# AN EXPLICIT ERROR TERM IN THEOREM A 

NICOLAS BERGERON AND CARLOS MATHEUS

## 1. Introduction

Recall that Theorem A above ensures the existence of a constant $\delta>0$ such that the number $N(V)$ of sLag fibrations with volume $\leq V$ in a generic twistor family of K3 surfaces is

$$
\begin{equation*}
N(V)=C \cdot V^{20}+O\left(V^{20-\delta}\right) \tag{1.1}
\end{equation*}
$$

where $C>0$ is the ratio of volumes of two concrete homogenous spaces.
The goal of this appendix is to prove that $\delta$ can be taken to be $\left(\frac{4}{697633}\right)^{-}$:
Theorem 1.1. In the same setting as Theorem $A$ above, one actually has

$$
N(V)=C \cdot V^{20}+O_{\varepsilon}\left(V^{\frac{13952656}{697633}+\varepsilon}\right)
$$

for all $\varepsilon>0$.

## 2. Reduction of Theorem 1.1 to dynamics in homogenous spaces

Filip derived his counting formula (1.1) from certain equidistribution results. More precisely, let $\Lambda_{\mathbb{Z}}$ be a lattice isomorphic to $H^{2}(S, \mathbb{Z})$, where $S$ is a K 3 surface. Fix $P \subset \Lambda_{\mathbb{R}}$ a positive-definite 3-plane. Denote by $\Lambda_{\mathbb{Z}}^{0}$ the set of primitive isotropic integral vectors and fix $e \in \Lambda_{\mathbb{Z}}^{0}$. For each $v \in \Lambda_{\mathbb{R}}=P \oplus P^{\perp}$, let $v:=(v)_{P} \oplus(v)_{P^{\perp}}$ with $(v)_{P} \in P$ and $(v)_{P \perp} \in P^{\perp}$. Consider the orthogonal group $G:=O\left(\Lambda_{\mathbb{R}}\right)$, the lattice $\Gamma:=O\left(\Lambda_{\mathbb{Z}}\right)$ and the maximal compact subgroup $K:=O(P) \times O\left(P^{\perp}\right)$ of $G$, and, for a fixed $e \in \Lambda_{\mathbb{Z}}^{0}$, denote by $H_{e}:=\operatorname{Stab}_{G}(e)$ and $\Gamma_{e}=\operatorname{Stab}_{\Gamma}(e)$.

The volumes of the locally homogenous spaces $X:=\Gamma \backslash G$ and $Y:=\Gamma_{e} \backslash H_{e}$ are finite. As it is observed in [3, pp. 4], the constants $C>0$ and $\delta>0$ in (1.1) are the constant described in [3, Theorem 3.1.3]. In particular,

$$
C=\frac{\operatorname{Vol} Y}{20 \cdot \operatorname{Vol} X}
$$

The constant $\delta>0$ is related to the dynamics of a certain one-parameter subgroup $a_{t}$ of $G \simeq S O(3,19)(\mathbb{R})$. More concretely, given $e$ and $P$ as above, let $e^{\prime}$ be the isotropic vector given by

$$
e^{\prime}:=(e)_{P} \oplus-(e)_{P^{\perp}} \quad \text { where } \quad e:=(e)_{P} \oplus(e)_{P^{\perp}}
$$

In this context, we denote by $\left\{a_{t}\right\}_{t \in \mathbb{R}} \subset G$ the one-parameter subgroup defined as

$$
a_{t} \cdot e=\exp (-t) \cdot e, \quad a_{t} \cdot e^{\prime}=\exp (t) \cdot e^{\prime},\left.\quad a_{t}\right|_{\left(e \oplus e^{\prime}\right)^{\perp}}=\mathrm{id} .
$$

Date: January 18, 2022.

