we can directly use efficient numerical methods to get the optimal solution for small $K$. However, for high-dimensional input $x$, we need to use other methods (e.g. Huang & Zhang, 2017). □

### 5.3 Necessary and Sufficient Conditions for Optimal Population Distribution

Applying the method of Lagrange multipliers for the optimization problem (5.13) and (5.20) yields

$$L[p(\theta)] = I_G[p(\theta)] - \lambda_1 \left( \int_{\Theta} p(\theta)d\theta - 1 \right) + \int_{\Theta} \lambda_2(\theta)p(\theta)d\theta,$$  \hspace{1cm} (5.28)\]

where $\lambda_1$ is a constant and $\lambda_2(\theta)$ is a function of $\theta$. According to Karush-Kuhn-Tucker (KKT) conditions (Boyd & Vandenberghe, 2004), we have

$$\lambda_2(\theta)p(\theta) = 0, \quad \lambda_2(\theta) \geq 0,$$  \hspace{1cm} (5.29)\]

and the necessary condition for optimal population density,

$$\frac{\partial L[p(\theta)]}{\partial p(\theta)} = \frac{1}{2} \left( \text{Tr} \left( NG(x)^{-1}S(x; \theta) \right) \right)_x - \lambda_1 + \lambda_2(\theta) = 0. \hspace{1cm} (5.30)$$

It follows from (5.29) and (5.30) that

$$\frac{1}{2} \left( \text{Tr} \left( NG(x)^{-1}S(x; \theta) \right) \right)_x = \lambda_1, \quad p(\theta) \neq 0, \hspace{1cm} (5.31)$$

$$\frac{1}{2} \left( \text{Tr} \left( NG(x)^{-1}S(x; \theta) \right) \right)_x = \lambda_1 - \lambda_2(\theta), \quad p(\theta) = 0. \hspace{1cm} (5.32)$$

Since $I_G[p(\theta)]$ is a concave function of $p(\theta)$, Eq. (5.31) and (5.32) are the necessary and sufficient conditions for the optimization problem (5.13) and (5.20).
5.4 Channel Capacity for Neural Population Coding

If $p(x)$ is unknown, then by Jensen’s inequality, we have

$$I \simeq I_G[p(x)] = \int_{\mathcal{X}} p(x) \ln \left( p(x)^{-1} \det \left( \frac{G(x)}{2\pi e} \right)^{1/2} \right) \, dx$$

$$\leq \ln \int_{\mathcal{X}} \det \left( \frac{G(x)}{2\pi e} \right)^{1/2} \, dx, \quad (5.33)$$

and the equality holds if and only if $p(x)^{-1} \det (G(x))^{1/2}$ is a constant. Thus

$$I_G[p^*(x)] = \max_{p(x)} I_G[p(x)] = \ln \int_{\mathcal{X}} \det \left( \frac{G(x)}{2\pi e} \right)^{1/2} \, dx, \quad (5.34)$$

$$p^*(x) = \frac{\det (G(x))^{1/2}}{\int_{\mathcal{X}} \det (G(\hat{x}))^{1/2} \, d\hat{x}}, \quad (5.35)$$

assuming $\int_{\mathcal{X}} \det (G(\hat{x}))^{1/2} \, d\hat{x} < \infty$.

Let us consider a specific example. Suppose $J(x) = J_0$ is a constant matrix, then it follows from (2.12) that

$$I_G = \frac{1}{2} \left\langle \ln \left( \det \left( \frac{J_0 + P(x)}{2\pi e} \right) \right) \right\rangle_x + H(X). \quad (5.36)$$

According to the maximum entropy probability distribution, we know that maximizing $H(X)$ results in a uniformly distributed $p(x)$. Hence we have $G(x) = J_0$ and $p^*(x)$ coincides with the uniform distribution (see 5.35). In this case, the maximum $I_G[p^*(x)]$ can be regarded as the channel capacity for this neural population.

If we consider a constraint on random variables $X$ and assume that the covariance matrix of $X$ is $\Sigma_0$ and satisfies

$$\Sigma_0^{-1} = P(x), \quad (5.37)$$

then it follows from the maximum entropy probability distribution that

$$H(X) \leq \frac{1}{2} \left( \det (2\pi e \Sigma_0) \right), \quad (5.38)$$

and the equality holds if and only if the p.d.f. of the input is a normal distribution: $p(x) = \mathcal{N}(\mu, \Sigma_0)$. Hence

$$I_G = \frac{1}{2} \ln \left( \det \left( \frac{J_0 + \Sigma_0^{-1}}{2\pi e} \right) \right) + H(X)$$

$$\leq \frac{1}{2} \ln \left( \det (\Sigma_0 J_0 + I_K) \right) = I_G[p^*(x)], \quad (5.39)$$
where \( I_G[p^*(x)] \) is the channel capacity of neural population. Here the equality holds if and only if \( p^*(x) = \mathcal{N}(\mu, \Sigma_0) \), which is consistent with Eq. (5.37).

Furthermore, if \( \zeta_1 \approx 0 \) (see 2.64), we have

\[
I \simeq I_G[p(x)] \simeq I_F[p(x)] = \int_{\mathcal{X}} p(x) \ln \left( p(x)^{-1} \det \left( \frac{J(x)}{2\pi e} \right)^{1/2} \right) dx. \tag{5.40}
\]

Similarly, we also get

\[
I_F[p^*(x)] = \max_{p(x)} \left( I_F[p(x)] \right) = \ln \int_{\mathcal{X}} \det \left( \frac{J(x)}{2\pi e} \right)^{1/2} dx, \tag{5.41}
\]

\[
p^*(x) = \frac{\det (J(x))^{1/2}}{\int_{\mathcal{X}} \det (J(\hat{x}))^{1/2} d\hat{x}}, \tag{5.42}
\]

assuming \( \int_{\mathcal{X}} \det (J(\hat{x}))^{1/2} d\hat{x} < \infty \). Here \( I_F[p^*(x)] \) is the channel capacity of the neural population. The distribution \( p^*(x) \) coincides with the Jeffrey’s prior in Bayesian probability (Jeffreys, 1961). In this case, if we suppose the covariance matrix of \( X \) is \( \Sigma_0 \), then similar to (5.38) and (5.39), we can get the channel capacity

\[
I_F[p^*(x)] = \frac{1}{2} \ln \left( \det (\Sigma_0 J_0) \right) \tag{5.43}
\]

with \( p^*(x) = \mathcal{N}(\mu, \Sigma_0) \).

