Codes for Simultaneous Transmission of Quantum
and Classical Information

Abstract—We consider the characterization as well as the
construction of quantum codes that allow to transmit both
quantum and classical information, which we refer to as ‘hybrid
codes’. We construct hybrid codes $[n, k, m, d]_q$ with length $n$ and
distance $d$, that simultaneously transmit $k$ qudits and $m$
symbols from a classical alphabet of size $q$. Many good codes such
as $[7, 1, 1, 3]_2$, $[9, 2, 2, 3]_2$, $[10, 3, 2, 3]_2$, $[11, 4, 2, 3]_2$, $[11, 1, 2, 4]_2$, $[13, 1, 4, 4]_2$, $[13, 1, 1, 5]_2$, $[14, 1, 2, 5]_2$, $[15, 1, 3, 5]_2$, $[19, 9, 1, 4]_2$, $[20, 9, 2, 4]_2$, $[21, 9, 3, 4]_2$, $[22, 9, 4, 4]_2$ have been found. All these
codes have better parameters than hybrid codes obtained from
the best known stabilizer quantum codes.

I. INTRODUCTION

The simultaneous transmission of both quantum and classical
information over a quantum channel was initially inves-
tigated in [6] from an information theoretic point of view,
and followed up by many others (see, e.g., [10], [11], [15]).

It was shown that there is an advantage to address the two
tasks of transmitting both quantum and classical information
simultaneously, compared to independent solutions.

For the finite length case, however, there are not many
constructions of error-correcting codes for simultaneous trans-
mission of quantum and classical information in the literature.

In [13], the authors consider the problem in the context of
so-called entanglement-assisted codes, i.e., when sender and
receiver share perfect entanglement. The examples given in
[13], however, fail to demonstrate an advantage in terms of
the parameters of the resulting codes when compared to, e.g.,
stabilizer quantum codes.

Here we study codes for simultaneous transmission of quan-
tum and classical information, which we refer to as ‘hybrid
quantum codes’ or just ‘hybrid codes’. Using the framework
of stabilizer codes [2], [7] and its generalization, that is,
codeword stabilized (CWS) codes [3] and union stabilizer
codes [9], we obtain hybrid codes for up to eleven qubits
by exhaustive or randomized search. We have found many
good hybrid codes that have advantage over the best known
quantum codes for transmitting quantum information only.
A general construction yields codes for up to 38 qubits. We also
formulate a linear program to bound the parameters of hybrid
codes.

II. BACKGROUND AND NOTATION

Our discussion is based on the theory of stabilizer quantum
codes and its connection to classical error-correcting codes
(see, e.g., [2]). Although we consider only codes for qubit
systems here, we state the theory for quantum systems com-
posed of qudits of dimension $q = p^k$, where $p$ is prime. A
quantum error-correcting code, denoted by $C = ([n, K, d])_q$, is
a $K$-dimensional subspace of the Hilbert space $H = (\mathbb{C}^q)^\otimes n$,
which is an $n$-fold tensor product of Hilbert spaces of dimen-
sion $q$. If the minimum distance of the code is $d$, then any error
affecting no more than $d-1$ of the subsystems can be detected
or acts as a multiple of identity on the code. For stabilizer
codes, the dimension $K$ is a power of $p$, and if $K = q^k$, we
use the notation $C = [n, k, d]_q$. For classical block codes, the
notation $C = ([n, M, d])_q$ is used, and if the code is linear with
cardinality $M = q^m$, we use the notation $C = [n, m, d]_q$.

Following [13], we use the notation $C = [n, k, m, d]_q$ for a
code that simultaneously transmits $k$ qudits and $m$ symbols
from a classical alphabet of size $q$. Similarly, we use the
notation $C = ([n, K:M, d])_q$ for such a code that encodes a
quantum system of dimension $K$ and one out of $M$ classical
messages.

Trivially, we have the following:

Lemma 1: Given a quantum code $C = ([n, K:M, d])_q$
of composite dimension $K:M$, there exists a hybrid code with
parameters $([n, K:M], d)_q$.

Proof: First, factor the code space into two subsystems
of dimension $K$ and $M$, respectively. Then, one uses the first
subsystem of dimension $K$ to transmit quantum information,
and the second subsystem of dimension $M$ just to transmit
classical information.

Similarly, we have the following conversion rule for hybrid
stabilizer codes.

