I. INTRODUCTION

A major obstacle in quantum information processing is the coherent manipulation of fragile quantum information in the presence of environmental noise. The coherence of quantum systems will be lost if the systems are perturbed by environmental noise. This process of losing quantum coherence is commonly called decoherence. One way to counteract the decoherence effect is by engineering a decoherence-free (DF) subsystem [1], [2], [3], [4], [5], [6], [7], [8], [9], [10]. According to the DF linear quantum subsystem theory developed in [7], the DF modes are defined as the uncontrollable and unobservable modes of a quantum linear system. The linear DF modes can be obtained using the standard uncontrollable and unobservable decomposition of a linear system [11], [7], [9].

In this paper, the definition of dark modes is as follows:

Definition 1: For quantum linear systems, the dark modes are uncontrollable and unobservable modes that are defined on an arbitrarily given Hilbert space which is associated with a subsystem.

According to the above definition, a dark mode x_D can be characterized by the following dynamical equation

$$\begin{aligned} dx(t) &= d\begin{pmatrix} x_D(t) \\ x_B(t) \\ x_d(t) \end{pmatrix} \\ &= \begin{pmatrix} \hat{A}_{11} & 0 \\ 0 & \hat{A}_{22} \end{pmatrix} x(t)dt + \begin{pmatrix} 0 \\ \hat{B}_2 \end{pmatrix} d\mathcal{W}(t), \\ d\mathcal{W}_{out}(t) &= (0 \mid \hat{C}_2)x(t)dt + d\mathcal{W}(t), \end{aligned} \tag{1}$$

where (x_D, x_B) are defined on the arbitrarily given Hilbert subspace $\mathcal{D}$ which is associated with a subsystem. For simplicity, we use the same notation $\mathcal{D}$ when referring to this subsystem. x_d is defined on a Hilbert subspace $\mathcal{N}$ (subsystem $\mathcal{N}$). As a result, the quantum linear system is defined on $\mathcal{D} \otimes \mathcal{N}$. $\mathcal{W}(t)$ is a noise process and $\mathcal{W}_{out}(t)$ is an output process of the system. Based on (1), we have

$$dx_D = \hat{A}_{11} x_D dt, \tag{2}$$

which implies that the dynamics of x_D is decoupled from x_B, the environmental noise and the noisy subsystem $\mathcal{N}$. x_B is called a bright mode if it interacts with the noisy subsystem $\mathcal{N}$ via $\hat{A}_{22}$. The above definition of dark mode is consistent with the literature. e.g., see [12], [13], [14], in which the formation of a dark mode is used to achieve mediation between subsystems while being decoupled from a given noisy subsystem.

In this paper, we develop a direct method for the decomposition of the system dynamics as in (1), based on a suitable coordinate transformation. After preliminaries are presented in Section II, a direct method to characterize dark modes is developed in Section III. Section IV discusses the synthesis of dark modes. By engineering the system-environment coupling operator, we can remove the direct coupling of the dark modes to the noise and subsystem $\mathcal{N}$. Assisted by suitable Hamiltonian engineering, the indirect coupling can be eliminated as well and dark modes are generated. In order to illustrate the applications of the dark mode theory, in Section V we study an optomechanical system which relies on dark modes to function.

Notation: A^T denotes the transpose of A. $A^\dagger$ is the Hermitian adjoint of A. $N(A) = \{v \mid Av = 0\}$ is the kernel of A, and $R(A) = \{Av, \forall v\}$ is the range of A. $R^\perp(A)$ is the orthogonal complement to $R(A)$. A^+ denotes the Moore-Penrose generalized inverse of A. $[X, Y] = XY - YX$. 0_n is an n-dimensional zero matrix, and I_n is an n-dimensional identity matrix. $\emptyset$ is the empty set. $\Re(a), \Im(a)$ are the real and imaginary parts of a complex number a. i is the imaginary unit. $\Sigma_n = \text{diag}\{\Sigma, \cdots, \Sigma\}$ is a block diagonal matrix containing n two-dimensional matrices Σ defined by $\Sigma = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}$. $\delta_{ij} = 0$ if $i \neq j$, and $\delta_{ij} = 1$ if $i = j$. Also, we use $\delta(\cdot)$ to denote the Dirac delta function. ρ denotes a quantum state which is a Hermitian operator satisfying $\text{trace}(\rho) = 1$ and $\rho \geq 0$. We set $\hbar = 1$.

II. PRELIMINARIES

A. Heisenberg-picture Evolution and Quantum Stochastic Differential Equations

The dynamics of a quantum system can be characterized by the evolution of a quantum state defined as $\rho(t) = U(t, t_0)\rho(0)U(t, t_0)$, where t_0 is the initial time and $U(t_0, t_0) = I$. $U(t, t_0)$ is the unitary operator which generates the quantum evolution [15], [16]. The expectation of a system

Petersen are with the School of Engineering and Information Technology, the University of New South Wales, Canberra 2600, ACT, Australia. e-mail: yu.pan.83.yp@gmail.com (Yu Pan), daoyidong@gmail.com (Daoyi Dong), i.r.petersen@gmail.com (Ian R. Petersen).

operator X at the state ρ is calculated by $\langle X\rangle_\rho = \text{trace}(X\rho)$. Accordingly, we can define the Heisenberg-picture evolution of the system operator $X(t)$ via the relation $\langle X(t)\rangle_{\rho(0)} = \langle X\rangle_{\rho(t)}$.