For another example, consider the Poisson neuron model given in (5.7) and suppose the input \( x \) is one dimension, \( K = 1 \). It follows from (5.8) and (5.42) that

\[
p^*(x) = \frac{\left( \int_{\Theta} p(\theta) \left( \frac{\partial g(x; \theta)}{\partial x} \right)^2 d\theta \right)^{1/2}}{\int_{\mathcal{X}} \left( \int_{\Theta} p(\theta) \left( \frac{\partial g(x; \theta)}{\partial x} \right)^2 d\theta \right)^{1/2} d\hat{x}}. \tag{5.44}
\]

If \( p(\theta) = \delta(\theta - \theta_0) \), Eq. (5.44) becomes

\[
p^*(x) = \frac{\left| \frac{\partial g(x; \theta_0)}{\partial x} \right|}{\int_{\mathcal{X}} \left| \frac{\partial g(\hat{x}; \theta_0)}{\partial \hat{x}} \right| d\hat{x}}. \tag{5.45}
\]

Atick & Redlich (1990) presented a redundancy measure to approximate Barlow’s optimality principle:

\[
\mathcal{R} = 1 - \frac{I(X; R)}{C(R)}, \tag{5.46}
\]

41
where $C(R)$ is the channel capacity. Here for neural population coding we have $C(R) \approx I_G[p^*(x)]$ and $I(X; R) \approx I_G$ (or $C(R) \approx I_F[p^*(x)]$ and $I(X; R) \approx I_F$). Hence we can minimize $\mathcal{R}$ by choosing an appropriate $J(x)$ to maximize $I_G$ (or $I_F$) and simultaneously satisfying (5.35) (or 5.42) (see Huang & Zhang, 2017, for further details).

6 Discussion

In this paper we have derived several information-theoretic bounds and approximations for effective approximation of MI in the context of neural population coding for large but finite population size. We have found some regularity conditions under which the asymptotic bounds and approximations hold. Generally speaking, these regularity conditions are easy to meet. Special examples that satisfy these conditions include the cases when the likelihood function $p(r|x)$ for the neural population responses is conditionally independent or has correlated noises with a multivariate Gaussian distribution. Under the general regularity conditions we have derived several asymptotic bounds and approximations of MI for a neural population and found some relationships among different approximations.

How to choose among these different asymptotic approximations of MI in a neural population with finite size $N$? For a flat prior distribution $p(x)$, we have $I_G \approx I_F$; that is, the two approximations $I_G$ and $I_F$ are about equally valid. For a sharply peaked prior distribution $p(x)$, $I_G$ is generally a better approximation to MI $I$ than $I_F$. Under suitable conditions (e.g. C1 and C2) for low-dimensional inputs, $I_G$, and $I_F$ are good approximations of MI $I$ not only for large $N$ but also for small $N$. For high-dimensional inputs, the FI matrix $J(x)$ (see Eq. 2.11) or matrix $P^{-1}(x)$ (see Eq. 2.15) often becomes degenerate, which causes a large error between $I_F$ and MI $I$. Hence, in this situation, $I_G$ is a better approximation to MI $I$ than $I_F$. For more convenient computation of the approximation, we have also introduced the approximation formula $I_{G+}$ which may substitute for $I_G$ as a proxy of MI $I$. For some special cases (see Corollary 4.1), $I_G$ and $I_{G+}$ are strictly equal to the true MI $I$. Our simulation results for the one-dimensional case shows that the approximations $I_G$, $I_{G+}$, and $I_F$ are all highly precise compared with the true MI $I$, even for small $N$ (Figure 1).
These approximation formulas satisfy additional constraints. By the Cramér-Rao lower bound, we know that $I_F$ is related to the covariance matrix of an unbiased estimator (see Eq. 3.3). By the van Trees’ Bayesian Cramér-Rao bound, we get a link between $I_{G_+}$ and the covariance matrix of a biased estimator (see Eq. 3.9). From the point of view of neural population decoding and Bayesian inference, there is a connection between MI (or $I_G$) and MAP (see Eq. 3.17).

For more efficient calculation of the approximation $I_G$ (or $I_{G_+}$) for high-dimensional inputs, we propose to apply an invertible transformation on the input variable so as to make the new variable closer to a normal distribution (see section 4.1). Another useful technique is dimensionality reduction which effectively approximates MI by further reducing the computational complexity for high-dimensional inputs. We found that $I_F$ could lead to huge errors as a proxy of the true MI $I$ for high-dimensional inputs even when $I_G$ and $I_{G_+}$ are strictly equal to the true MI $I$.

These approximation formulas are potentially useful for optimization problems of information transfer in neural population coding. We have proven that optimizing the population density distribution of parameters $p(\theta)$ is a convex optimization problem and have found a set of necessary and sufficient conditions. The approximation formulas are also useful for discussion of the channel capacity of neural population coding (section 5.4).

The information theory is a powerful tool for neuroscience and other disciplines, including diverse fields such as physics, information and communication technology, machine learning, computer vision, and bioinformatics. Finding effective approximation methods for computing MI is a key for many practical applications of information theory. Generally speaking, the FI matrix is easier to evaluate or approximate than MI. This is because calculation of MI involves averaging over both the input variable $x$ and the output variable $r$ (see Eq. 2.1), and typically $p(r)$ also needs to be calculated from $p(r|x)$ by another average over $x$ (see Eq. 2.2). By contrast, the FI matrix $J(x)$ involves averaging over $r$ only (see Eq. 2.13). Furthermore, it is often easier to find analytical forms of FI for specific models such as a population of tuning curves with Poisson spike statistics. Taking into account the computational efficiency, for practical applications we suggest using $I_G$ or $I_{G_+}$ as a proxy of the true MI $I$ for most cases.
These approximations could be very useful even when we do not need to know the exact value of MI. For example, for some optimization and learning problems, we only need to know how MI is affected by the conditional p.d.f. or likelihood function $p(r|x)$. In such situations, we may easily solve for the optimal parameters using the approximation formulas (Huang & Zhang, 2017; Huang et al., 2017). Further discussions of the applications will be given in separate publications.

**Appendix: The Proofs**

We consider a Taylor expanding of $L(r|\hat{x})$ around $x$. If $L(r|\hat{x})$ is twice differentiable for $\forall \hat{x} \in \mathcal{X}_\omega(x)$, then by condition $C1$ we get

$$
L(r|\hat{x}) - L(r|x) \\
= (\hat{x} - x)^T L'(r|x) + \frac{1}{2} (\hat{x} - x)^T L''(r|\hat{x}) (\hat{x} - x) \\
= y^T \tilde{v} - \frac{1}{2} y^T y + \frac{1}{2} y^T B y, \quad (A.1)
$$

where

$$
y = G^{1/2}(x) (\hat{x} - x), \quad (A.2)
$$

$$
\tilde{v} = v + v_1, \quad v = G^{-1/2}(x) l'(r|x), \quad v_1 = G^{-1/2}(x) q'(x), \quad (A.3)
$$

$$
\hat{x} = x + t (\hat{x} - x) \in \mathcal{X}_\omega(x), \quad t \in (0, 1), \quad (A.4)
$$

$$
\begin{align*}
B &= G^{-1/2}(x) CG^{-1/2}(x) = B_0 + B_1 + B_2, \\
C &= C_0 + C_1 + C_2, \quad (A.5)
\end{align*}
$$
and
\[
\begin{align*}
B_0 &= G^{-1/2}(x) C_0 G^{-1/2}(x), \\
B_1 &= G^{-1/2}(x) C_1 G^{-1/2}(x), \\
B_2 &= G^{-1/2}(x) C_2 G^{-1/2}(x), \\
C_0 &= l''(r|x) - (l''(r|x))_{r|x}, \\
C_1 &= l''(r|\hat{x}) - l''(r|x), \\
C_2 &= q''(\hat{x}) - q''(x).
\end{align*}
\] (A.6)

