Abstract

In this paper, we aim to resolve two fundamental issues in the dynamics of relativity: (i) Under what condition, the time-column space integrals of a Lorentz four-tensor constitute a Lorentz four-vector, and (ii) under what condition, the time-element space integral of a Lorentz four-vector is a Lorentz scalar; namely two “conservation laws”, which are mispresented in traditional textbooks, and widely used in fundamental research, such as relativistic analysis of the momentum of light in a medium, and gravitation theory. To resolve issue (i), we have developed a generalized Lorentz four-vector theorem. We use this theorem to verify Møller’s theorem; we surprisingly find that Møller’s theorem is flawed. We provide a corrected version of Møller’s theorem, and indicate that the corrected Møller’s theorem only defines a trivial zero four-vector for an electromagnetic stress-energy tensor of a finite closed physical system, even if this theorem is applicable. To resolve issue (ii), we have developed a generalized Lorentz scalar theorem. We use this theorem to verify the “invariant conservation law” in relativistic electrodynamics, which states that the divergence-less of four-current density results in the Lorentz invariance of total electric charge, as presented by Weinberg in his textbook. We unexpectedly find that there is no causality at all between the divergence-less and the Lorentz invariance. Thus the two “conservation laws” in traditional textbooks, which have magically attracted several generations of most outstanding scientists, turned out to be imaginary, creating a scientific myth in the modern theoretical and mathematical physics: Believing is seeing.

Keywords: Dynamics of relativity, Lorentz scalar, Four-vector, Electromagnetic stress-energy tensor

1. Introduction

In the dynamics of relativity, the energy and momentum of a physical system is described by a Lorentz four-tensor; such a tensor is usually called energy–momentum tensor [1, 2, 3], stress tensor [4], stress–energy tensor [5, 6], or momentum–energy stress tensor [7]. If the tensor is divergence-less, then the system is thought to be conserved [1, 2, 3], and it is a closed system [3]; thus the total energy and momentum can be obtained by carrying out space integration of the time-column elements of the tensor to constitute a Lorentz four-vector [1, 2, 3, 4, 5, 8, 9, 10, 11].

Mathematically speaking, if a tensor satisfies certain conditions, the space integrals of the tensor’s time-column elements can form a Lorentz four-vector. For the sake of convenience, we call such a mathematical statement “four-vector theorem”.

Laue set up a four-vector theorem for a tensor that is required to be time-independent [12]. Laue’s theorem only provides a sufficient condition (instead of a sufficient and necessary condition), and it cannot be used to judge the Lorentz property of the energy and momentum of electrostatic fields. In a recent study, Laue’s theorem is improved to be a theorem that has a sufficient and necessary condition, and it is successfully used to generally resolve the electrostatic field problem [6].

In contrast to Laue’s theorem, Møller provided a four-vector theorem for a tensor that is required to be divergence-less but allowed to be time-dependent [3]. Møller’s theorem only has a sufficient condition (instead of a sufficient and necessary condition) [13], but it is more attractive because the energy–momentum tensor for electromagnetic (EM)
radiation fields varies with time \[8, 9, 10, 11\]. It is widely recognized in the community that Möller’s theorem is absolutely rigorous so that this theorem has been widely used in quantum electrodynamics \[8\] and relativistic analysis of light momentum in a dielectric medium \[9, 10, 11\].

In this paper, we provide a generalized Lorentz four-vector theorem for a tensor that is not required to be time-independent, and not required to be divergence-less. This theorem has a sufficient and necessary condition. We use this theorem to verify Möller’s theorem, surprisingly finding that Möller’s theorem is flawed.

Like the four-vector theorem, a Lorentz scalar theorem is a mathematical statement that under what conditions, the time-element space integral of a four-vector is a Lorentz scalar. In Ref. \[6\], a scalar theorem for a four-vector that is required to be time-independent is set up, called “derivative von Laue’s theorem”, and it is successfully used to strictly resolve the invariance problem of total electric charge in relativistic electrodynamics.

The paper is organized as follows. In Sec. 2, proofs are given of Lorentz four-vector and scalar theorems. In Sec. 3, Møller’s theorem is proved to be flawed, and a corrected version of Møller’s theorem is provided. In Sec. 4, the known result in the dynamics of relativity that if a Lorentz four-vector is divergence-less, then the time-element space integral of a four-vector is a Lorentz scalar. In Ref. \[6\], a scalar theorem for a four-vector that is required to be time-independent is set up, called “derivative von Laue’s theorem”, and it is successfully used to strictly resolve the invariance problem of total electric charge in relativistic electrodynamics.

In this paper, we also provide a generalized Lorentz scalar theorem for a four-vector that is not required to be time-independent and not required to be divergence-less. We use this scalar theorem to identify the validity of a well-known result in the dynamics of relativity that if a Lorentz four-vector is divergence-less, then the time-element space integral of the time-element of a four-vector is a Lorentz scalar. In Ref. \[6\], a scalar theorem for a four-vector that is required to be time-independent is set up, called “derivative von Laue’s theorem”, and it is successfully used to strictly resolve the invariance problem of total electric charge in relativistic electrodynamics.

Theorem 2 are very similar, and without loss of generality, only the proof of Theorem 1 is given.

In this paper, we also provide a generalized Lorentz scalar theorem for a four-vector that is not required to be time-independent and not required to be divergence-less. We use this scalar theorem to identify the validity of a well-known result in the dynamics of relativity that if a Lorentz four-vector is divergence-less, then the time-element space integral of a four-vector is a Lorentz scalar. In Ref. \[6\], a scalar theorem for a four-vector that is required to be time-independent is set up, called “derivative von Laue’s theorem”, and it is successfully used to strictly resolve the invariance problem of total electric charge in relativistic electrodynamics.

The paper is organized as follows. In Sec. 2, proofs are given of Lorentz four-vector and scalar theorems. In Sec. 3, Møller’s theorem is proved to be flawed, and a corrected version of Møller’s theorem is provided. In Sec. 4, the validity of a well-known result in the dynamics of relativity is identified, and in Sec. 5 some conclusions and remarks are given.

2. Lorentz four-vector and scalar theorems

In this section, proofs are given of Lorentz four-vector and scalar theorems. Four-vector theorems provide a criterion to judge under what condition the space integrals of the time-column elements of a tensor constitute a Lorentz four-vector (Theorem 1) and under what condition the space integrals of the time-row elements of a tensor constitute a Lorentz four-vector (Theorem 2), while the scalar theorem provides a criterion to judge under what condition the space integral of the time-element of a four-vector is a Lorentz scalar (Theorem 3). The proofs of Theorem 1 and Theorem 2 are very similar, and without loss of generality, only the proof of Theorem 1 is given.

Suppose that an inertial frame of \(X'Y'Z'\) moves uniformly at \(\beta c\) relatively to the laboratory frame \(XYZ\), where \(c\) is the vacuum light speed. The Lorentz transformation of time-space four-vector \(X^\mu = (x, ct)\) is given by \[6, 7\]

\[x' = x + \xi (\beta \cdot x) \beta - \gamma \beta ct,\]
\[ct' = \gamma (ct - \beta \cdot x),\]

or conversely, given by

\[x = x' + \xi (\beta' \cdot x') \beta' - \gamma \beta' ct',\]
\[ct = \gamma (ct' - \beta' \cdot x'),\]

where \(\xi \equiv (\gamma - 1)/\beta^2 = \gamma^2/(\gamma + 1), \gamma \equiv (1 - \beta^2)^{-1/2}, \text{ and } \beta' = -\beta\).

According to the definition of tensors \[3\ p.108\], if \(\Omega^{\mu\nu}(x, t)\) is a Lorentz four-tensor given in \(XYZ\), where \(\mu, \nu = 1, 2, 3, \text{ and } 4\), with the index 4 corresponding to time component, then in \(X'Y'Z'\) the tensor \(\Omega^{\mu\nu}(x = x(x', t'), t = t(x', t'))\) is obtained through “double” Lorentz transformation of \(\Omega^{\mu\nu}(x, t)\), given by

\[\Omega^{\mu\nu}(x, t) = \frac{\partial X^\rho}{\partial X^\mu} \frac{\partial X^\sigma}{\partial X^\nu} \Omega^{\rho\sigma}(x, t),\]
\[\Omega^{\mu\nu}(x = x(x', t'), t = t(x', t')) = \frac{\partial X^\rho}{\partial X^\mu} \frac{\partial X^\sigma}{\partial X^\nu} \Omega^{\rho\sigma}(x = x(x', t'), t = t(x', t')),\]

where \(\partial X^\rho/\partial X^\mu\) and \(\partial X^\nu/\partial X^\sigma\) are obtained from Lorentz transformation Eqs. 1 and 2, while \(x = x(x', t')\) and \(t = t(x', t')\) denote Lorentz transformation Eqs. 3 and 4, respectively. Eq. 5 is the expression of \(\Omega^{\mu\nu}\) observed in \(XYZ\), and Eq. 6 is the expression of \(\Omega^{\mu\nu}\) observed in \(X'Y'Z'\).
Theorem 1. Suppose that $\Theta^{\mu\nu}(x, t)$ is an integrable Lorentz four-tensor, defined in the domain $V$ in the laboratory frame $XYZ$, where $V$ including its boundary is at rest in $XYZ$, namely any $x \in V$ is independent of $t$. The space integrals of the time-column elements of the tensor in $XYZ$ are defined as

$$P^\mu = \int_{V; t=const} \Theta^{\mu\nu}(x, t)d^3x.$$  

(7)

The space integrals of time-column elements of the tensor in $X'Y'Z'$ are defined as

$$P_{\nu}^\mu = \int_{V'; t', t=const} \Theta_{\nu}^{\mu\nu}(x, x', t)d^3x'.$$

(8)

where

$$\Theta_{\nu}^{\mu\nu}(x = x(x', t'), t) = \frac{\partial X_i}{\partial x} \frac{\partial X_4}{\partial x} \Theta^i(x = x(x', t), t).$$

(9)

The four-vector theorem states: $P^\mu = \int_{V; t=const} \Theta^\mu(x, t)d^3x$ is a Lorentz four-vector if and only if

$$\int_{V; t=const} \Theta^\mu(x, t)d^3x = 0 \quad \text{for} \quad \mu = 1, 2, 3, 4 \quad \text{and} \quad j = 1, 2, 3$$

(10)

holds.