It is explained in [3, Subsection 3.6.9] that ${ }^{1}$ the quantity $\delta$ in (1.1) is

$$
\begin{equation*}
\delta=\frac{\delta_{0}}{d_{l_{0}}+1} \tag{2.1}
\end{equation*}
$$

where $\left(d_{l}\right)_{l \in \mathbb{N}}$ are the exponents in [3] Proposition 3.5.10 (ii)], and $\delta_{0}>0, l_{0} \in \mathbb{N}$ are the constants in the following equidistribution statement in [3, Theorem 4.3.1]:

$$
\begin{equation*}
\int_{Y a_{t}} w d \mu_{Y a_{t}}=\frac{\operatorname{Vol} Y}{\operatorname{Vol} X} \int_{X} w d \mu_{X}+O\left(\|w\|_{l} e^{-\delta_{0} t}\right) \tag{2.2}
\end{equation*}
$$

for all Sobolev scales $l \geq l_{0}$ (see [3, §4.2.2] for the definition of the Sobolev norms in this context).

A quick inspection of the proof of [3, Proposition 3.5.10 (ii)] (related to the thickening of $K$ ) reveals that the exponents $d_{l}$ depend linearly on $l$. In fact, the constant $c_{1}(l)$ in [3, Equation (3.5.15)] gives the power of $\varepsilon$ associated to the volumes of $\varepsilon$-balls at the origin of $\mathfrak{p}_{\mathfrak{m}} \times \mathfrak{n}^{+} \times \mathfrak{a}$, that is, $c_{1}(l)=\operatorname{dim}(G)-\operatorname{dim}(K)$ (and, hence, $c_{1}(l)$ independs of $l$ ). Since the $l$-th derivative of $\chi_{\varepsilon}$ is bounded by a multiple of $\varepsilon^{-c_{1}(l)-l}$ and it is supported in a $\varepsilon$-neighborhood of $K$, the $l$-Sobolev norm of $\chi_{\varepsilon}$ is bounded by a multiple of $\varepsilon^{-l-c_{1}(l) / 2}$. Therefore,

$$
\begin{equation*}
d_{l}:=l+\frac{\operatorname{dim}(G)-\operatorname{dim}(K)}{2} \tag{2.3}
\end{equation*}
$$

## 3. EQUidistribution and rates of mixing

The constants $\delta_{0}>0$ and $l_{0} \in \mathbb{N}$ in (2.2) are described in [3, pp. 36] and they are related to the geometry of $Y \subset X$ and the rate of mixing of $a_{t}$.
3.1. Injectivity radius. We denote by $\operatorname{inj}(x)$ the local injectivity radius at a point $x \in X$ and we let $Y_{\varepsilon}:=\{y \in Y: \operatorname{inj}(y) \geq \varepsilon\}$. By [3, Proposition 4.1.3], we know that the arguments of [1, Lemma 11.2] provide a constant $p>0$ such that $\mu_{Y}\left(Y \backslash Y_{\varepsilon}\right)=O\left(\varepsilon^{p}\right)$. Actually, a close inspection of these arguments (of integration over Siegel sets) reveal that $p=1$ in our specific setting (of $G \simeq$ $S O(3,19)(\mathbb{R}))$ :

$$
\begin{equation*}
\mu_{Y}\left(Y \backslash Y_{\varepsilon}\right)=O(\varepsilon) \tag{3.1}
\end{equation*}
$$

3.2. Thickening of $Y$. Let us fix some parameter $0<p^{\prime}<1$ (very close to one in practice) and consider [3, Proposition 4.1.6] (of thickening of $Y$ ) where it is constructed a family of smooth versions $\phi_{\varepsilon}$ of the characteristic function of $Y$. As it turns out, $\phi_{\varepsilon}$ is the product of two functions: $\tau_{\varepsilon}$ is a bump function supported ${ }^{2}$ on $Y_{\varepsilon^{p^{\prime}}}$ and $\rho_{\varepsilon}$ is a bump function supported on the $\varepsilon$-neighborhood of the identity in a certain Lie group $N^{\prime}$ of dimension $\operatorname{dim}\left(N^{\prime}\right)=\operatorname{dim}(X)-\operatorname{dim}(Y)$.

[^0]The bump function $\rho_{\varepsilon}$ is obtained by rescaling of a fixed smooth bump function on $N^{\prime}$, so that its $l$-th Sobolev norm satisfies $\left\|\rho_{\varepsilon}\right\|_{l}=O\left(\varepsilon^{-l-\frac{\operatorname{dim}(X)-\operatorname{dim}(Y)}{2}}\right)$.