Lemma 2: Assume that a hybrid code $C = [n, k, m, d]_q$
with $k > 0$ exists. Then a code $C' = [n, k-1, m+1, d]_q$ exists as
well.

Proof: One of the $k$ qudits can be used to transmit
classical information only, decreasing $k$ and increasing $m$.

Note that the converse does not hold in general, as the
transmission of quantum information over a quantum channel
is more demanding than the transmission of classical informa-
tion.

Another trivial construction is to independently use a quan-
tum code of length $n_1$ and a classical code of length $n_2$.

Lemma 3: Assume that a quantum code $C_1 = [n_1, k_1, d]_q$
and a classical code $C_2 = [n_2, m_2, d]_q$ exist. Then there exists
a hybrid code with parameters $C = [n_1 + n_2, k_1+m_2, d]_q$.

Our goal is to find codes that have better parameters than the
codes that can be obtained by these trivial constructions.
III. Error correction conditions

A hybrid quantum code $C = \langle (n, K; M) \rangle_q$ can be described by a collection

$$\{C^{(\nu)} : \nu = 1, \ldots, M\}$$

(1)

of $M$ quantum codes $C^{(\nu)} = \langle (n, K, d) \rangle_q$. Each of the codes has length $n$, dimension $K$, and minimum distance $d$. The classical information $\nu$ determines which quantum code $C^{(\nu)}$ is used to encode the quantum information. In the following, we will use Greek letters when referring to classical information.

Assume that

$$\{|c^{(\nu)}_i \rangle : i = 1, \ldots, K\}$$

(2)

is an orthonormal basis for the code $C^{(\nu)}$. In order to be able to correct the linear span of error operators $\{E_k : k = 1, 2, \ldots\}$, each of the codes $C^{(\nu)}$ has to obey the Knill-Laflamme conditions \cite{12}, i.e.,

$$\langle c^{(\nu)}_i | E^{\dagger}_k E^{\dagger}_\ell c^{(\mu)}_j \rangle = \alpha^{(\nu)}_{k \ell} \delta_{ij}.$$  

(3)

Note that the constants $\alpha^{(\nu)}_{k \ell} \in \mathbb{C}$ may depend on the classical information $\nu$.

On the other hand, in order to be able to retrieve the classical information $\nu$ independently of the quantum information that is transmitted at the same time, one has to be able to perfectly distinguish the states $|c^{(\nu)}_i \rangle$ and $|c^{(\mu)}_j \rangle$ for $\nu \neq \mu$ and arbitrary $i$ and $j$ after an error. This is reflected by the condition

$$\langle c^{(\nu)}_i | E^{\dagger}_k E^{\dagger}_\ell c^{(\mu)}_j \rangle = 0, \quad \text{for } \mu \neq \nu.$$  

(4)

In particular, the states $|c^{(\nu)}_i \rangle$ and $|c^{(\mu)}_j \rangle$ have to be mutually orthogonal. Combining (2) and (3), we get the following necessary and sufficient condition for hybrid quantum codes.

**Theorem 4:** A hybrid quantum code $C = \langle (n, K; M) \rangle_q$ with orthonormal basis states $\{|c^{(\nu)}_i \rangle : i = 1, \ldots, K, \ \nu = 1, \ldots, M\}$ can correct all errors $\{E_k : k = 1, 2, \ldots\}$ if and only if

$$\langle c^{(\nu)}_i | E^{\dagger}_k E^{\dagger}_\ell c^{(\mu)}_j \rangle = \alpha^{(\nu)}_{k \ell} \delta_{ij} \delta_{\nu \mu}.$$  

(5)

**Proof:** As argued above, for $\mu = \nu$ condition (5) reduces to the Knill-Laflamme conditions. Now assume that $\mu \neq \nu$. When condition (4) is violated, i.e., $\langle c^{(\nu)}_i | E^{\dagger}_k E^{\dagger}_\ell c^{(\mu)}_j \rangle \neq 0$, the erroneous states $E_k |c^{(\nu)}_i \rangle$ and $E_\ell |c^{(\mu)}_j \rangle$ are non-orthogonal and can not be perfectly distinguished. On the other hand, when condition (4) holds, then the spaces $\mathcal{V}^{(\nu)}$ spanned by the images of the code $C^{(\nu)}$ under all error operators, i.e.,

$$\mathcal{V}^{(\nu)} = \left\{ E_k |c^{(\nu)}_i \rangle : i = 1, \ldots, K, \ k = 1, 2, \ldots \right\}$$

(6)

are mutually orthogonal. Therefore, there exists a measurement with associated orthogonal projections $P^{(\nu)}$ that can be used to retrieve the classical information $\nu$. Then, knowing the index $\nu$, one can apply the decoding algorithm for the code $C^{(\nu)}$ to retrieve the quantum information.