There are a few main points to understand Theorem 1 that should be noted, as follows.

(i) The importance of the definition Eq. (5) should be emphasized, otherwise the implication of $P^\mu = \int \Theta^{\mu\nu}d^3x'$ is ambiguous, and we cannot set up the transformation between $P^\mu$ and $P_{\nu}^\mu$. In Eq. (5), the space variables $x$ in $\Theta^{\mu\nu}(x, t)$ are replaced by $x = x(x', t')$, namely the space Lorentz transformation Eq. (3), while $t$ in $\Theta^{\mu\nu}(x, t)$ is kept as it is.

(ii) Observed in $XYZ$, like $P^\mu$, $P_{\nu}^\mu$ is only dependent on $t$ in general; confer Eq. (16). The quantity $t'$ in the integrand $\Theta^{\mu\nu}(x = x(x', t'), t)$ of $P^\mu = P_{\nu}^\mu(t) = \int_{V'; t', t = const} \Theta^\mu_{\nu}(x = x(x', t'), t)d^3x'$ is introduced as a constant parameter in a change of variables in the space integrals, and thus observed in $X'Y'Z'$, the boundary of $V'$ is moving so that $P^\mu = P_{\nu}^\mu(t)$ does not contain $t'$. (To better understand this, let us take a simple one-dimensional example, given by

$$I(t) = \int_a^b \cos(x - ct)dx = \int_{x_a}^{x_b} \cos[\gamma(x' + [\beta(c't' - ct)]y)dy = \sin(b - ct) - \sin(a - ct)$$

which does not contain $t'$ although the integrand $\cos[\gamma(x' + [\beta(c't' - ct)]y$ contains $t'$, and where a change of variable $x = \gamma(x' + |\beta|c't')$ is taken, with $dx = \gamma dx'$ and $t'$ as a constant parameter introduced, and the integral limits $x'_a = a/\gamma - |\beta|c't'$ and $x'_b = b/\gamma - |\beta|c't'$, with $a$ and $b$ being constants, are moving at a velocity of $|\beta|c$.)

(iii) If $\Theta^{\mu\nu}(x, t)$ is independent of $t$, then both $P^\mu$ and $P_{\nu}^\mu$ are independent of $t$, namely they are constants.

(iv) If $P^\mu = P_{\nu}^\mu(t)$ is set to be observed in $X'Y'Z'$, $t$ in $P_{\nu}^\mu = P_{\nu}^\mu(t)$ should be replaced by $t = \gamma(t' - \beta \cdot x'/c)$, namely the Lorentz transformation given by Eq. (4).

(v) The symmetry ($\Theta^{\mu\nu} = \Theta^{\nu\mu}$) and divergence-less ($\partial_\nu \Theta^{\mu\nu} = 0$) are not required, and there are no boundary conditions imposed on $\Theta^{\mu\nu}(x, t)$.

Theorem 2. Suppose that $\Theta^{\mu\nu}(x, t)$ is an integrable Lorentz four-tensor, defined in the domain $V$ in the laboratory frame $XYZ$, where $V$ including its boundary is at rest in $XYZ$, namely any $x \in V$ is independent of $t$. The space integrals of the time-row elements of the tensor in $XYZ$ are defined as

$$\Pi^\nu = \int_{V; t=const} \Theta^{\mu\nu}(x, t)d^3x.$$  

(11)
The space integrals of time-row elements of the tensor in $X^Y Z^Z$ are defined as
\[ \Pi^\nu = \int_{V; \, t, \, \nu \text{= const}} \Theta^{\nu} (x = x(x', t'), t) \mathrm{d}^3 x'. \]  
(12)

where
\[ \Theta^{\nu} (x = x(x', t'), t) := \frac{\partial X^\mu}{\partial x^\nu} \frac{\partial X^\nu}{\partial x^\nu} \Theta^{\mu} (x = x(x', t'), t). \]  
(13)

The space integrals of time-row elements of the tensor are given by $d^3 x$. I develop my theory in the present paper and the previous work [6]; called Technique-I for convenience. In this technique, the change of variables,
\[ \Theta^i (x = x(x', t'), t) \text{ in Technique-I, as shown in Eqs. (15) and (16) in the proof of Theorem 1. However, Technique-II requires } d^3 x \text{ contradicts both Technique-I and the e... } \]

Proof of Theorem 1. From Eqs. (9) and (13) we have
\[ P_i^i = \int_{V; \, t, \, \mu \text{= const}} \Theta^\mu (x = x(x', t'), t) \mathrm{d}^3 x' = \frac{\partial X^\mu}{\partial x^i} \frac{\partial X^i}{\partial x^\mu} \int_{V; \, t, \, \nu \text{= const}} \Theta^{\nu} (x = x(x', t'), t) \mathrm{d}^3 x'. \]  
(14)

Note that $x = x(x', t')$ in $\Theta^{\nu}$ is given by $x = x(x', t')$ in $\Theta^{\nu}$, where $x = x(x', t')$ is defined by $x = x(x', t')$. By the change of variables $x(x', t') = x$ or $(x', y', z'; t') \rightarrow (x, y, z)$ with $t'$ as a constant parameter, we obtain
\[ \frac{\partial X^\mu}{\partial x^i} \frac{\partial X^i}{\partial x^\mu} = \gamma \int_{V; \, t, \, \nu \text{= const}} \Theta^{\nu} (x = x(x', t'), t) \mathrm{d}^3 x, \]  
(16)

where $d^3 x = |\partial(x, y, z)/\partial(x', y', z')|d^3 x' = \gamma d^3 x'$ is employed, with the Jacobian determinant $|\partial(x, y, z)/\partial(x', y', z')| = \gamma$ being explained as the effect of Lorentz contraction physically. Since $t'$ is introduced as a constant parameter in the change of variables, $P_i^i$ is independent of $t'$.

1 What is the correct technique for change of variables in triple integrals? In relativistic electrodynamics, there are two techniques for a change of variables in space (triple) integrals. The first technique is the change of variables theorem, presented in mathematical analysis [13], and used to develop my theory in the present paper and the previous work [6]; called Technique-I for convenience. In this technique, the change of variable formula is given by $d^3 x = |\partial(x, y, z)/\partial(x', y', z')|d^3 x'$, where $\partial(x, y, z)/\partial(x', y', z') = \gamma$ is Jacobian determinant. The second technique is presented in some respected textbooks, such as the book by Jackson [4, p. 757]; called Technique-II for convenience. In the Technique-II, the integral domain $V$ is assumed to be at rest in the laboratory frame, and then a differential four-vector is constructed to define the change of variables in space integrals, given by $dS_{V} = (0, 0, 0, 1)d^3 x$ in the laboratory frame, and $dS_{V} = \gamma d^3 x$ with $\gamma = (1 - \beta^2)^{-\frac{1}{2}}$ in the frame moving at $\beta c$ with respect to the laboratory frame; thus leading to $dS_{V} = \gamma d^3 x = \gamma d^3 x_{\text{lab}}$ — the change of variable formula for Technique-II. Technique-II is widely accepted in the community as a strong basis to define EM momentum-energy four-vector [4, p. 757]. Unfortunately, Technique-II is fundamentally flawed, as shown below.

Since the integral domain $V$ is fixed in the laboratory frame, $d^3 x$ is the proper differential element, while $d^3 x'$ is a moving element. Just like a moving ruler, Lorentz contraction will be imposed on $d^3 x$, resulting in $d^3 x' = \gamma d^3 x/\gamma$, consistent with Jacobian determinant $|\partial(x, y, z)/\partial(x', y', z')| = \gamma$ in Technique-I, as shown in Eqs. (15) and (16) in the proof of Theorem 1. However, Technique-II requires $d^3 x' = \gamma d^3 x$, thus Technique-II contradicts both Technique-I and the effect of Lorentz contraction in Einstein’s special relativity. More seriously, Technique-II directly contradicts Lorentz invariance of total charge; in other words, if Technique-II were used, then a non-zero total charge would not be a Lorentz invariant, which is shown below.

First we show that Lorentz invariance of total charge is always valid in Technique-I. Without loss of generality, we assume that a charge distribution is created by charged particles which move at the same velocity, otherwise it can be treated discretely, as shown in Ref. [6]. Thus the total charge can be formulated as $Q = \int_{V} \rho(x) d^3 x$, where $\rho(x)$ with $d\rho/dt = 0$ is the charge distribution in the charge-rest frame (taken as the laboratory frame), $V$ is the volume at rest, and $Q$ is the (time-independent) total charge in $V$. In such a case, all charged particles are stationary and frozen in $V$ so that no current exists ($J = 0$). Observed in a frame moving at $\beta c \neq 0$ with respect to the charge-rest frame, the volume $V'$ is moving at $\beta c = -\beta c$, but there are no charged particles crossing through the boundary of $V'$ although the current $J' = -\gamma \beta J$ does not hold. In Technique-I, the change of variable formula is given by $d^3 x' = d^3 x/\gamma = \int_{V} \gamma (c \nu - \beta \cdot J) d^3 x'$, which is invariant. Thus we finish the proof that the total charge is always Lorentz invariant in Technique-I.