The function $\tau_{\varepsilon}$ is

$$
\tau_{\varepsilon}=\frac{\sum_{y_{j} \in \mathcal{F}} \beta_{y_{j}, \varepsilon}}{\sum_{y_{i} \in \mathcal{G}} \beta_{y_{i}, \varepsilon}}:=\frac{\sum_{y_{j} \in \mathcal{F}} \beta_{y_{j}, \varepsilon}}{\beta_{\mathcal{G}, \varepsilon}}
$$

where $\left\{y_{k}\right\} \subset Y_{\varepsilon^{p^{\prime}}}$ is a maximal collection of points such that the balls $B\left(y_{k}, \varepsilon^{3}\right) \subset$ $Y$ are mutually disjoint, $\mathcal{F}=\left\{y_{k}\right\} \cap Y_{4 \varepsilon^{p^{\prime}}}, \mathcal{G}=\left\{y_{k}\right\} \cap Y_{2 \varepsilon p^{\prime}}$, and the functions $\beta_{., \varepsilon}$ are translates of a bump function $\beta_{\varepsilon}$ whose $l$-th Sobolev norm is $\left\|\beta_{\varepsilon}\right\|_{l}=$ $O\left(\varepsilon^{-l+\frac{\operatorname{dim}(Y)}{2}}\right)$.

On one hand, since a ball $B$ of radius $\varepsilon$ at a point of $Y_{\varepsilon^{p^{\prime}}}$ has volume $O\left(\varepsilon^{\operatorname{dim}(Y)}\right)$, the cardinality of $\mathcal{G} \cap B$ is $O\left(\varepsilon^{-2 \operatorname{dim}(Y)}\right)$, the arguments in [1, pp. 1928] imply that the $L^{\infty}$-norm of the first $l$ derivatives of $1 / \beta_{\mathcal{G}, \varepsilon}$ is $O\left(\varepsilon^{-l-2 \operatorname{dim}(Y)}\right)$. On the other hand, the cardinality of $\mathcal{F}$ is $O\left(\varepsilon^{-3 \operatorname{dim}(Y)}\right)$ and $\left\|\beta_{y_{j}, \varepsilon}\right\|_{l}=\left\|\beta_{\varepsilon}\right\|_{l}$. It follows that

$$
\left\|\tau_{\varepsilon}\right\|_{l}=O\left(\varepsilon^{-l-\frac{9 \operatorname{dim}(Y)}{2}}\right)
$$

By inserting these facts into the definition of $\phi_{\varepsilon}$ in [3, Equation (4.1.7)], we deduce from Sobolev's lemma that

$$
\begin{equation*}
\left\|\phi_{\varepsilon}\right\|_{l}=O\left(\varepsilon^{-2 l-4 \operatorname{dim}(Y)-\frac{\operatorname{dim}(X)}{2}}\right) \tag{3.2}
\end{equation*}
$$

for all $l>\operatorname{dim}(X) / 2$, that is, the constant $C_{l}$ in [3, Proposition 4.1.6 (iii)] is

$$
C_{l}:=2 l+4 \operatorname{dim}(Y)+\frac{\operatorname{dim}(X)}{2}
$$

For later use, notice that $\phi_{\varepsilon}$ verifies $\int_{X} \phi_{\varepsilon} d \mu_{X}=\operatorname{Vol} Y+O\left(\operatorname{Vol}\left(Y \backslash Y_{\varepsilon^{p^{\prime}}}\right)\right)$. By combining this estimate with (3.1), we get

$$
\begin{equation*}
\int_{X} \phi_{\varepsilon} d \mu_{X}=\operatorname{Vol} Y+O\left(\varepsilon^{p^{\prime}}\right) \tag{3.3}
\end{equation*}
$$