Note that in the special case that the constants $\alpha^{(\nu)}_{k \ell}$ do not depend on $\nu$, condition (5) reduces to the Knill-Laflamme conditions for a quantum code $C = \langle (n, K; M) \rangle_q$ of dimension $KM$ with basis states $\{|c^{(\nu)}_i \rangle : i = 1, \ldots, K, \ \nu = 1, \ldots, M\}$.

Therefore, for hybrid codes to have better parameters than the codes given by Lemma 1 there should be at least a pair $\nu, \mu$ and errors $E_k, E_\ell$ such that $\alpha^{(\nu)}_{k \ell} \neq \alpha^{(\mu)}_{k \ell}$. In particular, when the error operators $E_k$ are unitary, $\alpha_{kk} = 1$. Then one should have $\alpha^{(\nu)}_{k \ell} \neq 0$ for some $\nu$ and $k \neq \ell$, which suggests that some of the codes $C^{(\nu)}$ might be taken to be degenerate codes. In that case, the dimension of the spaces $\mathcal{V}^{(\nu)}$ in (6) is smaller, and hence one might be able to find a larger number of such spaces that are mutually orthogonal. In general, however, it is not excluded that all the subcodes $C^{(\nu)}$ of a hybrid quantum code $C = \langle (n, K; M, d) \rangle_q$ are non-degenerate and at the same time the product $KM$ is strictly larger than the maximal dimension $K'$ of any quantum code $C' = \langle (n, K', d) \rangle_q$.

An alternative characterization of hybrid quantum codes in the Heisenberg picture of quantum mechanics was given as a special case in [1].

IV. Code construction

We outline the construction of hybrid quantum codes in the framework of CWS codes/union stabilizer codes. We start with a quantum code $C^{(0)} = \langle (n, K, d) \rangle_q$, which is a CWS code that might even be a stabilizer code $C^{(0)} = [n, k, d]_q$. The codes $C^{(\nu)}$ are chosen as images of the seed code $C^{(0)}$ under tensor products of generalized Pauli matrices, denoted by $t_\nu$. Thus we have

$$C^{(\nu)} = t_\nu C^{(0)}$$

(7)

with $\{t_\nu : \nu = 1, \ldots, M\}$ a set of $M$ translation operators. When $C^{(0)}$ is a non-degenerate quantum code, then all the codes $C^{(\nu)}$ will also be non-degenerate. Furthermore, in this situation $\alpha^{(\nu)}_{k \ell} = \delta_{k \ell}$ for generalized Pauli errors $E_k$ and $E_\ell$. Then the resulting code will be a quantum code of dimension $KM$. Therefore, the seed code $C^{(0)}$ is chosen to be degenerate.

Next we consider the classical codes associated with the quantum codes $C^{(\nu)}$. For simplicity, we first consider the special case of stabilizer codes. The stabilizer group $S$ of the code $C^{(0)}$ corresponds to a self-orthogonal classical code $C_0$. The code $C_0$ is contained in its symplectic dual $C_0^\ast$, i.e., $C_0 \subseteq C_0^\ast$, which corresponds to the normalizer $N$ of the stabilizer groups $S$ in the generalized $n$-qudit Pauli group.

For impure codes, we have

$$d = \min\{\text{wgt } c : c \in C_0^\ast \setminus C_0\} > \min\{\text{wgt } c : c \in C_0^\ast \setminus \{0\}\}.$$  

(8)

The codes $C^{(\nu)} = t_\nu C^{(0)}$ are associated with cosets $C_0^\ast + t_\nu$ of the normalizer code $C_0^\ast$, where we use the same symbol $t_\nu$ to denote the classical vector corresponding to the translation operator. When the cosets $C_0^\ast + t_\nu$ and $C_0^\ast + t_\mu$ are different, then the codes $C^{(\nu)}$ and $C^{(\mu)}$ will be orthogonal to each other.