Now we show why Technique-II contradicts the Lorentz invariance of total charge. In the laboratory frame (charge-rest frame), the four-current density is given by $J' = (J', J')$ with $J = 0$ and $J' = c \rho$, and the total charge $Q$ is defined by $\int_{V} \rho(x) d^3 x = \int_{V} J' d^3 x$. Observed in the frame moving at $\beta c$ with respect to the laboratory frame, we have $J'' = (J''', J')$ with $J'' = -\gamma \beta J'$ and $J' = c \rho' \gamma J'$, and the total charge $Q'$
From Eq. (16), with \( \partial X^\mu / \partial X^4 = \gamma \) and \( P^\mu = \int_{V: \; t = \text{const}} \Theta^4 (x, t) d^3 x \) taken into account, we have

\[
P^\mu = \frac{\partial X^\mu / \partial X^4}{\gamma} \int_{V: \; t = \text{const}} \Theta^4 (x, t) d^3 x + \frac{\partial X^\mu / \partial X^4}{\gamma} \int_{V: \; t = \text{const}} \Theta^{IJ} (x, t) d^3 x \]

\[
= \frac{\partial X^\mu / \partial X^4}{\gamma} \int_{V: \; t = \text{const}} \Theta^4 (x, t) d^3 x + \frac{\partial X^\mu / \partial X^4}{\gamma} \int_{V: \; t = \text{const}} \Theta^{IJ} (x, t) d^3 x \]

\[
= \frac{\partial X^\mu / \partial X^4}{\gamma} \int_{V: \; t = \text{const}} \Theta^4 (x, t) d^3 x + \frac{\partial X^\mu / \partial X^4}{\gamma} \int_{V: \; t = \text{const}} \Theta^{IJ} (x, t) d^3 x \]

\[
= \frac{\partial X^\mu / \partial X^4}{\gamma} \int_{V: \; t = \text{const}} \Theta^4 (x, t) d^3 x + \frac{\partial X^\mu / \partial X^4}{\gamma} \int_{V: \; t = \text{const}} \Theta^{IJ} (x, t) d^3 x \]

\[
= \frac{\partial X^\mu / \partial X^4}{\gamma} \int_{V: \; t = \text{const}} \Theta^4 (x, t) d^3 x + \frac{\partial X^\mu / \partial X^4}{\gamma} \int_{V: \; t = \text{const}} \Theta^{IJ} (x, t) d^3 x \]

(17)

If \( P^\mu \) is a Lorentz four-vector, then

\[
P^\mu = \frac{\partial X^\mu / \partial X^4}{\gamma} \int_{V: \; t = \text{const}} \Theta^4 (x, t) d^3 x \]

must hold. Inserting Eq. (18) into Eq. (17), we have

\[
= \frac{\partial X^\mu / \partial X^4}{\gamma} \int_{V: \; t = \text{const}} \Theta^4 (x, t) d^3 x = 0,
\]

(19)

namely,

\[
\begin{pmatrix}
1 + \epsilon \beta_1^2 & \epsilon \beta_3 & -\gamma \beta_z & \gamma \\
\mathbf{1} + \mathbf{1} & \epsilon & -\gamma & \gamma \\
\mathbf{1} & \mathbf{1} + \mathbf{1} & \mathbf{1} & -\gamma \\
-\gamma & -\gamma & -\gamma & \gamma
\end{pmatrix}
\begin{pmatrix}
a_{ij}^{11} & a_{ij}^{12} & a_{ij}^{13} \\
a_{ij}^{21} & a_{ij}^{22} & a_{ij}^{23} \\
a_{ij}^{31} & a_{ij}^{32} & a_{ij}^{33} \\
a_{ij}^{41} & a_{ij}^{42} & a_{ij}^{43}
\end{pmatrix}
= \begin{pmatrix}
0 \\
0 \\
0 \\
0
\end{pmatrix}
\]

(20)

is defined by \( cQ' = \int_0^1 (cQ')^3 dx' = \int_0^1 J^d dx' \). According to Technique-II, we have \( dS^d = (dS, dS^d) = (dS', dS') = (\gamma dS, dS') \), with \( dS' = -\gamma \beta dS_4 \) and \( dS_4' = \gamma dS_4 \). From this we have

\[
\int_V J^d dS_4 = \int_V J^d dS_4 = \int_V J^d dS_4 = \int_V J^d dS_4
\]

\[
\Rightarrow [1 + (\gamma \beta)^2] \int_V J^d dS_4 = \int_V J^d dS_4
\]

\[
\Rightarrow \gamma^2 cQ = cQ' \]

\[
Q = Q' \text{ if } Q \neq 0 \text{ holds, where } \beta \neq 0 \text{ is assumed } \Rightarrow \gamma > 1.
\]

Thus we finish the proof that a non-zero total charge \( Q \neq 0 \) is not a Lorentz invariant in Technique-II.

From above analysis we can conclude that Technique-II, presented in [4, p. 757], has three flaws: (i) contradicting the effect of Lorentz contraction in special relativity, (ii) contradicting the change of variables theorem in mathematical analysis [11], and (iii) contradicting the Lorentz invariance of total charge.

So far we have shown that total charge \( Q \neq 0 \) is never a Lorentz invariant in Technique-II, while total charge \( Q \) is always a Lorentz invariant in Technique-I; both cases have nothing to do with the boundary conditions of \( J' = (J, \epsilon Q) \).

Two subtle issues for checking Lorentz invariance of total charge. In analysis of the Lorentz invariance of total charge in a volume in specific cases, a subtle issue is about how to define the volume. If there are charged particles crossing through the boundary of the volume, the total charge in the volume may not be Lorentz invariant [15], possibly leading to a doubt of the completeness of Maxwell EM theory [15]. Thus the correct volume is supposed to be moving at the same velocity as that of the charge, as argued above. Another subtle issue is how to correctly understand the definition of total charge. For example, by analysis of an infinite straight charged wire, Bilić puzzled that the standard definition \( Q = \int_0^1 p d^3 x \) and the so-called covariant definition \( Q = \int J^d dS_4 \) are not equivalent in general [15]; now we know that the problem turned out to be here: the transformation of triple integral \( \int_0^1 p d^3 x = \int J^d dS_4 = \int J^d dS_4 \) contradicts the change of variables theorem in mathematical analysis [11], as shown above.
where \( a^{ij} = \int_{V: x=const} \Theta^{ij}(x,t) d^3x \), with \( \lambda = 1, 2, 3, 4 \) and \( j = 1, 2, 3 \).

From above it is seen that Eq. (20) \( \Rightarrow \) Eq. (18) through Eq. (17) is valid. Thus for \( \Psi' \) to be a Lorentz four-vector, the sufficient and necessary condition is given by

\[
a^{ij} = \int_{V: x=const} \Theta^{ij}(x,t) d^3x = 0 \quad \text{for} \quad \lambda = 1, 2, 3, 4 \quad \text{and} \quad j = 1, 2, 3. \tag{21}
\]

The sufficiency of Eq. (21) is apparent because we directly have Eq. (21) \( \Rightarrow \) Eq. (20) \( \Rightarrow \) Eq. (19) \( \Rightarrow \) Eq. (18) from Eq. (17). The necessity is based on the fact that a four-vector must follow Lorentz rule between any two inertial frames, while keeping the integrals of the right-hand side to be computed in \( XYZ \) the su-

cient and necessary condition is given by

\[
\Psi = \int_{V: t=const} \Lambda^4(x,t) d^3x
\]

is a Lorentz scalar if and only if

\[
\int_{V: x=const} \Lambda^i(x,t) d^3x = 0 \quad \text{for} \quad i = 1, 2, 3 \quad \text{or} \quad \int_{V: t=const} \Lambda(x,t) d^3x = 0 \tag{23}
\]

holds.

**Proof.** Corresponding to \( \Psi = \int_{V: x=const} \Lambda^4(x,t) d^3x \) given by Eq. (22), we first have to define \( \Psi' = \int \Lambda^4 d^3x' \) in \( X'Y'Z' \), because the implication of \( \Psi' = \int \Lambda^4 d^3x' \) itself is ambiguous before the dependence of \( \Lambda^4 \) on \( x', t' \) and \( t \) is defined. For this end, from Lorentz transformation we have

\[
\Lambda^4(x,t) = \frac{\partial X^4}{\partial x} \Lambda^4(x,t) \Rightarrow \Lambda^4(x = x(x',t'),t) = \frac{\partial X^4}{\partial x} \Lambda^4(x = x(x',t'),t) \tag{24}
\]

where the space variables \( x \) in \( \Lambda^4(x,t) \) are replaced by \( x = x(x',t') \), namely the space Lorentz transformation Eq. (3), but \( t \) in \( \Lambda^4(x,t) \) is kept as it is.

Making integration in Eq. (24) with respect to \( (x,y,z) \) over \( V \) in the laboratory frame, we have

\[
\int_{V: t=const} \Lambda^4(x = x(x',t'),t) d^3x = \frac{\partial X^4}{\partial x} \int_{V: t=const} \Lambda^4(x = x(x',t'),t) d^3x. \tag{25}
\]

By the change of variables \( (x,y,z) \rightarrow (x',y',z';t') \) with \( t' \) as a constant parameter in the left-hand side of Eq. (25), while keeping the integrals of the right-hand side to be computed in \( XYZ \) frame, we obtain

\[
\int_{V': t,t'=const} \Lambda^4(x = x(x',t'),t') y d^3x' = \frac{\partial X^4}{\partial x} \int_{V: t=const} \Lambda^4(x,t) d^3x. \tag{26}
\]

where \( d^3x = |\partial(x,y,z)/\partial(x',y',z')| d^3x' \) is taken into account, with \( \partial(x,y,z)/\partial(x',y',z') = \gamma \) the Jacobian determinant. We define

\[
\Psi' = \int_{V': t,t'=const} \Lambda^4(x = x(x',t'),t') d^3x', \tag{27}
\]
Thus with the both sides of Eq. (26) divided by \( \gamma \), we have

\[
\Psi' = \int_{V': t' = \text{const}} \Lambda^4(x = x(x', t'), t') d^3 x' = \frac{\partial X^4}{\partial X^3} \gamma \int_{V': t' = \text{const}} \Lambda^4(x, t) d^3 x = \expV = \Psi - \beta \cdot \int_{V': t' = \text{const}} \Lambda(x, t) d^3 x,
\]

where \( \partial X^4/\partial X^3 = \gamma \), \( (\partial X^4/\partial X^3)\Lambda^i = -\gamma \beta \cdot \Lambda^i \), and the definition \( \Psi = \int_{V': t' = \text{const}} \Lambda^4(x, t) d^3 x \) given by Eq. (22) are employed.

