Abstract

We describe the generators and prove a number of relations for the construction of a planar algebra from the restricted quantum group $\bar{U}_q(\mathfrak{sl}_2)$. This is a diagrammatic description of $\text{End}\bar{U}_q(\mathfrak{sl}_2)(X^{\otimes n})$, where $X := X^+_2$ is a two dimensional $\bar{U}_q(\mathfrak{sl}_2)$ module.

1 Introduction

The restricted quantum group, $\bar{U}_q(\mathfrak{sl}_2)$, for $q = e^{i\pi p}$, $2 \leq p \in \mathbb{N}$, is a finite dimensional quotient of $U_q(\mathfrak{sl}_2)$ with non-semisimple representation theory, and was conjectured in [3] to have a representation category equivalent to the representation category of the $W_p$ logarithmic conformal field theory. An equivalence as abelian categories was proven in [15], however [8] showed that $\bar{U}_q(\mathfrak{sl}_2)$ has modules whose tensor product does not commute, and so the category is not braided. This example does not appear in the subcategory generated by irreducible modules, which is the focus of our construction.

Planar algebras are a type of diagrammatic algebra first introduced as an axiomatization of the standard invariant of subfactors, and shown to have close relations to statistical mechanics and knot theory. The standard example of a planar algebra is the Temperley-Lieb algebra, which can be constructed from $U_q(\mathfrak{sl}_2)$, as a description of $\text{End}U_q(\mathfrak{sl}_2)(X^{\otimes n})$, where $X$ is a two-dimensional irreducible module [5, 10]. We aim to generalize this construction to the restricted quantum group.

The $\bar{U}_q(\mathfrak{sl}_2)$ planar algebra is a diagrammatic description of $\text{End}\bar{U}_q(\mathfrak{sl}_2)(X^{\otimes n})$, where $X$ is a two dimensional $\bar{U}_q(\mathfrak{sl}_2)$ module. It was shown in [6] that for $n < 2p - 1$, this is isomorphic to the Temperley-Lieb algebra with parameter $q + q^{-1}$, and for $n \geq 2p - 1$ contains extra generators, $\alpha_i$ and $\beta_i$, $1 \leq i \leq n - 2p + 2$. We define these generators explicitly in terms of the $\bar{U}_q(\mathfrak{sl}_2)$ action which allow us to prove combinatorially a number of relations on them. The main focus of the paper is the relations in Theorem 3.1 and their proofs. We also conjecture a formula for the dimensions of the planar algebra at the end of Section 2. Some of these relations were previously proven in [6], however we include proofs here for completeness. Other relations in Theorem 3.1 generalize their results for $p = 2$.

It was conjectured in [6] that $\alpha_i$ and $\beta_i$, along with the Temperley-Lieb algebra, generate $\text{End}_{\bar{U}_q(\mathfrak{sl}_2)}(X^{\otimes n})$. We do not claim to have a proof of this, although we note that $\alpha_1\alpha_{p+1}$ and $\beta_1\beta_{p+1}$ give maps between the highest and lowest weight copies of $P^+_p$ appearing in the decomposition of $X^{\otimes 3p-1}$, which is where we would expect any new generators to appear, and so lends evidence to support the conjecture. Further, we make the following conjecture:

---

Keywords: Planar Algebras, Quantum Groups, Restricted Quantum Groups, Tensor Categories
Conjecture 1.1. The extension of the Temperley-Lieb algebra by the generators $\alpha_1$ and $\beta_1$ with the relations in Theorem 7.1 fully describe $\text{End}_{\mathcal{U}_q(sl_2)}(X^{\otimes n})$.

The reasoning for this conjecture comes from considering diagrammatic descriptions of morphisms between modules, which can be considered as the reasoning behind many relations. Hence knowing the diagrammatic descriptions of all such morphisms suggests that the possibility of there being any unknown relations is less likely. These diagrammatic descriptions will be detailed in [11], and are also described in [12].

The paper is outlined as follows: In Section 2, we review the definition of $\tilde{U}_q(sl_2)$, along with the modules, fusion rules, and module homomorphisms relevant to our construction, as well as giving details on the dimensions of the planar algebra. In Section 3, we introduce the planar algebra construction, and define the generators $\alpha$ and $\beta$, along with a number of relations on them. The proofs of the $\tilde{U}_q(sl_2)$ relations are given in Section 4. A basis for $\text{End}_{\mathcal{U}_q(sl_2)}(X^{\otimes 2p})$ is also given at the end of Section 4. We record a number of combinatorial identities used in the proofs in the Appendix. For more detailed proofs, see [12].

2 $\tilde{U}_q(sl_2)$

For $q = e^{i\pi/p}$, $p \geq 2$, and $p \in \mathbb{N}$, the restricted quantum group $\tilde{U}_q(sl_2)$ over a field $K$ is the Hopf algebra generated by $E, F, K$ subject to the relations:

$$KEK^{-1} = q^2E \quad KFK^{-1} = q^{-2}F \quad EF - FE = \frac{K - K^{-1}}{q - q^{-1}}$$

$$E^p = 0 \quad F^p = 0 \quad K^{2p} = 1$$

and coproduct $\Delta$, counit $\epsilon$, and antipode $S$:

$$\Delta : E \mapsto E \otimes K + 1 \otimes E \quad F \mapsto F \otimes 1 + K^{-1} \otimes F \quad K \mapsto K \otimes K$$

$$\epsilon : E \mapsto 0 \quad F \mapsto 0 \quad K \mapsto 1$$

$$S : E \mapsto -EK^{-1} \quad F \mapsto -KF \quad K \mapsto K^{-1}$$

The modules for $\tilde{U}_q(sl_2)$ were given in [1][6][8][10][19], and the modules relevant to our construction consist of the following: $2p - 2$ simple modules, $X_s^\pm$, $1 \leq s < p$, two simple projective modules $X_s^\pm$ and $2p - 2$ non-simple indecomposable projective modules $P_s^\pm$. For the simple modules $X_s^\pm$, $1 \leq s \leq p$, they can be given in terms of a basis as $\{\nu_n^s\}_{n=0,...,s-1}$ with the action of $\tilde{U}_q(sl_2)$ given by:

$$K\nu_n = \pm q^{s-1-2n}\nu_n$$
$$E\nu_n = [n][s-n]\nu_{n-1}$$
$$F\nu_n = \nu_{n+1}$$

where $\nu_{-1} = 0$ and $[n] = q^{n-1} - q^{-n} = q^{n-1} + q^{n-3} + ... + q^{3-n} + q^{1-n}$. The projective modules $P_s^\pm$, $1 \leq s < p$, for a given choice of $p$, can be given in terms of the basis $\{u_i^s, b_i^s\}_{0 \leq i \leq s-1} \cup \{x_j^s, y_j^s\}_{0 \leq j \leq p-s-1}$. The action of $\tilde{U}_q(sl_2)$ is given by:

$$Ka_i = \pm q^{s-1-2i}a_i \quad Kb_i = \pm q^{s-1-2i}b_i$$
$$Kx_j = \mp q^{p-s-1-2j}x_j \quad Ky_j = \mp q^{p-s-1-2j}y_j$$
$$Ea_i = \pm [i][s-i]a_{i-1} \quad Eb_i = \pm [i][s-i]b_{i-1} + a_{i-1} \quad Eb_0 = x_{p-s-1}$$
$$Ex_j = \mp [j][p-s-j]x_{j-1} \quad Ey_j = \mp [j][p-s-j]y_{j-1} \quad Ey_0 = a_{s-1}$$
$$F_a_i = a_{i+1} \quad Fb_i = b_{i+1} \quad Fb_{s-1} = y_0$$
$$Fx_j = x_{j+1} \quad Fx_{p-s-1} = a_0 \quad Fy_j = y_{j+1}$$

where $x_{-1} = a_{-1} = a_s = y_{p-s} = 0$, [4].