We consider an open quantum system coupled to the environment through m inputs. The coupling operators associated with the m inputs are given by $\{L_i, i = 1, \cdots, m\}$. We use H_0 to denote the Hamiltonian of the open quantum system. $\{b_i(t), i = 1, \cdots, m\}$ are the bosonic field annihilation operators defined on the m input fields. The field operators satisfy the relation $[b_i(t), b_j^\dagger(s)] = \delta(t-s)$ for $i = j$ and $[b_i(t), b_j^\dagger(s)] = 0$ for $i \neq j$. The quantum Wiener process is formally defined by $\tilde{B}_i(t) = \int_0^t b_i(s)ds$. As a consequence, $d\tilde{B}_i(t) = \tilde{B}_i(t+dt) - \tilde{B}_i(t)$ is the operator-valued quantum Ito increment. Introducing standard approximations which lead to the Markovian dynamics of the quantum system and using the quantum Ito calculus, we can obtain [15], [16], [17]

$$\begin{aligned} dU(t,t_0) &= \{\sum_{i=1}^m (b_i^\dagger(t)L_i - L_i^\dagger b_i(t)) \\ &- (\frac{1}{2}\sum_{i=1}^m L_i^\dagger L_i + \mathrm{i}H_0)\}U(t,t_0)dt,\ t \geq t_0. \end{aligned} \quad (3)$$

Based on (3), the Heisenberg-picture evolution of $X(t)$ is derived as the quantum stochastic differential equation (QSDE)

$$\begin{aligned} dX(t) &= -\mathrm{i}[X(t), H_0(t)] + \sum_{i=1}^m \{L_i^\dagger(t)X(t)L_i(t) \\ &- \frac{1}{2}L_i^\dagger(t)L_i(t)X(t) - \frac{1}{2}X(t)L_i^\dagger(t)L_i(t) \\ &+ d\tilde{B}_i^\dagger(t)[X(t), L_i(t)] + [L_i^\dagger(t), X(t)]d\tilde{B}_i(t)\}, \end{aligned} \quad (4)$$

with the input-output relation given by

$$\begin{aligned} d\tilde{B}_{i,out}(t) &= U^\dagger(t,t_0)d\tilde{B}_i(t)U(t,t_0) \\ &= L_i(t) + d\tilde{B}_i(t). \end{aligned} \quad (5)$$

Here $\tilde{B}_{i,out}(t) = \int_0^t b_{i,out}(s)ds$ and $b_{i,out}(t)$ is the bosonic field annihilation operator defined on the i-th output.

B. Quantum Linear Systems

Quantum linear systems can be conveniently modelled using the QSDEs of system operators. In this paper, we consider a quantum linear system composed of n harmonic oscillators, with n_1 oscillators defined on $\mathcal{D}$ and $n-n_1$ oscillators defined on $\mathcal{N}$. Each harmonic oscillator is identified by its position operator x_i and momentum operator p_i. A linear combination of the operators $\{x_i, p_i\}, i = 1, \cdots, n$ is called a mode of the quantum system. The position and momentum operators satisfy the canonical commutation relation $[x_i, p_j] = \mathrm{i}\hbar\delta_{ij} = \mathrm{i}\delta_{ij}$. For convenience, the position and momentum operators are collected into a single vector as $x = (x_1, p_1, \cdots, x_n, p_n)^T$, which satisfies $xx^T - (xx^T)^T = \mathrm{i}\Sigma_n$. Suppose that the system Hamiltonian H_0 and the system-environment coupling operators are given by

$$H_0 = x^T G x, \quad L_i = c_i^T x,\ i = 1, 2, \cdots, m, \quad (6)$$

with G being a $2n \times 2n$ real symmetric matrix and c_i being a column vector of $2n$ scalars. According to (4), the dynamics of $x(t)$ are described by the following linear system equation

$$dx(t) = Ax(t)dt + Bd\mathcal{W}(t). \quad (7)$$

Here $\mathcal{W} = (X_1, P_1, \cdots, X_m, P_m)^T$ and $\{(X_i, P_i), i = 1, \cdots, m\}$ are defined by $X_i = (\tilde{B}_i + \tilde{B}_i^\dagger)/\sqrt{2}, P_i = (\tilde{B}_i - \tilde{B}_i^\dagger)/\sqrt{2}\mathrm{i}$. $\mathcal{W}(t)$ is the noise process due to the environmental couplings. The coefficient matrices of (7) are given by

$$\begin{aligned} A &= \Sigma_n(G + C^T\Sigma_m C/2) \in \mathbb{R}^{2n\times 2n}, \\ B &= \Sigma_n C^T \Sigma_m \in \mathbb{R}^{2n\times 2m}, \end{aligned} \quad (8)$$

where the following definition is used [7]

$$C = \sqrt{2}(\Re(c_1), \Im(c_1), \cdots, \Re(c_m), \Im(c_m))^T \in \mathbb{R}^{2m\times 2n}. \quad (9)$$

Using (5), the input-output relation of the system can be written as

$$d\mathcal{W}_{out}(t) = Cx(t)dt + d\mathcal{W}(t). \quad (10)$$

A quantum linear system as expressed by (7) and (10) can be described by a triplet (A, B, C).

A coordinate transformation $x = \mathcal{T}x, \mathcal{T} \in \mathbb{R}^{2n\times 2n}$ yields the following transformed system

$$\begin{aligned} dx(t) &= \mathcal{T}^{-1}A\mathcal{T}x(t)dt + \mathcal{T}^{-1}Bd\mathcal{W}(t), \\ d\mathcal{W}_{out}(t) &= C\mathcal{T}x(t)dt + d\mathcal{W}(t). \end{aligned} \quad (11)$$

C. Symplectic Matrices

Σ is a symplectic since $\Sigma^T\Sigma\Sigma = -\Sigma^T = \Sigma$. Consider the commutator $[x_i, p_i]$ as a bilinear form which can be expressed as $(x_i\ \ p_i)\Sigma(x_i\ \ p_i)^T$. Since $\Sigma^T\Sigma\Sigma = \Sigma$, $\Sigma(x_i\ \ p_i)^T$ is the symplectic transformation that preserves the commutation relation between the canonically conjugate operators of the harmonic oscillator. The same argument also applies to Σ_n. As a result, the symplectic matrix Σ_n plays a fundamental role in the transformations of the physically realizable quantum systems, e.g. see [18], [19], [20]. The transfer function of the passive symplectic system (11) obeys the relation $G(\mathrm{i}\omega)^\dagger G(\mathrm{i}\omega) = G(\mathrm{i}\omega)G(\mathrm{i}\omega)^\dagger = I_m$ for all $\omega \in \mathbb{R}$ [9].

III. Characterization of Dark Modes

We will refer to the following result from [7].

Lemma 1: $\Sigma_n v$ and v are orthogonal column vectors, i.e. $(\Sigma_n v)^T v = -v^T\Sigma_n v = 0$. If v is a normalized vector, i.e. $v^T v = 1$, then $\Sigma_n v$ is a normalized vector as well.

Define a $\mathcal{P}$-matrix as

$$\mathcal{P}_{m,n}(X) = \begin{pmatrix} \Sigma_m X \Sigma_n \\ X \end{pmatrix}, \quad (12)$$

where X is an arbitrary $2m\times 2n$ matrix. $\mathcal{P}_{m,n}(X)$ is a $4m\times 2n$ matrix. We can prove the following lemma.