The hybrid quantum code $C$ is associated with the classical code

$$C^\ast = \bigcup_{\nu=1}^M C_0^\ast + t_\nu.$$  

(9)
When the union of the codes in (2) is an additive code, the hybrid quantum code will be a stabilizer code. Note that, in general, we have the chain of classical codes
\[ C \leq C_0 \leq C^*_0 \leq C^*. \] (10)

The minimum distance of the quantum code associated with \( C^* \) is computed as
\[ d' = \min \{ \text{wgt} \, c : c \in C^* \setminus C \}. \] (11)

It turns out that the minimum distance of a hybrid code associated with the codes \( C_0 \leq C^* \) is given by
\[ d = \min \{ \text{wgt} \, c : c \in C^* \setminus C_0 \}. \] (12)

Note that the minimum in (12) is taken over a smaller set compared to (11), as \( C \leq C_0 \), and hence \( d \geq d' \).

In summary, we have the following construction.

Theorem 5: Let \( C_0 = (n, q^{n-k}, d_0)_q \) be a classical additive code that is contained in its symplectic dual \( C^*_0 \). Further, let \( C^* = (n, q^{n+k+m}, d')_q \) be an additive code containing \( C^*_0 \). Then there exists a hybrid stabilizer code \( C = [n, k, m, d]_q \), encoding \( k \) qudits and \( m \) classical symbols. The minimum distance of \( C \) is given by
\[ d = \min \{ \text{wgt} \, c : c \in C^* \setminus C_0 \}. \] (13)

Proof: There are \( q^n \) cosets of the code \( C^*_0 \) in the code \( C^* \). Using the representatives \( t_c \) of the cosets \( C^*/C^*_0 \), we obtain the translated codes \( C^{(i)} = t_c C^{(0)} \) which are mutually orthogonal. All these codes have the same minimum distance given by
\[ d'' = \min \{ \text{wgt} \, c : c \in C^*_0 \setminus C_0 \}. \] (14)
\[ \geq \min \{ \text{wgt} \, c : c \in C^* \setminus C_0 \} = d. \] (15)

Hence, condition (5) holds for \( \nu = \mu \). It remains to show that the distance between the quantum codes \( C^{(\nu)} \) is at least \( d \), i.e., that (4) holds for all operators \( E_i \) of weight at most \( d - 1 \). When we treat the linear span of all codes \( C^{(\nu)} \) as a larger stabilizer code, the minimum distance would be given by (11). When \( E_i E_j \) is an element of the stabilizer of \( C^{(0)} \), for \( \nu \neq \mu \) we compute
\[ \langle c^{(\nu)}_i | E_i E_j | c^{(\mu)}_j \rangle = \langle c^{(0)}_i | t_i t_j E_i E_j t_{\mu} t_{\mu} | c^{(0)}_j \rangle \] (16)
\[ = \langle c^{(0)}_i | t_i t_{\mu} E_i | c^{(0)}_j \rangle \] (17)
\[ = \langle c^{(0)}_i | t_i t_{\mu} | c^{(0)}_j \rangle = \langle c^{(\nu)}_i | c^{(\mu)}_j \rangle = 0. \] (18)

Hence we can not only exclude the elements of \( C \), but also those of \( C_0 \) when computing the minimum distance in (15).

In terms of classical codes, the task of constructing a good hybrid stabilizer code can be carried out in two steps. First, one has to find a good additive code \( C^*_0 \) that contains its symplectic dual \( C_0 \). This defines the seed code \( C^{(0)} \) used to encode the quantum information. Then, using \( m \) additional generators for encoding the classical information, one obtains the code \( C \) with \( C^*_0 \leq C^* \).

V. LINEAR PROGRAMMING BOUNDS

In order to obtain bounds on the parameters of hybrid stabilizer codes \([n, k, m, d]_q \), we consider the homogeneous weight enumerators of the associated code \( C_0 \) and its symplectic dual \( C^*_0 \), as well as the code \( C^* \) and its symplectic dual \( C \):
\[ W_{C_0}(X, Y) = \sum_{w=0}^{n} A_w^+ X^{n-w} Y^w, \] (19)
\[ W_{C^*_0}(X, Y) = \sum_{w=0}^{n} A_w^- X^{n-w} Y^w, \] (20)
\[ W_C(X, Y) = \sum_{w=0}^{n} B_w^+ X^{n-w} Y^w, \] (21)
\[ W_{C^*}(X, Y) = \sum_{w=0}^{n} B_w^- X^{n-w} Y^w. \] (22)