By condition C1, we know that the matrix $B_1 + B_2$ is continuous and symmetric for $\hat{x} \in X_\omega$ and $\|B_1 + B_2\| = O(1)$. By the definition of continuous functions, we can prove the following: for any $\varepsilon \in (0, 1)$, there is an $\varepsilon \in (0, \omega)$ such that for all $y \in Y_\varepsilon$

\[-\varepsilon I_K \leq B_1 + B_2 \leq \varepsilon I_K, \] (A.7)

where

\[Y_\varepsilon = \left\{ y \in \mathbb{R}^K : \|y\| < \varepsilon \sqrt{N} \right\}. \] (A.8)

Hence,

\[|y^T (B_1 + B_2) y| < \varepsilon \|y\|^2. \] (A.9)

Here $\hat{x} = x + tG^{-1/2}(x) y$, $\varepsilon$ is a function of $r$, $\varepsilon = \varepsilon(r) = O(1)$, and

\[Y_\varepsilon \subseteq Y_\omega = \left\{ y \in \mathbb{R}^K : \|y\| < \omega \sqrt{N} \right\}. \] (A.10)

We define the sets

\[
\begin{align*}
\hat{Y}_\varepsilon &= \left\{ y \in \mathbb{R}^K : \|y\| \geq \varepsilon \sqrt{N} \right\}, \\
\hat{Z}_\varepsilon &= \left\{ z \in \mathbb{R}^K : |z_k| < \varepsilon \sqrt{N/K}, \forall k = 1, 2, \ldots, K \right\}, \\
\hat{Z}_\varepsilon &= \left\{ z \in \mathbb{R}^K : |z_k| \geq \varepsilon \sqrt{N/K}, \forall k = 1, 2, \ldots, K \right\}, \\
\hat{Z}_\varepsilon &= \left\{ z \in \mathbb{R}^K : \|z + \bar{v}_1 \| \leq \varepsilon \sqrt{N} \right\},
\end{align*}
\] (A.11)

where

\[\varepsilon = \varepsilon/2. \] (A.12)

$1(\cdot)$ denotes an indicator random variable,

\[1_{\mathcal{R}_\varepsilon} = \begin{cases} 1, & r \in \mathcal{R}_\varepsilon(x) \\ 0, & r \not\in \mathcal{R}_\varepsilon(x) \end{cases}, \quad 1_{\mathcal{\bar{R}}_\varepsilon} = \begin{cases} 1, & r \in \mathcal{\bar{R}}_\varepsilon(x) \\ 0, & r \not\in \mathcal{\bar{R}}_\varepsilon(x) \end{cases}, \] (A.13)
and
\[
\begin{align*}
\mathcal{R}_\varepsilon(x) &= \left\{ r \in \mathcal{R} : \| \tilde{v} \| < \varepsilon \sqrt{N} \right\}, \\
\mathcal{R}_\varepsilon(x) &= \left\{ r \in \mathcal{R} : \| \tilde{v} \| > \varepsilon \sqrt{N} \right\}.
\end{align*}
\]

For all \( z \in \mathcal{Z}_\varepsilon \), we have \( \| z + \tilde{v}_1 \mathcal{R}_\varepsilon \|_2 \leq \| z \|_2 + \| \tilde{v}_1 \mathcal{R}_\varepsilon \|_2 < \varepsilon \sqrt{N} \), then
\[
\mathcal{Z}_\varepsilon \subseteq \tilde{\mathcal{Z}}_\varepsilon.
\]

It follows from (A.3) and (A.6) that
\[
\langle v \rangle_{r|x} = 0, \quad \langle B_0 \rangle_{r|x} = 0,
\]
and
\[
\begin{align*}
\left\langle \left\langle \tilde{v}^T \tilde{v} \right\rangle_{r|x} \right\rangle_x &= \left\langle \left\langle L'(r|x)^T G^{-1} \left( x \right) L'(r|x) \right\rangle_{r|x} \right\rangle_x \\
&= \left\langle \text{Tr} \left( \left\langle L'(r|x) L'(r|x)^T \right\rangle_{r|x} G^{-1} \left( x \right) \right) \right\rangle_x \\
&= K + \zeta \\
&= K + O \left( N^{-1} \right),
\end{align*}
\]
and it follows from condition C1 that
\[
\begin{align*}
\zeta &= \left\langle \text{Tr} \left( \frac{1}{p(x)} \frac{\partial^2 p(x)}{\partial x \partial x^T} G^{-1} \left( x \right) \right) \right\rangle_x \\
&= \left\langle \text{Tr} \left( \left( q'(x)^T q'(x) + q''(x) \right) G^{-1} \left( x \right) \right) \right\rangle_x \\
&\leq \langle N^{-1} \left( \| q'(x)^T q'(x) \| + \| q''(x) \| \right) \| NG^{-1}(x) \| \rangle_x \\
&= O \left( N^{-1} \right).
\end{align*}
\]

Combining conditions C1 and C2, (A.3), (A.4) and (A.6), we find
\[
\begin{align*}
\left\langle \| B_0 \|^{2m} \right\rangle_{r|x} &\leq \left\langle \left\langle \| N^{-1} C_0 \|^{2m} \| NG^{-1}(x) \|^{2m} \right\rangle_{r|x} \right\rangle_x = O \left( N^{-1} \right), \\
\left\langle \| B_0 \|^{2m+1} \right\rangle_{r|x} &\leq \left\langle \left\langle \| NG^{-1}(x) \|^{2m+1} \| N^{-1} C_0 \|^{2m+1/2} \| NG^{-1}(x) \|^{1/2} \right\rangle_{r|x} \right\rangle_x = O \left( N^{-1} \right), \\
\left\langle \| v \|^{2m_0} \right\rangle_{r|x} &\leq \left\langle \left\langle \| N^{-1} l'(r|x)^T l'(r|x) \|^{m_0} \right\rangle_{r|x} \right\rangle_N \| NG^{-1}(x) \|^{m_0} = O \left( 1 \right), \\
\left\langle \| v_1 \|^{2m_0} \right\rangle_{r|x} &\leq \left\langle \left\langle \| N^{-1} q'(x)^T q'(x) \|^{m_0} \| NG^{-1}(x) \|^{m_0} \right\rangle_{r|x} \right\rangle_N = O \left( N^{-m_0} \right).
\end{align*}
\]
together with the power mean inequality,
\[
\left\langle \left( \tilde{\mathbf{v}}^T \tilde{\mathbf{v}} \right)^{m_0} \right\rangle_{r|x} \leq \left\langle (\|\mathbf{v}\| + \|\mathbf{v}_1\|)^{2m_0} \right\rangle_{r|x} \\
\leq 2^{2m_0-1} \left\langle \|\mathbf{v}\|^{2m_0} + \|\mathbf{v}_1\|^{2m_0} \right\rangle_{r|x} \\
= O(1), \quad (A.20)
\]
where \( m \in \mathbb{N}, m_0 \in \{1, 2\} \). Notice that \( \|\mathbf{G}^{-1}(\mathbf{x})\| = O(N^{-1}) \). Here we note that for all conformable matrices \( \mathbf{A} \) and \( \mathbf{B} \),
\[
\begin{aligned}
& |\text{Tr} (\mathbf{AB})| \leq \|\mathbf{A}\| \|\mathbf{B}\|, \\
& \|\mathbf{AB}\| \leq \|\mathbf{A}\| \|\mathbf{B}\|. \\
& (A.21)
\end{aligned}
\]
By (2.25c) we have
\[
\text{Tr} \left( N^{-1} J(x) \right)^2 = \left\langle \left( N^{-1} l'(r|x) \right)^T l'(r|x) \right\rangle_{r|x} \\
\leq \left\langle \left( N^{-1} l'(r|x) \right)^T l'(r|x) \right\rangle_{r|x} = O(1). \quad (A.22)
\]
Then it follows from (2.25b) and (A.22) that
\[
\det(\mathbf{G}(\mathbf{x})) = O \left( N^K \right). \quad (A.23)
\]