Lemma 2: Suppose a normalized vector v is in $N(\mathcal{P}_{m,n}(X))$, i.e.

$$\mathcal{P}_{m,n}(X)v = \begin{pmatrix} \Sigma_m X \Sigma_n \\ X \end{pmatrix} v = 0. \quad (13)$$

Then $\Sigma_n v$ is a normalized vector in $N(\mathcal{P}_{m,n}(X))$ as well.

Proof: $\Sigma_n v$ is normalized from Lemma 1. Using (13) we have $\Sigma_m \Sigma_m X \Sigma_n v = 0$. Hence, $-I_m X \Sigma_n v = 0$. Therefore, $\Sigma_m X \Sigma_n (\Sigma_n v) = -\Sigma_m X v = 0$ and $X(\Sigma_n v) = 0$ hold, which proves that $\Sigma_n v$ is also in the kernel of $\mathcal{P}_{m,n}(X)$. ∎

Lemma 2 implies that if a vector v is in the intersection of $N(B^T)$ and $N(C)$ (v is decoupled from the direct interaction with the input and output), then its symplectic transformation $\Sigma_n v$ is also in $N(B^T) \cap N(C)$. This will result in a symplectic coordinate transformation matrix $\mathcal{T}$ in generating the dark modes.

As explained in Sec. II-B, the vector $x(t)$ can be decomposed as $x(t) = (x_{\mathcal{D}}^T \quad x_{\mathcal{N}}^T)^T$, where $x_{\mathcal{D}} = (x_1 \ p_1 \cdots x_{n_1} \ p_{n_1})^T$ is the collection of the system operators for the n_1 harmonic oscillators that constitute the subsystem $\mathcal{D}$, and $x_{\mathcal{N}} = (x_{n_1+1} \ p_{n_1+1} \cdots x_n \ p_n)^T$ is the collection of the system operators for the $n - n_1$ harmonic oscillators that constitute the subsystem $\mathcal{N}$. Accordingly, C is decomposed as $C = (C_1 \quad C_2), C_1 \in \mathbb{R}^{2m \times 2n_1}, C_2 \in \mathbb{R}^{2m \times 2(n-n_1)}$. Note that $x_{\mathcal{D}}$ is directly coupled to the input $\mathcal{W}(t)$ via $B_1 = \Sigma_{n_1} C_1^T \Sigma_m \in \mathbb{R}^{2n_1 \times 2m}$, and to the output via C_1. The system Hamiltonian can be written as $H_0 = H_{int} + H_{\mathcal{D}} + H_{\mathcal{N}}$ with $H_{int} = x^T G_{int} x$ being the interaction Hamiltonian between the two subsystems, and the internal Hamiltonians of the two subsystems are written as $H_{\mathcal{D}} = x^T G_{\mathcal{D}} x$ and $H_{\mathcal{N}} = x^T G_{\mathcal{N}} x$, respectively. We decompose $G_{int} \in \mathbb{R}^{2n \times 2n}$ as $G_{int} = \begin{pmatrix} G_{1,int} \\ G_{2,int} \end{pmatrix}$ with $G_{1,int} \in \mathbb{R}^{2n_1 \times 2n}$. Furthermore, for simplicity we denote $\mathcal{P}_{m+n,n_1}(\begin{pmatrix} C_1 \\ G_{1,int}^T \end{pmatrix}) \in \mathbb{R}^{2(m+n) \times 2n_1}$ as $\mathcal{P}$. The rank defect of this $\mathcal{P}$ may indicate the existence of dark modes.

Lemma 3: If $\text{rank}(\mathcal{P}) = q < 2n_1$, then the system equations (7) and (10) can be transformed to

$$\begin{aligned} & d\begin{pmatrix} x_D(t) \\ x_B(t) \\ x_d(t) \end{pmatrix} \\ = & \left(\begin{array}{c|c} P_1^T \Sigma_n G P_1 & P_1^T \Sigma_n G_{\mathcal{D}} P_2 \\ \hline P_2^T \Sigma_n G_{\mathcal{D}} P_1 & P_2^T A P_2 \end{array}\right) x(t) dt \\ + & \left(\begin{array}{c} 0 \\ \hline P_2^T \Sigma_n C^T \Sigma_m \end{array}\right) d\mathcal{W}(t), \\ & d\mathcal{W}_{out}(t) = (0 \quad CP_2) x(t) dt + d\mathcal{W}(t), \end{aligned} \tag{14}$$

under a proper coordinate transformation $x = \mathcal{T} x = (P_1 \quad P_2) x$, with x_D containing at least two modes.

Proof: We have $\text{rank}(N(\mathcal{P})) + \text{rank}(\mathcal{P}) = 2n_1$ due to the rank-nullity theorem. If $\text{rank}(\mathcal{P}) = q < 2n_1$, then $\text{rank}(N(\mathcal{P})) = 2n_1 - q > 0$. Then we can construct a transformation matrix $\mathcal{T} = (P_1 \quad P_2)$ by letting

$$P_1 = \begin{pmatrix} \cdots & v_i & \Sigma_{n_1} v_i & \cdots \\ 0 & 0 & 0 & 0 \end{pmatrix} \in \mathbb{R}^{2n \times (2n_1 - q)}, \tag{15}$$