The weight enumerators of \( C_0 \) and \( C^*_0 \), as well as those of \( C \) and \( C^* \), are related by the MacWilliams transformation, i.e.,
\[ W_{C^*_0}(X, Y) = \frac{1}{|C^*_0|} W_{C_0}(X + (q^2 - 1) Y, Y - X), \] (23)
\[ W_C(X, Y) = \frac{1}{|C|} W_{C^*}(X + (q^2 - 1) Y, Y - X). \] (24)

Nestedness of the codes implies the condition
\[ 0 \leq B_w^+ \leq A_w^+ \leq A_w = B_w, \quad \text{for } w = 0, \ldots, n. \] (25)

When the hybrid code has minimum distance \( d \), we have
\[ A_w^+ = A_w = B_w, \quad \text{for } w = 0, \ldots, d - 1. \] (26)

Additionally, we have:
\[ A_w^+ = A_0 = B_0 = 1, \] (27)
\[ \sum_{w=0}^{n} A_w^+ = q^{n-k}, \quad \sum_{w=0}^{n} A_w = q^{n+k}, \] (28)
\[ \sum_{w=0}^{n} B_w^+ = q^{n-k-m}, \quad \sum_{w=0}^{n} B_w = q^{n+k+m}. \] (29)

When a hybrid stabilizer code \([n, k, m, d]_q \) exists, the linear program for the variables \( B_w^+, A_w^+, A_w, B_w \) given by (23)–(29) has an integer solution. For qubit codes, we can strengthen the linear program by additionally considering the shadow enumerator (14)
\[ S_{C_0}(X, Y) = \frac{1}{|C|} W_{C_0}(X + (q^2 - 1) Y, Y - X), \] (30)
which has to have non-negative integer coefficients.

Using CPLEX V12.6.3.0, we checked whether the integer program is feasible. More precisely, we first fix the length \( n \), number of qudits \( k \), and number \( M = 2^m \) of classical symbols. Then we look for the largest minimum distance \( d \) for which the integer program is found to be feasible. The resulting bounds on the parameters \([n, k, m, d]_q \) are listed in Table I i.e., for fixed parameters \( n, k, \) and \( d \), the largest possible value for \( m \) is given. For \( n > 14 \), there seem to be some precision issues, so we list only the bounds for \( n \leq 14 \).
TABLE I: (LP bound) Upper bound on the number of classical bits \( m \) in any \([n, k, m, d]_2\) hybrid stabilizer code with fixed length \( n \leq 14 \) and dimension \( k \) for distance \( d = 3, 4, 5 \). For \( k = 0 \), we list the largest dimension of a classical linear binary code. Note that there is, e.g., no stabilizer code \([13, 5, 4]_2\), excluding the corresponding entry in the table marked with *.

\]

VI. RESULTS

Based on the construction discussed in Section IV, we perform a search for \( C = [n, k, m, d]_2 \) codes with distance \( d \geq 3 \). We start with the self-dual codes from the classification in [4, 5]. In a first step, we construct impure quantum codes \([n, 1, d]_2\), and then look for additional vectors for the encoding of classical information, resulting in an \([n, 1: m', d]_2\) hybrid code. In some cases it turns out that we can encode more than one qubit, i.e., the code \([n, 1: m', d]_2\) is in fact a hybrid code with parameters \([n, k: m'-k+1, d]_2\).

For distance \( d = 4 \) and \( d = 5 \), we have exhaustively searched using all self-dual codes listed in [4, 5] up to length \( n = 11 \). For \( d = 3 \), we have exhaustively searched all self-dual codes listed in [4, 5] up to \( n = 10 \). We also have conducted randomized search for \( n = 11 \). Finally, we appended some qubits in the state \( |0\rangle \) to good quantum codes and found new hybrid codes. The results are summarized as follows.

**Theorem 6:** There exist hybrid codes with the following parameters:

\([7, 1:1, 3]_2\), \([9, 2:2, 3]_2\), \([10, 3:2, 3]_2\), \([11, 4:2, 3]_2\),
\([11, 1:2, 4]_2\), \([13, 1:4, 4]_2\),
\([13, 1:1, 5]_2\), \([14, 1:2, 5]_2\), \([15, 1:3, 5]_2\),
\([19, 9:1, 4]_2\), \([20, 9:2, 4]_2\), \([21, 9:3, 4]_2\), \([22, 9:4, 4]_2\).