The maps between indecomposable modules can be summarized as follows:
• \( \dim(\text{Hom}(X^\pm_s, X^\pm_t)) = 0 \) for \( s \neq t \) or \( s = t, \) for \( 1 \leq s, t \leq p. \)

• \( \text{Hom}(X^\pm_s, X^\mp_t) = 0 \) for \( 1 \leq s, t \leq p. \)

• \( \dim(\text{Hom}(P^\pm_s, X^\pm_t)) = 0 \) for \( s \neq t \) or \( s = t, \) for \( 1 \leq s, t \leq p - 1. \)

• \( \text{Hom}(P^\pm_s, X^\mp_t) = 0 \) for \( 1 \leq s, t \leq p - 1. \)

• \( \dim(\text{Hom}(P^\pm_s, P^\mp_t)) = 0 \) for \( s \neq t \) or \( 2 \) for \( s = t, \) \( 1 \leq s, t \leq p - 1. \)

• \( \dim(\text{Hom}(P^\pm_s, P^\mp_t)) = 0 \) for \( s \neq p - t \) or \( 2 \) for \( s = p - t, \) \( 1 \leq s, t \leq p - 1. \)

The non-zero, and non-identity parts of these maps can be given in terms of bases by:

\[
\begin{align*}
\mathcal{P}^\pm_s & \to X^\pm_s : b_i \mapsto \nu_i \\
X^\pm_s & \to \mathcal{P}^\pm_s : \nu_i \mapsto a_i \\
\mathcal{P}^\pm_s & \to \mathcal{P}^\pm_s : b_i \mapsto a_i \\
\mathcal{P}^\pm_s & \to \mathcal{P}^\mp_s : b_i \mapsto f_1 \tilde{x}_i + f_2 \tilde{y}_i \\
x_j & \mapsto f_2 \tilde{a}_j \\
y_j & \mapsto f_1 \tilde{a}_j
\end{align*}
\]

where \( f_1, f_2 \in \mathbb{K}, \) and we denote the elements of \( \mathcal{P}^\mp_s \) with \( \sim. \)

From now on, we denote the module \( X^+_s \) by \( X. \) The fusion rules for \( \hat{U}_q(\mathfrak{sl}_2) \) modules were given in \([8, 17].\) The fusion rules relevant to our planar algebra construction are:

\[
\begin{align*}
X^+_i \otimes X^+_i & \simeq X^+_i \otimes X^+_i \simeq X^+_j, \quad i, j \in \{+,-\} \\
X^+_i \otimes P^+_i & \simeq P^+_i \otimes X^+_i \simeq P^+_j, \\
X \otimes X^+_t & \simeq X^+_t \otimes X \simeq X^+_t \oplus X^+_t+1, \quad 2 \leq t \leq p - 1 \\
X \otimes X^+_p & \simeq X^+_p \otimes X \simeq \mathcal{P}^+_p-1, \\
X \otimes \mathcal{P}^+_p-1 & \simeq \mathcal{P}^+_p-1 \otimes X \simeq \mathcal{P}^+_p-2 \oplus 2X^+_p, \\
X \otimes \mathcal{P}^+_u & \simeq \mathcal{P}^+_u \otimes X \simeq \mathcal{P}^+_u-1 \oplus \mathcal{P}^+_u+1, \quad 2 \leq u \leq p - 2 \\
X \otimes \mathcal{P}^+_1 & \simeq \mathcal{P}^+_1 \otimes X \simeq \mathcal{P}^+_2 \oplus 2X^+_p
\end{align*}
\]

From this, it follows that \( X^+_1 \) first appears in the decomposition of \( X^{\otimes(s-1)}, \) \( \mathcal{P}^+_1 \) first appears in the decomposition of \( X^{\otimes(2p-1-1)}, \) \( X^-_p \) in \( X^{\otimes(2p-1)}, \) and \( \mathcal{P}^-_u \) in \( X^{\otimes(3p-u-1)}, \) \( 1 \leq u \leq p - 1, \) does not appear at all in the decomposition of \( X^{\otimes n}. \)

Using these fusion rules, along with the maps between modules, we can describe the dimensions of \( \text{End}(X^{\otimes n}). \) We denote by \( D_{i,n} \) the multiplicity of \( X^+_i \) in the decomposition of \( X^{\otimes n}, \) \( 1 \leq i \leq p. \) \( M_{2p-j,n} \) denotes the multiplicity of \( \mathcal{P}^-_j, \) \( 1 \leq j \leq p - 1, \) \( M_{2p,n} \) the multiplicity of \( X^-_p, \) and \( M_{3p-j,n} \) the multiplicity of \( \mathcal{P}^-_j. \) For a given choice of \( p, \) we then have:

\[
D_n = M_{2p,n}^2 + \sum_{i=1}^{p} M_{i,n}^2 + \sum_{j=1}^{p-1} (2M_{p+j,n}^2 + 2M_{2p+j,n}^2 + 2M_{p-j,n}^2 + 2M_{p+j,n}M_{p+j,n} + 4M_{p+j,n}M_{3p-j,n})
\]

By use of the fusion rules to give module multiplicities in the decomposition of \( X^{\otimes n}, \) the following was proven in section 4.5 of \([6].\)

**Proposition 2.1.** For \( n < 2p - 1, \) \( D_n \) is equal to the Catalan number, \( C_n := \frac{1}{(n+1)} \left( \begin{array}{c} 2n \\ n \end{array} \right), \) and \( D_{2p-1} = C_{2p-1} + 3. \)

Another proof is contained in Section 4.3 of \([12].\) In general, the dimensions \( D_n \) can be calculated from the \( \hat{U}_q(\mathfrak{sl}_2) \) fusion rules and homomorphisms, or by use of results in Section 4.9 of \([6].\) Alternatively, we have the following:
Let \( \left\{ \begin{array}{c} a \\ b \end{array} \right\} := \left( \begin{array}{c} a \\ b \end{array} \right) - \left( \begin{array}{c} a \\ b-1 \end{array} \right) \), and
\[
G_{n,i} := \sum_{j=0}^{\left\lfloor \frac{n}{1+2} \right\rfloor} \left\{ \begin{array}{c} n \\ i+1-j \end{array} \right\} \left\{ \begin{array}{c} n \\ j \end{array} \right\} + \left( \frac{t+1}{2} \right) \left( \frac{t}{2} + 1 \right) \left\{ \begin{array}{c} n \\ \frac{t}{2} \end{array} \right\}^2
\]

Conjecture 2.1.

It can be verified numerically for small values of \( n \) that this agrees with the formula for \( p = 2 \) given in Section 2.4.3 of [6].

The module \( X := X^n \) has basis \( \{ \nu_0, \nu_1 \} \), with \( \bar{U}_q(\mathfrak{sl}_2) \) action:
\[
\begin{align*}
K(\nu_0) &= q\nu_0 & E(\nu_0) &= 0 \\
K(\nu_1) &= q^{-1}\nu_1 & E(\nu_1) &= \nu_0 \\
F(\nu_0) &= 0 & F(\nu_1) &= \nu_0
\end{align*}
\]

The action of \( \bar{U}_q(\mathfrak{sl}_2) \) on \( X^{\otimes n} \) is given by use of the coproduct.

We denote by \( \rho_{i_1,...,i_n} \) the element of \( X^{\otimes n} \) with \( \nu_i \) at positions \( i_1,...,i_n \), and \( \nu_0 \) elsewhere. We also occasionally omit the \( \otimes \) sign, and combine indices. For example, \( \rho_{1,3,5} = \nu_1 \otimes \nu_0 \otimes \nu_1 \otimes \nu_0 \otimes \nu_0 = \nu_{10001} \). The elements of \( X^{\otimes n} \) can be described in terms of the \( K \)-action on them. For \( x \in X^{\otimes n} \), with \( K(x) = \lambda x \), \( \lambda \in \mathbb{K} \), we call \( \lambda \) the weight of \( x \). Alternatively for basis elements we can write this as \( K(\rho_{i_1,...,i_n}) = q^{\sum_{i=2}^n x_i} \), and refer to \( n \) also as the weight. \( X^{\otimes n} \) will then have the set of weights \( \{ q^2, q^2-2, ..., q^{2^n-2}, q^{2^n-1} \} \). Denoting the set of elements of \( X^{\otimes n} \) with weight \( q^{2^n-2n} \) by \( X_{n,z} \), we have \( X^{\otimes n} = \bigsqcup_{z=0}^{n} X_{i,z} \). The weight spaces \( X_{0,z}, X_{2,z} \) both have a single element, which we denote by \( x_{0,z} := (\nu_0)^{\otimes z}, x_{2,z} := (\nu_1)^{\otimes z} \), respectively, and occasionally drop the second index if the context is clear. We have \( \rho_{i_1,...,i_n} \in X_{n,z} \). We record a number of combinatorial relations involving \( \bar{U}_q(\mathfrak{sl}_2) \) and its action on \( X^{\otimes n} \) in the Appendix.

3 The \( \bar{U}_q(\mathfrak{sl}_2) \) Planar Algebra

For detailed introductions to planar algebras, see [7,14]. Our construction of the \( \bar{U}_q(\mathfrak{sl}_2) \) planar algebra is a diagrammatic description of \( \text{End}(X^{\otimes n}) \), or more generally, \( \text{Hom}(X^{\otimes n}, X^{\otimes m}) \), similar to the constructions of [2,5,9,13]. It was shown in [6] that for \( n \leq 2p - 1 \), this is isomorphic to the Temperley-Lieb algebra on \( n \) points with parameter \( \delta = q + q^{-1} \), and for \( n \geq 2p - 1 \), \( \text{End}(X^{\otimes n}) \) contains extra generators, \( \alpha_i, \beta_i, 1 \leq i \leq n - 2p + 1 \), which are described in Section 2.1. We then prove a number of relations on these generators.