A.1 Proof of Lemma 2.1

It follows from (A.1) that
\[
\Gamma_\omega = \left\langle \ln \int_{\mathcal{X}_\omega(x)} \exp \left( L(r|\hat{x}) - L(r|\mathbf{x}) \right) d\hat{x} \right\rangle_{r|x|} \mathbf{x} \\
= -\left\langle \frac{1}{2} \ln (\det(\mathbf{G}(\mathbf{x}))) \right\rangle_{\mathbf{x}} \\
+ \left\langle \ln \left( \int_{\mathcal{Y}_\omega} \exp \left( \mathbf{y}^T \tilde{\mathbf{v}} - \frac{1}{2} \mathbf{y}^T \mathbf{y} + \frac{1}{2} \mathbf{y}^T \mathbf{B} \mathbf{y} \right) d\mathbf{y} \right) \right\rangle_{r|x|} \mathbf{x}. \quad (A.24)
\]
For \( \mathbf{y} \in \mathcal{Y}_\epsilon \), according to the definitions in (A.13) and (A.14), we have
\[
\left| \mathbf{y}^T \tilde{\mathbf{v}} \tilde{\mathbf{v}}_1 \right| \leq \|\mathbf{y}\| \left\| \tilde{\mathbf{v}} \tilde{\mathbf{v}}_1 \right\| \\
\leq \left( N\epsilon^2 \right)^{1/2} \left\| \tilde{\mathbf{v}} \tilde{\mathbf{v}}_1 \right\| \\
\leq 2 \tilde{\mathbf{v}}^T \tilde{\mathbf{v}} \tilde{\mathbf{v}}_1. \quad (A.25)
\]

47
Then by condition $C_1$, we get
\[
\langle \tilde{v}^T \tilde{v} \rangle_{r|x} \leq \left( \frac{\| \tilde{v} \|^4}{(\hat{\epsilon} \sqrt{N})^2} \right)_{r|x} 
\leq N^{-1}(\hat{\epsilon}_0)^{-2} \langle \| \tilde{v} \|^4 \rangle_{r|x} = O\left(N^{-1}\right), \tag{A.26}
\]
where $\hat{\epsilon}_0$ is a positive constant and $\hat{\epsilon}_0 \in [\min \hat{\epsilon}(r), \max \hat{\epsilon}(r)]$. By (A.9), (A.17) and (A.24), we get
\[
\hat{\Gamma}_\omega \geq \left( \ln \left( \int \Psi \hat{\epsilon}^{-1} \exp \left( -\frac{1}{2} z^T z \right) d\hat{z} \right) \right)_{r|x} 
\geq \frac{1}{2} \left( \int \hat{\epsilon}^{-1} \exp \left( -\frac{1}{2} z^T z \right) \right)_{r|x} 
\geq \frac{1}{2} \left( \int \hat{\epsilon}^{-1} \exp \left( -\frac{1}{2} z^T z \right) \phi_\hat{\epsilon}(z) d\hat{z} \right)_{r|x} 
\geq \frac{1}{2} \left( \int \left( \hat{\epsilon}^{-1} \exp \left( -\frac{1}{2} z^T z \right) \right)_{r|x} + \frac{K + \zeta}{2 (1 + \epsilon)} + O\left(N^{-1}\right), \tag{A.27}
\right.
\]
where $z = y - \tilde{v}1_{\hat{R}_\hat{\epsilon}(x)}$, the last step in (A.27) follows from Jensen’s inequality, and
\[
\begin{align*}
\phi_\hat{\epsilon}(z) &= \Psi^{-1}_{\hat{\epsilon}} \exp \left( -\frac{1 + \epsilon}{2} z^T z \right), \\
\Psi_{\hat{\epsilon}} &= \int \hat{\epsilon}^{-1} \exp \left( -\frac{1 + \epsilon}{2} z^T z \right) d\hat{z}.
\end{align*}
\tag{A.28}
\]
Integrating by parts yields
\[
\left( \frac{1}{2\pi} \right)^{K/2} \exp \left( -\frac{1 + \epsilon}{2} z^T z \right) d\hat{z} = O\left(N^{-K/2}e^{-N\delta}\right) \tag{A.29}
\]
and
\[
\left( \frac{2\pi}{1 + \epsilon} \right)^{K/2} \geq \Psi_{\hat{\epsilon}} \geq \left( \frac{2\pi}{1 + \epsilon} \right)^{K/2} \left( 1 - O\left(N^{-K/2}e^{-N\delta}\right) \right) \tag{A.30}
\]
for some $\delta > 0$. 

48
Then from (A.27), we get
\[
\left\langle \left\langle \left( \int_{\mathcal{Z}_\ell} \left( z + \bar{v}_1 R_{\ell} \right)^T B_0 \left( z + \bar{v}_1 R_{\ell} \right) \phi_\ell (z) d\mathbf{z} \right) \right\rangle \right\rangle_{r|x|x} = \left( \frac{2\pi}{1+\epsilon} \right)^{K/2} \tilde{\Psi}_\ell^{-1} \left\langle \left\langle z^T B_0 z 1_{\mathcal{Z}_\ell} \right\rangle \right\rangle_{r|x|x} \geq \left( \frac{2\pi}{1+\epsilon} \right)^{K/2} \tilde{\Psi}_\ell^{-1} O \left( N^{-1} \right),
\]
where
\[
\begin{cases}
\langle \cdot \rangle_z = \int_{\mathbb{R}^K} (\cdot) \phi_0 (z) d\mathbf{z} \\
\phi_0 (z) = \left( \frac{1+\epsilon}{2\pi} \right)^{K/2} \exp \left( -\frac{1+\epsilon}{2} z^T z \right).
\end{cases}
\]
Here notice that
\[
\left( \frac{2\pi}{1+\epsilon} \right)^{K/2} \tilde{\Psi}_\ell^{-1} = 1 + O \left( N^{-K/2} e^{-Na} \right)
\]
and
\[
\left\langle \left\langle z^T B_0 z 1_{\mathcal{Z}_\ell} \right\rangle \right\rangle_{r|x|x} = \left\langle \left\langle \left\langle z^T B_0 z \right\rangle \right\rangle_1 \right\rangle_{r|x|x} \geq \left\langle \left\langle \| B_0 \|^2 \right\rangle \right\rangle_{r|x|x}^{1/2} \left\langle \left\langle \| z \|^4 \right\rangle \right\rangle_{r|x|x}^{1/2} = O \left( N^{-1} \right).
\]
Hence, from the consideration above, we find
\[
\hat{\Gamma}_\omega \geq \frac{K}{2} \ln \left( \frac{2\pi}{1+\epsilon} \right) + \frac{K}{2(1+\epsilon)^2} + O \left( N^{-1} \right).
\]
Since \( \epsilon \) is arbitrary, let it go to zero. Thus, combining (A.24) and (A.35) yields
\[
\Gamma_\omega = -\left\langle \frac{1}{2} \ln \left( \det \left( G(x) \right) \right) \right\rangle_{x} + O \left( N^{-1} \right).
\]
Considering
\[
\left\langle \ln \left( \frac{p(r)}{p(r|x) p(x)} \right) \right\rangle_{r|x|x} \geq \Gamma_\omega,
\]
and combining (2.3) and (A.36), we immediately get Eq. (2.53).