3.3. Wavefront lemma. The proof of Lemma 4.1.10 in [3] says that

$$
\int_{X} w \cdot\left(\phi_{\varepsilon} \cdot a_{t}\right) d \mu_{X}=\int_{Y} w\left(y a_{t}\right) d \mu_{Y}(y)+O(\varepsilon \operatorname{Lip}(w))+O\left(\varepsilon^{p p^{\prime}}\|w\|_{L^{\infty}}\right)
$$

where $p>0$ is the parameter such that $\mu_{Y}\left(Y \backslash Y_{\varepsilon^{p^{\prime}}}\right)=O\left(\varepsilon^{p p^{\prime}}\right)$. Therefore, we deduce from (3.1) and Sobolev's lemma that

$$
\begin{equation*}
\int_{X} w \cdot\left(\phi_{\varepsilon} \cdot a_{t}\right) d \mu_{X}=\int_{Y} w\left(y a_{t}\right) d \mu_{Y}(y)+O\left(\varepsilon^{p^{\prime}}\|w\|_{l}\right) \tag{3.4}
\end{equation*}
$$

for all $l>1+\operatorname{dim}(X) / 2$.
3.4. Reduction of equidistribution to rate of mixing. By following [3, pp. 36], let us compute the constants $\delta_{0}>0$ and $l_{0} \in \mathbb{N}$ in 2.2 in terms of the following quantitative mixing statement: there exists $\delta_{0}^{\prime}>0$ such that

$$
\begin{equation*}
\left|\int_{X} \alpha \cdot(\beta \cdot g) d \mu-\left(\int_{X} \alpha d \mu\right)\left(\int_{X} \beta d \mu\right)\right|=O\left(\|\alpha\|_{l}\|\beta\|_{l}\|g\|^{-\delta_{0}^{\prime}}\right) \tag{3.5}
\end{equation*}
$$

for all $l \geq l_{0}^{\prime}$. (Here, $\mu=\mu_{X} / \operatorname{Vol} X$ is the normalized Haar measure.)
For this sake, we observe that (3.5) says that

$$
\int_{X} w \cdot\left(\phi_{\varepsilon} \cdot a_{t}\right) d \mu_{X}=\frac{1}{\operatorname{Vol} X}\left(\int_{X} w d \mu_{X}\right)\left(\int_{X} \phi_{\varepsilon} d \mu_{X}\right)+O\left(\|w\|_{l}\left\|\phi_{\varepsilon}\right\|_{l} e^{-t \delta_{0}^{\prime}}\right)
$$

for $l \geq l_{0}^{\prime}$.
By (3.2) and (3.3), the previous estimate implies

$$
\int_{X} w \cdot\left(\phi_{\varepsilon} \cdot a_{t}\right) d \mu_{X}=\frac{\operatorname{Vol} Y}{\operatorname{Vol} X}\left(\int_{X} w d \mu_{X}\right)+O\left(\varepsilon^{p^{\prime}}\|w\|_{l}\right)+O\left(\|w\|_{l} \varepsilon^{-C_{l}} e^{-t \delta_{0}^{\prime}}\right)
$$

for all $l \geq \max \left\{l_{0}^{\prime},\lfloor\operatorname{dim}(X) / 2\rfloor+1\right\}$.
By plugging (3.4) into the estimate above, we conclude that

$$
\int_{Y a_{t}} w d \mu_{Y a_{t}}=\frac{\operatorname{Vol} Y}{\operatorname{Vol} X}\left(\int_{X} w d \mu_{X}\right)+O\left(\varepsilon^{p^{\prime}}\|w\|_{l}\right)+O\left(\|w\|_{l} \varepsilon^{-C_{l}} e^{-t \delta_{0}^{\prime}}\right)
$$

for all $l \geq l_{0}:=\max \left\{l_{0}^{\prime},\lfloor\operatorname{dim}(X) / 2\rfloor+2\right\}$.
By taking $\varepsilon:=e^{-\delta_{0}^{\prime \prime} t}$ and by optimizing $3^{3}$ the value of $\delta_{0}^{\prime \prime}$, we obtain that

$$
\int_{Y a_{t}} w d \mu_{Y a_{t}}=\frac{\operatorname{Vol} Y}{\operatorname{Vol} X}\left(\int_{X} w d \mu_{X}\right)+O\left(\|w\|_{l_{0}} e^{-t \delta_{0}}\right)
$$