From Eq. (28) we obtain the sufficient and necessary condition for \( \Psi = \Psi' \) (Lorentz scalar), given by

\[
\int_{V': t' = \text{const}} \Lambda^4(x, t) d^3 x = 0 \quad \text{for} \quad i = 1, 2, 3 \quad \text{or} \quad \int_{V': t' = \text{const}} \Lambda(x, t) d^3 x = 0.
\]

The sufficiency is apparent, while the necessity comes from the fact that \( \beta \) is arbitrary. Thus we complete the proof.

There are some main points to understand Theorem 3 that should be noted:

(i) If \( \Lambda^0(x, t) \) is independent of \( t \), namely \( \partial \Lambda^0/\partial t \equiv 0 \), then both \( \Psi \) and \( \Psi' \) are constants.

(ii) The divergence-less \( (\partial_\nu \Lambda^\nu = 0) \) is not required, and there are no boundary conditions imposed on \( \Lambda^\nu(x, t) \).

(iii) Asymmetry arising from resting \( V \) and moving \( V' \). Directly from Eq. (34), we have

\[
\Lambda^4 = \gamma(\Lambda^4 - \beta \cdot \Lambda) = \int_{V'} \Lambda^4 d^3 x' = \int_{V'} \gamma(\Lambda^4 - \beta \cdot \Lambda) d^3 x' = \Psi' = \Psi - \beta \cdot \int_{V} \Lambda d^3 x
\]

with \( d^3 x' = d^3 x/\gamma \) used, namely Eq. (28). Conversely, from Eq. (4) we have

\[
\Lambda^4 = \gamma(\Lambda^4 - \beta' \cdot \Lambda') = \int_{V} \Lambda^4 d^3 x = \int_{V} \gamma(\Lambda^4 - \beta' \cdot \Lambda') d^3 x = \Psi = \gamma^2 \Psi' - \gamma^2 \beta' \cdot \int_{V'} \Lambda d^3 x
\]

with \( d^3 x = \gamma d^3 x' \) used. We find that

\[
\Psi' = \Psi - \beta \cdot \int_{V'} \Lambda d^3 x \quad \text{and} \quad \Psi = \gamma^2 \Psi' - \gamma^2 \beta' \cdot \int_{V'} \Lambda d^3 x
\]

are not symmetric, although

\[
\Lambda^4 = \gamma(\Lambda^4 - \beta \cdot \Lambda) \quad \text{and} \quad \Lambda^4 = \gamma(\Lambda^4 - \beta' \cdot \Lambda')
\]

are symmetric. This asymmetry comes from the fact that \( V \) is fixed in \( XYZ \), while \( V' \) is moving in \( X'Y'Z' \).

3. Application of Theorem 1

In this section, Möller’s theorem is proved to be flawed; based on Theorem 1, a counterexample is given. A corrected version of Möller’s theorem is provided, with a detailed elucidation given of why the corrected Möller’s theorem only defines a trivial zero four-vector for an EM stress-energy tensor.
Møller’s theorem. Suppose that $\Theta^{\mu\nu}(x,t)$ is an integrable Lorentz four-tensor, defined in the domain $V$ in the laboratory frame $XYZ$, where $\mu, \nu = 1, 2, 3, \text{and } 4$, with the index 4 corresponding to time component, and the boundary of $V$ is at rest in $XYZ$. All the elements of the tensor have first-order partial derivatives with respect to time-space coordinates $X^\mu = (x, ct)$. Møller’s theorem states: If $\Theta^{\mu\nu}(x,t)$ is divergence-less ($\partial \Theta^{\mu\nu}(x,t) = 0$), and $\Theta^{\mu\nu}(x,t) = 0$ holds on the boundary of $V$ for any time ($-\infty < t < +\infty$) — zero boundary condition, then the time-column space integrals
\[ P^\mu = \int_{V: \tau = \text{const}} \Theta^{\mu\nu}(x,t) d^3x \] constitute a Lorentz four-vector [3, pp.166-169].

Proof. First from Møller’s sufficient condition we demonstrate that the time-column space integrals, given by Eq. (30), are time-independent ($\partial P^\mu / \partial t \equiv 0$), then we prove that the sufficient condition is not enough to make Eq. (30) be a four-vector, and we conclude that Møller’s theorem is flawed.

Since $\Theta^{\mu\nu}(x,t) = 0$ holds on the boundary of $V$, using 3-dimensional Gauss’s divergence theorem we obtain
\[ \int_{V: \tau = \text{const}} \partial_i \Theta^{\mu\nu}(x,t) d^3x = 0, \quad \text{with } i = 1, 2, 3. \] (31)

Because the boundary of $V$ is at rest in the laboratory frame, we have
\[ \int_{V: \tau = \text{const}} \frac{\partial}{\partial t} (\cdots) d^3x = \frac{\partial}{\partial t} \int_{V: \tau = \text{const}} (\cdots) d^3x. \] (32)

From $\partial_i \Theta^{\mu\nu}(x,t) = 0$, with Eq. (31), Eq. (32), and $X^4 = ct$ taken into account, we have
\[ 0 = \int_{V: \tau = \text{const}} \partial_i \Theta^{\mu\nu}(x,t) d^3x = \int_{V: \tau = \text{const}} \partial_i \Theta^{\mu\nu}(x,t) d^3x + \int_{V: \tau = \text{const}} \partial_i \Theta^{\mu\nu}(x,t) d^3x = \int_{V: \tau = \text{const}} \partial_i \Theta^{\mu\nu}(x,t) d^3x = \int_{V: \tau = \text{const}} \Theta^{\mu\nu}(x,t) d^3x \] (33)
or
\[ \frac{\partial P^\mu}{\partial t} \equiv \frac{\partial}{\partial t} \int_{V: \tau = \text{const}} \Theta^{\mu\nu}(x,t) d^3x \equiv 0 \] (34)

Thus $P^\mu = \int_{V: \tau = \text{const}} \Theta^{\mu\nu}(x,t) d^3x$ is constant although the integrand $\Theta^{\mu\nu}(x,t)$ may depend on $t$. However it should be emphasized that
\[ \frac{\partial}{\partial t} \int_{V: \tau = \text{const}} \Theta^{\mu\nu}(x,t) d^3x = 0 \quad \text{for } j = 1, 2, 3 \] may not hold. \hspace{1cm} (35)

From the divergence-less ($\partial_i \Theta^{\mu\nu} = 0$) and the zero-boundary condition ($\Theta^{\mu\nu} = 0$ on boundary), we have achieved a conclusion that the time-column space integrals $P^\mu = \int_{V: \tau = \text{const}} \Theta^{\mu\nu}(x,t) d^3x$ are time-independent constants. In
what follows, we will show that the divergence-less and the zero-boundary condition is not sufficient to make \( P^\mu = \int_{V: t=\text{const}} \Theta^{\mu \nu}(x,t) d^3x \) be a four-vector. In other words, Møller’s sufficient condition is not sufficient.

From Eqs. (15)-(17) in the proof of Theorem 1, we have

\[
P^{\mu} = \int_{V: t'=\text{const}} \Theta^{\mu \nu}(x = x(x', t), t) d^3x' = \frac{\partial X^\mu}{\partial x^4} \frac{\partial X^4}{\partial \nu} \int_{V: t=\text{const}} \Theta^{4 \tau}(x,t) d^3x = \frac{\partial X^\mu}{\partial x^4} \frac{\partial X^4}{\partial \nu} \int_{V: t=\text{const}} \Theta^{4 \tau}(x,t) d^3x + \frac{\partial X^n}{\partial x^4} P^{\tau}, \quad \text{(with } j = 1, 2, 3). \tag{36}
\]

(allowed to be \( t \)-dependent) (t-independent)

Thus like Eq. (17), we obtain a necessary condition for constant \( P^\mu \) to be a Lorentz four-vector, given below

\[
a^{\lambda j} = \int_{V: t=\text{const}} \Theta^{\lambda i}(x,t) d^3x = 0 \quad \text{for } \lambda = 1, 2, 3, 4 \quad \text{and } j = 1, 2, 3. \tag{37}
\]

However Møller’s sufficient condition does not include this condition, and accordingly, Møller’s theorem is flawed. Thus we finish the proof.

**Counterexample for Møller’s theorem.** To further convince readers, given below is a pure mathematical counterexample to disprove Møller’s theorem based on Theorem 1.

Suppose that there is a symmetric Lorentz four-tensor

\[
A^{\mu \nu}(x,t) = \begin{pmatrix}
0 & 0 & 0 & f(x,y,z) \\
0 & 0 & 0 & f(x,y,z) \\
0 & 0 & 0 & f(x,y,z) \\
f(x,y,z) & f(x,y,z) & f(x,y,z) & -(ct)(f_x + f_y + f_z)
\end{pmatrix}, \tag{38}
\]

defined in the cubic domain \( V (-\pi \leq x, y, z \leq \pi) \), where \( f(x,y,z) = (\sin x)^2(\sin y)^2(\sin z)^2 \) is independent of time, with \( \int f(x,y,z) d^3x = \pi^3 \), and \( f_x \equiv \partial f/\partial x, f_y \equiv \partial f/\partial y, \) and \( f_z \equiv \partial f/\partial z \). \( A^{\mu \nu}(x,t) \) is divergence-less \( (\partial_\mu A^{\mu \nu} = 0 \iff \partial_\nu A^{\mu \nu} = 0 \text{ because of } A^{\mu \nu} = A^{\nu \mu}) \), and satisfies the Møller’s zero boundary condition: \( A^{\mu \nu}(x,t)=0 \) holds on the boundary \( x, y, z = \pm \pi \) for \(-\infty < t < +\infty\). Thus \( A^{\mu \nu}(x,t) \) satisfies the sufficient condition of Møller’s theorem, and

\[
M^\mu = \int_{V: t=\text{const}} A^{\mu 4}(x,t) d^3x = (\pi^3, \pi^3, \pi^3, 0) \tag{39}
\]

is supposed to be a Lorentz four-vector.