On the other hand, by conditions (2.54a) and (2.54b), we have
\[
\begin{align*}
\left\langle \bar{v}^T \bar{v}_1 R_{\ell} \right\rangle_{r|x} & \leq \left\langle \frac{\| \bar{v} \|^2 + 2\tau}{\hat{\epsilon} \sqrt{N}} \right\rangle_{r|x} \leq N^{-\tau} \left( \hat{\epsilon}_0 \right)^{-2\tau} \left\langle \| \bar{v} \|^{2+2\tau} \right\rangle_{r|x} = o(1) \\
\left\langle \left\langle z^T B_0 z 1_{\mathcal{Z}_\ell} \right\rangle \right\rangle_{r|x} & \geq -\left\langle \left\langle \| B_0 \|^2 \right\rangle \right\rangle_{r|x}^{1/2} \left\langle \left\langle \| z \|^4 \right\rangle \right\rangle_{r|x}^{1/2} = o(1).
\end{align*}
\]
Similarly we can get (2.55). This completes the proof of Lemma 2.1

A.2 Proof of Lemma 2.2

Define the sets

$$\Omega_\epsilon(x) = \left\{ r \in \mathcal{R} : y^T B_0 y < \epsilon \| y \|^2, \forall y \in \mathbb{R}^K \right\}$$  (A.39)

and

$$\Theta_\epsilon(x) = \left\{ r \in \mathcal{R} : \int_{\bar{X}_\epsilon(x)} \frac{p(r|x)p(\hat{x})}{p(r|x)p(x)} d\hat{x}' < \epsilon \det(G(x))^{-1/2} \right\},$$  (A.40)

where $\bar{X}_\epsilon(x) = X - X_\epsilon(x)$, assuming $\epsilon \in (0, 1/2)$ and $p(x) > 0$.

Then by Markov’s inequality, we have

$$\langle 1_{\Omega_\epsilon} \rangle_{r|x} \leq \mathbb{P}_{r|x} \left\{ \| B_0 \|^2 \geq \epsilon^2 \right\} \leq \epsilon^{-2} \langle \| B_0 \|^2 \rangle_{r|x} = O \left( N^{-1} \right),$$  (A.41)

and by (2.26b),

$$\langle 1_{\Theta_\epsilon} \rangle_{r|x} = \mathbb{P}_{r|x} \left\{ \int_{\bar{X}_\epsilon(x)} \frac{p(r|x)p(\hat{x})}{p(r|x)p(x)} d\hat{x}' \geq \epsilon \det(G(x))^{-1/2} \right\}$$

$$= \mathbb{P}_{r|x} \left\{ \det(G(x))^{1/2} \int_{\bar{X}_\epsilon(x)} p(\hat{x}|r) d\hat{x} > \epsilon p(x|r) \right\}$$

$$= O \left( N^{-\eta} \right).$$  (A.42)

Consider the following equality,

$$\left\langle \ln \frac{p(r)}{p(r|x)p(x)} \right\rangle_{r|x} = \left\langle 1_{\Theta_\epsilon} \ln \frac{p(r)}{p(r|x)p(x)} \right\rangle_{r|x} + \left\langle 1_{\Theta_\epsilon} \ln \frac{p(r)}{p(r|x)p(x)} \right\rangle_{r|x}.$$  (A.43)

For the last term in (A.43), Jensen’s inequality implies that

$$\left\langle \left\langle 1_{\Theta_\epsilon} \ln \frac{p(r)}{p(r|x)p(x)} \right\rangle_{r|x} \right\rangle_x \leq \left\langle \left\langle 1_{\Theta_\epsilon} \right\rangle_{r|x} \right\rangle_x \ln \frac{1}{\left\langle \left\langle 1_{\Theta_\epsilon} \right\rangle_{r|x} \right\rangle_x} = o \left( N^{-1} \right).$$  (A.44)
For the first term in (A.43), it follows from (A.40) and (A.9) that
\[
\left\langle 1_{\Theta_{e}} \ln \frac{p(r)}{p(r|x) p(x)} \right\rangle_{r|x} \\
\leq \left\langle 1_{\Theta_{e}} \ln \left( \int_{\mathcal{Y}_{e}(x)} \exp \left( L(r|x) - L(r) \right) d\lambda \right) + \epsilon \det (G(x))^{-1/2} \right\rangle_{r|x} \\
\leq -\frac{K}{2} \ln (\det (G(x))) \\
+ \left\langle 1_{\Theta_{e}} \ln \left( \int_{\mathcal{Y}_{e}} \exp \left( y^{T} \tilde{v} - \frac{1}{2} (1 - \epsilon) y^{T} y + \frac{1}{2} y^{T} B_{0} y \right) dy + \epsilon \right) \right\rangle_{r|x} \cdot (A.45)
\]

The last term (A.45) is upper-bounded by
\[
\left\langle 1_{\Theta_{e} \cap \Omega_{c}} \ln \left( \int_{\mathbb{R}^{K}} \exp \left( y^{T} \tilde{v} - \frac{1}{2} (1 - 2\epsilon) y^{T} y \right) dy + \epsilon \right) \right\rangle_{r|x} \quad (A.46)
\]
\[
+ \left\langle 1_{\Theta_{e} \cap \Omega_{c}} \ln \left( \int_{\mathbb{R}^{K}} \exp \left( y^{T} \tilde{v} - \frac{1}{2} (1 - \epsilon) y^{T} y + \frac{1}{2} y^{T} B_{0} y \right) dy + \epsilon \right) \right\rangle_{r|x} \cdot (A.47)
\]

The term (A.46) is equal to
\[
\left\langle 1_{\Theta_{e} \cap \Omega_{c}} \ln \left( \left( \frac{2\pi}{1 - 2\epsilon} \right)^{K/2} \exp \left( \frac{\tilde{v}^{T} \tilde{v}}{2 (1 - 2\epsilon)} + \epsilon \right) \right) \right\rangle_{r|x} \\
\leq \left\langle 1_{\Theta_{e} \cap \Omega_{c}} \left( \frac{\tilde{v}^{T} \tilde{v}}{2 (1 - 2\epsilon)} + \ln \left( \left( \frac{2\pi}{1 - 2\epsilon} \right)^{K/2} + \epsilon \right) \right) \right\rangle_{r|x} \cdot (A.48)
\]

