NOTE ON THE DECOMPOSITION OF STATES

DONGHOON HYEON AND JAEKWANG KIM

Abstract. We derive a sharp decomposition formula for the state polytope of the Hilbert point and the Hilbert-Mumford index of reducible varieties by using the decomposition of characters and basic convex geometry. This proof captures the essence of the decomposition of the state polytopes in general, and considerably simplifies an earlier proof by the authors which uses a careful analysis of initial ideals of reducible varieties.

1. Introduction & Preliminaries

In this article, we take a new look at the decomposition formula for state polytopes [HK] from a more general point of view. We shall work over an algebraically closed field $k$ of characteristic zero. Let $G$ be a linear algebraic group and $R$ be a maximal torus of it. Let $W$ be a rational representation of $G$ and $w \in W$ be a point. Recall that the state $\Xi_w(R)$ of $w$ with respect to $R$ is the set of the characters $\chi \in X(R)$ such that $w \chi \neq 0$. Since $w = \sum \chi \omega \chi \neq 0$, we have $\Xi_w(R) = \Xi_{cw}(R)$ for any nonzero $c \in k$. Hence we may define the state $\Xi_p(R)$ of $p \in \mathbb{P}(W)$ to be $\Xi_w(R)$ for any affine point $w \in W$ over $p$. (We conflate a vector space $W$ with the affine scheme $\text{Spec Sym}(W^*)$.)

We shall be concerned with the states of Hilbert points of homogeneous ideals. Let $S = k[x_0, \ldots, x_n]$ and let $P(u)$ be a rational polynomial in one variable $u$ and $Q(u) = \binom{\text{dim} + m}{m} - P(u)$. If $m$ is at least the Gotzmann number of $P(u)$, then for any saturated homogeneous polynomial $I \subset k[x_0, \ldots, x_n]$ whose Hilbert polynomial is $P$, the $m$th Hilbert point $[I]_m$ of $I$ is well defined as a $Q(m)$-dimensional subspace of the degree $m$ piece $S_m$:

$$[I]_m : [I_m \hookrightarrow S_m] \in \text{Gr} Q(m) S_m \hookrightarrow \mathbb{P} \left( \bigwedge^{Q(m)} S_m \right).$$

The dual $m$th Hilbert point $[I]_m^*$ is defined by

$$[I]_m^* : [S_m \twoheadrightarrow S_m/I_m] \in \text{Gr} P(m) S_m \hookrightarrow \mathbb{P} \left( \bigwedge^{P(m)} S_m \right).$$

The collection of $m$th Hilbert points form a closed subscheme $\text{Hilb}_P \mathbb{P}(V)$, called the Hilbert scheme, of the Grassmannian. Working out the geometric invariant theory

(GIT) of suitable Hilbert schemes give rise to various moduli spaces \[\text{Mum62}\], and our main motivation for the study in this article is the construction of the moduli of curves. The link between GIT and the study of state polytopes is given by the following fundamental observation (numerical criterion): If \(G\) is reductive and \(V\) is a rational representation, \(v \in V\) is GIT unstable if and only if there is a torus \(R\) of \(G\) such that the convex hull of \(\Xi_v(R)\) does not contain the trivial character.

The monomial basis of \(\bigwedge^{Q(m)} S_m\) consists of \(x^\alpha := x^{\alpha(1)} \wedge \cdots \wedge x^{\alpha(Q(m))}\), the wedge product of \(Q(m)\) degree \(m\) monomials \(x^{\alpha(i)}\)'s. The basis members are also the \(R\)-weight vectors of \(\bigwedge^{Q(m)} S_m\), where \(R\) is the maximal torus of \(G = GL(S_1)\) diagonalized by \(x_0, \ldots, x_n\). Indeed, let \(\chi_i\) be the character of \(R\) determined by \(t \cdot x_i = \chi_i(t) x_i\). Then by letting \(t_i\) denote \(\chi_i(t)\) and using the usual multivector notation \(t^\gamma = \prod_{i=0}^n t_i^{x_i}\), \(t \in T, \gamma \in \mathbb{Z}^{n+1}\), we have \(tx^\alpha = t^{\sum_{i=1}^{Q(m)} \alpha(i)} x^\alpha\), which means precisely that \(\bigwedge^{Q(m)} S_m\) is a monomial ideal. We let \(\alpha\) denote the set of states by \(\Xi_{|I_m}(R)\) and its convex hull by \(\mathcal{P}_m(I)\). We call \(\mathcal{P}_m(I)\) the \(m\)th state polytope of \(I\), following \[\text{BMS88}\].