with $\{v_i, \Sigma_{n_1} v_i, i = 1, 2, \cdots, (2n_1 - q)/2, v_i \in \mathbb{R}^{2n_1 \times 1}\}$ being the basis vectors of $N(\mathcal{P})$. Here we have made use of Lemma 2. Note that the last $2(n - n_1)$ rows of P_1 are set as 0. v_i is chosen to be orthogonal to $v_j, \Sigma_{n_1} v_j$ for all $j < i$. By this construction, the column vectors of P_1 are mutually orthogonal. Next, we construct $P_2 \in \mathbb{R}^{2n \times (2n - 2n_1 + q)}$ as $P_2 = (v_{(2n_1-q)/2+1} \ \Sigma_n v_{(2n_1-q)/2+1} \cdots v_n \ \Sigma_n v_n)$ which is composed of mutually-orthogonal normalized column vectors which are orthogonal to all the column vectors of P_1. Here we can choose P_2 to have this form based on Lemma 1. Then we can verify that $\mathcal{T} \in \text{Sp}(2n) \cap \text{O}(2n)$, where $\text{Sp}(2n)$ is the symplectic group of $2n \times 2n$ matrices and $\text{O}(2n)$ is the orthogonal group of $2n \times 2n$ matrices. The transformed coefficient matrices in (11) can be calculated using the relations $CP_1 = 0, B^T P_1 = 0, P_1^T G_{int} = 0$ as well as $P_1^T \Sigma_n G_{int} = 0$. Also note that $P_1^T G_{\mathcal{N}} = 0$ and $P_1^T \Sigma_n G_{\mathcal{N}} = 0$ are automatically satisfied because the last $2(n - n_1)$ rows of P_1 are zero. Therefore, we have $P_1^T A P_2 = P_1^T \Sigma_n G P_2 = P_1^T \Sigma_n G_{\mathcal{D}} P_2$ and $P_2^T A P_1 = P_2^T \Sigma_n G_{\mathcal{D}} P_1$. The resulting system equations are thus given by (14). ∎

The modes x_D in (14) are not directly coupled to the noise. However, x_D may be indirectly coupled to the noise via x_B and x_d. Therefore, dark modes can only be generated after we remove the coupling between x_D and x_B, x_d. This can be done by engineering the Hamiltonian $H_{\mathcal{D}}$ of the subsystem $\mathcal{D}$. The following theorem provides a sufficient condition for the existence of dark modes.

Theorem 1: Suppose $\text{rank}(\mathcal{P}) = q < 2n_1$ and the transformed system is given by (14). If the condition

$$P_1^T G_{\mathcal{D}} P_2 = 0 \tag{16}$$

is satisfied, then x_D are dark modes and the system equations become

$$\begin{aligned} d\begin{pmatrix} x_D(t) \\ x_B(t) \\ x_d(t) \end{pmatrix} &= \left(\begin{array}{cc} P_1^T \Sigma_n G P_1 & 0 \\ 0 & P_2^T A P_2 \end{array}\right) x(t) dt \\ &+ \left(\begin{array}{c} 0 \\ \hline P_2^T \Sigma_n C^T \Sigma_m \end{array}\right) d\mathcal{W}(t), \\ d\mathcal{W}_{out}(t) &= (0 \quad CP_2) x(t) dt + d\mathcal{W}(t). \end{aligned} \tag{17}$$

Proof: According to Lemma 3, the condition (16) can be explicitly written as

$$\begin{aligned} (v_i^T \ 0) G_{\mathcal{D}} v_{(2n_1-q)/2+j} &= 0, \\ -(v_i^T \ 0) \Sigma_n G_{\mathcal{D}} v_{(2n_1-q)/2+j} &= 0, \\ (v_i^T \ 0) G_{\mathcal{D}} \Sigma_n v_{(2n_1-q)/2+j} &= 0, \\ -(v_i^T \ 0) \Sigma_n G_{\mathcal{D}} \Sigma_n v_{(2n_1-q)/2+j} &= 0, \end{aligned} \tag{18}$$

for $i = 1, \cdots, (2n_1 - q)/2, \ j = 1, \cdots, (2n - 2n_1 + q)/2$. The elements of the matrix $P_1^T \Sigma_n G_{\mathcal{D}} P_2$ are expressed as

$$\begin{aligned} & (v_i^T \ 0) \Sigma_n G_{\mathcal{D}} v_{(2n_1-q)/2+j}, \\ & (v_i^T \ 0) G_{\mathcal{D}} v_{(2n_1-q)/2+j}, \\ & (v_i^T \ 0) \Sigma_n G_{\mathcal{D}} \Sigma_n v_{(2n_1-q)/2+j}, \\ & (v_i^T \ 0) G_{\mathcal{D}} \Sigma_n v_{(2n_1-q)/2+j}, \end{aligned} \tag{19}$$

for $i = 1, \cdots, (2n_1 - q)/2, \ j = 1, \cdots, (2n - 2n_1 + q)/2$. Hence, we can conclude that $P_1^T \Sigma_n G_{\mathcal{D}} P_2 = 0$ by (18). Similarly, we can prove $P_2^T \Sigma_n G_{\mathcal{D}} P_1 = 0$. ∎

Condition (16) proposes a Hamiltonian engineering problem. Additionally, it is straightforward to identify the bright modes using (17). x_B contains q modes which are linear combinations of the operators in $x_{\mathcal{D}}$. If these modes are

coupled to the subsystem $\mathcal{N}$ via the interaction terms in $P_2^T A P_2$, then they are bright modes.

We can also consider the special case $C_1 = 0$. In this case, the sufficient conditions for the existence of dark modes are simplified as rank$(\mathcal{P}_{n,n_1}(G_{1,int}^T)) < 2n_1$ and (16).

The dark modes are governed by the dynamical equation $\dot{x}_D = P_1^T \Sigma_n G P_1 x_D$. If $P_1^T \Sigma_n G P_1 = 0$, then $\dot{x}_D = 0$ and the dark modes are invariant. This fact can be summarized as the following theorem.

Theorem 2: Suppose rank$(\mathcal{P}) = q < 2n_1$ and the transformed system is given by (14). If the condition

$$P_1^T G_{\mathcal{D}} = 0 \tag{20}$$

is satisfied, then the dark modes x_D are invariant.

Remark 1: The results of this section are closely related to the Popov-Belevitch-Hautus (PBH) controllability/observability criterion. Consider an equivalent statement of the PBH observability criterion: (C, A) is unobservable if and only if there is a $v \neq 0$ with $Av = \lambda v$ and $Cv = 0$. Using $v \in N(C)$ we have $\Sigma_n G v = \lambda v$, which leads to $\lambda v^T = -v^T G \Sigma_n$. Similarly, if $v^T A = \mu v^T, v^T B = 0$ for the same $v \neq 0$, then the unobservable mode is also uncontrollable and we have $-v^T \Sigma_n G = \mu v^T$ using $v^T B = 0$. Suppose P_1, P_2 are constructed using the same procedure as Lemma 3. Then we have $v^T \Sigma_n G P_2 = -v^T \mu P_2 = 0$ and $P_2 \Sigma_n G v = \lambda P_2 v = 0$ since v is orthogonal to the column vectors of P_2. Using the coordinate transformation we can prove that the eigenvector v corresponds to an uncontrollable and unobservable mode of the system. Here, $v \in N(B^T) \cap N(C)$ is equivalent to a rank-defect condition, and $\Sigma_n G v = \lambda v, -v^T \Sigma_n G = \mu v^T$ are conditions on the system Hamiltonian. So the PBH conditions combined with the direct method of this paper can be used to characterize linear DF modes. Furthermore, imposing the additional requirement that the dark mode is in the subsystem $\mathcal{D}$, then C should be replaced with C_1 and the interaction between the dark mode and the subsystem $\mathcal{N}$ should be eliminated. Using this approach we will arrive at the sufficient conditions that are similar to the ones of Theorem 1.