Diagrammatically, \( \text{Hom}(X^{\otimes n}, X^{\otimes m}) \) is represented by a box with \( n \) points along the top, and \( m \) points along the bottom, where zero points represent a map to/from \( X^1 \approx \mathbb{K} \). Each point on the box is connected to a string, up to isotopy, with strings not allowed to intersect. Removing a closed loop from a diagram corresponds to multiplying by \( \delta \in \mathbb{K} \). Multiplication of maps is given by adjoining a diagram below another diagram, and smoothing strings. Tensor products are given by by adjoining diagrams side by side. The identity element in \( \text{End}(X^{\otimes n}) \) is given by \( n \) vertical strings. The identity map \( \mathbb{K} \rightarrow \mathbb{K} \) is given by an empty box. We often use a single thick string to represent multiple parallel strings.

The Temperley-Lieb Algebra, \( TL_n(\delta) \), is the algebra generated by \( \{ 1, e_1, ..., e_{n-1} \} \), \( \delta \in \mathbb{K} \), with relations:
\[
\begin{align*}
e_i^2 &= \delta e_i \\
e_i e_{i+1} e_i &= e_i \\
e_i e_j &= e_j e_i, \ |i-j| > 1
\end{align*}
\]
We define the following maps on $\alpha$.

**3.1 The Generators.**

Our main focus now is to describe these generators and their properties.

We saw in Proposition 2.1 that $\dim X = [n]_q$, where $[n]_q = \frac{q^n - 1}{q - 1}$.

The following Proposition comes from Section 4.4 of [6]:

**Proposition 3.1.** $\text{End}_{\mathcal{U}_q(sl_2)}(X^{\otimes n}) \simeq TL_n(q + q^{-1})$, for $n < 2p - 1$.

**Proof.** The generators $e_i$ correspond to a map $e : X \otimes X \to \mathbb{K} \to X \otimes X$, $e \in \text{End}(X^{\otimes n})$, acting on the $i$th and $(i+1)$th positions in $X^{\otimes n}$. Explicitly, this is given by:

- $e : x_0 \otimes x_0 \mapsto 0$
- $e : x_1 \otimes x_1 \mapsto 0$
- $e : x_0 \otimes x_1 \mapsto q^{-1}x_0 \otimes x_1 - x_1 \otimes x_0$
- $e : x_1 \otimes x_0 \mapsto q^{-1}x_1 \otimes x_0 - x_0 \otimes x_1$

This correspondence with the generators $\rho$ clearly extends to all elements of $TL_n$, and so gives an injective map from $\text{End}(X^{\otimes n})$ to $TL_n$. (To see the injectivity, consider, for example, $e_i e_2$ and $e_2 e_i$, acting on $v_{10}$.) From Proposition 2.1 we have $\dim(\text{End}(X^{\otimes n})) = \dim(TL_n)$. Hence $\text{End}_{\mathcal{U}_q(sl_2)}(X^{\otimes n}) \simeq TL_n(q + q^{-1})$.

The generator $e$ can be split into two maps: $\cup : X \otimes X \to X_1^+$ and $\cap : X_1^+ \to X \otimes X$. In terms of $\nu_{ij}$, they are given as:

$$
\cup(\nu_{00}) = \cup(\nu_{11}) = 0
$$

$$
\cup(\nu_{01}) = -q\nu
$$

$$
\cup(\nu_{10}) = \nu
$$

$$
\cap(\nu) = q^{-1}\nu_{10} - \nu_{01}
$$

where $X_1^+$ has basis $\{\nu\}$. These extend to maps $\cup_i, \cap_i$, acting on the $i$th and $(i+1)$th points such that $\cap_i \cup_i \simeq e_i$. Note that technically we need to add the condition that moving a cup or cap rightwards multiplies it by $-1$ to ensure rigidity, however this is not required for our results.

The following corollary is a well known result:

**Corollary 3.1.1.** The projection $X^{\otimes n} \to X_1^{\otimes n} \to X^{\otimes n}$, is given by the Jones-Wenzl projection, $f_n$.

Explicitly, this projection is given by $\rho_{i_1,\ldots,i_n} \mapsto q^{k_n - \frac{1}{2}(k^2 - k) - \sum_{j=1}^k (i_j)} \frac{[n-1]!}{[m-1]!} F_k x_n$. This can then be shown to satisfy the Jones-Wenzl recursion relation.

We saw in Proposition 2.1 that $\dim(\text{End}(X^{\otimes (2p-1)})) = C_{2p-1} + 3$, and so $\text{End}(X^{\otimes (2p-1)})$ must contain extra generators. Our main focus now is to describe these generators and their relations.

### 3.1 The Generators, $\alpha$ and $\beta$.

We define the following maps on $X^{\otimes (2p-1)}$:

$$
\alpha(\rho_{i_1,\ldots,i_{2p-1}}) := q^{(k(2p-1) - \frac{1}{2}(k^2 - k) - \sum_{j=1}^{2p-1} (i_j))} \frac{[k]!}{[p-1]!} F_{k-1} x_{2p-1}
$$

$$
\beta(\rho_{i_1,\ldots,i_{2p-1}}) := q^{(k(2p-1) - \frac{1}{2}(k^2 - k) - \sum_{j=1}^{2p-1} (i_j))} \frac{[2p-1-k]!}{[p-1]!} F_{k-1} x_0
$$

The Jones-Wenzl Projections, [18], in the Temperley-Lieb algebra are defined inductively by:

$$
f_1 := 1
$$

$$
f_{n+1} := f_n \otimes 1 - \frac{[n]}{[n+1]} f_{n} e_n f_{n}
$$
where we take $E^{-1} = 0$, $F^{-1} = 0$. We often use a second, simplified definition; let $x \in X_{k,2p-1}$, and $e_x, f_x \in K$, such that $E^k x = e_x x_0$, $F^{2p-1-k} x = f_x x_{2p-1}$. Then we have:

$$
\alpha(x) = e_x E^{p-k-1} x_{2p-1} \\
\beta(x) = f_x F^{k-p} x_0
$$

These are equivalent to the generators defined in [6], up to a constant. In terms of weight spaces, the generators act as:

$$
\alpha : X_{k,2p-1} \to X_{k+p,2p-1} \\
\beta : X_{k,2p-1} \to X_{k-p,2p-1}
$$

Then $\alpha$ is zero for $k \geq p$ and $\beta$ is zero for $k < p$. Hence $\alpha^2 = \beta^2 = 0$. From their action on weight spaces, it is clear that $\alpha, \beta \notin TL_{2p-1}$. Let $\gamma := (-1)^{p-1}([p-1]!)^2$. The following properties of $\alpha$ and $\beta$ were given in [6]:

**Proposition 3.2.**

$$
\gamma^{-1} \alpha \beta + \gamma^{-1} \beta \alpha = \gamma f_{2p-1}
$$

$\gamma^{-1} \alpha \beta$ and $\gamma^{-1} \beta \alpha$ give projections onto the two copies of $X_p^-$ appearing in the decomposition of $X^{\otimes (2p-1)}$, $\alpha$ and $\beta$ are then maps between these two modules.

See Sections 4.1, 4.2 and 4.5 for proofs.

The maps $\alpha$ and $\beta$ can be given diagrammatically as boxes with $2p-1$ points along the top and bottom (or a single thick string to represent multiple strings). They then form the generators of the $\bar{U}_q(\mathfrak{sl}_2)$ planar algebra.

We denote by $\alpha_i$, $\beta_i$ the elements $1^{\otimes (i-1)} \otimes \alpha \otimes 1^{\otimes (n-2p-i+2)}$, $1^{\otimes (i-1)} \otimes \beta \otimes 1^{\otimes (n-2p-i+2)} \in End(X^{\otimes n})$.