The term (A.47) is equal to
\[
\left\langle 1_{\Theta_{e} \cap \Omega_{c}} \ln \left( \left( \frac{2\pi}{1 - \epsilon} \right)^{K/2} \exp \left( \frac{1}{2} \left( z + \frac{\tilde{v}^{T} z}{1 - \epsilon} \right)^{T} B_{0} \left( z + \frac{\tilde{v}^{T} z}{1 - \epsilon} \right) + \frac{\tilde{v}^{T} B_{0} \tilde{v}}{2 (1 - \epsilon)} \right) \right) \right\rangle_{r|x} \\
\leq \left\langle 1_{\Theta_{e} \cap \Omega_{c}} \left( \frac{K}{2} \ln \left( \frac{2\pi}{1 - \epsilon} \right) + \frac{\tilde{v}^{T} \tilde{v}}{2 (1 - \epsilon)} + \frac{\tilde{v}^{T} B_{0} \tilde{v}}{2 (1 - \epsilon)^{2}} \right) \right\rangle_{r|x} \quad (A.49a)
\]
\[
+ \left\langle 1_{\Theta_{e} \cap \Omega_{c}} \ln \left( \exp \left( \frac{1}{2} z^{T} B_{0} z + \frac{z^{T} B_{0} \tilde{v}}{1 - \epsilon} - \frac{\tilde{v}^{T} B_{0} \tilde{v}}{(1 - \epsilon)^{3}} \right) \right) \right\rangle_{r|x} \cdot (A.49b)
\]

where
\[
\begin{align*}
\left\langle \cdot \right\rangle_{z} &= \int_{\mathbb{R}^{K}} \left( \cdot \right) \phi_{1}(z) \, dz \\
\phi_{1}(z) &= \left( \frac{1 - \epsilon}{2\pi} \right)^{K/2} \exp \left( - \frac{1 - \epsilon}{2} z^{T} z \right) \cdot (A.50)
\end{align*}
\]
Notice that
\[ \langle 1_{\Omega_c \cap \Omega_e} \rangle_{r|x} \leq \langle 1_{\Omega_e} \rangle_{r|x} = O\left(N^{-1}\right) \]  
(A.51)
and
\[ \langle 1_{\Omega_c \cap \Omega_e} \rangle_{r|x} = 1 - \langle 1_{\Omega_c \cup \Omega_e} \rangle_{r|x} = 1 + O\left(N^{-1}\right). \]  
(A.52)
Then by (A.19), we get
\[
\left\langle 1_{\Omega_c \cap \Omega_e} \left( \left\langle \exp\left(z^T B_0 z \right) \right\rangle_z^{1/2} - 1 \right) \right\rangle_{r|x}
\leq \left\langle 1_{\Omega_c \cap \Omega_e} \sum_{m=0}^{\infty} \frac{1}{m!} \left\langle \left(z^T B_0 z \right)^m \right\rangle_z^{1/2} \right\rangle_{r|x} - \langle 1_{\Omega_c \cap \Omega_e} \rangle_{r|x} = O\left(N^{-1}\right),
\]  
(A.53)
and by (2.51),
\[
0 \leq \left\langle \hat{v}^T \hat{v} \mathbb{1}_{\Omega_c \cap \Omega_e} \right\rangle_{r|x} \leq \left\langle \| \hat{v} \|^4 \right\rangle_{r|x} \langle 1_{\Omega_e} \rangle_{r|x}^{1/2} = O\left(N^{-1}\right),
\]  
(A.54)
and by Cauchy–Schwarz inequality and (A.53), the term (A.49b) is upper bounded by
\[
\left\langle 1_{\Omega_c \cap \Omega_e} \ln \left( \left\langle \exp\left(z^T B_0 z \right) \right\rangle_z^{1/2} \left\langle \exp\left(\frac{2z^T B_0 \hat{v}}{1 - \epsilon} - \frac{2\hat{v}^2 B_0^2 \hat{v}}{(1 - \epsilon)^3} \right) \right\rangle_z^{1/2} + \epsilon \left(\frac{1 - \epsilon}{2\pi}\right)^{K/2} \right) \right\rangle_{r|x}
\leq \left\langle 1_{\Omega_c \cap \Omega_e} \left( \left\langle \exp\left(z^T B_0 z \right) \right\rangle_z^{1/2} + \epsilon \left(\frac{1 - \epsilon}{2\pi}\right)^{K/2} \right) \right\rangle_{r|x}
\leq \left\langle 1_{\Omega_c \cap \Omega_e} \left( \left\langle \exp\left(z^T B_0 z \right) \right\rangle_z^{1/2} + \epsilon \left(\frac{1 - \epsilon}{2\pi}\right)^{K/2} - 1 \right) \right\rangle_{r|x} = O\left(N^{-1}\right).
\]  
(A.57)
Since \( \epsilon \) is arbitrary, we can let it go to zero. Then taking everything together, we get
\[
\left\langle \ln \left( \frac{p(r)}{p(r|x) p(x)} \right) \right\rangle_x \leq -\left\langle \frac{1}{2} \ln \left( \det \left( \frac{G(x)}{2\pi \epsilon} \right) \right) \right\rangle_x + O\left(N^{-1}\right). \]  
(A.58)
Putting (A.58) into (2.3) yields (2.56).

On the other hand, we have
\[
\langle \ln \frac{p(r)}{p(r|x) p(x)} \rangle_{r|x} x
= \langle 1_{\Theta \cap \Omega} \ln \frac{p(r)}{p(r|x) p(x)} \rangle_{r|x} x
+ \langle 1_{\Theta \cap \bar{\Omega}} \ln \frac{p(r)}{p(r|x) p(x)} \rangle_{r|x} x.
\]
(A.59)

For term (A.60), it follows from Jensen’s inequality that
\[
\langle \ln \frac{p(r)}{p(r|x) p(x)} \rangle_{r|x} x \leq \langle 1_{\bar{\Omega}} \rangle_{r|x} x \ln \frac{1}{\langle 1_{\bar{\Omega}} \rangle_{r|x} x} = o(1)
\]
(A.61)
and
\[
\langle 1_{\Theta \cap \bar{\Omega}} \ln \frac{p(r)}{p(r|x) p(x)} \rangle_{r|x} x \leq \langle 1_{\Theta \cap \bar{\Omega}} \rangle_{r|x} x \ln \frac{1}{\langle 1_{\Theta \cap \bar{\Omega}} \rangle_{r|x} x} = o(1),
\]
(A.62)

where
\[
\begin{cases}
\langle 1_{\bar{\Omega}} \rangle_{r|x} x \leq P \left( \| B_0 \|^2 \geq \epsilon^2 \right) \leq e^{-2} \langle \| B_0 \|^2 \rangle_{r|x} x = o(1), \\
\langle 1_{\Theta \cap \bar{\Omega}} \rangle_{r|x} x \leq \langle 1_{\bar{\Omega}} \rangle_{r|x} x = o(1).
\end{cases}
\]
(A.63)

Similarly we can get (2.57). This completes the proof of Lemma 2.2.

A.3 Proof of Theorem 2.1

By Lemma 2.1 and Lemma 2.2 we immediately get (2.58). The proof of (2.59) is similar.