This connection to PBH criterion also suggests that the direct method of this paper can be used to characterize and engineer a mode that is only uncontrollable and unobservable from some specific inputs and outputs. The details of this application is presented in the Appendix.

So far we have obtained a theory to characterize general dark modes. As shown in Theorem 1, the existence of dark modes is conditioned in terms of the environmental couplings and the system Hamiltonian. In the next section, we consider the synthesis of dark modes through engineering the system-environment couplings followed by engineering the Hamiltonian.

IV. Engineering the system-environment couplings and Hamiltonian

Consider

$$\mathcal{P}_{m,n}(C) = \begin{pmatrix} \Sigma_m C \Sigma_n \\ C \end{pmatrix}, \tag{21}$$

where $C \in \mathbb{R}^{2m \times 2n}$ is the coefficient matrix for the environmental couplings associated with the subsystem $\mathcal{D}$. We assume that (21) is full column rank. As we have proven, no dark modes exist in this case.

Firstly, we demonstrate that adding couplings alone cannot reduce the column rank of the matrix. With the additional couplings, the coefficient matrix becomes

$$C' = \begin{pmatrix} C \\ C_e \end{pmatrix}, \tag{22}$$

where $C_e \in \mathbb{R}^{2m' \times 2n}$ is associated with the m' additional inputs. The updated $\mathcal{P}$-matrix for this system is thus $\mathcal{P}_{m+m',n}(C')$, the column rank of which is still $2n$ given that $\mathcal{P}_{m,n}(C)$ is full column rank.

For this reason, it is necessary to increase the dimension of the system. We consider three basic types of interconnections for increasing the dimension of the system, namely, cascade, direct coupling and coherent feedback [21], [22], [23], [24].

A. Cascade

Suppose the original system and the additional system are defined by the triplets (A_1, B_1, C_1) and (A_2, B_2, C_2), respectively. Moreover, we assume that $C_1, C_2 \in \mathbb{R}^{2m \times 2n}$. To form the cascade, the output of the original system is taken as the input to the additional system, which can be modelled as

$$\begin{aligned} dx_i(t) &= A_i x_i(t) dt + B_i d\mathcal{W}_i(t), \quad i = 1, 2, \\ d\mathcal{W}_{i,out} &= C_i x_i(t) dt + d\mathcal{W}_i(t), \\ d\mathcal{W}_2(t) &= d\mathcal{W}_{1,out}. \end{aligned} \tag{23}$$

The above equations can be rewritten as

$$\begin{aligned} dx_e(t) &= \begin{pmatrix} A_1 & 0 \\ B_2 C_1 & A_2 \end{pmatrix} x_e(t) dt + \begin{pmatrix} B_1 \\ B_2 \end{pmatrix} d\mathcal{W}_1(t), \\ d\mathcal{W}_{2,out} &= \begin{pmatrix} C_1 & C_2 \end{pmatrix} x_e(t) dt + d\mathcal{W}_1(t), \end{aligned} \tag{24}$$

where we have defined $x_e = \begin{pmatrix} x_1 & x_2 \end{pmatrix}^T$. So we have

$$\mathcal{P}_{m,2n}(\begin{pmatrix} C_1 & C_2 \end{pmatrix}) = \begin{pmatrix} \Sigma_m C_1 \Sigma_n & \Sigma_m C_2 \Sigma_n \\ C_1 & C_2 \end{pmatrix}, \tag{25}$$

whose column rank is $2n$ if we let $C_1 = C_2$. Therefore, it is possible to generate $4n - 2n = 2n$ dark modes which are not influenced by the couplings associated with $\begin{pmatrix} C_1 & C_2 \end{pmatrix}$.

It is easy to see that a weaker sufficient condition for $\mathcal{P}_{m,2n}(\begin{pmatrix} C_1 & C_2 \end{pmatrix})$ to be not full column rank is that at least one column vector of $\begin{pmatrix} \Sigma_m C_2 \Sigma_n \\ C_2 \end{pmatrix}$ lies in the column space of $\begin{pmatrix} \Sigma_m C_1 \Sigma_n \\ C_1 \end{pmatrix}$.

B. Direct coupling

The original system and the additional system are defined by the triplets (A_1, B_1, C_1) and (A_2, B_2, C_2), with $C_1, C_2 \in \mathbb{R}^{2m \times 2n}$. The direct coupling is implemented by adding an interaction Hamiltonian $H_{int} = x^T G_{int} x$ between the two systems. If both $\mathcal{P}_{m,n}(C_1)$ and $\mathcal{P}_{m,n}(C_2)$ are full column rank, then we have

$$\mathcal{P}_{2m,2n}(\begin{pmatrix} C_1 & 0 \\ 0 & C_2 \end{pmatrix}) = \begin{pmatrix} \mathcal{D}_{m,n}(C_1) & 0 \\ 0 & \mathcal{D}_{m,n}(C_2) \end{pmatrix}, \tag{26}$$

which is still full column rank. No dark modes exist in the augmented system.