All these codes have better parameters than codes obtained from the best quantum codes using Lemma 2.

Below, we provide more details on these codes. In presenting each \([n, k, m, d]_2\) code, we first list the generators of the stabilizer of the corresponding \([n, k, d]_2\) impure quantum code \( C^{(0)} \), with its \( 2k \) logical operators between a single and a double horizontal line. The stabilizer of the code \( C^{(0)} \), corresponding to the classical code \( C_0 \), is generated by the rows above the single horizontal line, while the normalizer of the code \( C^{(0)} \), corresponding to the symplectic dual code \( C_0^* \), is generated by the rows above the double horizontal line. Below the double horizontal line, we list the additional generators that are used to encode \( m \) classical bits.

A quantum code that encodes a single qubit and is able to correct a single error requires at least five qubits. For five and six qubits, linear programming shows that we can only transmit a single qubit and no additional classical bit when we want to correct a single errors, i.e., for distance \( d \geq 3 \).

Increasing the length to seven qubits, it is still only possible to encode a single qubit when a single error has to be corrected. The stabilizer of an impure code \([7, 1, 3]_2\) is generated by the elements of the Pauli group given in first six lines above the single horizontal line in the matrix (34). Note that the element in the second line has only weight two. The next two elements between the single and the double horizontal line correspond to the logical operators on the encoded qubit. Starting with this impure code, we are able to transmit an extra classical bit, i.e., we obtain a hybrid code with parameters \([7, 1:1, 3]_2\). The additional generator that is used to encode one classical bit is given below the double horizontal line.

\[
\begin{align*}
\begin{pmatrix}
X & I & I & Z & Y & Y & Z \\
Z & I & I & I & I & I & X \\
I & X & I & X & Z & I & I \\
I & Z & I & Z & I & X & X \\
I & I & X & I & Z & I & X \\
I & I & Z & Z & X & X & I \\
I & I & I & X & Y & Y & X
\end{pmatrix}
\end{align*}
\]

The weight enumerators of the associated classical codes are as follows:

\[
\begin{align*}
W_{C_0}(X, Y) &= X^7 + X^5Y^2 + 2X^4Y^3 + 7X^3Y^4 \\
&+ 24X^2Y^5 + 23XY^6 + 6Y^7 \\
W_{C_0}(X, Y) &= X^7 + X^5Y^2 + 20X^4Y^3 + 43X^3Y^4 \\
&+ 72X^2Y^5 + 83XY^6 + 36Y^7 \\
W_{C^*}(X, Y) &= X^7 + X^5Y^2 + 36X^4Y^3 + 91X^3Y^4 \\
&+ 152X^2Y^5 + 163XY^6 + 68Y^7
\end{align*}
\]

It can be seen that all codes contain a single word of weight two, and hence the minimum distance of the hybrid code is three.

We have not found a hybrid quantum code with parameters \([7, 1:2, 3]_2\) which is not ruled out by linear programming.

For eight qubits, there is a quantum code with parameters \([8, 3, 3]_2\). Using Lemma 2, we obtain an optimal hybrid code with parameters \([8, 2:1, 3]_2\), as well as a code \([8, 1:2, 3]_2\). We
have not found a hybrid code with parameters [8, 1:3, 3]2 that might exist.

For nine qubits, we found a hybrid code [9, 2:2, 3]2 given in (31). The rows above the single horizontal line generate the stabilizer of an impure code [9, 2, 3]2. Taking all possible products of the two generators below the double horizontal line in (31) we obtain the four translation operators t(1) = id, t(2), t(3), and t(4) = t(2)t(3) used to encode two extra classical bits.

The corresponding weight enumerators are as follows:

\[
W_C^0(X, Y) = X^9 + 2X^7Y^2 + 8X^5Y^4 + 4X^4Y^5 + 22X^3Y^6 + 56X^2Y^7 + 31XY^8 + 4Y^9
\]

\[
W_C^0(X, Y) = X^9 + 2X^7Y^2 + 38X^6Y^3 + 84X^5Y^4 + 222X^4Y^5 + 494X^3Y^6 + 562X^2Y^7 + 443XY^8 + 202Y^9
\]

\[
W_C(X, Y) = X^9 + 2X^7Y^2 + 86X^6Y^3 + 324X^5Y^4 + 926X^4Y^5 + 1934X^3Y^6 + 2466X^2Y^7 + 1835XY^8 + 618Y^9
\]

For ten qubits, we found a hybrid code [10, 3:2, 3]2 given in (32). The rows above the single horizontal line generate the stabilizer of an impure code [10, 3, 3]2. Taking all possible products of the two generators below the double horizontal line in (32) we obtain the four translation operators t(1) = id, t(2), t(3), and t(4) = t(2)t(3) used to encode two extra classical bits.