A.4 Proof of Theorem 2.2

First, we have
\[
G(x) = J^{1/2}(x) \left( I_K + \Psi(x) \right) J^{1/2}(x).
\]
(A.64)

Since $J(x)$ and $G(x)$ are symmetric and positive-definite, $I_K + \Psi(x)$ is also symmetric and positive-definite. The eigendecomposition of $\Psi(x)$ is given by
\[
\Psi(x) = U_x \Lambda_x U_x^T,
\]
(A.65)
where $\mathbf{U}_x \in \mathbb{R}^{K \times K}$ is an orthogonal matrix, and the matrix $\mathbf{A}_x \in \mathbb{R}^{K \times K}$ is a $K \times K$ diagonal matrix with $K$ nonnegative real numbers on the diagonal, $\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_K \geq -1$. Then we have

$$\langle \text{Tr} (\mathbf{A}_x) \rangle_x = \langle \text{Tr} (\Psi (x)) \rangle_x = \langle \text{Tr} (\mathbf{P}(x) \mathbf{J}^{-1}(x)) \rangle_x = \varsigma \quad (A.66)$$

and

$$\langle \ln (\det (\mathbf{I}_K + \Psi (x))) \rangle_x = \langle \text{Tr} (\ln (\mathbf{I}_K + \mathbf{A}_x)) \rangle_x \leq \langle \text{Tr} (\mathbf{A}_x) \rangle_x = \varsigma. \quad (A.67)$$

Notice that $\ln (1 + x) \leq x$ for $\forall x \in (-1, \infty)$. It follows from (A.64) and (A.67) that

$$\langle \ln (\det (\mathbf{G}(x))) \rangle_x = \langle \ln (\det (\mathbf{J}(x))) \rangle_x = \langle \ln (\det (\mathbf{I}_K + \Psi (x))) \rangle_x \leq \varsigma. \quad (A.68)$$

From (2.12), (2.11) and (A.68), we obtain (2.62).

If $\mathbf{P}(x)$ is positive-semidefinite, then $\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_K \geq 0$, $\varsigma \geq 0$ and $\langle \ln (\det (\mathbf{I}_K + \Psi (x))) \rangle_x \geq 0$. Hence we can get (2.63).

On the other hand, it follows from (2.64), (A.67) and the power mean inequality that

$$|\varsigma| \leq \left\langle \sum_{k=1}^K |\lambda_k| \right\rangle_x \leq \sqrt{K} \left\langle \left( \sum_{k=1}^K \lambda_k^2 \right)^{1/2} \right\rangle_x = \sqrt{K} \left\langle \|\Psi (x)\| \right\rangle_x = \sqrt{K} \varsigma_1 = O(N^{-\beta}). \quad (A.69)$$

Let $\lambda_k^- = \min (0, \lambda_k)$ for $\forall k \in \{1, 2, \cdots, K\}$, then

$$\left\langle \sum_{k=1}^K \ln (1 + \lambda_k^-) \right\rangle_x \leq \langle \ln (\det (\mathbf{I}_K + \Psi (x))) \rangle_x. \quad (A.70)$$

Notice that $-1 < \lambda_k^- \leq 0$, then by (A.69), we have

$$\left\langle \sum_{k=1}^K \ln (1 + \lambda_k^-) \right\rangle_x = \left\langle \sum_{m=1}^\infty \frac{-1}{m} \sum_{k=1}^K (\lambda_k^-)^m \right\rangle_x = O(N^{-\beta}). \quad (A.71)$$

From (2.12), (2.11), (A.68), (A.70) and (A.71), we immediately get (2.65). This completes the proof of Theorem 2.2 \hfill \Box

**A.5 Proof of Theorem 4.1**

Considering the change of variables theorem, for any real-valued function $f$ and invertible transformation $T$, we have

$$\int_{\mathcal{X}} f(\mathbf{x}) d\mathbf{x} = \int_{\mathcal{X}} f(T(\mathbf{x})) |\det (DT(\mathbf{x}))| d\mathbf{x}, \quad (A.72)$$
and for \( p(x) \) and \( p(\tilde{x}) \),
\[
p(\tilde{x})|_{\tilde{x} = T(x)} = |\text{det} \left( DT(x) \right)|^{-1} p(x).
\]
(A.73)

Then, it follows from (4.2), (A.72) and (A.73) that
\[
\begin{align*}
p(r) &= \int X p(r|x)p(x)dx = \int \tilde{X} p(r|\tilde{x})p(\tilde{x})d\tilde{x}, \\
H(\tilde{X}) &= -\int \tilde{X} p(\tilde{x}) \ln p(\tilde{x})d\tilde{x} \\
&= -\int X p(x) \ln \left( p(x) |\text{det} \left( DT(x) \right)|^{-1} \right) dx \\
&= H(X) + \int X p(x) \ln |\text{det} \left( DT(x) \right)| dx, \\
G(x) &= DT(x)^T G(\tilde{x})DT(x).
\end{align*}
\]
(A.74)

Substituting (A.73) and (A.74) into (2.1), we can directly obtain (4.3). Moreover, if \( p(\tilde{x}) \) and \( p(r|\tilde{x}) \) fulfill conditions \( C1, C2 \) and \( \xi = O(N^{-1}) \), then by Theorem 2.1, we immediately obtain Eq. (4.4). This completes the proof of Theorem 4.1.

A.6 Proof of Corollary 4.1

It follows from (2.21) and Theorem 4.1 that
\[
I_G = I_{G, r} = I(X; R) = I(Y; R) = \frac{1}{2} \ln \left( \det \left( \frac{1}{2\pi\sigma} \left( AA^T + \Sigma^{-1}_f \right) \right) \right) + H(Y)
\]
(A.75)

and
\[
H(Y) = \frac{1}{2} \ln \left( \det \left( 2\pi\sigma\Sigma_f \right) \right) = H(X) + \langle \ln |\text{det} \left( D(x) \right)| \rangle_x.
\]
(A.76)

Here notice that
\[
J(x) = \left\langle \frac{\partial \ln p(r|x) \partial \ln p(r|x)}{\partial x \partial x^T} \right\rangle_{r|x}
= \left\langle \frac{\partial y^T \partial \ln p(r|y) \partial \ln p(r|y)}{\partial x \partial y \partial y^T} \right\rangle_{r|y}
= D(x)^T AA^T D(x)
\]
(A.77)

and
\[
P(x) = -\frac{\partial^2 \ln p(x)}{\partial x \partial x^T} = -\frac{\partial y^T \partial^2 \ln p(y)}{\partial x^T} \frac{\partial y}{\partial x^T} = D(x)^T \Sigma_f^{-1} D(x).
\]
(A.78)

Hence combining (A.75)–(A.78), we can immediately obtain (4.9). This completes the proof of Corollary 4.1.

\[\square\]
A.7 Proof of Theorem 4.2

First, we have

\[
\left\langle \ln \left( \frac{\det(\mathbf{G}(\mathbf{x}))}{2\pi e} \right) \right\rangle_{\mathbf{x}}
= \left\langle \ln \left( \frac{\det(\mathbf{G}_{1,1}(\mathbf{x}))}{2\pi e} \right) \right\rangle_{\mathbf{x}}
+ \ln \left( \frac{\det(\mathbf{G}_{2,2}(\mathbf{x}))}{2\pi e} \right) + \ln(\det(\mathbf{I}_{K_2} - \mathbf{A}_x)) \right\rangle_{\mathbf{x}}. 
\]  

(A.79)

Then by the eigendecomposition of \( \mathbf{A}_x \), we have

\[
\mathbf{A}_x = \mathbf{U}_x \mathbf{\Lambda}_x \mathbf{U}_x^T, 
\]  

(A.80)

where \( \mathbf{U}_x \) and \( \mathbf{\Lambda}_x \) are \( K_2 \times K_2 \) eigenvector matrix and eigenvalue matrix, respectively.