C. Coherent feedback

We consider two types of coherent feedback. The first type is modelled as

$$\begin{aligned} dx_1(t) &= A_1x_1(t)dt + B_1d\mathcal{W}_1(t) + B_2d\mathcal{W}_2(t), \\ dx_2(t) &= A_2x_2(t)dt + B_3d\mathcal{W}_3(t), \\ d\mathcal{W}_{i,out} &= C_ix_1(t)dt + d\mathcal{W}_i(t), \quad i = 1, 2, \\ d\mathcal{W}_{3,out} &= C_3x_2(t)dt + d\mathcal{W}_3(t), \end{aligned} \tag{27}$$

where the original system and the additional system are defined by the triplets $(A_1, (B_1, B_2), (C_1, C_2)), A_1 \in \mathbb{R}^{2n\times 2n}, B_1, B_2 \in \mathbb{R}^{2n\times 2m}, C_1, C_2 \in \mathbb{R}^{2m\times 2n}$ and $(A_2, B_3, C_3), A_2 \in \mathbb{R}^{2n\times 2n}, B_3 \in \mathbb{R}^{2n\times 2m}, C_3 \in \mathbb{R}^{2m\times 2n}$, respectively. The additional system serves as the coherent controller, which processes the output $d\mathcal{W}_{1,out}(t)$ of the original system and feeds its output back to the original system. To close the loop we let $d\mathcal{W}_3 = d\mathcal{W}_{1,out}$ and $d\mathcal{W}_2 = d\mathcal{W}_{3,out}$. The closed-loop system is expressed as

$$\begin{aligned} dx_e(t) &= \begin{pmatrix} A_1 + B_2C_1 & B_2C_3 \\ B_3C_1 & A_2 \end{pmatrix} x_e(t)dt \\ &+ \begin{pmatrix} B_1 + B_2 \\ B_3 \end{pmatrix} d\mathcal{W}_1(t), \\ d\mathcal{W}_{2,out} &= (C_1 + C_2 \quad C_3)x_e(t)dt + d\mathcal{W}_1(t). \end{aligned} \tag{28}$$

Similar to the cascade case, if we let $C_3 = C_1 + C_2$, then the matrix $\mathcal{P}_{m,2n}((C_1 + C_2 \quad C_3))$ for the closed-loop system does not have full column rank.

The second type of closed-loop system is the cross feedback between two systems. In this case, the additional system is defined by $(A_2, (B_3, B_4), (C_3, C_4)), B_3, B_4 \in \mathbb{R}^{2n\times 2m}, C_3, C_4 \in \mathbb{R}^{2m\times 2n}$ with two inputs and two outputs. The system equations are given by

$$\begin{aligned} dx_1(t) &= A_1x_1(t)dt + B_1d\mathcal{W}_1(t) + B_2d\mathcal{W}_2(t), \\ dx_2(t) &= A_2x_2(t)dt + B_3d\mathcal{W}_3(t) + B_4d\mathcal{W}_4(t), \\ d\mathcal{W}_{i,out} &= C_ix_1(t)dt + d\mathcal{W}_i(t), \quad i = 1, 2, \\ d\mathcal{W}_{j,out} &= C_jx_2(t)dt + d\mathcal{W}_j(t), \quad j = 3, 4. \end{aligned} \tag{29}$$

The cross feedback is realized by letting $d\mathcal{W}_3 = d\mathcal{W}_{1,out}$ and $d\mathcal{W}_2 = d\mathcal{W}_{4,out}$, which transform the system equations to

$$\begin{aligned} dx_e(t) &= \begin{pmatrix} A_1 & B_2C_4 \\ B_3C_1 & A_2 \end{pmatrix} x_e(t)dt \\ &+ \begin{pmatrix} B_1 & B_2 \\ B_3 & B_4 \end{pmatrix} \begin{pmatrix} d\mathcal{W}_1(t) \\ d\mathcal{W}_4(t) \end{pmatrix}, \\ d\mathcal{W}_{2,out}(t) &= (C_2 \quad C_4)x_e(t)dt + d\mathcal{W}_4(t), \\ d\mathcal{W}_{3,out}(t) &= (C_1 \quad C_3)x_e(t)dt + d\mathcal{W}_1(t). \end{aligned} \tag{30}$$

By (30), if we let $C_3 = C_1$ and $C_4 = C_2$, the rank-defect condition of Theorem 1 is satisfied and dark modes may exist.

Example 1: In this example we consider the cross feedback design using two linear systems. The system operators are denoted as $(x_i, p_i), i = 1, 2$, where x_i, p_i are position and momentum operators of the harmonic oscillators, respectively. Each system has two inputs and two outputs. The four coupling operators $L_i = \sqrt{\kappa}(x_1 + \mathrm{i}p_1)/\sqrt{2}, i = 1, 2, L_j = \sqrt{\kappa}(x_2 + \mathrm{i}p_2)/\sqrt{2}, j = 3, 4$ have equal coupling strength. We can obtain the following coefficient matrices for (29):

$$\begin{aligned} &B_1 = B_2 = B_3 = B_4 = -\sqrt{\kappa}\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \\ &C_1 = C_2 = C_3 = C_4 = -B_1^T. \end{aligned} \tag{31}$$

Using the closed-loop equation (30), it is straightforward to verify that $x_1 - x_2$ and $p_1 - p_2$ are dark modes which are decoupled from L_1 and L_4 if

$$P_1^T \begin{pmatrix} A_1 & B_2C_4 \\ B_3C_1 & A_2 \end{pmatrix} P_2 = 0 \tag{32}$$

holds for

$$P_1 = \frac{1}{\sqrt{2}}\begin{pmatrix} I_2 \\ -I_2 \end{pmatrix}, \quad P_2 = \frac{1}{\sqrt{2}}\begin{pmatrix} I_2 \\ I_2 \end{pmatrix}. \tag{33}$$

This condition leads to

$$A_1 = A_2, \tag{34}$$

or $G_1 = G_2$. Therefore, a sufficient condition for the existence of dark modes is that the Hamiltonians of the two systems are the same. Eq. (34) shows that cross feedback provides a robust realization for dark modes. The structures and parameters of the two linear systems can be uncertain, as long as two identical systems can be fabricated for cross feedback. Also, it is worth mentioning that in this case we have generated the dark modes under the condition that each system is coupled to full-rank noises $\{B_i\}$.

D. Hamiltonian engineering

We consider the solution G to the Hamiltonian engineering problems $P_1^TGP_2 = 0$ and $P_1^TG = 0$ for the generation of dark modes and invariant modes.

First, $G = I$ and $G = 0$ are special solutions to $P_1^TGP_2 = 0$, and $G = 0$ is a solution to $P_1^TG = 0$. Also we have the following result.

Theorem 3: If $R(P_2)$ is invariant under G, then G is a solution to $P_1^TGP_2 = 0$. The general solution to $P_1^TG = 0$ is given by

$$G = (I - P_1P_1^T)Z(I - P_1P_1^T), \tag{35}$$

with Z being an arbitrary matrix.