For any fixed sufficiently large \(m\), Bayer and Morrison proved that

**Theorem 1.1.** \[\text{BMS88}\] Theorem 3.1] There is a canonical bijection between the vertices of \(\mathcal{P}_m(I)\) and the initial ideals in \(\prec I\) as \(\prec\) runs through all term orders on \(k[x_0, x_1, \ldots, x_n]\).

Using the Bayer-Morrison theorem and basic properties of monomial orders and initial ideals, decomposition formulae for initial ideals, state polytopes, and Hilbert-Mumford indices were achieved in \[\text{HK}\]:

**Theorem 1.2.** \[\text{HK}\] Let \(X\) be a chain of projective varieties \(X_1, \ldots, X_\ell\) defined by a saturated homogeneous ideal \(I_X = \cap I_{X_i}\), i.e. \(X = \cup_{i=1}^\ell X_i\) and \(X_i\) meets \(X_j\) when and only when \(|i - j| = 1\). Suppose that there is a homogeneous coordinate system \(x_0, x_1, \ldots, x_n\) and a sequence \(n_0 = 0 < n_1 < \cdots < n_\ell = n\) such that

\[
X_i \subseteq \{x_0 = \cdots = x_{n_i-1} = 0, x_{n_i+1} = x_{n_i+2} = \cdots = x_n = 0\}.
\]

Then the state polytope of \(X\) is given by the following decomposition formula

\[
\mathcal{P}_m(I_X) = \sum_{i=1}^\ell \mathcal{P}_m(I_{X_i} \cap k[x_{n_{i-1}}, \ldots, x_n]) + \sum_{i=1}^{\ell-1} \mathcal{P}_m(I_{T_i} \cap k[x_{n_{i-1}}, \ldots, x_n])
\]

where \(T_i = \langle x_{n_{i-2}}, \ldots, x_{n_{i-1}-1}, x_{n_{i+1}}, \ldots, x_n \rangle\) for \(2 \leq i \leq \ell - 1\), and \(T_1 = \langle x_{n_0}, x_{n_1+1}, \ldots, x_n \rangle\) and \(T_\ell = \langle x_{n_{\ell-2}}, x_{n_{\ell-2}+1}, \ldots, x_{n_{\ell-1}-1} \rangle\).

Here, \(\mathcal{P}_m(I_{X_i} \cap k[x_{n_{i-1}}, \ldots, x_n])\) is regarded as a convex polytope in the subspace \(\{a \in \mathbb{R}^{n+1} | a_i = 0, \forall i < n_{i-1}, \forall i > n_i\}\). Similarly, \(\mathcal{P}_m(I_{T_i} \cap k[x_{n_{i-1}}, \ldots, x_n])\) is also regarded as a convex polytope in the relevant vector subspace. Note that \(\mathcal{P}_m(I_{T_i} \cap k[x_{n_{i-1}}, \ldots, x_n])\) is a point since \(T_i\) is a monomial ideal. We let \(\tau\) denote the point \(\sum_{i=1}^{\ell-1} \mathcal{P}_m(I_{T_i} \cap k[x_{n_{i-1}}, \ldots, x_n])\). We shall show in Section 2.1 that Theorem 1.2 is a direct consequence of the fact that the characters of a direct sum is the sum of the characters (Proposition 2.1).
Proposition 1.3. \(\text{[HK]}\) Let \(X\) be as in Theorem 1.2 and \(\rho : G_m \to GL_{n+1}\) be a \(1\)-parameter subgroup of \(GL_{n+1}\) diagonalized by \(\{x_0, \ldots, x_n\}\) with weights \(\{r_0, \ldots, r_n\}\) and \(\rho_i\) be the restriction of \(\rho\) to \(GL(kx_{i-1} + \cdots + kx_n)\). Then the Hilbert-Mumford index \(\mu([X]^*_m, \rho)\) of the (dual) \(m\)th Hilbert point of \(X\) with respect to \(\rho\) is given by

