## 1 Introduction

This package provides functions for estimating Gaussian and non-Gaussian spatial regression models and extensions, including spatially and non-spatially varying coefficient models, models with group effects, spatial

unconditional quantile regression models, and low rank spatial econometric models. All these models are estimated computationally efficiently.

An approximate Gaussian process (GP or kriging model), which is interpretable in terms of the Moran coefficient (MC), is used for modeling the spatial process. The approximate GP is defined by a linear combination of the Moran eigenvectors (MEs) corresponding to positive eigenvalue, which are known to explain positive spatial dependence. The resulting spatial process describes positively dependent map patterns (i.e.,  $MC > 0$ ), which are dominant in regional science (Griffith, 2003). Below, the `spmoran` package is used to analyse the Boston housing dataset.

The sample codes used below are available from <https://github.com/dmuraka/spmoran>. While this vignette mainly focuses on Gaussian regression modeling, another vignette focusing on non-Gaussian regression modeling and count regression modeling is also available from the same GitHub page (and Murakami 2021).

```
library(spmoran)
```

## 2 Gaussian spatial regression models

### 2.1 Basic models

This section considers the following model:

$$y_i = \sum_{k=1}^K x_{i,k} \beta_k + f_{MC}(s_i) + \epsilon_i, \quad \epsilon_i \sim N(0, \sigma^2),$$

which decomposes the explained variable  $y_i$  observed at the  $i$ -th sample site into trend  $\sum_{k=1}^K x_{i,k} \beta_{i,k}$ , spatial process  $f_{MC}(s_i)$  depending on location  $s_i$ , and noise  $\epsilon_i$ . The spatial process is required to eliminate residual spatial dependence and estimate/infer regression coefficients  $\beta_k$  appropriately. ESF and RE-ESF define  $f_{MC}(s_i)$  using the MC-based spatial process to efficiently eliminate residual spatial dependence. These processes are defined by the weighted sum of the Moran eigenvectors (MEs), which are spatial basis functions (distinct map pattern variables; see Griffith, 2003).

#### 2.1.1 Eigenvector spatial filtering (ESF)

ESF specifies  $f_{MC}(s_i)$  using an MC-based deterministic spatial process (see Griffith, 2003). Below is a code estimating the linear ESF model. In the code, the `meigen` function extracts the MEs, and the `esf` function estimates the model.

```
require(spdep)
data(boston)
y <- boston.c[, "CMEDV" ]
x <- boston.c[,c("CRIM", "ZN", "INDUS", "CHAS", "NOX", "RM", "AGE")]
coords<- boston.c[,c("LON", "LAT")]

#####Distance-based ESF
meig <- meigen(coords=coords)
res <- esf(y=y,x=x,meig=meig, vif=10)
res
```

```
## Call:
## esf(y = y, x = x, vif = 10, meig = meig)
##
## ----Coefficients-----
##               Estimate      SE    t_value    p_value

## AGE        -0.07820247 0.01564970 -4.9970593 8.274067e-07
##
## ----Spatial effects (residuals)-----
##                               Estimate
## SD                           6.8540461
## Moran.I/max(Moran.I) 0.6701035
##
## ----Error statistics-----
##                               stat
## resid_SE      4.476459
## adjR2         0.762328
## logLik      -1453.376154
## AIC         2996.752308
## BIC         3186.946458
```

While the `meigen` function is slow for large samples, it can be substituted with the `meigen_f` function performing a fast eigen-approximation. Here is a fast ESF code for large samples:

```
meig_f<- meigen_f(coords)
res  <- esf(y=y, x=x, meig=meig_f,vif=10, fn="all")
```

### 2.1.2 Random effects ESF (RE-ESF)

RE-ESF specifies  $f_{MC}(s_i)$  using an MC-based spatial random process, again to eliminate residual spatial dependence (see Murakami and Griffith, 2015). Here is a sample example:

```
res  <- resf(y = y, x = x, meig = meig)
res

## Call:
## resf(y = y, x = x, meig = meig)
##
## ----Coefficients-----
##               Estimate      SE    t_value    p_value
## (Intercept)  6.63220299 3.94484191  1.6812342 9.340110e-02

## Use method="ml" for comparison of models with different fixed effects (x)
```

The residual spatial process  $f_{MC}(s_i)$  is plotted as follows:

```
plot_s(res)
```

For large data, the `meigen_f` function is available again:

```
meig_f <- meigen_f(coords)
res <- resf(y = y, x = x, meig = meig_f)
```

The `meigen_f` function is available for all the regression models explained below.