Proof: The fact that $R(P_2)$ is invariant under G implies $GP_2 = P_2M$ for a matrix M. Then $P_1^TGP_2 = 0$ follows since $P_1^TP_2 = 0$.

The general solution to $P_1^TG = 0$ is given by

$$G = (I - (P_1^T)^+P_1^T)Z(I - (P_1^T)^+P_1^T), \tag{36}$$

with Z being an arbitrary matrix. It is easy to verify that $(P_1^T)^+ = P_1$. ■

V. Application to the Dark Modes of a Quantum Optomechanical System

In this section, we apply our theoretical results to the analysis of optomechanical dark modes and bright modes. Optomechanical systems are conventionally used for the fundamental study of light-matter interaction. Recently, they have

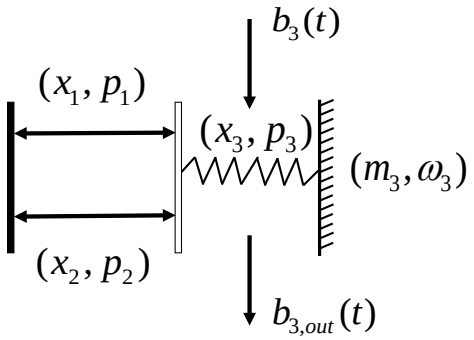

Fig. 1. An optomechanical dark mode. The position and momentum operators of the two optical modes are (x_1, p_1) and (x_2, p_2). The mechanical oscillator is characterized by (x_3, p_3). The mechanical oscillator is coupled to the environment due to thermal dissipation.

also found applications in quantum storage [25]. As mentioned in Section I, dark modes and bright modes play vital roles in these applications.

We consider an optomechanical system which has been experimentally realized in [12]. The system is depicted in Fig. 1. The two optical modes within optical cavities are coupled to a mechanical oscillator via the radiation pressure of the optical fields. The optical modes are modelled as harmonic oscillators with the system variables (x_1, p_1) and (x_2, p_2), respectively. m_3 and ω_3 are the mass and frequency of the mechanical oscillator, and the mechanical mode is characterized by the variables x_3 and p_3. The mechanical oscillator is subjected to thermal noise, which can be modelled by a coupling operator $L = \sqrt{\kappa} b_3 = \sqrt{\kappa}(x_3 + \mathrm{i}p_3)/\sqrt{2}$. κ is the coupling strength. Since the direct coupling strength between the cavity and the environment is relatively small, we can ignore the corresponding optical losses.

This optomechanical setup is proposed to mediate the coupling between the two optical modes using the mechanical oscillator. However, the mechanical damping will undermine the mediated coupling and cause losses to the optical modes. One way to solve this problem is to exploit the optomechanical dark modes [12]. The dark modes are decoupled from the mechanical oscillator. The dark modes are the superposition of different optical modes. Therefore, the formation of stable dark modes is the result of the interaction and energy transfer between the optical fields. This process can be used to mediate an effective coupling between the optical modes and at the same time minimize the losses [12]. Another way to mediate coupling is to switch between dark and bright modes. Here, the bright mode is used to capture the photons, while the dark mode is used to store them.

For the proposed optomechanical system, we have

$$C = \sqrt{\kappa}(0_2 \quad 0_2 \quad I_2). \tag{37}$$

Hence, we have $C_1 = \sqrt{\kappa}(0_2 \quad 0_2)$ for the engineering of dark modes that consist of optical modes only. The interaction Hamiltonian between the cavity and the mechanical oscillator is given by $H_{int} = \lambda_1 a_1^\dagger a_1 x_3 + \lambda_2 a_2^\dagger a_2 x_3$, with $a_i = (x_i + \mathrm{i}p_i)/\sqrt{2}, i = 1, 2$. Applying a standard linearization procedure [26] to H_{int}, we can obtain G_{int} as

$$\left(\begin{array}{cc|cc|cc} 0_2 & & 0_2 & & \gamma_1 & 0 \\ & & & & 0 & 0 \\ \hline 0_2 & & 0_2 & & \gamma_2 & 0 \\ & & & & 0 & 0 \\ \hline \gamma_1 & 0 & \gamma_2 & 0 & 0_2 & \\ 0 & 0 & 0 & 0 & & \end{array}\right), \tag{38}$$

where $\gamma_i, i = 1, 2$ is determined by κ and λ_i. The $\mathcal{P}$-matrix as defined in Theorem 1 is given by

$$\left(\begin{array}{c} 0_4 \\ \hline 0_4 \\ \gamma_1 \quad 0 \quad \gamma_2 \quad 0 \\ 0 \quad 0 \quad 0 \quad 0 \\ \hline 0_4 \\ 0 \quad 0 \quad 0 \quad 0 \\ 0 \quad -\gamma_1 \quad 0 \quad -\gamma_2 \end{array}\right), \tag{39}$$

which is not full column rank. Therefore we can obtain

$$P_1 = \begin{pmatrix} a & 0 \\ 0 & a \\ b & 0 \\ 0 & b \\ 0 & 0 \\ 0 & 0 \end{pmatrix}, \quad P_2 = \begin{pmatrix} eI_2 & 0_2 \\ fI_2 & 0_2 \\ 0_2 & I_2 \end{pmatrix}, \tag{40}$$

with the condition $a\gamma_1 + b\gamma_2 = 0$. $(e \quad f)^T$ and $(a \quad b)^T$ are required to be orthogonal. We then choose $G_{\mathcal{D}}$ such that $P_1^T G_{\mathcal{D}} P_2 = 0$. Finally, we can obtain the optomechanical dark modes as $ax_1 + bx_2 = \frac{\gamma_2}{\sqrt{\gamma_1^2+\gamma_2^2}} x_1 - \frac{\gamma_1}{\sqrt{\gamma_1^2+\gamma_2^2}} x_2$ and its canonical conjugate mode $\frac{\gamma_2}{\sqrt{\gamma_1^2+\gamma_2^2}} p_1 - \frac{\gamma_1}{\sqrt{\gamma_1^2+\gamma_2^2}} p_2$. It has been experimentally verified in [12] that these two modes are decoupled from the mechanical dissipation.