However because

\[
\int_{V: t=\text{const}} A^{41}(x,t) d^3x = \int_{V: t=\text{const}} A^{42}(x,t) d^3x = \int_{V: t=\text{const}} A^{43}(x,t) d^3x = \pi^3 \neq 0 \tag{40}
\]

\( A^{\mu \nu}(x,t) \) does not satisfy the sufficient and necessary condition Eq. (10) of Theorem 1, and accordingly, \( M^\mu = \int_{V: t=\text{const}} A^{\mu 4}(x,t) d^3x \) is not a four-vector. Thus Møller’s theorem is disproved by this counterexample based on Theorem 1.

Obviously, Møller’s theorem can be easily corrected by adding the condition Eq. (37), as follows.

**Corrected Møller’s theorem.** Suppose that \( \Theta^{\mu \nu}(x,t) \) is an integrable Lorentz four-tensor, defined in the domain \( V \) in the laboratory frame \( XYZ \), where \( \mu, \nu = 1, 2, 3, \) and 4, with the index 4 corresponding to time component, and the boundary of \( V \) is at rest in \( XYZ \). It is assumed that \( \Theta^{\mu \nu}(x,t) \) is divergence-less \( (\partial_\nu \Theta^{\mu \nu}(x,t) = 0) \), and \( \Theta^{\mu \nu}(x,t) = 0 \)
holds on the boundary of $V$ for any time ($-\infty < t < +\infty$) — zero boundary condition. The corrected Møller’s theorem states: The time-column space integrals

$$P^\mu = \int_{V: \tau = \text{const}} \Theta^{\mu\nu}(x, t) d^3x$$

constitute a Lorentz four-vector if and only if

$$\int_{V: \tau = \text{const}} \Theta^{\mu\nu}(x, t) d^3x = 0 \quad \text{for} \quad \mu = 1, 2, 3, 4 \quad \text{and} \quad j = 1, 2, 3.$$  

holds.

However we would like to indicate, by enumerating specific examples as follows, that the corrected Møller’s theorem has a limited application.

Example 1 for corrected Møller’s theorem. Consider Minkowski EM stress-energy tensor for “a pure radiation field in matter” \[10\], given by

$$\tilde{T}^{\mu\nu} = (T^{\mu\nu})^T,$$

with

$$T^{\mu\nu} = \begin{pmatrix} T^M & c \mathbf{g}_A \\ c \mathbf{g}_M & W_{em} \end{pmatrix},$$

where $\tilde{T}^{\mu\nu}$ is the transpose of $T^{\mu\nu}$, with $\partial_\tau \tilde{T}^{\mu\nu} = \partial_\tau T^{\mu\nu} = [\nabla \cdot T^M + \partial \mathbf{g}_M/\partial t, \nabla \cdot (c \mathbf{g}_A) + \partial W_{em}/\partial (ct)]$; $\mathbf{g}_A = \mathbf{E} \times \mathbf{H}/c^2$ is the Abraham momentum; $\mathbf{g}_M = \mathbf{D} \times \mathbf{B}$ is the Minkowski momentum; $W_{em} = 0.5(\mathbf{D} \cdot \mathbf{E} + \mathbf{B} \cdot \mathbf{H})$ is the EM energy density; and $T^M = -\mathbf{D} \cdot \mathbf{E} - \mathbf{B} \cdot \mathbf{H}$ is the Minkowski stress tensor, with $\mathbf{I}$ the unit tensor \[6\]. We first assume that the corrected Møller’s theorem is applicable for this EM tensor. Then let us see what conclusion we can get.

The pre-assumption of corrected Møller’s theorem is the tensor’s divergence-less plus a zero-boundary condition. The zero-boundary condition requires that all the tensor elements be equal to zero on the boundary for any time ($-\infty < t < +\infty$). Thus for the EM stress-energy tensor given by Eq. (43), the pre-assumption requires $\partial_\tau \tilde{T}^{\mu\nu} = 0$ holding within the finite domain $V$ of a physical system, and Poynting vector $\mathbf{E} \times \mathbf{H} = 0$ and Minkowski momentum $\mathbf{D} \times \mathbf{B} = 0$ holding on the boundary of $V$ for any time ($-\infty < t < +\infty$).

Physically, the pre-assumption is extremely strong and severe, because it requires that (i) within the domain $V$, there are no any sources ($\partial_\tau \tilde{T}^{\mu\nu} = 0$), and (ii) the EM energy and Minkowski momentum never flow through the closed boundary of $V$ for any time ($\mathbf{E} \times \mathbf{H} = 0$ and $\mathbf{D} \times \mathbf{B} = 0$ for $-\infty < t < +\infty$). Thus this physical system is never provided with any EM energy and momentum. According to energy-momentum conservation law, no EM fields can be supported within the domain $V$ in such a case, leading to a zero field solution. Thus the corrected Møller’s theorem only defines a trivial zero four-vector for an EM stress-energy tensor of a finite closed physical system, even if this theorem is applicable.

Example 2 for corrected Møller’s theorem. Nevertheless, the corrected Møller’s theorem may define a non-zero four-vector in general. As an example, consider the tensor given by

$$B^{\mu\nu}(x, t) = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & f(x, y, z) \end{pmatrix},$$

defined in the cubic domain $V (-\pi \leq x, y, z \leq \pi)$, where $f(x, y, z) = (\sin x)^2(\sin y)^2(\sin z)^2$, with $\int_V f(x, y, z) d^3x = \pi^3$. $B^{\mu\nu}(x, t)$ is divergence-less ($\partial_\tau B^{\mu\nu} = 0$), and satisfies the zero boundary condition: $B^{\mu\nu}(x, t) = 0$ on the boundary $(x, y, z = \pm \pi)$ for $-\infty < t < +\infty$; thus the pre-assumption of corrected Møller’s theorem is satisfied. On the other hand, $\int_{V: \tau = \text{const}} B^{\mu\nu}(x, t) d^3x = 0$ holds for $\mu = 1, 2, 3, 4$ and $j = 1, 2, 3$; thus $B^{\mu\nu}(x, t)$ also satisfies the sufficient and necessary condition Eq. (42) for the corrected Møller’s theorem. Accordingly, $\int_{V: \tau = \text{const}} B^{\mu\nu}(x, t) d^3x = (0, 0, 0, \pi^3) \neq 0$ is a four-vector — the corrected Møller’s theorem may define a non-zero four-vector in general.
Conclusion for corrected Møller’s theorem. In conclusion, the corrected Møller’s theorem may define a non-zero four-vector in general; however, it only defines a trivial zero four-vector for an EM stress-energy tensor of a finite closed physical system. Thus the application of the theorem is limited.

Differences between three four-vector theorems. We have three four-vector theorems: Theorem 1 and corrected Møller’s theorem (both presented in the present paper), and generalized von Laue’s theorem (presented in Ref. [6]). For the convenience to compare, we write down the generalized von Laue’s theorem from Ref. [5] as follows.

Generalized von Laue’s theorem. Assume that \( \Theta^{\mu\nu}(x) \) is an integrable Lorentz four-tensor, defined in the domain \( V \) in the laboratory frame \( XYZ(\mu, \nu = 1, 2, 3, \text{and} 4, \text{with the index} 4 \text{corresponding to time component},) \), \( V \) including its boundary is at rest in \( XYZ, \text{and} \Theta^{\mu\nu} \) is independent of time (\( \partial \Theta^{\mu\nu} / \partial t \equiv 0 \)). The generalized von Laue’s theorem states: The time-column-element space integrals \( P^\mu = \int_V \Theta^{\mu\nu}(x) d^3x \) constitute a Lorentz four-vector if and only if \( \int_S \Theta^{\mu\nu}(x) d^3x = 0 \) holds for all \( \mu = 1, 2, 3, \text{and} \nu = 1, 2, 3, \nu = 4 \).

Between the corrected Møller’s theorem and the above generalized von Laue’s theorem, the difference is that in the corrected Møller’s theorem, the divergence-less (\( \partial \Theta^{\mu\nu} = 0 \)) plus a zero boundary condition (\( \Theta^{\mu\nu} = 0 \) on boundary) is taken as a pre-assumption, and \( \Theta^{\mu\nu}(x, t) \) is allowed to be time-dependent, while in the generalized von Laue’s theorem, \( \partial \Theta^{\mu\nu} / \partial t \equiv 0 \) is taken as a pre-assumption, and \( \Theta^{\nu\mu}(x, t) \equiv \Theta^{\mu\nu}(x) \) is not allowed to be time-dependent, but no boundary condition is required. Compared with the corrected Møller’s theorem and the generalized von Laue’s theorem, Theorem 1 does not have any pre-assumption; however, the three theorems have the same definition \( P^\mu \), as shown below.