for $l_{0}:=\max \left\{l_{0}^{\prime},\lfloor\operatorname{dim}(X) / 2\rfloor+2\right\}$ and $\delta_{0}:=\frac{p^{\prime}}{p^{\prime}+C_{l_{0}}} \delta_{0}^{\prime}$.
Since $0<p^{\prime}<1$ is an arbitrary parameter, we deduce that (2.2) holds for $l_{0}:=\max \left\{l_{0}^{\prime},\lfloor\operatorname{dim}(X) / 2\rfloor+2\right\}$ and any choice of

$$
\begin{equation*}
0<\delta_{0}<\frac{\delta_{0}^{\prime}}{1+2 l_{0}+4 \operatorname{dim}(Y)+\frac{\operatorname{dim}(X)}{2}} \tag{3.6}
\end{equation*}
$$

## 4. RATES OF MIXING AND REPRESENTATION THEORY

Definition 4.1. 1. A unitary representation $\pi$ of $G$ in a (separable) Hilbert space $\mathcal{H}_{\pi}$ is a morphism $G \rightarrow \mathrm{U}\left(\mathcal{H}_{\pi}\right)$ such that for any $v \in \mathcal{H}_{\pi}$ the map $G \rightarrow \mathcal{H}_{\pi}$; $g \mapsto \pi(g) v$ is continuous. If this map is smooth one says that $v$ is a $C^{\infty}$-vector of $\pi$. We denote by $\mathcal{H}_{\pi}^{\infty}$ the set of $C^{\infty}$-vectors of $\pi$.
2. Given two vectors $v, w \in \mathcal{H}_{\pi}$, we define the matrix coefficient $c_{v, w}: G \rightarrow \mathbb{C}$ of $\pi$ as the continuous map $g \mapsto\langle\pi(g) v, w\rangle$. The coefficient $c_{v, w}$ is said to be $K$-finite if both the vector spaces generated by $\pi(K) \cdot v$ and $\pi(K) \cdot w$ are finite dimensional.
3. Let $p(\pi)$ be the infimum of the set of real numbers $p \geq 2$ such that all $K$-finite matrix coefficients of $\pi$ are in $L^{p}(G)$.

[^1]4. Say that a unitary representation $\sigma$ of $G$ is weakly contained in $\pi$ if any matrix coefficient of $\sigma$ can be obtained as the limit, with respect to the topology of uniform convergence on compact subsets, of a sequence of matrix coefficients of $\pi$.

Given an element $g=n a k \in G$, we write $a=e^{H(g)}$. The Harish-Chandra function is $\Xi=\Xi_{G}: G \rightarrow \mathbb{R}$ defined by

$$
\Xi(g)=\int_{K} e^{-\rho\left(H\left(k g^{-1}\right)\right)} d k
$$

where $\rho$ is half the sum of the positive restricted roots counting multiplicities. The Harish-Chandra function decreases exponentially fast along $A^{+}$; modulo a polynomial factor of a logarithmic argument, it decreases like $e^{-\rho(H)}$.

Let $d=\operatorname{dim}(K)$ be the dimension of $K$ and fix a basis $\mathcal{B}$ of the Lie algebra $\mathfrak{k}$ of $K$. Given a smooth vector $v \in \mathcal{F}_{\pi}^{\infty}$ we set

$$
S(v)=\sum_{\operatorname{ord}(D) \leq\lfloor d / 2\rfloor+1}\|\pi(D) v\|,
$$

where $D$ varies among all monomials in elements of $\mathcal{B}$ of degree $\leq\lfloor d / 2\rfloor+1$ and, if $X_{1}, \ldots, X_{r}$ are elements of $\mathcal{B}$, we have $\pi\left(X_{1} \cdots X_{r}\right)=\pi\left(X_{1}\right) \cdots \pi\left(X_{r}\right)$ and each $\pi\left(X_{i}\right)$ acts by derivation.