Since \( \mathbf{G}(\mathbf{x}), \mathbf{G}_{1,1}(\mathbf{x}) \) and \( \mathbf{G}_{2,2}(\mathbf{x}) \) are positive-definite, then \( \mathbf{I}_K - \mathbf{A}_x \) is also positive-definite and \( \mathbf{A}_x \) is positive-semidefinite, with \( 0 \leq (\mathbf{\Lambda}_x)_{k,k} = \lambda_k < 1 \) for \( \forall k \in \{1, 2, \cdots, K_2\} \). Moreover, it follows from (4.33) that

\[
\begin{cases} 
0 \leq \langle \text{Tr}(\mathbf{\Lambda}_x) \rangle_{\mathbf{x}} = \langle \text{Tr}(\mathbf{A}_x) \rangle_{\mathbf{x}} \ll 1, \\
0 \leq \langle \text{Tr}(\mathbf{\Lambda}_x^m) \rangle_{\mathbf{x}} = \left\langle \sum_{k=1}^{K_2} \lambda_k^m \right\rangle_{\mathbf{x}} \leq \langle \text{Tr}(\mathbf{\Lambda}_x) \rangle_{\mathbf{x}} \ll 1.
\end{cases} 
\]  

(A.81)

Then by (A.81) we have

\[
\left\langle \ln(\det(\mathbf{I}_{K_2} - \mathbf{A}_x)) \right\rangle_{\mathbf{x}} = \left\langle \text{Tr}(\ln(\mathbf{I}_{K_2} - \mathbf{A}_x)) \right\rangle_{\mathbf{x}} = \sum_{m=1}^{\infty} \frac{-1}{m} \left\langle \text{Tr}(\mathbf{A}_x^m) \right\rangle_{\mathbf{x}} \simeq 0. 
\]  

(A.82)

Substituting (A.82) into (A.79) and then combining with (2.12), we get (4.35).

If Eq. (4.36) holds, then \( \mathbf{A}_x = 0 \) and \( \mathbf{I}_G = \mathbf{I}_{G_1} \). Conversely, if \( \mathbf{I}_G = \mathbf{I}_{G_1} \), then

\[
0 = \left\langle \ln(\det(\mathbf{I}_{K_2} - \mathbf{A}_x)) \right\rangle_{\mathbf{x}} \leq -\left\langle \text{Tr}(\mathbf{A}_x) \right\rangle_{\mathbf{x}} \leq 0, 
\]  

(A.83)

\( \mathbf{A}_x = 0 \), and Eq. (4.36) holds. This completes the proof of Theorem 4.2. \( \square \)
A.8 Proof of Theorem 4.3

Similar to (A.79), we have
\[
\left\langle \ln \left( \det \left( \frac{G(x)}{2\pi e} \right) \right) \right\rangle_x = \left\langle \ln \left( \det \left( \frac{G_{1,1}(x)}{2\pi e} \right) \right) \right\rangle_x + \ln \left( \det \left( \frac{P_{2,2}(x)}{2\pi e} \right) \right) + \ln \left( \det (I_{K_2} + B_x) \right) \right\rangle_x. 
\]  
(A.84)

Similar to (A.65), the eigendecomposition of \( B_x \) is given by
\[
B_x = U_x \Lambda_x U_x^T, 
\]  
(A.85)
where \( U_x \) and \( \Lambda_x \) are \( K_2 \times K_2 \) eigenvector matrix and eigenvalue matrix, respectively.

If the matrix \( B_x \) is positive-semidefinite and satisfies (4.38), then \( (\Lambda_x)_{k,k} = \lambda_k \geq 0 \) for \( \forall k \in \{1, 2, \ldots, K_2\} \) and
\[
0 \leq \left( \ln \left( \det (I_{K_2} + B_x) \right) \right)_x = \left\langle \sum_{k=1}^{K_2} \ln (1 + \lambda_k) \right\rangle_x 
\leq \left\langle \text{Tr} (\Lambda_x) \right\rangle_x = \text{Tr} (\left\langle B_x \right\rangle_x) \ll 1. 
\]  
(A.86)
Substituting (A.86) into (A.84), we immediately get (4.41). If \( C_x = 0 \), then \( \ln \left( \det (I_{K_2} + B_x) \right) = 0 \) and \( I_G = I_{G_2} \). And if \( I_G = I_{G_2} \), then \( \ln \left( \det (I_{K_2} + B_x) \right) = 0 \), \( B_x = 0 \) and \( C_x = 0 \). □

A.9 Proof of Corollary 4.2

Notice that
\[
\begin{align*}
H(X) &= H(X_1) + H(X_2), \\
H(X_2) &= \frac{1}{2} \ln \left( \det (2\pi e \Sigma_{x_2}) \right), \\
P_{2,1}(x) &= P_{1,2}(x) = 0, \\
P_{2,2}(x) &= \Sigma_{x_2}^{-1},
\end{align*}
\]  
(A.87)
and the matrices
\[
C_x = J_{2,2}(x) - J_{2,1}(x) G_{1,1}^{-1}(x) J_{1,2}(x), 
\]  
(A.88)
\[
B_x = P_{2,2}^{-1/2}(x) C_x P_{2,2}^{-1/2}(x) 
\]  
(A.89)
are positive-semidefinite, and the proof is similar to (4.74). Then by Theorem 4.3 we immediately get (4.41). Substituting (A.87) into (4.41) yields (4.44) with strict equality if and only if $C_x = 0$. This completes the proof of Corollary 4.2. □

A.10 Proof of Proposition 5.2

By writing $p(\theta)$ as a sum of two density functions $p_1(\theta)$ and $p_2(\theta)$,

$$p(\theta) = \alpha p_1(\theta) + (1 - \alpha) p_2(\theta),$$

(A.90)

we have

$$G(x) = N \int_{\Theta} p(\theta)S(x; \theta)d\theta + P(x) = \alpha G_1(x) + (1 - \alpha) G_2(x),$$

(A.91)

where $0 \leq \alpha \leq 1$ and

$$G_1(x) = N \int_{\Theta} p_1(\theta)S(x; \theta)d\theta + P(x),$$

(A.92)

$$G_2(x) = N \int_{\Theta} p_2(\theta)S(x; \theta)d\theta + P(x).$$

(A.93)

Using the Minkowski determinant inequality and the inequality of weighted arithmetic and geometric means, we find

$$\det (G(x))^{1/K} = \det (\alpha G_1(x) + (1 - \alpha) G_2(x))^{1/K}$$

$$\geq \alpha \det (G_1(x))^{1/K} + (1 - \alpha) \det (G_2(x))^{1/K}$$

$$\geq \left( \det (G_1(x))^{\alpha} \det (G_2(x))^{(1-\alpha)} \right)^{1/K}. \quad (A.94)$$

It follows from (A.91) and (A.94) that

$$\ln (\det (\alpha G_1(x) + (1 - \alpha) G_2(x))) \geq \alpha \ln (\det (G_1(x))) + (1 - \alpha) \ln (\det (G_2(x))),$$

(A.95)

where the equality holds if and only if $G_1(x) = G_2(x)$. Thus $\ln (\det (G(x)))$ is concave about $p(\theta)$. Therefore $I_C[p(\theta)]$ is a concave function about $p(\theta)$. Similarly we can prove that $I_F[p(\theta)]$ is also a concave function about $p(\theta)$. This completes the proof of Proposition 5.2. □