Note that any $G_{\mathcal{D}}$ satisfying $P_1^T G_{\mathcal{D}} P_2 = 0$ will generate the above dark modes. Here we assume a specific realization of the Hamiltonian $H_{\mathcal{D}}$ of the optical harmonic oscillators as $H_{\mathcal{D}} = \frac{p_1^2}{m_1} + m_1\omega_1^2 x_1^2 + \frac{p_2^2}{m_2} + m_2\omega_2^2 x_2^2$. It is straightforward to verify that $P_1^T G_{\mathcal{D}} P_2 = 0$ if and only if $m_1 = m_2$ and $\omega_1 = \omega_2$. In other words, the dark modes exist if the two optical modes have the same energy. Experimentally, this can be realized by driving the optical modes with different frequencies $\omega_{l1} = \omega_{c1} - \omega_m$ and $\omega_{l2} = \omega_{c2} - \omega_m$, where $\{\omega_{ci}, i = 1, 2\}$ are the cavity resonance frequencies.

Using (17), we have $dx_D(t) = P_1^T \Sigma_n G P_1 x_D(t) dt$ and

$$\begin{aligned} d\begin{pmatrix} x_B(t) \\ x_d(t) \end{pmatrix} &= \begin{pmatrix} 0 & P_2^T A P_2 \end{pmatrix} x(t) dt \\ &+ P_2^T \Sigma_n C^T \Sigma_m d\mathcal{W}(t), \end{aligned} \tag{41}$$

with

$$\begin{aligned} &P_2^T A P_2 \\ &= \begin{pmatrix} 0 & \frac{1}{m_1} & 0 & 0 \\ -m_1\omega_1^2 & 0 & -e\gamma_1 - f\gamma_2 & 0 \\ 0 & 0 & -\frac{\kappa}{2} & \frac{1}{m_3} \\ -e\gamma_1 - f\gamma_2 & 0 & -m_3\omega_3^2 & -\frac{\kappa}{2} \end{pmatrix}, \\ &P_2^T \Sigma_n C^T \Sigma_m = -\sqrt{\kappa} \begin{pmatrix} 0_2, \\ I_2 \end{pmatrix}, \end{aligned} \tag{42}$$

where we have $e = \frac{\gamma_1}{\sqrt{\gamma_1^2+\gamma_2^2}}$ and $f = \frac{\gamma_2}{\sqrt{\gamma_1^2+\gamma_2^2}}$. According to (42), the bright mode $ep_1 + fp_2$ is directly coupled to the mechanical mode, while $ex_1 + fx_2$ is an indirect-coupled bright optical mode.

VI. Conclusion

We have developed a direct method for the characterization and synthesis of dark modes. The key is to ensure that the interaction Hamiltonian between the subsystems does not affect the dark modes. Sufficient conditions are derived in terms of environmental couplings and the system Hamiltonian, which provides a straightforward and tractable way to engineer dark modes.

Appendix

Uncontrollable and unobservable modes from a specific input and output

In order to decouple modes from a specific input and output, we may decompose C as $C = (C_1^T \quad C_2^T)^T$. Here $C_1 \in \mathbb{R}^{2n_1 \times 2n}$ is associated with n_1 coupling operators from n_1 inputs, and $C_2 \in \mathbb{R}^{2(m-n_1)\times 2n}$ is associated with the other $m - n_1$ inputs. The modes are required to decouple from the given n_1 inputs and outputs. If $\text{rank}(\begin{pmatrix} \Sigma_{n_1} C_1 \Sigma_n \\ C_1 \end{pmatrix}) = q < 2n$, we can construct a transformation matrix $\mathcal{T} = (P_1 \quad P_2) \in \mathbb{R}^{2n\times 2n}$, where $P_1 \in \mathbb{R}^{2n\times(2n-q)}$ is chosen as $P_1 = (v_1 \ \Sigma_n v_1 \cdots v_{(2n-q)/2} \ \Sigma_n v_{(2n-q)/2})$ with $\{v_i, \Sigma_n v_i\}$ being mutually-orthogonal basis vectors of $N(\begin{pmatrix} \Sigma_{n_1} C_1 \Sigma_n \\ C_1 \end{pmatrix})$. The q column vectors of $P_2 \in \mathbb{R}^{2n\times q}$ are chosen to be mutually-orthogonal normalized vectors which are orthogonal to the column vectors of P_1. The coordinate transformation yields

$$\begin{aligned} d\begin{pmatrix} x_{d1} \\ x_{d2} \end{pmatrix} &= \begin{pmatrix} P_1^T A P_1 & P_1^T A P_2 \\ P_2^T A P_1 & P_2^T A P_2 \end{pmatrix} x dt \\ &+ \begin{pmatrix} 0 & P_1^T \Sigma_n C_2^T \Sigma_{m-n_1} \\ P_2^T \Sigma_n C_1^T \Sigma_{n_1} & P_2^T \Sigma_n C_2^T \Sigma_{m-n_1} \end{pmatrix} d\mathcal{W}, \\ d\mathcal{W}_{out} &= \begin{pmatrix} 0 & C_1 P_2 \\ C_2 P_1 & C_2 P_2 \end{pmatrix} x dt + d\mathcal{W}. \end{aligned} \tag{43}$$

Theorem 4: A sufficient condition for the modes x_{d1} to be decoupled from the n_1 inputs is $P_1^T A P_2 = 0$.

Proof: First, we decompose $d\mathcal{W}$ and $d\mathcal{W}_{out}$ as $(d\mathcal{W}_{d1}^T \quad d\mathcal{W}_{d2}^T)^T$ and $(d\mathcal{W}_{d1,out}^T \quad d\mathcal{W}_{d2,out}^T)^T$, where $\mathcal{W}_{d1}$ and $\mathcal{W}_{d1,out}$ are associated with C_1. Using this decomposition we have

$$\begin{aligned} dx_{d1} &= P_1^T A P_1 x_{d1} dt + P_1^T \Sigma_n C_2^T \Sigma_{m-n_1} d\mathcal{W}_{d2}, \\ d\mathcal{W}_{d1,out} &= C_1 P_2 x_d dt + d\mathcal{W}_{d1}, \end{aligned} \tag{44}$$

given that $P_1^T A P_2 = 0$ is satisfied. According to (44), x_{d1} are decoupled from the input $\mathcal{W}_{d1}$, and the corresponding output $\mathcal{W}_{d1,out}$ is decoupled from x_{d1} as well. Thus we have proven that x_{d1} is neither controllable nor observable from the n_1 inputs. ■