Proposition 4.2. For all positive $\varepsilon$ and $k \in \mathbb{N}^{*}$, there exists a constant $C=C(\varepsilon, k)$ such that if $\pi$ is a unitary representation of $G$ with $p(\pi) \leq 2 k$, then for all $v, w \in$ $\mathcal{H}_{\pi}^{\infty}$ and for all positive $t$ we have:

$$
\begin{equation*}
\left|\left\langle\pi\left(a_{t}\right) v, w\right\rangle\right| \leq C S(v) S(w) e^{-(p / k-\varepsilon) t} \tag{4.1}
\end{equation*}
$$

where $p=\rho(H)$ and $H$ is the infinitesimal generator of the one-parameter subgroup $\left(a_{t}\right)$.
Proof. Up to replacing $\pi$ by the tensor product $\pi^{\otimes k}$ we may suppose that $k=1$; see [2, p. 108]. It then follows from [2, Theorem 1] that $\pi$ is weakly contained in the (right) regular representation $L^{2}(G)$. We are then reduced to prove the proposition in the case where $\pi$ is the regular representation of $G$ (and $k=1$ ); see the proof of [2, Theorem 2] for more details on this last reduction.

Now consider $v$ and $w$ in $L^{2}(G) \cap C^{\infty}(G)$. The functions

$$
\varphi: x \mapsto \sup _{k \in K}|v(x k)| \text { and } \psi: x \mapsto \sup _{k \in K}|w(x k)|
$$

are both positive and $K$-invariant, and we have:

$$
\left|\left\langle\pi\left(a_{t}\right) v, w\right\rangle_{L^{2}(G)}\right| \leq \int_{G} \varphi\left(x a_{t}\right) \psi(x) d x=\left|\left\langle\pi\left(a_{t}\right) \varphi, \psi\right\rangle_{L^{2}(G)}\right| .
$$

Now the Sobolev lemma (see [5], Proposition 2.6]) implies that the $L^{\infty}$ norms of $\varphi$ and $\psi$ can be estimated in terms of their Sobolev norms along $K$. More precisely: there exists a constant $c$ such that the for all $x \in G$,

$$
\varphi(x)^{2}=\sup _{k \in K}|v(x k)|^{2} \leq c \sum_{\operatorname{ord}(D) \leq\lfloor d / 2\rfloor+1}\|(\rho(D) v)(x \cdot)\|_{L^{2}(K)} .
$$

Integrating over $G$ (here we assume for simplicity that the measure of $K$ is 1 ) one concludes that $\|\varphi\|_{L^{2}(G)} \leq \sqrt{c} S(v)$ and similarly for $\psi$. It remains to prove that there exists a constant $d_{\varepsilon}$ such that if $\varphi, \psi \in L^{2}(G)$ are two $K$-invariant, positive functions of norm 1 , then

$$
\left|\left\langle\pi\left(a_{t}\right) \varphi, \psi\right\rangle\right| \leq d_{\varepsilon} e^{-(p / k+\varepsilon) t} .
$$

First it follows from the computations of [2, pp. 106-107] that

$$
\begin{aligned}
|\langle\pi(g) \varphi, \psi\rangle| & =\int_{K}\left(\int_{N A} \varphi(n a) \psi\left(n a k g^{-1}\right) e^{2 \rho(\log a)} d n d a\right) d k \\
& \leq\|\varphi\|_{L^{2}(G)} \int_{K}\left(\int_{N A} \psi\left(n a H\left(k g^{-1}\right)\right)^{2} e^{2 \rho(\log a)} d n d a\right)^{1 / 2} d k \\
& =\|\varphi\|_{L^{2}(G)} \cdot\|\psi\|_{L^{2}(G)} \int_{K} e^{-\rho\left(H\left(k g^{-1}\right)\right)} d k=\|\varphi\|_{L^{2}(G)} \cdot\|\psi\|_{L^{2}(G)} \Xi(g) .
\end{aligned}
$$

Now recall that, up to "polynomial factors of logarithmic arguments", the function $\Xi\left(a_{t}\right)$ decreases like $e^{-t \rho(H)}=e^{-p t}$. The proposition follows.