\[
\mu([X]^*_m, \rho) = \sum_{i=0}^{m} \mu([X]^*_m, \rho_i) - \sum_{i=1}^{m} \left( \frac{mP_i(m)}{n_i - n_{i-1} + 1} \sum_{k=n_i}^{n} r_k \right) + \frac{mP_i(m)}{n+1} \sum_{i=0}^{m-1} r_i + m \sum_{i=1}^{m-1} r_{n_i}
\]

where \(P_i(m)\) is the Hilbert polynomial of \(I_X \subset k[x_0, \ldots, x_n]\) and \(P_i(m)\), the Hilbert polynomial of \(I_X \cap k[x_{i-1}, \ldots, x_n]\) regarded as an ideal in \(k[x_{i-1}, \ldots, x_n]\).

We close this section with an observation that will be used in Section 3. We shall prove that the Hilbert-Mumford index of \([I_X]^*_m\) and that of the dual Hilbert point \([I_X]^*_m\) are the same. Let \(\rho\) be a one-parameter subgroup of \(SL(S)\). We recall the fact that \(\lim_{t \to 0} \rho(t) \cdot [I_X]^*_m = [\text{in}_{<\rho} I_X]^*_m\) where \(<\rho\) is the \(\rho\)-weight order with the reverse lexicographic tie-breaking \(\text{[BMS]}\). Then the Hilbert-Mumford index is

\[
\mu([I_X]^*_m, \rho) = \mu([\text{in}_{<\rho} I_X]^*_m, \rho) = - \sum_{x^\alpha \in [\text{in}_{<\rho} I_X]^*_m} \text{wt}_\rho(x^\alpha).
\]

Let \(\{f_0, \ldots, f_n\}\) be the dual basis of \(\{x_0, \ldots, x_n\}\). Use the multi-vector notation \(f^\alpha = \prod_{i=0}^{n} f_i^{\alpha_i}\). Then \(f^\alpha_1 \land \cdots \land f^\alpha_{P(m)}\) appears in \(\bigwedge^{P(m)}(S/I_X)^*_m\) with a nonzero Pfaffian if and only if \(x^{\alpha_1}, \ldots, x^{\alpha_{P(m)}}\) form a basis of \((S/I_X)^*_m\). Since \(\rho\) is a co-character of the special linear group, the weights of all monomials of \(S_m\) sum up to zero. Also, \(\rho\) acts on \(\bigwedge \bigwedge S_m\) and \(\bigwedge \bigwedge S^*_m\) with opposite weights. Hence we have

\[
\mu([I_X]^*_m, \rho) = \max \left\{ - \sum_{x^\alpha \in B} \text{wt}_\rho(f^\alpha) \middle| B \text{ a monomial basis of } (S/I_X)^*_m \right\} = - \sum_{x^\alpha \in S_m \setminus \in_{<\rho}(I_X)} (-\text{wt}_\rho(x^\alpha)) = - \sum_{x^\alpha \in [\text{in}_{<\rho}(I_X)]^*_m} \text{wt}_\rho(x^\alpha).
\]

2. Decomposition of states

Let \(G = GL(V)\) and let \(V_i, i = 1, \ldots, v\), be vector subspaces of \(V\) that span \(V\). Note that \(V = \bigoplus_{i=1}^{v} V_i\) is not necessarily a direct sum. Then

\[
S^m V = \bigoplus_{i=1}^{v} S^m V_i + \bigoplus_{\sum_{j=1}^{m_j=m} j=1}^{v} \bigotimes_{0<m_j<m} S^{m_j} V_j.
\]

For a notational convenience, we let \(W\) denote \(S^m V\), \(W_j = S^m V_j\) for \(1 \leq j \leq v\) and

\[
W_{v+1} = \bigoplus_{\sum_{j=1}^{m_j=m} j=1}^{v} \bigotimes_{0<m_j<m} S^{m_j} V_j.
\]

Let \(R\) be a maximal torus of \(GL(V)\) which preserves the subspaces \(V_i\). Then one can choose a basis of \(B = \{v_1, \ldots, v_M\}\) of \(V\) diagonalizing the \(R\)-action such that
V_j is the linear subspace spanned by \{v_{M_1}, v_{M_1+1}, \ldots, v_{M_j}\}. We identify GL(V_j) with the subgroup of GL(V) which preserves V_j and acts trivially on Span(v_i | i < M_j, i > M_j').