**Theorem 3.1.** The generators, $\alpha_i$ and $\beta_i$, satisfy the following properties:

$$
\alpha^2 = \beta^2 = 0 \\
\alpha \beta \alpha = \gamma \alpha \\
\beta \alpha \beta = \gamma \beta \\
\gamma = (-1)^{p-1}([p-1]!)^2 \\
\alpha_i \alpha_j = \alpha_j \alpha_i = \beta_i \beta_j = \beta_j \beta_i = 0, \ |i-j| < p \\
\alpha_i \alpha_{i+p} = \alpha_{i+p} \alpha_i \\
\beta_i \beta_{i+p} = \beta_{i+p} \beta_i \\
\alpha \beta + \beta \alpha \gamma f_{2p-1}
$$
Denote by $R_n$ the (clockwise) $(n,n)$-point annular rotation tangle. We then have:

\[
\begin{align*}
\alpha \cap_i &= \cup_i \alpha = \beta \cap_i = \cup_i \beta = 0, \quad 1 \leq i \leq 2p - 2 \\
\alpha_{i+1} \cap_i &= \alpha_i \cap_{i+2p-2} \\
\beta_{i+1} \cap_i &= \beta_i \cap_{i+2p-2} \\
\cup_i \alpha_{i+1} &= \cup_i \alpha_{i+2p-2} \\
\cup_i \beta_{i+1} &= \cup_i \beta_{i+2p-2} \\
R_{4p-2}(\alpha) &= \alpha \\
R_{4p-2}(\beta) &= \beta \\
\sum_{i=0}^{4p-1} k_i R_{4p}^i (\alpha \otimes 1) &= 0 \\
\sum_{i=0}^{4p-1} k_i R_{4p}^i (\beta \otimes 1) &= 0
\end{align*}
\]

where $k_i = (-1)^i[i - 2]k_1 + (-1)^i[i - 1]k_2$, for arbitrary $k_1, k_2 \in K$.

Diagrammatically, these relations are:

![Figure 1: Relation 1](image1)

![Figure 2: Relation 2 and 3](image2)

![Figure 3: Relation 4](image3)
\[ \beta^n \beta^n = 0, \; n < p \]

Figure 4: Relation 4

\[ \alpha^p \alpha^p = \beta^p \beta^p, \quad \beta^p \alpha^p = \beta^p \beta^p \]

Figure 5: Relation 5 and 6

\[ \alpha \beta + \beta \alpha = \gamma f_{2p-1} \]

\]

Figure 12: Relation 15
We also have the partial traces given by:

\[
\begin{align*}
\alpha & \rightarrow \alpha = \beta = \beta = 0 \\
\alpha & \rightarrow \beta = \beta = \beta = 0
\end{align*}
\]

Figure 14: The partial trace of \(\alpha\) and \(\beta\).

\[e_i\alpha_j = \alpha_j e_i = e_i \beta_j = \beta_j e_i = 0, \quad 0 \leq i - j \leq 2p - 3\] \hspace{1cm} (17)
\[e_i\alpha_{j+1} = e_i e_{i+1} ... e_{i+2p-3} e_{i+2p-2} \alpha_i\] \hspace{1cm} (18)
\[\alpha_i e_i = e_i e_{i+2} ... e_{i+2p-3} e_{i+2p-4} e_i\] \hspace{1cm} (19)
\[e_i \beta_{i+1} = e_i e_{i+1} ... e_{i+2p-3} e_{i+2p-4} \beta_i\] \hspace{1cm} (20)
\[\beta_i e_i = \beta_i e_{i+2} ... e_{i+2p-3} e_{i+2p-4} \beta_i\] \hspace{1cm} (21)

Relation (17) was given in Section 4.7 of [6], and relations (18)-(21) generalize their results in Appendix C for \(p = 2\) to all \(p\).

We note that there are generalizations of relations (15) and (16) to higher \(n > 2p\). These generalizations can be stated as any sum over all diagrams with \(n\) strings along the top and
bottom and containing a single \( \alpha \) (respectively \( \beta \)) is linearly dependent. They further generalize to sums over all diagrams containing multiple \( \alpha \) or \( \beta \) for \( n \geq 3p \). We omitted to include these generalizations in Theorem 3.1 as we expect they can be constructed from the relations already given.

4 Proofs of Relations.

The aim for the remainder of this paper is to give proofs of the relations in Theorem 3.1. Relation 1 follows immediately from the action of \( \alpha \) and \( \beta \) on the weight spaces.

4.1 Proof that \( \text{End}(X^{\otimes(2p-1)}) \simeq TL_{2p-1}(q + q^{-1}) \oplus \mathbb{K} \alpha \oplus \mathbb{K} \beta \oplus \mathbb{K} \alpha \beta \).

From Proposition 2.1 we have that \( \dim(\text{End}(X^{\otimes(2p-1)})) = \dim(TL_{2p-1}(q + q^{-1})) + 3 \). From the actions of \( \alpha \), \( \beta \), and \( \alpha \beta \) in terms of weight spaces, we know that they are not in the Temperley-Lieb algebra. Hence we only need to check that \( \alpha, \beta \in \text{End}(X^{\otimes(2p-1)}) \), which is straightforward.

Note that \( \text{Im}(\alpha) \) and \( \text{Im}(\beta) \) are both \( p \) dimensional, with weights \( \{q^{2p-1}, q^{2p-3}, \ldots, q^{1-2p}\} = \{-q^{p-1}, -q^{p-3}, \ldots, -q^{1-p}\} \), and so \( \text{Im}(\alpha) \simeq \text{Im}(\beta) \simeq X_p^- \).

4.2 Relations 2 and 3. \( \alpha \beta \alpha \gamma = \gamma \alpha \), \( \beta \alpha \beta \gamma = \gamma \beta \).

Let \( x \in X_{k,2p-1} \), and \( e_x, f_x \in \mathbb{K} \), such that \( E^k x = e_x x_0, F^{2p-1-k} = f_x x_{2p-1} \). Using equations A.4 and A.5 it follows that:

\[
\begin{align*}
F^j \alpha(x) &= e_x \frac{[2p-k-1]}{[k!]} F^k x_0, \quad 0 \leq k \leq p - 1 \\
E^j \beta(x) &= f_x \frac{[2p-k+j-1]}{[k!]} F^{p-k-j} x_0
\end{align*}
\]

We can use these to apply \( \alpha \) and \( \beta \) repeatedly, giving:

\[
\begin{align*}
\beta(\alpha(x)) &= e_x \frac{[2p-k-1]}{[k!][p]} F^k x_0, \quad 0 \leq k \leq p - 1 \\
\gamma(\beta(\alpha(x))) &= e_x \frac{[2p-k-1]}{[k!]} [p-k+1][p-1] F^{p-k} x_0, \quad 0 \leq k \leq p - 1 \\
\beta(\gamma(\beta(\alpha(x)))) &= e_x \frac{[2p-k-1]}{[k!][p-k]} F^{p-k} x_0, \quad 0 \leq k \leq p - 1
\end{align*}
\]

Simplifying the coefficients in terms of our choice of \( p \), we have:

\[
\begin{align*}
\frac{[2p-k-1]}{[k!][p]} &= (-1)^{p-1}([p-1]!)^2, \quad 0 \leq k \leq p - 1 \\
\frac{[2p-k-1]}{[k!][p-k+1][p-1][p]} &= (-1)^{p-1}([p-1]!)^2, \quad 0 \leq k \leq p - 1 \\
\frac{[2p-k-1]}{[k!][p-k+1][p-1][p]} &= (-1)^{p-1}([p-1]!)^2, \quad 0 \leq k \leq p - 1
\end{align*}
\]

Let \( \gamma := (-1)^{p-1}([p-1]!)^2 \), then it follows that:

\[
\begin{align*}
\alpha(\beta(\alpha(x))) &= \gamma \alpha(x) \\
\beta(\gamma(\beta(\alpha(x)))) &= \gamma \beta(x)
\end{align*}
\]

Given that \( \text{Im}(\alpha) \simeq \text{Im}(\beta) \simeq X_p^- \), it follows that \( \gamma^{-1} \alpha \beta \) and \( \gamma^{-1} \beta \alpha \) are the projections onto the two copies of \( X_p^- \) in \( X^{\otimes(2p-1)} \).
4.3 Relation \( \alpha_i \alpha_j = \alpha_j \alpha_i = \beta_i \beta_j = \beta_j \beta_i = 0, \quad |i - j| < p. \)

This follows from considering \( \alpha_1 \alpha_{1+k}, \alpha_{1+k} \alpha_1, \beta_1 \beta_{1+k}, \) and \( \beta_{1+k} \beta_1 \) acting on \( X^\otimes 2p-1-k. \) We give the proof for the case \( \alpha_1 \alpha_{1+k}. \) The other cases follow similar arguments.