We shall apply this proposition to the (quasi-)regular representation $\pi$ of $G$ in the subspace $L_{0}^{2}(\Gamma \backslash G)$ of $L^{2}(\Gamma \backslash G)$ that is orthogonal to the space of constant functions. It follows from [4] that $p(\pi)=20$. Proposition 4.2 therefore applies with $k=10$. Note that in our case $p=10$.

Now let $\alpha$ and $\beta$ be two smooth functions in $L^{2}(X)$ then

$$
\alpha_{0}:=\alpha-\int_{X} \alpha d \mu \text { and } \beta_{0}:=\beta-\int_{X} \beta d \mu \in L_{0}^{2}(X)
$$

and we have:

$$
\left\langle\pi(g) \alpha_{0}, \beta_{0}\right\rangle_{L_{0}^{2}(X)}=\int_{X} \alpha \cdot(\beta \cdot g) d \mu-\left(\int_{X} \alpha d \mu\right)\left(\int_{X} \beta d \mu\right) .
$$

From Proposition 4.2 and the fact that $S(\alpha) \leq\|\alpha\|_{\lfloor d / 2\rfloor+1}$ we conclude that

$$
\left|\int_{X} \alpha \cdot\left(\beta \cdot a_{t}\right) d \mu-\left(\int_{X} \alpha d \mu\right)\left(\int_{X} \beta d \mu\right)\right|=O\left(\|\alpha\|_{l}\|\beta\|_{l} e^{-t \delta_{0}^{\prime}}\right)
$$

for any $l \geq l_{0}^{\prime}:=\lfloor\operatorname{dim}(K) / 2\rfloor+1$ and any $\delta_{0}^{\prime}<1$.

## 5. END OF PROOF OF ThEOREM 1.1

The explicit value of $\delta$ announced in Theorem 1.1 can be easily derived from the discussion above. Indeed, we just saw in Section 4 that $\delta_{0}^{\prime}=1-$ and $l_{0}^{\prime}=$ $\lfloor\operatorname{dim}(K) / 2\rfloor+1$. Because $174=\operatorname{dim}(K)<\operatorname{dim}(X)=231$ and $\operatorname{dim}(Y)=210$, we deduce from (3.6) that $l_{0}=\lfloor\operatorname{dim}(X) / 2\rfloor+2=117$ and

$$
\delta_{0}=\left(\frac{1}{1+2 \times 117+4 \times 210+\frac{231}{2}}\right)^{-}=\left(\frac{2}{2381}\right)^{-}
$$

Finally, by inserting these informations into (2.3) and (2.1), we conclude that

$$
\begin{gathered}
\delta=\frac{\delta_{0}}{l_{0}+\frac{57}{2}+1}=\left(\frac{4}{697633}\right)^{-} \approx\left(5.7336737224 \cdots \times 10^{-6}\right)^{-} . \\

[^0]:    ${ }^{1}$ Indeed, [3] pp. 29] says that the optimal choice of $\delta$ occurs precisely when the terms $\varepsilon e^{20 T}=$ $e^{(20-\delta) T}$ and $\varepsilon^{-d_{l_{0}}} e^{\left(20-\delta_{0}\right) T}=e^{\left(20-\delta_{0}+\delta d_{l_{0}}\right) T}$ have the same order in $T$.
    ${ }^{2}$ In fact, Filip sets $p^{\prime}=1 / 2$ for his construction of $\tau_{\varepsilon}$, but any value of $0<p^{\prime}<1$ can be taken here: indeed, the construction of $\tau_{\varepsilon}$ can be made as soon as the local product structure statement [3] Proposition 4.1.5] holds (and this is the case for any choice of $0<p^{\prime}<1$ because $\varepsilon^{p^{\prime}} \gg 2 \varepsilon$ for all sufficiently small $\varepsilon>0$ ).

[^1]:    ${ }^{3}$ I.e., we choose $\delta_{0}^{\prime \prime}>0$ so that $\varepsilon^{p^{\prime}}=\varepsilon^{-C_{l_{0}}} e^{-t \delta_{0}^{\prime}}$.