Let \(\chi_i\) be the character of \(R\) determined by \(t.v_i = \chi_i(t)v_i\). Set \(R_j = R \cap GL(V_j)\). Then there is a natural projection \(\pi_j : R \rightarrow R_j\) defined by

\[
\pi_j(t) = \begin{cases} 
\chi_i(t), & M_j \leq s \leq M_j' \\
1, & \text{else}
\end{cases}
\]

Then \(\pi_j\)'s induce injective group homomorphisms \(\pi_j^* : X(R_j) \hookrightarrow X(R)\). We shall identify \(X(R_j)\) with its image in \(X(R)\) under \(\pi_j^*\).

**Proposition 2.1.** Let \(I\) be a subspace of \(W\), \(I_j = I \cap W_j\), and suppose that the sum \(I = \sum_{j=1}^{\nu+1} I_j\) is direct. Let \(\dim I = N\) and \(\dim I_j = N_j\), \(1 \leq j \leq \nu + 1\). We have the decomposition of states

\[
\Xi_{[\bigwedge^N I]}(R) = \sum_{j=1}^\nu \Xi_{[\bigwedge^{N_j} I_j]}(R_j) + \Xi_{[\bigwedge^{N_{\nu+1}} I_{\nu+1}]}(R).
\]

**Proof.** Let \(\xi\) be an affine point over \(\left[\bigwedge^N I\right] \in \mathbb{P}(\bigwedge^N \mathbb{S}^m V)\), and let \(\xi_j\) be an affine point over \(\left[\bigwedge^{N_j} I_j\right] \in \mathbb{P}(\bigwedge^{N_j} W_j)\). The affine point \(\xi_j\) generates the one-dimensional subspace \(\bigwedge^{N_j} I_j\). Let \(j \leq \nu\). Consider the \(R\)-weight decomposition of \(\xi_j\). Since \(I_j\) is contained in the \(R\)-module \(W_j = \mathbb{S}^m V_j\), the \(R\)-weight decomposition of \(\xi_j\) is precisely the \(R_j\)-weight decomposition i.e.

\[
\xi_j = \sum_{\chi \in X(R_j)} (\xi_j)_\chi = \sum_{\chi \in X(R_j)} (\xi_j)_\chi.
\]

Since the sum \(I = \sum_{j=1}^{\nu+1} I_j\) is direct, we have

\[
\bigwedge^N I \simeq \bigotimes_{j=1}^{\nu+1} \left(\bigwedge^{N_j} I_j\right)
\]

and hence the \(R\)-weight decomposition of \(\xi\) is given as

\[
(2) \quad \xi = \sum_{\chi^{(i)} \in X(R_j)} \bigotimes_{j=1}^{\nu+1} (\xi_j)^{\chi^{(i)}}.
\]

A summand \(\bigotimes_{j=1}^{\nu+1} (\xi_j)^{\chi^{(i)}}\) has a weight \(\sum_{j=1}^{\nu+1} \chi^{(j)} \in X(R)\) and it is a state of \(\xi\) if and only if the weight vector \(\sum_{j=1}^{\nu+1} (\xi_j)^{\chi^{(i)}}\) is nonzero if and only if \(\chi^{(j)}\) is a state of \(\xi_j\), \(\forall j\). It follows that every state of \(\xi\) is a sum of states of \(\xi_i\)'s and vice versa. \(\square\)