Let \( x \in X_{j,k}, 0 \leq j \leq k, \) with \( E^j x = e_x x_{0,k}, y \in X_{1,2p-1-k}, 0 \leq y \leq 2p-1-k, \) with \( E^y Y = e_y x_{0,2p-1-k}, \) and \( z \in X_{m,k}, 0 \leq m \leq k, \) with \( E^m z = e_z x_{0,k}. \) Consider \( \alpha_1 (\alpha_1 + k (x \otimes y \otimes z)). \)

By use of equation A.6, we have:

\[
\begin{align*}
4.4 Relations 5 and 6, \quad & \alpha_i \alpha_{i+p} = \alpha_{i+p} \alpha_i, \quad \beta_i \beta_{i+p} = \beta_{i+p} \beta_i, \\
& \text{We prove the case} \quad \lambda, 1 + \lambda, 1 - l - m - 1 \in K. \quad \text{To act} \quad \alpha_1 \text{on this, we need} \quad E^{2p-1-k} \text{acting on} \quad x_{2p-1-k,2p-1-k} \\
& \text{in the middle tensor term. However, as} \quad E^p = 0, \text{this will be zero if} \quad 2p - 1 - k \geq p, \text{and hence} \quad \alpha_1 \alpha_{1+k} = 0 \text{if} \quad k \leq p - 1. \\
\end{align*}
\]

Then we have \( E^{j+l+m} ((K^1 E^{j-l-i-1} x_{p-1,p-1} \otimes z) = \)

\[
\begin{align*}
\lambda_{j+l+m}(E^{j-l-i-1} x_{p-1,p-1} \otimes z) = \\
\end{align*}
\]

As \( E^p = 0, \) we only need to consider the terms where \( j + l + i + m \leq p - 1, \) which gives \( i \leq p - j - l - m - 1. \) Hence we have \( \alpha_{1+p}(\alpha_1 (x \otimes y \otimes z)) = \)

\[
\begin{align*}
\sum_{i=0}^{p-j-l-1} \lambda_{j+l+m} e_x e_y q^{(p+1)} (E^{j} x_{p,p} \otimes (K^1 E^{j-l-i-1} x_{p-1,p-1} \otimes z)
\end{align*}
\]

Next we have \( \alpha_{1+p}(x \otimes y \otimes z) = \)

\[
\begin{align*}
\sum_{p-j-l-1}^{p-j-l-i-1} e_y e_x q^{(p+1)} (E^{j} x_{p,1} \otimes (K^1 E^{j-l-i-1} x_{p,p-1}) \otimes z)
\end{align*}
\]

Then we have:

\[
E^{j+p-r-1} (x \otimes (E^{j} x_{p-1,p-1}) = e_x \lambda_{j+p-r-1} q^{(p-1)} (x_{0,2p-1})
\]

12
Again as $E^p = 0$, we only need consider the terms where $j + p - r - 1 \leq p - 1$, which gives $r \geq j$.

Hence we have $\alpha_1 (\alpha_{1+p} (x \otimes y \otimes z)) =$

$$
P_{r=j}^{p-l-m-1} e_y e_z q^p \lambda_{l+m} \lambda_{r,p-l-m-1} \lambda_{j,j+p-r-1} q^{p(j-1)} \times (E^{-r-j} x_{2p-1,2p-1}) \otimes (K^r E^{p-l-m-r-1} x_{p,p})
$$

\[ = \sum_{r=j}^{p-l-m-1} \left( \sum_{s=0}^{t} e_x e_y e_z \lambda_{l+m} \lambda_{t+j,p-l-m-1} \lambda_{j,p-t-1} q^{p(j-1)} \times \lambda_{s-r-1} (E^{s} x_{p,p}) \otimes (K^s E^{t-s-j} x_{p-1,p-1}) \otimes (K^{t+j} E^{p-l-m-j-t-1} x_{p,p}) \right) \]

Let $t = r - j$, then this becomes:

$$
P_{r=j}^{p-l-m-j-1} \left( \sum_{s=0}^{t} e_x e_y e_z \lambda_{l+m} \lambda_{t+j,p-l-m-1} \lambda_{j,p-t-1} q^{p(j-1)} \times \lambda_{s,r-1} (E^{s} x_{p,p}) \otimes (K^s E^{t-s} x_{p-1,p-1}) \otimes (K^{t+j} E^{p-l-m-j-t-1} x_{p,p}) \right) \]

Using the summation identity $\sum_{u=0}^{w} \sum_{v=0}^{w} x_{u,v} = \sum_{v=0}^{w} \sum_{u=0}^{w} x_{u,v}$, this becomes:

$$
P_{r=j}^{p-l-m-j-1} \left( \sum_{s=0}^{t} \sum_{l=s}^{p-l-m-j-1} e_x e_y e_z \lambda_{l+m} \lambda_{t+j,p-l-m-1} \lambda_{j,p-t-1} q^{p(j-1)} \times \lambda_{s,r-1} (E^{s} x_{p,p}) \otimes (K^s E^{t-s} x_{p-1,p-1}) \otimes (K^{t+j} E^{p-l-m-j-t-1} x_{p,p}) \right) \]

Let $n = t - s$, then we have:

$$
P_{r=j}^{p-l-m-j-1} \left( \sum_{s=0}^{t} \sum_{l=s}^{p-l-m-j-1} e_x e_y e_z \lambda_{l+m} \lambda_{n+s+j,p-l-m-1} \lambda_{j,p-n-s-1} q^{p(j-1)} \times \lambda_{s,n+s} (E^{s} x_{p,p}) \otimes (K^s E^{n} x_{p-1,p-1}) \otimes (K^{n+s+j} E^{p-l-m-j-n-s-1} x_{p,p}) \right) \]

Letting $s = i$ we have:

$$
P_{r=j}^{p-l-m-j-1} \left( \sum_{i=0}^{t} \sum_{l=i}^{p-l-m-j-1-i} e_x e_y e_z \lambda_{l+m} \lambda_{n+i+j,p-l-m-1} \lambda_{j,p-n-i-1} q^{p(j-1)} \times \lambda_{i,n+i} (E^{i} x_{p,p}) \otimes (E^{n} x_{p-1,p-1}) \otimes (K^{n} E^{p-l-m-j-n-i-1} x_{p,p}) \right) \]

This is now the same summation as $\alpha_1 + p \alpha_1$, hence we want to show that the coefficients are equal for both. We then want to show:

$$
q^{2p-j-2i-j-2l-2m+1} \lambda_{l+m} \lambda_{n+i+j,p-l-m-1} \lambda_{j,p-n-i-1} \times \lambda_{i,n+i} (E^{i} x_{p,p}) \otimes (E^{n} x_{p-1,p-1}) \otimes (K^{n} E^{p-l-m-j-n-i-1} x_{p,p}) \]

for $0 \leq i \leq p - l - m - j - 1$ and $0 \leq n \leq p - l - m - j - 1 - i$. For this we need to use equation [A.8]. The coefficients then simplify to give:

$$
\begin{align*}
\lambda_{i,n+i} & = q^{(2p-j-2i-j-2l-2m+1)} \lambda_{l+m} \lambda_{n+i+j,p-l-m-1} \lambda_{j,p-n-i-1} \\
& \times \lambda_{i,n+i} (E^{i} x_{p,p}) \otimes (E^{n} x_{p-1,p-1}) \otimes (K^{n} E^{p-l-m-j-n-i-1} x_{p,p})
\end{align*}
$$

13
As \([p - x] = [x]\), we have \(((x!)!(p - 1 - x)!) = ([p - 1]!)\). Therefore it reduces to:
\[
([p - 1]!) = q^{-2p}([p - 1]!)
\]

Hence the coefficients are equal, and so we have \(\alpha_1\alpha_{1+p} = \alpha_{1+p}\alpha_1\).