From Eq. (45), we know that the same definition of \( P^\mu \) is used in both Theorem 1 and the corrected Møller’s theorem, given by

\[
P^\mu = \int_{V^3: \ t = \text{const}} \Theta^{\mu\nu}(x = x(x', t'), t) d^3x' = \frac{\partial X^\mu}{\partial x'} \frac{\partial X^\nu}{\partial x'} \gamma \int_{V^3: \ t = \text{const}} \Theta^{\nu\mu}(x, t) d^3x.
\]

If \( \Theta^{\nu\mu}(x, t) \) is independent of \( t \), namely \( \Theta^{\nu\mu}(x, t) \equiv \Theta^{\nu\mu}(x) \), then the above Eq. (45) becomes

\[
P^\mu = \int_{V^3: \ t = \text{const}} \Theta^{\mu\nu}(x = x(x', t'), t) d^3x' = \frac{\partial X^\mu}{\partial x'} \frac{\partial X^\nu}{\partial x'} \gamma \int_{V^3: \ t = \text{const}} \Theta^{\nu\mu}(x) d^3x.
\]

This is exactly the case of von Laue’s theorem presented in Ref. [6], where \( \Theta^{\mu\nu}(x = x(x', t')) \) is written as \( \Theta^{\mu\nu}(x', c't') \), and \( t \) does not show up.

Adaptability of Theorem 1. Since Theorem 1 does not have a pre-assumption, it may have a better adaptability. To show this, a specific example is given below.

Suppose that there is a symmetric Lorentz four-tensor

\[
R^{\mu\nu}(x, t) = \begin{pmatrix}
0 & 0 & 0 & x \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
x & 0 & 0 & -c t
\end{pmatrix},
\]

defined in the cubic domain \( V (\pi \leq x, y, z \leq \pi) \) with its boundary \( S (x, y, z = \pm \pi) \).

From Eq. (47) we know that

(i) \( \partial_t R^{\mu\nu} = 0 \) holds but \( R^{\mu\nu}(x, t) \) does not have a zero-boundary condition ( \( R^{4i}(x, t) = \pi \neq 0 \) on the boundary: \( x = \pi \text{ and} -\pi \leq y, z \leq \pi, \text{for example} \)). Thus the corrected Møller’s theorem does not apply.

(ii) \( \partial R^{\mu\nu} / \partial t \equiv 0 \) does not hold, because of \( \partial R^{4i} / \partial t = -c \neq 0 \). Thus the generalized von Laue’s theorem does not apply either.

(iii) \( \int_{V^3: \ t = \text{const}} R^{\mu\nu}(x, t) d^3x = 0 \) for \( \mu = 1, 2, 3, 4 \text{and} j = 1, 2, 3 \) holds, satisfying the sufficient and necessary
condition Eq. (10) of Theorem 1. Thus \( N^\mu = \int_{V: const} \mathcal{E}\mathcal{B}(x)\,d^3x = \int_{V: const} (x, 0, 0, -ct) \,d^3x = (0, 0, 0, -8\pi c \,ct) \) is a Lorentz four-vector.

From above example we see that Theorem 1 has a better adaptability. It is interesting to indicate that Theorem 1 can be used to analyze the EM stress-energy tensor for a plane light wave in a dielectric medium\(^2\).

4. Application of Theorem 3

In relativistic electrodynamics, there are two main-stream arguments for the Lorentz invariance of total electric charge. One comes from an assumption that the total electric charge is an experimental invariant, as presented in the textbook by Jackson [4] p.555; the other comes from a well-accepted result that the divergence-less of current density four-vector makes the total charge be a Lorentz scalar, as claimed in the textbook by Weinberg [2] p.411. In this section, by enumerating a counterexample we use Theorem 3 to disproven Weinberg’s claim.

---

\(^2\)Application of Theorem 1 to Minkowski EM stress-energy tensor for a plane wave in a dielectric medium. For a plane light wave propagating in a moving uniform medium with \( n \) as the refractive index of the medium, there is a photorectic frame \( [\xi] \). Observed in the photorectic frame (taken as the laboratory frame here), (i) the EM fields \( E = 0, H = 0, D = D_0 \cos \Psi, B = B_0 \cos \Psi \) hold, with \( D_0 \neq 0 \) and \( B_0 \neq 0 \) the constant amplitudes, leading to EM energy density \( W_{\text{em}} = 0.5(D \cdot E + B \cdot H) = 0 \) and Abraham momentum \( \mathbf{g}_0 = E \times H/c^2 = 0 \), but the Minkowski momentum \( \mathbf{g}_\alpha = D \times B \neq 0 \); (ii) the wave angular frequency \( \omega = 0 \) and the wave phase \( \varphi = (\omega t - k_\alpha \cdot x) = (k_\alpha \cdot x) \) hold, with \( k_\alpha \) the wave vector, leading to all the EM fields behaving as static \([17]\). The Minkowski EM stress-energy tensor \( \mathcal{P}^{\mu\nu} \) is given by Eq. (43), with \( \mathcal{P}^{\mu\nu} = -DE - BH + \mathcal{W}_{\text{em}} = 0 \) and \( c_\alpha = 0 \) holding ⇒ the holding of \( \int_{V: const} \mathcal{P}^{\mu\nu}d^3x = 0 \) and \( \int_{V: const} \mathcal{E}^\mu\mathcal{B}^\nu d^3x = 0 \) ⇒ the holding of \( \int_{V: const} \mathcal{P}^{\mu\nu}d^3x = 0 \) for \( \alpha = 1, 2, 3, 4 \) and \( j = 1, 2, 3 \). According to the sufficient and necessary condition Eq. (10) of Theorem 1, \( \mathcal{P}^{\mu\nu}\)-time-column (= \( \mathcal{P}^{\mu\nu}\)-time-row) space integrals \( \mathcal{P}^{\mu\nu} = \int_{V: const} \mathcal{P}_{\mu\nu}d^3x = c \int_{V: const} \mathcal{E}_{\mu\nu}d^3x \) constitute a Lorentz four-vector, which is time-independent (because of all the EM fields behaving static in the photo-rest frame ⇒ \( d\mathcal{P}^{\mu\nu}/dt \equiv 0 \)). Thus we conclude from Theorem 1 that for a plane wave in a medium, the total Minkowski momentum and energy contained in a given domain \( V \) constitute a Lorentz four-vector. Especially, if there is only one photon contained in \( V \) and Einstein light-quantum hypothesis is taken into account, namely \( \int W_{\text{em}}d^3x = h\omega_0 \), then \( \int \mathcal{G}_{\mu\nu}d^3x = \int \left(D_0 \cdot B_0\right)k_\alpha d^3x = h\omega_0 \) is the momentum of the photon in \( V \), and \( (\partial k_\alpha, \mu_\mu/c) \equiv (h\omega_0, \omega/c) \) is the photon’s four-momentum, where a Lorentz invariant expression \( \mathcal{P}^{\mu\rho} = (W_{\text{em}}/c^2)k_\alpha \) is used \([7]\) see Eq. (37) there), and \( h \) is the reduced Planck constant. We have known \( \mathcal{P}^{\mu\rho} = (h\omega_0, \omega/c) \) is a (wave) four-vector, and thus the Planck constant \( h \) must be a Lorentz invariant \([7]\).

Question 1: Is the generalized von Laue’s theorem \([6]\) applicable for identifying the Lorentz property of light momentum and energy for a plane light wave in a medium? The answer is yes, because its pre-assumption \( d\mathcal{P}^{\mu\nu}/dt \equiv 0 \) is satisfied, as shown above.

Question 2: Is the corrected Müller’s theorem applicable for identifying the Lorentz property of light momentum and energy for a plane light wave in a medium? The answer is no, because this plane light wave is a non-trivial solution of Maxwell equations (non-zero field solution), and the pre-assumption of corrected Müller’s theorem cannot be satisfied, namely the divergence-less \( \partial \mathcal{P}^{\mu\nu} = 0 \), \( \mathcal{P}^{\mu\nu} = \{\nabla \cdot T^\mu_{\nu3} + \mathcal{g}_{\nu3} \partial_t \mathcal{E}_3 - \mathcal{g}_{\nu3} \partial_t \mathcal{B}_3, \nabla \cdot (\mathcal{g}_{\mu3} \partial_t \mathcal{E}_3 + \mathcal{g}_{\mu3} \partial_t \mathcal{B}_3)\} \) holds; otherwise, there is no energy flowing and no wave. On the other hand, we have \( \int_{V: const} \cos^2 \Psi d^3x > 0 \) holding; thus leading to the holding of \( \int_{V: const} \cos^2 \Psi d^3x > 0 \) for a plane wave in free space. Note: \( \int_{V: const} \cos^2 \Psi d^3x = \) comes from the fact that \( V \neq 0 \) is a finite 3D volume, and \( \cos^2 \Psi \geq 0 \) holds with the zero points only appearing on discrete planes, and thus must exist a smaller volume \( V' \subset V \), where \( \cos^2 \Psi > 0 \) exactly holds ⇒ the holding of \( \int_{V: const} \cos^2 \Psi d^3x > 0 \) for a plane wave in free space. Thus: Further specific explanation: Why is \( \int_{V: const} \mathcal{g}_{\mu3} d^3x = \int_{V: const} \left(\mathcal{E} \times H + E_0 \times H_0 \cos^2 \Psi\right) \,d^3x = 0 \equiv E_0 \times H_0 \neq 0 \) holds; otherwise, there is no energy flowing and no wave. On the other hand, we have \( \int_{V: const} \cos^2 \Psi d^3x > 0 \) holding; thus leading to the holding of \( \int_{V: const} \cos^2 \Psi d^3x > 0 \) for a plane wave in free space. Note: \( \int_{V: const} \cos^2 \Psi d^3x > 0 \) comes from the fact that \( V \neq 0 \) is a finite 3D volume, and \( \cos^2 \Psi \geq 0 \) holds with the zero points only appearing on discrete planes, and thus must exist a smaller volume \( V' \subset V \), where \( \cos^2 \Psi > 0 \) exactly holds ⇒ the holding of \( \int_{V: const} \cos^2 \Psi d^3x > 0 \) for a plane wave in free space.
For a physical system defined in the domain $V$ with $S$ as its closed boundary, we will show that the divergence-less ($\partial_p J^\mu = 0$) of current density four-vector $J^\mu = (J, cp)$ plus a boundary zero-integral given by $\oint_S J(x, t) \cdot dS = 0$ makes the total charge $Q$ in $V$ be a time-independent constant; however, it is not enough to make the constant be a Lorentz scalar.