2.1. **Proof of Theorem 1.2** We shall now deduce Theorem 1.2 from Proposition 2.1. Let \(X = X_1 \cup X_2 \subset \mathbb{P}(V^*)\) be a chain of subvarieties \(X_i\) and suppose that there exists a homogeneous coordinate system \(x_0, \ldots, x_t, \ldots, x_n \in V\) such that

(1)

\[
X_1 \subset \{x_{t+1} = \cdots = x_n = 0\} \\
X_2 \subset \{x_0 = \cdots = x_{t-1} = 0\}.
\]

We also assume that \(X_1 \cap X_2 \neq \emptyset\), and that \(X_1, X_1, X_2\) are cut out by saturated homogeneous ideals \(I_{X_1}\) and \(I_X = I_{X_1} \cap I_{X_2}\).
Let $V_1$ (resp. $V_2$) be the subspace of $V$ spanned by $\{x_0, \ldots, x_\ell\}$ (resp. $\{x_{\ell}, \ldots, x_n\}$). Let $W = S^mV$, $W_i = S^mV_1$ for $i = 1, 2$, and $W_3 = \bigoplus_{i+j=m, i \neq 0} S^iV_1 \otimes S^jV_2$ where $V_1 = \sum_{i=0}^{\ell-1} k x_i$ and $V_2 = \sum_{i=\ell}^n k x_i$. Evidently we have $W = \sum_{i=1}^3 W_i$. Let $R$ be the maximal torus of $\text{GL}(V)$ diagonalized by $x_0, \ldots, x_n$ and $R_i = R \cap \text{GL}(V_i)$ for each $i$, where $\text{GL}(V_i)$ is identified with a suitable subgroup of $\text{GL}(V)$ as in the discussion preceding Proposition 2.1. Of course, $R_1$ (resp. $R_2$) is identified with the maximal torus of $\text{GL}(V_1)$ (resp. $\text{GL}(V_2)$) diagonalized by $x_0, \ldots, x_\ell$ (resp. $x_{\ell}, \ldots, x_n$).

For each $m \geq 2$, we have

$$\langle I_X \rangle_m = (I_X \cap W_1) + (I_X \cap W_2) + (I_X \cap W_3).$$

We claim that the property of coordinates (†) implies that this is a direct sum decomposition. Indeed, since $W_1 \cap W_2$ is the 1-dimensional space $k x_\ell^m$ and $x_\ell^n$ does not vanish at $\{p\} = X_1 \cap X_2$, $I_X \cap W_1 \cap W_2 = 0$. Since $W_1$ and $W_2$ meet $W_3$ trivially, the claim follows and we may apply Proposition 2.1.

Note that the three terms on the right-hand side of (3) are $I_X \cap k[x_0, \ldots, x_\ell]_m$, $I_X \cap k[x_{\ell}, \ldots, x_n]_m$ and $T_m$ respectively, where $T = \langle x_0, \ldots, x_{\ell-1}\rangle \langle x_{\ell+1}, \ldots, x_n\rangle$. Then by Proposition 2.1 we have

$$\Xi_{\mathbb{A}^N(1_X)_m}(R) = \Xi_{\mathbb{A}^{N_1} (1_X \cap W_1)}(R_1) + \Xi_{\mathbb{A}^{N_2} (1_X \cap W_2)}(R_2) + \Xi_{\mathbb{A}^{N_3} T_m}(R)$$

where $N$ and $N_i$ denote the appropriate dimensions. As observed in the introduction, we may naturally identify the characters $\prod_{i=0}^m x_i^{a_i}$ with the Laurent monomials $\prod_{i=0}^n x_i^{a_i} \in k[x_0, \ldots, x_n]$, where $X_i$ is the projection $t = (t_0, \ldots, t_N) \mapsto t_1$. Identifying the characters with monomials and taking the convex hull of both sides, we obtain Theorem 1.2 for the case $\ell = 2$ from which, as observed in [HK], the general case follows by a simple induction.

**Remark 2.2.** Note that since $T$ is a monomial ideal, $\Xi_{\mathbb{A}^{N_3} T_m}(R)$ consists of one point $\chi^\tau$ where $\chi = \sum x^{a} \in T_m \alpha$.