4.5 Relation 7 \(\alpha\beta + \beta\alpha = \gamma f_{2p-1}\).

From Section 4.2, we have:
\[
\beta(\rho_{1,\ldots,i_k,2p-1}) = q^{k(2p-1) - \frac{1}{2}(k^2 - k) - \left(\sum_{j=1}^{k} i_j\right)} \left([2p - k - 1]!\right) F^{k} x_0, \quad 0 \leq k \leq p - 1
\]
\[
\alpha(\rho_{1,\ldots,i_k,2p-1}) = q^{k(2p-1) - \frac{1}{2}(k^2 - k) - \left(\sum_{j=1}^{k} i_j\right)} \left([k]!\right) \left([2p-k-1]!\right) E^{2p-k-1} x_{2p-1}, \quad p \leq k \leq 2p - 1
\]

The Jones-Wenzl projection, \(f_{2p-1}\), is given by:
\[
f_{2p-1}(\rho_{1,\ldots,i_k,2p-1}) = q^{k(2p-1) - \frac{1}{2}(k^2 - k) - \left(\sum_{j=1}^{k} i_j\right)} \left([2p-k-1]!\right) F^{k} x_0
\]
\[
\gamma f_{2p-1}(\rho_{1,\ldots,i_k,2p-1}) = q^{k(2p-1) - \frac{1}{2}(k^2 - k) - \left(\sum_{j=1}^{k} i_j\right)} \left([2p-k-1]!\right) F^{k} x_0
\]

Hence \(\beta(\rho_{1,\ldots,i_k,2p-1}) = \gamma f_{2p-1}(\rho_{1,\ldots,i_k,2p-1})\), for \(0 \leq k \leq p - 1\). Note, that although we should consider this equal to zero for \(k \geq p\), here we are only using \(\frac{p}{2}\) to represent the relevant element of \(X^{\otimes(2p-1)}\), which is non-zero. From equations A.11 and A.12 we have:

\[
([z-k]!) F^{k} x_{0,z} = ([k]!) E^{z-k} x_{z,z}
\]

It follows that \(\alpha(\rho_{1,\ldots,i_k,2p-1}) = \gamma f_{2p-1}(\rho_{1,\ldots,i_k,2p-1})\), for \(p \leq k \leq 2p - 1\). Hence \(\alpha\beta + \beta\alpha = \gamma f_{2p-1}\).

4.6 Relation 8 \(\alpha \cap_i = \cup_i \alpha = \beta \cap_i = \cup_i \beta = 0, \quad 1 \leq i \leq 2p - 2\).

From Proposition 3.2, we have that the image of \(\alpha\) and \(\beta\) is \(X^p_{-}\). However, \(X^p_{-}\) is irreducible, and does not appear in the decomposition of \(X^\otimes n\) until \(n = 2p - 1\). Capping or cupping \(\alpha\) or \(\beta\) gives a map between \(X^p_{-}\) and \(X^{\otimes(2p-3)}\). Hence this map must be zero.

4.7 Relations 9 and 10 \(\alpha_{i+1} \cap_i = \alpha_i \cap_{i+2p-2} = \beta_i \cap_{i+2p-2}\).

Given \(\cap(\nu) = q^{-1} \nu_{10} - \nu_{01}\), we can write relation 9 explicitly as:
\[
q^{-1} \alpha(\rho_{1,\ldots,i,2p-2} \otimes \nu_1) \otimes \nu_0 = \alpha(\rho_{1,\ldots,i,2p-2} \otimes \nu_0) \otimes \nu_1
\]
\[
= q^{-1} \nu_1 \otimes (\alpha(\nu_0 \otimes \rho_{1,\ldots,i,2p-2} - \nu_0 \otimes \alpha(\nu_1 \otimes \rho_{1,\ldots,i+1,2p-2}))
\]

Using equation A.6, this simplifies to become:
\[
q^{n-1} \lambda_{n+1} (E^{p-n-2} x_{2p-1,2p-1}) \otimes \nu_0 - q^n (E^{p-n-1} x_{2p-1,2p-1}) \otimes \nu_1
\]
\[
= q^{-1} \nu_1 \otimes (E^{p-n-1} x_{2p-1,2p-1}) - q^{2p-2} \lambda_{n+1} \nu_0 \otimes (E^{p-n-1} x_{2p-1,2p-1})
\]

Using equation A.13 and A.14 both sides can be shown to equal \(q^{-1} E^{p-n-1} x_{2p,2p}\). The proof of relation 10 is similar, with both sides reducing to \(q^{-1} E^{p-n-1} x_{0,2p}\).

4.8 Relations 11, 12, and 14 \( \cup_i \alpha_{i+1} = \cup_{i+2p-2} \alpha_i, \cup_i \beta_{i+1} = \cup_{i+2p-2} \beta_i, R_{4p-2}(\alpha) = \alpha, R_{4p-2}(\beta) = \beta\).

These can be proven diagrammatically from relations 9 and 10. We demonstrate the proof for \(\alpha\), with \(\beta\) following similarly.
Hence $\alpha$ is rotation invariant. Continuing with this, we have:

and so we have the cupping relation.

### 4.9 Partial Traces

The partial trace of $\alpha$ and $\beta$ can be derived easily from the cupping and capping relations (relations 9 - 12), and shown to be zero. We demonstrate the case for alpha:

The partial trace of $\alpha_\beta$ and $\beta_\alpha$ is given in Figure 15. Note that the left partial trace follows from the right partial trace and the cupping and capping relations. We give the proof for $\beta_\alpha$, with the proof for $\alpha_\beta$ following similarly.

Consider $X^{\otimes 2p-2} \ominus \cap$. Its elements take the form $q^{-1} \rho_{i_1, \ldots, i_n, 2p-2} \otimes \nu_0 - \rho_{i_1, \ldots, i_n, 2p-2} \otimes \nu_1$. We want to apply $\left(\beta \otimes 1\right)$ to this. From Section 4.2, we had that given $x \in X_{k, 2p-1}$, $0 \leq k \leq p - 1$,

$$\beta(\alpha(x)) = e_x \frac{[2p-k-1]!}{([k]![p])} \times \left(F_n x_0, 2p-1\right)$$

We then have:

$$\beta(\alpha(\rho_{i_1, \ldots, i_n, 2p-2} \otimes \nu_0)) = q^{n(2p-1)-\frac{1}{2}(n^2-n)-(\sum_{j=1}^n i_j)} \lambda_{n, n+1} \frac{[2p-n-2]!}{[n+1][p]} \times$$

$$\times \left(F^{n+1} x_{0, 2p-2} \otimes \nu_0 + q^n \times 2p+2 [n+1](F^n x_{0, 2p-2} \otimes \nu_1)\right)$$

$$\beta(\alpha(\rho_{i_1, \ldots, i_n, 2p-2} \otimes \nu_0)) = q^{n(2p-1)-\frac{1}{2}(n^2-n)-(\sum_{j=1}^n i_j)} \frac{[2p-n-1]!}{[p]} \times$$

$$\times \left(F^{n} x_{0, 2p-2} \otimes \nu_0 + q^n [n](F^{n-1} x_{0, 2p-2} \otimes \nu_1)\right)$$

15
Note that as \( \rho_{i_1,...,i_n,2p-2} \otimes \nu_1 \in X_{n+1,2p-1} \), and \( \alpha \) is zero on \( X_{n,2p-1} \) for \( n \geq p \), we will have to treat the case \( n = p - 1 \) separately. For \( 0 \leq n \leq p - 2 \), we have:

\[
(\beta \alpha \otimes 1)(q^{-1}\rho_{i_1,...,i_n,2p-2} \otimes \nu_{10} - \rho_{i_1,...,i_n,2p-2} \otimes \nu_{01})
\]

\[
= q^{(n(2p-1)-\frac{1}{2}(n^2-n)-1-\sum_{j=1}^{n} i_j)} \left( \lambda_{n,n+1} \frac{(2p - n - 2)!}{[n + 1][p]} \right) \times \left( (F^{n+1}x_{0,2p-2}) \otimes \nu_{01} + q^{n-2p+2}[n + 1](F^n x_{0,2p-2}) \otimes \nu_{10} \right)
\]

\[
- q^{(n(2p-1)-\frac{1}{2}(n^2-n)-\sum_{j=1}^{n} i_j)} \left( \frac{(2p - n - 1)!}{[p]} \right) \left( (F^{n}x_{0,2p-2}) \otimes \nu_{01} + q^{n-2p+1}[n](F^{n-1}x_{0,2p-2}) \otimes \nu_{11} \right)
\]

Applying \( 1 \otimes 2^{p-2} \otimes \cup \), this simplifies to give zero. For the case \( n = p - 1 \), as \( \rho_{i_1,...,i_{p-1},2p-2} \otimes \nu_1 \in X_{p,2p-1} \), we have:

\[
(\beta \alpha \otimes 1)(q^{-1}\rho_{i_1,...,i_{p-1},2p-2} \otimes \nu_{10} - \rho_{i_1,...,i_{p-1},2p-2} \otimes \nu_{01})
\]

\[
= -q^{(p-1)(2p-1)-\frac{1}{2}(p-1)(p-2)-\sum_{j=1}^{p-1} i_j)} \left( \frac{(p-1)!}{[p]} \right) \left( (F^{p-1}x_{0,2p-2}) \otimes \nu_{01} + q^{-p}[p-1](F^{p-2}x_{0,2p-2}) \otimes \nu_{11} \right)
\]

Applying \( 1 \otimes 2^{p-2} \otimes \cup \) to this, we get:

\[
q^{(p-1)(2p-1)+1-\frac{1}{2}(p-1)(p-2)-\sum_{j=1}^{p-1} i_j)} ((p-1)!)^p F^{p-1}x_{0,2p-2}
\]