The corresponding weight enumerators are as follows:

\[
W_C^0(X, Y) = X^{10} + 3X^8Y^2 + 6X^6Y^4 + 10X^4Y^6 + 105X^2Y^8 + 3Y^{10}
\]

\[
W_C^0(X, Y) = X^{10} + 3X^8Y^2 + 80X^7Y^3 + 186X^6Y^4 + 432X^5Y^5 + 1540X^4Y^6 + 2325X^3Y^7 + 2288XY^8 + 663Y^{10}
\]

\[
W_C(X, Y) = X^{10} + 3X^8Y^2 + 128X^7Y^3 + 522X^6Y^4 + 1824X^5Y^5 + 5000X^4Y^6 + 7872X^3Y^7 + 9477XY^8 + 663Y^{10}
\]

A hybrid code [10, 3:2, 3]2 with ten qubits is given in (32), and the corresponding weight enumerators are given in (31)–(33).

 Via linear programming it is found that this code is optimal in the sense that it encodes the maximal possible number m of additional classical bits among all codes [10, 3;m, 3]2.

The first non-trivial hybrid code with distance d = 4 has been found for eleven qubits. A hybrid code [11, 1:2, 4]2 is given in (33). We found a hybrid code [11, 4:2, 3]2 as well which is given in (34).

Appending two qubits in the state |0\rangle to the impure quantum code [11, 1:4]2 given above the double horizontal line in (33), one obtains an impure code [13, 1:4]2. This code can additionally transmit four classical bits, i.e., one obtains the hybrid code [13, 1:4, 2]2 given in (35).

A related construction is the following:

**Theorem 7:** Let C₁ = [n, k₁, d₁]q ⊂ C₂ = [n, k₂, d₂]q be nested quantum codes. Further, let C₃ = [n₃, k₂ - k₁, d₃]q be a classical linear code. Then there is a hybrid quantum code C = [n + n₃, k₁:(k₂ - k₁), d₃]q with d ≥ \min(d₁, d₂ + d₃).

**Proof:** Let G₁ be a generator matrix for the normalizer of C₁, and let G₁₂ together with G₁ be a generator matrix for the normalizer of C₂. Further, let G₃ be a generator matrix of

$C_3$, and let $\omega \in \mathbb{F}_{q^2} \setminus \mathbb{F}_q$. The hybrid code is given by the following matrix:

$$
\begin{pmatrix}
0 & \omega I \\
G_1 & 0 \\
G_{12} & G_3
\end{pmatrix}
$$

(46)

The matrix above the double horizontal line corresponds to the normalizer of the impure quantum code obtained by appending $n_3$ qubits in the state $| 0 \rangle$ to the code $C_1$. The distance of this code is $d_1$. Any vector involving the matrix $G_{12}$ will have weight at least $d_2 + d_3$. Hence, $d \geq \max(d_1, d_2 + d_3)$. From the nested stabilizer codes $[11, 1, 5] \subset [11, 4, 3]$ and classical codes $[n_1, n_3 - 1, 2]$, one obtains hybrid codes $[13, 1, 1, 5], [14, 1, 2, 5], \text{and } [15, 1, 3, 5]$. Similarly, we have the results shown in Table III. In the first column we list the nested quantum codes, in the second column the parameters of the hybrid codes obtained using Theorem 7 and in the last column we give the parameters of the best known stabilizer code from [3] which has the same length and minimum distance as the hybrid code.

VII. Discussion

We have characterized hybrid quantum codes for the simultaneous transmission of quantum and classical information in terms of generalized Knill-Laflamme conditions. Using the framework of CWS codes/union stabilizer codes, we have formulated a linear program to obtain bounds on the parameters of codes. Moreover, we found several examples of hybrid codes that demonstrate the advantage of simultaneous transmission of quantum and classical information.

The code conditions derived in Section III suggest that one should start with good impure quantum codes. Theorem 7 uses trivial impure codes. In order to find a direct construction of hybrid codes with good parameters, a first step could be to develop methods to construct good non-trivial impure codes.