### 2.2. Decomposition of vertices

Let $P_1, \ldots, P_r$ be polytopes in $\mathbb{R}^n$. In general, every face $F$ of the Minkowski sum $\sum_{i=1}^r P_i$ has a unique decomposition $F = \sum_{i=1}^r F_i$ into a sum of faces $F_i$ of $P_i$. The converse is easily seen to be false: If the origin $0$ is a vertex of a polytope $P$, then $0 + v = v$ is not a vertex of $2P$ for any nonzero vertex $v$ of $P$. The following lemma guarantees that vertices always sum up to be a vertex provided that the polytopes are positioned well enough.

**Lemma 2.3.** Let $P_1, P_2$ be polytopes in $\mathbb{R}^n$. Suppose that $P_1$ and $P_2$ are contained in affine hyperplanes $H_1$ and $H_2$ respectively such that $H_1 \cap H_2$ is of dimension one. Then the vertices of the Minkowski sum $P_1 + P_2$ are precisely the sums of vertices of $P_1$ and $P_2$.

**Proof.** It is evident that a vertex of $P_1 + P_2$ is a sum of vertices of $P_1$ and $P_2$ since for any subsets $S_1$ and $S_2$ of $\mathbb{R}^n$, the sum of their convex hulls is the convex hull of their sum $S_1 + S_2$. To prove the converse, we start by choosing affine coordinates $x_1, \ldots, x_n$ judiciously so that

$$H_1 = \left\{ x \in \mathbb{R}^n \mid \sum_{i=1}^n x_i = N_1, x_i = 0 \forall i > n_1 \right\}$$
and
\[
H_2 = \left\{ x \in \mathbb{R}^n \ \middle| \sum_{i=1}^{n} x_i = N_2, x_i = 0 \forall i < n_1 \right\}.
\]

Let \( \{v_1, \ldots, v_s\} \) and \( \{w_1, \ldots, w_s\} \) be the sets of vertices of \( P_1 \) and \( P_2 \), respectively. We aim to show that \( v_i + w_j \) is a vertex of \( P_1 + P_2 \), for any \( i, j \). Suppose it is not the case - suppose without losing generality \( v_i + w_1 \) is not a vertex. Then there exist \( \lambda_{ij} \) for \( i = 1, \ldots, r, j = 1, \ldots, s \) such that \( \sum_{i,j} \lambda_{ij} = 1 \), \( 0 \leq \lambda_{ij} \leq 1 \), \( \lambda_{11} = 0 \) and
\[
 v_i + w_1 = \sum_{i,j} \lambda_{ij} (v_i + w_1).
\]

By rearranging the terms, we have
\[
\left(1 - \sum_j \lambda_{ij}\right) v_i - \sum_{j \neq 1} \lambda_{ij} v_i = \sum_{j \neq 1} \lambda_{ij} w_j + \left(\sum_i \lambda_{i1} - 1\right) w_1 \in H_1 \cap H_2,
\]
which implies that \( x_{n_1} \) is the only nonzero coordinate of each side. Moreover, \( 1 - \sum_j \lambda_{ij} \neq 0 \) or \( \sum_i \lambda_{i1} - 1 \neq 0 \) since \( \sum_{i,j} \lambda_{ij} = 1 \). Suppose the \( 1 - \sum_j \lambda_{ij} \neq 0 \) (the other case is proved similarly) and let \( v_1 = (v_{i0}, v_{i1}, \ldots, v_{in_1}) \). Then we have
\[
 v_{1k} = \sum_{i \neq 1 \atop 1 \leq i \leq s} \mu_{ij} v_{ik} \quad k \neq n_1
\]
where \( \mu_{ij} = \lambda_{ij}/1 - \sum_{j=1}^{s} \lambda_{ij} \) and \( \sum_{i \neq 1 \atop 1 \leq i \leq s} \mu_{ij} = 1 \).