We now want to give an explicit formula for the following diagram:

\[
\begin{array}{ccc}
& f_{p-1} & \\
-\gamma & & \\
& f_{p-1} & \\
\end{array}
\]

Given \( \rho_{i_1,...,i_{m+1},2p-2} \), we can rewrite it as \( \rho_{i_1,...,i_{m},p-1} \otimes \rho_{i_{m+1}+1-p,...,i_{n}+1-p,p-1} \). Applying \( f_{p-1} \otimes 1 \otimes p^{-1} \) to this we get:

\[
q^{(m(p-1)-\frac{1}{2}(m^2-m)-\sum_{j=1}^{m} i_j)} (p-1)! \left( F^{m}x_{0,p-1} \otimes \rho_{i_{m+1}+1-p,...,i_{n}+1-p,p-1} \right)
\]

\[
= \sum_{k_1,...,k_m} \left( m(p-1)-\frac{1}{2}(m^2-m)-\sum_{j=1}^{m} k_j \right) \left( p-1 \right)! \rho_{k_1,...,k_{m-1}+1-p,\rho_{k_{m},p-1} \otimes \rho_{i_{m+1}+1-p,...,i_{n}+1-p,p-1}
\]

Given \( \cup(\nu_{01}) = \nu \), \( \cup(\nu_{10}) = -q \nu \), \( \cup(\nu_{00}) = \cup(\nu_{11}) = 0 \), applying cups repeatedly to this, we get zero if \( n \neq p - 1 \) or if \( \{k_1,...,k_m\} \cap \{2p-1-i_{m+1},...,2p-1-i_n\} \neq \emptyset \). If \( n = p - 1 \) and \( \{k_1,...,k_m\} \cap \{2p-1-i_{m+1},...,2p-1-i_n\} = \emptyset \), then we have:

\[
\sum_{k_1,...,k_m} (-1)^{p-1} q^{(m(p-1)-\frac{1}{2}(m^2-m)-\sum_{j=1}^{m} i_j)} (p-1)! \left( m! \right) \nu
\]

\[
= \sum_{k_1,...,k_m} (-1)^{p-1} q^{(p-1)-\frac{1}{2}(m^2-m)-\sum_{j=1}^{m} k_j)} (p-1)! \left( m! \right) \nu
\]
Note that for each choice of $k_1, ..., k_m$, there is a unique choice of $k_1, ..., k_n$ satisfying the above conditions, i.e. \( \{k_1, ..., k_m, 2p - 1 - i_{m+1}, ..., 2p - 1 - i_n\} = \{1, ..., p - 1\} \), and so we have that:

\[
\sum_{l=1}^{m} k_l = \frac{1}{2} (p^2 - p) - (2p - 1)(n - m) + \sum_{r=m+1}^{n} i_r
\]

Using this, we can simplify to get:

\[
\sum_{k_1, ..., k_m} (-1)^{p-1} q \left( \frac{p^2 - p - (2p - 1)(n - m)}{2} \right)^{\nu} = (-1)^{p-1} q \left( \frac{p^2 - p - (2p - 1)(n - m)}{2} \right)^{\nu}
\]

Given $\rho_{x_1, ..., x_n, z}$, let $\tilde{r}_1, ..., \tilde{r}_{z-n}$ be the positions of the zeros. As $\cap(\nu) = q^{-1} \nu_{10} - \nu_{01}$, we have that the z-fold cap is given by:

\[
\sum_{n=0}^{z} \left( \sum_{r_1, ..., r_n} (-1)^{z-n} q^{-n} \rho_{r_1, ..., r_n, z+1-\tilde{r}_{z-n}, ..., z+1-\tilde{r}_1, z} \right)
\]

Taking $z = p - 1$, this becomes:

\[
\sum_{n=0}^{p-1} \left( \sum_{r_1, ..., r_n} (-1)^{p-1-n} q^{-n} \rho_{r_1, ..., r_n, 2p-1-\tilde{r}_{p-1-n}, ..., 2p-1-\tilde{r}_1, 2p-2} \right)
\]

Applying $f_{p-1} \otimes 1^{p-1}$ to this we get:

\[
\sum_{n=0}^{p-1} \left( \sum_{r_1, ..., r_n} (-1)^{p-1-n} q^{n(p-2) - \frac{1}{2} (n^2 - n) - \left( \sum_{j=1}^{n} r_j \right)} \times \frac{([p - 1 - n]!) (n!)}{(p - 1)!!} \right) \times \frac{E^n x_{0, p-1}}{\rho_{p-1-n, ..., p-\tilde{r}_1, p-1}}
\]

As \( \sum_{j=1}^{n} r_j + \sum_{l=1}^{p-1-n} \tilde{r}_l = \frac{1}{2} (p^2 - p) \), this becomes:

\[
\sum_{n=0}^{p-1} \left( \sum_{r_1, ..., r_{p-1-n}} \sum_{s_1, ..., s_{n}} (-1)^{p-1-n} q^{n(p-1) - \frac{1}{2} (p^2 - p) + \left( \sum_{j=1}^{n} s_j \right) - \left( \sum_{k=1}^{p-1} t_k \right)} \times \frac{([p - 1 - n]!) (n!)}{(p - 1)!!} \right) \times \frac{E^n x_{0, p-1}}{\rho_{p-1-n, ..., p-\tilde{r}_1, p-1}}
\]

\[
= q^{1-p^2} \frac{(-1)^{p-1}}{(p - 1)!!} E^{p-1} x_{0, p-2}
\]

17
Where we have taken $t_1 := s_1, \ldots, t_n := s_n, t_{n+1} := 2p - 1 - \tilde{r}_{p-1-n}, \ldots, t_{p-1} := 2p - 1 - \tilde{r}_1$.

Combining this with the first part we get:

$$q \left(1 - p^2 - \frac{1}{2} (p^2 - p) - \left( \sum_{i=1}^{n} i \right) \right) \frac{(-1)^{2p-2}}{([p-1]!)} F^{p-1} x_{0,2p-2}$$

Multiplying by $-\gamma$, this becomes:

$$(1-p^2 - \frac{1}{2} (p^2 - p) - \left( \sum_{i=1}^{n} i \right)) \frac{(-1)^{2p-2}}{([p-1]!)} F^{p-1} x_{0,2p-2}$$

which is equal to the partial trace of $\beta \alpha$.

This map is also the second (non-identity) endomorphism on $P^+_1$. Details of this endomorphism for all $P^+_1$, as well as homomorphisms between indecomposable modules, will be discussed in a future paper \[11\].

4.10 Relations 15 and 16, $\sum_{i=0}^{4p-1} k_i R_{4p}^i (\alpha \otimes 1) = 0$, $\sum_{i=0}^{4p-1} k_i R_{4p}^i (\beta \otimes 1) = 0$.

Let $R_n$ denote the clockwise rotation tangle acting on $n$ points.

Figure 16: The rotation tangle $R_8$.

We want to show the relations $\sum_{i=0}^{4p-1} k_i R_{4p}^i (\alpha \otimes 1) = 0$, $\sum_{i=0}^{4p-1} k_i R_{4p}^i (\beta \otimes 1) = 0$. These in turn allow the proof of a large number of other relations, and simplification of diagrams containing $\alpha$ and $\beta$. The proof consists of two steps; first we show that the diagrams $\{R_{4p}^i \alpha\}$, $\{R_{4p}^i \beta\}$ are linearly dependent, so that the coefficients can be non-zero. We then give a general solution for the coefficients.

We demonstrate the proof for $\alpha$, with the proof for $\beta$ following similarly. Diagrammatically, $\sum_{i=0}^{4p-1} k_i R_{4p}^i (\alpha \otimes 1) = 0$ is given by Figure 12. From this, we see that there are $4p$ different diagrams, each of which acts on weight spaces by $X_{k,2p} \mapsto X_{k+p,2p}$. We want to show that the total number of maps acting as $X_{k,2p} \mapsto X_{k+p,2p}$ is less than $4p$. A list of module maps was given in Section 2, and from this we see that all module maps act as $X_{k,2p} \mapsto X_{k,2p}$ except for maps between $P_1^+$ and $P_{p-4}^-$. (As $X_p^-$ does not appear in the decomposition of $X^{\otimes 2p}$). For example, for $p = 3$, the maps not preserving weight spaces are:
Hence there are two maps acting as $X_{k, 2p} \mapsto X_{k + p, 2p}$, and two acting as $X_{k, 2p} \mapsto X_{k - p, 2p}$. Denote the multiplicity of $P_{1}$ in $X^\otimes 2p$ by $M$. From this, we see that the total number of maps acting as $X_{k, 2p} \mapsto X_{k + p, 2p}$ is $2M + 2$. By considering module decompositions, we find that $M_{i+1} = 2p - 1$. Hence the diagrams $\{ R_{i} \}$ are linearly dependent.