**Constant of total electric charge.** From $\partial_p J^\mu = 0 \Rightarrow \nabla \cdot J + \partial_p J^p = 0$, with $Q = \int_V \rho \, d^3x$ taken into account we have $\oint_S J(x, t) \cdot dS + dQ/dt = 0$. If $\oint_S J(x, t) \cdot dS = 0$ holds, then we have $dQ/dt = 0 \Rightarrow Q = \text{const}$. Physically, the current density $J = \rho u$ is a charge density flow, where $u$ is the charge moving velocity, and $\oint_S J(x, t) \cdot dS = 0$ means that there is no net charge flowing into or out of $V$. Thus the total electric charge $Q$ in $V$ is constant. (It is should be emphasized that only from $\partial_p J^\mu = 0$ without $\oint_S J(x, t) \cdot dS = 0$ considered, one cannot derive $Q = \text{const}$ in $V$.)

**Counterexample of Weinberg’s claim.** Why is $\partial_p J^\mu = 0$ not a sufficient condition to make $Q = \text{const}$ be a Lorentz scalar, even additionally plus a zero-boundary condition $J^\mu = (J, cp) = 0$ on $S$ \(\Rightarrow \oint_S J(x, t) \cdot dS = 0\)? To understand this, consider a mathematical four-vector, given by

$$W^\mu(x, t) = (W, W^4) = \left( f(x, y, z), 0, 0, -(ct) f_x \right)$$

defined in the cubic domain $V (\pi \leq x, y, z \leq \pi)$, where $W = (f(x, y, z), 0, 0)$, $W^4 = -(ct) f_x$, and $f(x, y, z) = (sin x)^2 (sin y)^2 (sin z)^2$, with $\int_V f(x, y, z) \, d^3x = \pi^3$. $W^\mu(x, t)$ satisfies the zero-boundary condition, namely $W^\mu = (W, W^4) = 0$ holds on the boundary $S (x, y, z = \pm \pi)$ \(\Rightarrow \oint_S W \cdot dS = 0\).

Like the current density four-vector $J^\mu$, $W^\mu$ is divergence-less ($\partial_p W^\mu = 0$), and it has a zero-boundary condition \(\Rightarrow \oint_S W \cdot dS = 0\); however, because of $\int_{V: \text{const}} W^4 \, d^3x = (\pi^3, 0, 0) \neq 0$, $W^\mu$ does not satisfy the sufficient and necessary condition Eq. (23) of Theorem 3. Thus according to Theorem 3, $\Psi = \int_{V: \text{const}} W^4 \, d^3x = \int_{V: \text{const}} -{(ct)f_x} \, d^3x (\neq 0)$ is not a Lorentz scalar. To better understand this, from Eq. (28) we have

$$\Psi^\prime = \Psi - \beta \cdot \int_{V: \text{const}} W^4 \, d^3x = \Psi - \beta x \pi^3,$$

and $\Psi^\prime = \Psi$ cannot hold for any $\beta x \neq 0$. Thus Weinberg’s claim is disproved, namely $\partial_p J^\mu = 0$ is not a sufficient condition to make $\int_{V: \text{const}} J^4 \, d^3x = \int_{V: \text{const}} \rho \, d^3x = eQ$ be a scalar.

The current density four-vector $J^\mu = (J, cp)$ and the above counterexample $W^\mu = (W, W^4)$ are all divergence-less, while the Lorentz property of their time-element space integrals does not depend on the divergence-less. Now let us take a look of four-vectors that are not divergence-less, and see what difference they may have.

**Example 1.** Consider a four-vector, given by $\Gamma^\mu = (\Gamma, \Gamma^4) = (\sin x \sin y \sin z, 0, 0, 0)$ defined in the cubic domain $V (\pi \leq x, y, z \leq \pi)$, with $\partial_p \Gamma^\mu = \partial_p \Gamma^4 = \cos x \sin y \sin z \neq 0$ holding except for some individual discrete points, and $\int_{V: \text{const}} \Gamma^4 \, d^3x = 0$ holding. According to Theorem 3, $\int_{V: \text{const}} \Gamma^4 \, d^3x (\neq 0)$ is a Lorentz scalar, because $\Psi^\prime = \Psi - \beta \cdot \int_{V: \text{const}} \Gamma^4 \, d^3x = \Psi$. Put it simply, for $\partial_p \Gamma^\mu = 0$, $\int \Gamma^4 \, d^3x$ is a Lorentz scalar.

**Example 2.** Consider a four-vector, given by $U^\mu = (U, U^4) = (\sin^2 x \sin^2 y \sin^2 z, 0, 0, 0)$ defined in the cubic domain $V (\pi \leq x, y, z \leq \pi)$, with $\partial_p U^\mu = 2 \cos x \sin x \sin y \sin z \neq 0$ holding except for some individual discrete points, and $\int_{V: \text{const}} U^4 \, d^3x = 0$ holding. According to Theorem 3, $\int_{V: \text{const}} U^4 \, d^3x (\neq 0)$ is not a Lorentz scalar, because $\Psi^\prime = \Psi - \beta \cdot \int_{V: \text{const}} U^4 \, d^3x = \Psi - \beta x \pi^3 \Rightarrow \Psi^\prime \neq \Psi$ for any $\beta x \neq 0$. Put it simply, for $\partial_p U^\mu = 0$, $\int U^4 \, d^3x$ is not a Lorentz scalar.

From above Example 1 and Example 2, we know that $\int \Gamma^4 \, d^3x$ is a Lorentz scalar for $\partial_p \Gamma^\mu = 0$, and $\int U^4 \, d^3x$ is not a Lorentz scalar for $\partial_p U^\mu = 0$. We have known that $\int J^4 \, d^3x$ is a Lorentz scalar for $\partial_p J^\mu = 0$, while the counterexample of Weinberg’s claim tells us that $\int W^4 \, d^3x$ is not a Lorentz scalar for $\partial_p W^\mu = 0$. Thus we can generally conclude that whether the time-element space integral of a four-vector is a Lorentz scalar has nothing to do with the divergence-less property of the four-vector.

13
The invariance problem of total electric charge has been resolved by using “derivative von Laue’s theorem” in Ref. [6], which indicates that the invariance comes from two facts: (a) $J^\mu$ is a four-vector and (b) the moving velocity of any charged particles is less than vacuum light speed. This explanation removes the assumption that the total charge is an experimental invariant [3, p.555].

The difference between the derivative von Laue’s theorem [6] and Theorem 3 is that the derivative von Laue’s theorem has a pre-assumption of $\partial \mathcal{N}^\mu / \partial t \equiv 0$, namely $\mathcal{N}^\mu = (\Lambda, \mathcal{L})$ is not allowed to be time-dependent, while Theorem 3 does not. For example, we also can use the derivative von Laue’s theorem [6] to analyze the four-vector $\mathcal{F}^\mu = (\mathcal{F}^x, \mathcal{F}^z) = (\sin x \sin y \sin z, 0, 0, 0)$ discussed above because $\partial \mathcal{F}^\mu / \partial t \equiv 0$ holds, but we cannot use it to analyze $W^\mu(\mathbf{x}, t)$ given by Eq. (48), because $\partial W^\mu / \partial t \equiv 0$ does not hold. Thus Theorem 3 has a better adaptability.

5. Conclusions and remarks

In this paper, we have developed Lorentz four-vector theorems (Theorem 1 for column four-vector and Theorem 2 for row four-vector; they are essentially the same) and Lorentz scalar theorem (Theorem 3). Based on Theorem 1, we have found that the well-established Møller’s theorem is flawed, and a corrected version of Møller’s theorem is provided (see Sec.3). Based on Theorem 3, we have disproved Weinberg’s claim, and obtained a general conclusion for the Lorentz property of a four-vector’s time-element space integral (see Sec.4).

We have shown that the sufficient condition of Møller’s theorem makes the time-column space integrals of a tensor be time-independent constants; however, it is not a sufficient condition to make the integrals constitute a Lorentz four-vector. The corrected Møller’s theorem has a limited application; especially for an EM stress-energy tensor, the corrected Møller’s theorem only defines a trivial zero four-vector.

We have shown that there are three four-vector theorems: (a) generalized von Laue’s theorem; (b) corrected Møller’s theorem; and (c) Theorem 1. The generalized von Laue’s theorem, presented in Ref. [6], has a pre-assumption that tensor $\Theta^{\mu\nu}$ is required to be time-independent ($\partial \Theta^{\mu\nu} / \partial t \equiv 0$). The corrected Møller’s theorem, provided in the present paper, also has a pre-assumption that tensor $\Theta^{\mu\nu}$ is required to be divergence-less ($\partial_t \Theta^{\mu\nu} = 0$) and required to satisfy a zero boundary condition ($\Theta^{\mu\nu} = 0$ on boundary) but $\Theta^{\mu\nu}$ is allowed to be time-dependent. Compared with the generalized von Laue’s theorem and corrected Møller’s theorem, Theorem 1 does not have any pre-assumption, while the three theorems have the same sufficient and necessary condition. Thus Theorem 1 has a better adaptability, as shown by a specific example described by Eq. (47) in Sec.3.

However it should be noted that, just because the generalized von Laue’s theorem has a pre-assumption of $\partial \Theta^{\mu\nu}(\mathbf{x}, t) / \partial t \equiv 0$ (but no boundary condition required) and the corrected Møller’s theorem has a pre-assumption of $\partial_t \Theta^{\mu\nu}(\mathbf{x}, t) \equiv 0$ plus $\Theta(\mathbf{x}, t) = 0$ on boundary (zero boundary condition), the four-vector $P^\mu = \int_{V, \text{reconst}} \Theta^{\mu\nu}(\mathbf{x}, t) \partial^3 x$ defined by the two theorems is time-independent ($\partial P^\mu / \partial t \equiv 0$). Thus the generalized von Laue’s theorem and the corrected Møller’s theorem can be taken as “conservation laws” in a traditional sense.