The \( n_1 \)th coordinate also satisfies the above condition because
\[
 v_{1n_1} = N_1 - \sum_{k=0}^{n_1-1} v_{1k} = N_1 - \sum_{k=0}^{n_1-1} \sum_{i \neq 1} \mu_{ij} v_{ik} = \sum_{i \neq 1} \mu_{ij} N_1 - \sum_{i \neq 1} \sum_{k=0}^{n_1-1} \mu_{ij} v_{ik}
\]
\[
= \sum_{i \neq 1} \mu_{ij} \left( N_1 - \sum_{k=0}^{n_1-1} v_{ik} \right) = \sum_{i \neq 1} \mu_{ij} v_{in_1}
\]
which means that \( v_1 = \sum_{i \neq 1} \left( \sum_{j=1}^{s} \mu_{ij} \right) v_i \). But this is a contradiction since \( v_1 \) is a vertex of \( P_1 \).

As an immediate corollary, we obtain:

**Corollary 2.4.** Retain notations from Theorem 1.2. Let \( \mathcal{V}_i \) denote the set of vertices of \( \mathcal{P}_m(I_{X_i} \cap k[x_{n_i-1}, \ldots, x_n]) \), \( i = 1, \ldots, \ell \). Then the vertices of \( \mathcal{P}_m(I_X) \) are precisely
\[
\left\{ \tau + \sum_{i=1}^{\ell} v_i \ \mid \ v_i \in \mathcal{V}_i \right\}.
\]

**Proof.** The \( \ell = 2 \) case follows from Lemma 2.3. The state polytopes \( \mathcal{P}_m(I_{X_1} \cap k[x_0, x_1, \ldots, x_{n_1}]) \) and \( \mathcal{P}_m(I_{X_2} \cap k[x_{n_1}, x_{n_1+1}, \ldots, x_n]) \) are in the affine hyperplanes
\[
H_1 = \left\{ x \in \mathbb{R}^n \mid \sum_{i=0}^{n_1} x_i = Q_1(m), x_i = 0, \forall i > n_1 \right\}
\]
and
\[
H_2 = \left\{ x \in \mathbb{R}^n \mid \sum_{i=n_1}^n x_i = Q_2(m), \ x_i = 0, \ \forall i < n_1 \right\}
\]
respectively, where \( Q_1(m) = \dim I_{X_1} \cap k[x_0, x_1, \ldots, x_{n_1}]_m \) and \( Q_2(m) = \dim I_{X_2} \cap k[x_{n_1}, x_{n_1+1}, \ldots, x_n]_m \). Since \( H_1 \cap H_2 \) is one dimensional, Lemma 2.3 applies. The general, \( \ell \geq 2 \) case follows by an induction. \( \square \)

3. Decomposition of Hilbert-Mumford index

Retain the notations from Section 2.1. To prove Proposition 1.3, as in [HK] we shall assume that \( \ell = 2 \) as the general case follows by a simple induction. We let \( Q(m) = \dim(I_X)_m \) and \( P(m) = \dim(S/I_X)_m = \dim S_m - Q(m) \). Likewise, \( Q_1(m) = \dim(I_{X_1})_m \) and \( P_1(m) = \dim S^m V_1 - Q_1(m) \). Let \( \rho \) be a 1-PS of \( R \) and let \( \rho_i \) be the induced 1-PS of \( R_i, i = 1, 2 \). These are obtained by composing with the projections \( R \to R_i \). Recall that, if the sum of the \( \rho \)-weights is zero, the Hilbert-Mumford index is given by
\[
\mu([I_X]_m, \rho) = \max(-\langle \chi, \rho \rangle \mid \chi \in \Xi_{[I_X]_m}(R))
\]
where \( \langle \ , \ \rangle \) denotes the natural paring of the character group and the 1-PS group i.e. \( \chi \circ \rho(t) = t^{\langle \chi, \rho \rangle} \) for any \( t \in \mathbb{G}_m(k) \).