Consider applying $\cap \otimes 2p$ to $\sum_{i=0}^{4p-1} k_{i} R_{i} \otimes 1 = 0$. As capping off $\alpha$ gives zero, this reduces to $(k_{1} + \delta k_{4p} + k_{1}) \cap \otimes 2p - 1 = 0$, so $k_{1} + \delta k_{4p} + k_{1} = 0$. Repeating this at every position, we get the general condition $k_{i-1} + \delta k_{i} + k_{i+1} = 0$. Using this, we can rewrite the coefficients as:

$k_{i} = (-1)^{i} [i - 1] k_{1} + (-1)^{i} [i - 1] k_{2}, \quad k_{i+1} = (-1)^{i+1} k_{i}$

W denote $P_{\alpha} := \sum_{i=0}^{4p-1} k_{i} R_{i} (\alpha \otimes 1), P_{\beta} := \sum_{i=0}^{4p-1} k_{i} R_{i} (\beta \otimes 1)$. These generalize a large number of relations. For example, consider $\beta_{2} P_{\alpha} \beta_{2}$, with $k_{1} = 1, k_{2} = 0$. This gives:

Considering $\alpha_{1} \beta_{1} P_{\alpha_{1}}$ with $k_{1} = 1, k_{2} = 0$, gives $k_{i} = (-1)^{i} [i - 2]$ and:

whereas $\alpha_{1} \beta_{1} P_{\alpha_{1}}$ with $k_{1} = 0, k_{2} = 1$, gives $k_{i} = (-1)^{i} [i - 1]$ and:
$\gamma^{-1} P_\alpha \beta P_{\beta} = - k_3 \alpha - \ldots - k_{2p} \alpha$

$P_\alpha$ and $P_\beta$ can also be used to reduce compositions of $\alpha$ and $\beta$. For example, consider $\beta_3(P_{\alpha_1} \otimes 1)$ with $k_1 = 1$, $k_{2p-1} = 0$, which gives $k_2 = -\delta^{-1}[3]$, $k_i = (-1)^{i+1} \delta^{-1}[3][i-1] + (-1)^i[i-2]$ and:

Note that this can not be used to reduce diagrams of the form $\alpha_1 \beta_{p+1}$, $\beta_1 \alpha_{p+1}$, etc. These diagrams describe maps between copies of $X_p^+$ in $X^{\otimes (3p-1)}$.

Relations 15 and 16 can be taken as stating that at most $4p - 2$ of the diagrams appearing in the relations are linearly independent, depending on the choice of the remaining two diagrams. Given that the dimension $D_{2p} = C_{2p} + 12p - 6$, we can use this to state the following:

**Proposition 4.1.** $\text{End}_{\tilde{U}_q(sl_2)}(X^{\otimes 2p})$ has basis

$$\{TL_{2p}, \alpha_1, \alpha_2, \alpha_2 e_1 e_2, \ldots, \alpha_2 e_1 e_2 \ldots e_{2p-2}, e_1 \alpha_2, e_2 e_1 \alpha_2, \ldots, e_{2p-2} e_2 e_{2p-3} \ldots e_1 \alpha_2,$$

$$\beta_1, \beta_2, \beta_2 e_1 e_2, \ldots, \beta_2 e_1 e_2 \ldots e_{2p-2}, e_1 \beta_2, e_2 e_1 \beta_2, \ldots, e_{2p-2} e_2 e_{2p-3} \ldots e_1 \beta_2,$$

$$\alpha_1 \beta_1, \alpha_2 \beta_2, \alpha_2 \beta_2 e_1 e_2, \ldots, \alpha_2 \beta_2 e_1 e_2 \ldots e_{2p-2}, e_1 \alpha_2 \beta_2, e_2 e_1 \alpha_2 \beta_2, \ldots, e_{2p-2} e_2 e_{2p-3} \ldots e_1 \alpha_2 \beta_2\}$$

**Appendix A. Combinatorial Relations.**

There are a number of generalized relations for $\tilde{U}_q(sl_2)$ and its action on $X^{\otimes n}$, which we record here. The quantum group $\tilde{U}_q(sl_2)$ and its relations can be used to give the following generalized
conditions:

\[ \Delta^k(K) = K^\otimes k + 1 \] (A.1)

\[ \Delta^k(E) = \sum_{i=0}^{k} (1^\otimes i) \otimes E \otimes (K^\otimes (k-i)) \] (A.2)

\[ \Delta^k(F) = \sum_{i=0}^{k} ((K^{-1})^\otimes i) \otimes F \otimes (1^\otimes (k-i)) \] (A.3)

\[ EF^k = F^k E + \left( \frac{[k]}{q-q^{-1}} \right) (q^{1-k} F^{k-1}K - q^{k-1} F^{k-1}K^{-1}) \] (A.4)

\[ FE^k = E^k F + \left( \frac{[k]}{q-q^{-1}} \right) (q^{1-k} F^{k-1}K - q^{k-1} F^{k-1}K) \] (A.5)

\[ \Delta E^k = \sum_{i=0}^{k} \lambda_{i,k} E^i \otimes K^i E^{k-i} \] (A.6)

\[ \Delta F^k = \sum_{i=0}^{k} \lambda_{i,k} K^{-i} F^i \otimes F^{k-i} \] (A.7)

\[ \lambda_{i,k} = q^{(i^2-ik)} \frac{([k]!)}{([i]!)([k-i]!)} \] (A.8)

The \( \bar{U}_q(\mathfrak{sl}_2) \) action on the basis elements satisfies the following:

\[ E^n \rho_{i_1, \ldots, i_n, z} = q^{\left( n z - \frac{1}{2} (n^2 - n) - \sum_{j=1}^{n} i_j \right)} \frac{([n]!)}{([n]!)} x_{0,z} \] (A.9)

\[ F^{z-n} \rho_{i_1, \ldots, i_n, z} = q^{\left( n z - \frac{1}{2} (n^2 - n) - \sum_{j=1}^{n} i_j \right)} \frac{([z-n]!)}{([z-n]!)} x_{z,z} \] (A.10)

\[ F^k x_{0,z} = \sum_{1 \leq i_j \leq z} q^{\left( \frac{1}{2} (k^2 + k) - \sum_{j=1}^{k} i_j \right)} \frac{([k]!)}{([k]!)} \rho_{i_1, \ldots, i_k, z} \] (A.11)

\[ E^k x_{z,z} = \sum_{1 \leq i_j \leq z} q^{\left( \frac{1}{2} (z-k)(z-k+1) - \sum_{j=1}^{z-k+1} i_j \right)} \frac{([k]!)}{([k]!)} \rho_{i_1, \ldots, i_{k-1}, z} \] (A.12)

\[ E^k x_{z+1,z+1} = q \left( E^{k-1} x_{z,z} \right) \otimes \nu_0 + q^{-k} \left( E^k x_{z,z} \right) \otimes \nu_0 \] (A.13)

\[ E^k x_{0,z+1} = q \left( E^k x_{0,z} \right) \otimes \nu_0 + q^{k-z-1} \left( E^{k-1} x_{0,z} \right) \otimes \nu_0 \] (A.14)

\[ F^k x_{0,z+1} = q \left( F^k x_{0,z} \right) \otimes \nu_0 + q^{k-z-1} \left( F^{k-1} x_{0,z} \right) \otimes \nu_0 \] (A.15)

These come from considering all contributions to the coefficient as different orderings of the integers \( i_1, \ldots, i_n \), where each ordering describes the order in which the zeroes appeared. For the standard ordering with \( i_1 < i_2 < \ldots < i_n \), its contribution to the coefficient is just \( q^{-z+i_1} q^{-z+i_2} \ldots q^{-z+i_n} = q^{-(n z + \sum_{j=1}^{n} i_j)} \). Interchanging two integers in the ordering multiplies this by \( q^{\pm 2} \), and the coefficient comes from considering all possible permutations.

For integers \( 1 \leq i_1 < i_2 < \ldots < i_n \leq z \), we have:

\[ \xi_{n,z} := \sum_{1 \leq i_j \leq z} q^{-2(\sum_{j=1}^{n} i_j)} = q^{-n z - \frac{([z]!)}{([n]!)([z-n]!)}} \] (A.17)

\[ \xi_{n,z} = q^{-2z} \xi_{n-1,z-1} + \xi_{n,z-1} \] (A.18)

where the recurrence relation comes from considering the two cases in \( \xi_{n,z} \), when \( i_n = z \) and when \( i_n \neq z \).