We also have shown that there are three flawed four-vector theorems: (i) Møller’s theorem, which is also called “Møller’s version of Laue’s theorem” in Ref. [6]; (ii) Landau-Lifshitz version of Laue’s theorem; and (iii) Weinberg’s version of Laue’s theorem. Møller’s version is disproved in the present paper by taking the mathematical tensor Eq. (38) as a counterexample, while Landau-Lifshitz and Weinberg’s versions are disproved in Ref. [6] by taking the EM tensor of a charged metal sphere in free space as a counterexample. All the sufficient conditions of the three disproved versions of Laue’s theorem include the divergence-less of a tensor ($\partial_t \Theta^{\mu\nu}(\mathbf{x}, t) = 0$). Accordingly, it is not appropriate for $\partial_t \Theta^{\mu\nu}(\mathbf{x}, t) = 0$ to be recognized as “conservation law” in traditional textbooks, such as in the book by Panofsky and Phillips [18] p. 310.

It is worthwhile to point out that the counterexample Eq. (38) for Møller’s version of Laue’s theorem, $A^{\mu\nu}(\mathbf{x}, t)$, is also a counterexample of Landau-Lifshitz and Weinberg’s versions of Laue’s theorem, because $A^{\mu\nu}(\mathbf{x}, t)$ is both divergence-less ($\partial_t A^{\mu\nu} = 0$) and symmetric ($A^{\mu\nu} = A^{\nu\mu}$), while Landau-Lifshitz version takes the divergence-less of a tensor as a sufficient condition, and Weinberg’s version takes the divergence-less plus a symmetry of a tensor as a sufficient condition. In other words, $A^{\mu\nu}(\mathbf{x}, t)$ given by Eq. (38) is a common counterexample to disprove Møller’s, Landau-Lifshitz, and Weinberg’s versions of Laue’s theorem.

There is a well-known result in the dynamics of relativity that if a Lorentz four-vector is divergence-less, then the time-element space integral of the four-vector is a Lorentz scalar; for example, Weinberg claims that “for any conserved four-vector”, namely for any four-vector $J^\mu = (\mathbf{J}, c\rho)$ that satisfies equation $\partial_t J^\mu = 0, cQ = \int J^\mu \partial^3 x = 0$, $J^\mu$ is a Lorentz scalar. In this paper, we have also shown that $J^\mu$ is not a Lorentz scalar but a Lorentz four-vector.
\[ \int cpd^3x \] “defines a time-independent scalar” \[ p.41 \], and Møller also claims a proof of such a result in his textbook \[ 3, p.168 \]. However in the present paper, we have shown based on Theorem 3 in Sec.4 that this well-known result is not correct. We have found a general conclusion for the Lorentz property of a four-vector’s time-element space integral, stating that whether the time-element space integral of a four-vector is a Lorentz scalar has nothing to do with the four-vector’s divergence-less property. Accordingly, it is not appropriate for \( \partial_\mu \Lambda^\mu(x,t) = 0 \) to be called “invariant conservation Law” in the textbook by Weinberg \[ p.40 \].

In conclusion, we have generally resolved two of the most controversial problems in the dynamics of relativity

\[ 19, 21 \] (a) Under what condition, the time-column space integrals of a Lorentz four-tensor constitute a Lorentz four-vector (Theorem 1), and (b) under what condition, the time-element space integral of a Lorentz four-vector is a Lorentz scalar (Theorem 3).

References

\[ \text{In this book} \[ 29 \], with the help of exterior calculus, Thirring claims that (i) \( \partial_\mu \Lambda^\mu = 0 \) makes \( \int A^\mu d^4x \) be a Lorentz scalar, and (ii) \( \partial_\mu T^\mu = 0 \) makes \( \int T^\mu d^4x \) be a Lorentz four-vector. However, claim (i) can be directly disproved by a simple counterexample \( \Lambda^\mu = k^\mu \), and claim (ii) can be directly disproved by a simple counterexample \( T^\mu = k^\mu K^\nu \), where \( K^\nu = (k_\nu, \omega/c) \) is the wave four-vector for a plane wave in free space, first shown by Einstein \[ 20 \], with \( k_\nu \) the wave number, \( \omega \) the angular frequency, and \( k_0 = \omega/c \) holding. This is illustrated as follows. Apparently, \( \partial_\mu K^\nu = 0 \) and \( \partial_\mu (k^\mu K^\nu) = 0 \) are both valid because \( K^\nu \) is independent of space and time variables \( (x,t) \). Suppose that \( \int K^\mu d^4x = \omega (k_\nu/c) \int d^4x \) is given in the laboratory frame; then we have \( \int K^\mu d^4x = \omega (k_\nu/c) \int d^4x \gamma = (1 - \beta k_\nu/c) k_\nu \int d^3x \) in the frame moving with respect to the laboratory frame at a velocity of \( \beta c \) along the wave vector \( k_\nu \). Thus we have \( \int K^\mu d^4x \neq \int K^\mu d^4x \) for \( \beta c \neq 0 \); in other words, \( \int K^\mu d^4x \) is not a Lorentz scalar, and Thirring’s claim (i) is disproved. On the other hand, we have \( \int T^\mu d^4x = \int K^\mu K^\nu d^4x = K^\mu (K^\nu d^4x) \). Because \( K^\mu \) is a four-vector but \( K^\mu d^4x \) is not a Lorentz scalar, \( K^\mu (K^\nu d^4x) \) or \( \int T^\mu d^4x \) must not be a four-vector. Thus Thirring’s claim (ii) is disproved as well. [Proof by contradiction: If \( \int T^\mu d^4x = K^\nu (K^\nu d^4x) \) are a four-vector, then \( X_\mu (K^\nu d^4x) = X_\mu (K^\nu d^4x) \) would hold, where \( X^\mu = (x^\mu, c) \) is the time-space four-vector, and \( X_\mu K^\nu = \omega (k_\nu / c) \) is the scalar of phase. From \( \Lambda(\mu, k^\nu) (K^\nu d^4x) = \text{scalar} \) and \( \Lambda_\mu (\mu, k^\nu) = \text{scalar} \), it follows that \( (K^\mu d^4x) \) must be a scalar, but \( (K^\mu d^4x) \) is not a scalar. Thus \( \int T^\mu d^4x = K^\mu (K^\nu d^4x) \) cannot be a Lorentz four-vector] An interesting question: Why is \( K^\mu d^4x \) not a scalar for the wave four-vector \( K^\nu = (k_\nu, \omega/c) \) while \( J^\mu d^4x \) is a scalar for the current density four-vector \( J^\mu = (J^\mu, \rho/c) \)? That is because the moving velocity of any charged particle is less than the vacuum light speed \( c \), and there is a particle-rest frame where the particle current \( J = 0 \Rightarrow J^\mu d^4x = 0 \) holds, with the sufficient and necessary condition Eq.1 of Theorem 3 satisfied, \( \Rightarrow J^\mu d^4x = 0 \). However for \( \Lambda^\mu = (k_\nu, \omega/c) \), there is no such a frame where \( \Lambda_\mu = 0 \Rightarrow k_\nu d^4x = 0 \) holds; thus \( \int K^\mu d^4x \) is not a scalar. Why is there no such a frame for \( k_\nu = 0 \)? As we know, the photon momentum–energy four-vector is given by \( h k_\nu = (h k_\nu, h \omega/c) \), with \( h \) the Planck constant. According to Einstein's hypothesis of constancy of light speed, there is no photon-rest frame in free space, and the photon momentum \( h k_\nu \neq 0 \) holds in any frames.

As misrepresented in traditional textbooks, conservation of momentum–energy can be expressed by the fundamental geometric law \( \partial_\mu T^\mu = 0 \) \[ p.83 \] \[ 21 \] \[ 17 \], and it is often used for relativistic analysis of the Abraham-Minkowski debate on the momentum of light in a medium \[ 9, 10 \] \[ 11 \], and also thought to play an important role in gravitation theory \[ 21 \] p.132. Thus clarifying the two fundamental issues in the present paper has a general significance.
Material to help reading

What is done in my manuscript?

(1) By setting up Theorems 1, 2, and 3, my paper has resolved two fundamental issues in the dynamics of relativity, namely “conservation laws”, which are misrepresented in traditional textbooks, and widely used in current fundamental research.

(2) In traditional textbooks, the two “conservation laws” in the dynamics of relativity are shown to be

(i) $\partial_\mu \Lambda^\mu = 0$ makes $\int \Lambda^\mu d^4x$ be a Lorentz scalar,  
(ii) $\partial_\mu T^{\mu\nu} = 0$ makes $\int T^{\mu\nu} d^4x$ be a Lorentz four-vector.

However, they are directly disproved by simple counterexamples $\Lambda^\mu = K^\mu$ and $T^{\mu\nu} = K^\mu K^\nu$, as clearly shown in footnote 3 of my paper, where $K^\mu = (k_\omega, \omega/c)$ is the wave four-vector for a plane wave in free space, first shown by Einstein, with $k_\omega$ the wave vector, $\omega$ the angular frequency, and $|k_\omega| = \omega/c$ holding.

The “conservation laws” (i) and (ii) in traditional textbooks have magically attracted several generations of most outstanding scientists; however, they turned out to be imaginary, creating an epic-like scientific myth in the modern theoretical physics and mathematical physics: believing is seeing, just like a new version of “N-ray Affair”, and also reminding us of Einstein’s words of wisdom: unthinking respect for authority is the greatest enemy of truth. Thus clarifying the two fundamental issues in my paper has a general significance.