For any \( \chi \in \Xi_{[I_X]_m}(R) \), due to (11), we have \( \chi = \chi_1 + \chi_2 + \tau \), \( \chi_i = t_i \circ \chi \) where \( t_i : R_i \to R \) is the inclusion. And \( \tau \) is the character with which \( \rho \) acts on \( \bigwedge^{\max} (I \cap \sum_{i+j=m, ij \neq 0} S^i V_1 \otimes S^j V_2) = T_m \) where \( T = \langle x_0, \ldots, x_{\ell-1} \rangle \langle x_{\ell+1}, \ldots, x_n \rangle \). Hence we have
\[
\langle \chi, \rho \rangle = \langle \chi_1, \rho_1 \rangle + \langle \chi_2, \rho_2 \rangle + \langle \tau, \rho \rangle.
\]
Clearly, the minimum of \( \langle \chi, \rho \rangle \) is achieved precisely when each \( \chi_i \) pairs minimally with \( \rho \). Let \( \rho' \) be the 1-ps of \( SL(V) \) associated to \( \rho \) i.e. if \( r_i \) are the weights of \( \rho \), then \( \rho' \) is the 1-ps with weights \( r_i - w \) where \( w \) is the average of the weight \( \frac{1}{\dim V_1} \sum_{i=1}^n r_i \). Conflating a 1-ps with its weight vector, we may write \( \rho = \rho' + (w, w, \ldots, w) \).

The minimum of \( \langle \chi, \rho \rangle \) is achieved by
\[
\sum_{x^\alpha \in (\mathfrak{m}_{\rho}^\times I_X)_m} \chi^\alpha
\]
where we used the multiplicative multi-vector notation \( \chi^\alpha = \prod \chi_i^\alpha_i \) as in the discussion preceding Theorem 1.1. Note that
\[
\langle \chi, \rho \rangle = \langle \chi, \rho' \rangle + \langle \chi, (w, w, \ldots, w) \rangle
\]
\[
= -\mu([I_X]_m, \rho) + w \sum_{x^\alpha \in (\mathfrak{m}_{\rho}^\times I_X)_m} \langle \sum_{i=0}^n \alpha_i \rangle
\]
\[
= -\mu([I_X]_m, \rho) + w \mu(Q(m)).
\]
Similarly, let \( \rho'_i \) denote the 1-ps of \( SL(V_i) \) associated to \( \rho_i, i = 1, 2 \), whose weights are shifted by the average weight \( w_i = \frac{\sum_{x \in V_i} |_{\rho_i} (x_i)}{\dim V_i} \). Clearly, \( \chi_i \) pairs with \( \rho_i \) minimally if and only if it pairs with \( \rho'_i \) minimally, and
\[
\min(\chi_i, \rho_i) = -\mu([I_{X_i} \cap S^m V_i]_m, \rho_i) + w_i m Q_i(m).
\]
Hence we have
\begin{equation}
\mu([I_m, \rho]) = \min \langle \chi_1, \rho_1 \rangle - \min \langle \chi_2, \rho_2 \rangle - \langle \tau, \rho \rangle + mwQ(m)
\end{equation}

Substitute \( \dim S^mV - Q(m) = P(m) \) and \( \dim S^mV_i - P_i(m) = Q_i(m) \). And subsequently, substitute \( \sum_{x^a \in S^mV} wt_\rho(x^a) \) for \( mw \dim S^mV \) and \( \sum_{x^a \in S^mV_i} wt_\rho(x^a) \) for \( mw_i \dim S^mV_i \). Then we get
\begin{equation}
\mu([I_m, \rho]) = \mu([I_1 \cap k[x_0, \ldots, x_\ell]], \rho_1) + \mu([I_2 \cap k[x_\ell, \ldots, x_n]], \rho_2)
\end{equation}

since \( S^mV \sqcup (S^mV_2 \setminus \{x^m_\ell\}) \sqcup T_m = S^mV \). Recall from the closing moment of the introduction that \([I_m, \rho]\) and \([I_1, \rho]\) have the same Hilbert-Mumford indices, and that \( \rho \) acts with opposite weights on \( \mathbb{P}(\wedge S^m_m) \) in which the dual Hilbert points live. That is, if \( w^* \) is the average of the weights for the \( \rho \) action on \( \mathbb{P}(\wedge S^*_m) \), then \( w^* = -w \) so that the signs of the terms \( mwP(m) \), \( w_i mP_i(m) \) are reversed. Hence \( \mu([I_m, \rho]) \) is precisely the assertion of Proposition \ref{prop:mu} for the case \( \ell = 1 \).