## 2.2 Extended models

### 2.2.1 Models with non-spatially varying coefficients (coefficients varying wrt covariate value)

Influence from covariates can vary depending on covariate value. For example, distance to railway station might have a strong impact on housing price if the distance is small, while it might be weak if the distance is large. To capture such an effect, the `resf` function estimates coefficients varying with respect to covariate value. I call such coefficients non-spatially varying coefficients (NVCs). If `nvc=TRUE`, the `resf` function

estimates the following model considering NSVs and residual spatial dependence:

$$y_i = \sum_{k=1}^K x_{i,k} \beta_{i,k} + f_{MC}(s_i) + \epsilon_i, \quad \beta_{i,k} = b_k + f(x_{i,k}), \quad \epsilon_i \sim N(0, \sigma^2),$$

where  $f(x_{i,k})$  is a smooth function of  $x_{i,k}$  capturing the non-spatial influence. Here is a code estimating a spatial NVC model (with selection of constant or NVC):

```
res <- resf(y = y, x = x, meig = meig, nvc=TRUE)
res

## Call:
## resf(y = y, x = x, nvc = TRUE, meig = meig)
##

```

By default, this function selects constant or NVC through BIC minimization. “Non-spatially varying coefficients” in the “Variance parameter” section summarizes the estimated standard errors of the NVCs. Based on the result, coefficients on {NOX, RM} are NVCs, and coefficients on the others are constants. The NVC on RM, which is the 6-th covariate, is plotted as below. The solid line in the panel denotes the estimated NVC, and the gray area denotes the 95% confidence interval. This plot shows that RM is positively significant only if RM is large.

```
plot_n(res,6)
```

The NVC can also be spatially plotted as below:

```
plot_s(res,6)
```

On the other hand, the residual spatial process  $f_{MC}(s_i)$  is plotted as

```
plot_s(res)
```

Sometimes, the user may wish to assume NVCs only on the first three covariates and constant coefficients on

the others. The following code estimates such a model:

```
res <- resf(y = y, x = x, meig = meig, nvc=TRUE, nvc_sel=1:3)
```

## 2.2.2 Models with spatially varying coefficients

This package implements an ME-based spatially varying coefficient (M-SVC) model (Murakami et al., 2017), which is formulated as

$$y_i = \sum_{k=1}^K x_{i,k} \beta_{i,k} + f_{MC}(s_i) + \epsilon_i, \quad \beta_{i,k} = b_k + f_{MC,k}(s_i), \quad \epsilon_i \sim N(0, \sigma^2),$$

This model defines the  $k$ -th coefficient at site  $i$  by  $\beta_{i,k} = [\text{constant mean } b_k] + [\text{spatially varying component } f_{MC,k}(s_i)]$ . Geographically weighted regression (GWR) is known as another SVC estimation approach. Major advantages of the M-SVC modeling approach over GWR are as follows:

- The M-SVC model estimates the spatial scale (or MC value) of each SVC, while the classical GWR assumes a common scale across SVCs.
- The M-SVC model can assume SVCs on some covariates and constant coefficients on the others. This is achieved by simply assuming  $\beta_{i,k} = b_k$
- This model is faster and available for very large samples. In addition, the model is free from memory limitations if the `besf_vc` function is used (see Section 4).
- Model selection (i.e., constant coefficient or SVC) is implemented without losing its computational efficiency.

Here is a sample code estimating an SVC model without coefficient type selection. In the code, `x` specifies covariates assuming SVCs, while `xconst` specifies covariates assuming constant coefficients. If `x_sel = FALSE`, the types of coefficients on `x` are fixed.

```
y <- boston.c[, "CMEDV"]
x <- boston.c[,c("CRIM", "AGE")]
xconst <- boston.c[,c("ZN", "DIS", "RAD", "NOX", "TAX", "RM", "PTRATIO", "B")]
coords <- boston.c[,c("LON", "LAT")]
meig <- meigen(coords=coords)
res <- resf_vc(y=y, x=x, xconst=xconst, meig=meig, x_sel = FALSE )
```

```

##
## Note: AIC and BIC are based on the restricted/marginal likelihood.
##      Use method="ml" for comparison of models with different fixed effects (x and xconst)
```

Estimated SVCs can be plotted as

```
plot_s(res,0) # Spatially varying intercept
```

```
plot_s(res,1) # 1st SVC
```

```
plot_s(res,2) # 2nd SVC
```

On the other hand, by default, the `resf_vc` function selects constant or SVCs through a BIC minimization (i.e., `x_sel=TRUE` by default). Here is a code:

```
res <- resf_vc(y=y,x=x,xconst=xconst,meig=meig )
```

### 2.2.3 Models with spatially and non-spatially varying coefficients

The spatially and non-spatially varying coefficient (SNVC) model is defined as

$$y_i = \sum_{k=1}^K x_{i,k} \beta_{i,k} + f_{MC}(s_i) + \epsilon_i, \quad \beta_{i,k} = b_k + f_{MC,k}(s_i) + f(x_{i,k}), \quad \epsilon_i \sim N(0, \sigma^2),$$

This model defines the  $k$ -th coefficient as  $\beta_{i,k} = [\text{constant mean } b_k] + [\text{spatially varying component } f_{MC,k}(s_i)] + [\text{non-spatially varying component } f(x_{i,k})]$ . Murakami and Griffith (2020) showed that, unlike SVC models that tend to be unstable owing to spurious correlation among SVCs (see Wheeler and Tiefelsdorf, 2005), this SNVC model is stable and quite robust against spurious correlations. Therefore, I recommend using the SNVC model, even if the purpose of the analysis is estimating SVCs.

An SNVC model is estimated by specifying `x_nvc = TRUE` in the `resf_vc` function as follows:

```
res <- resf_vc(y=y,x=x,xconst=xconst,meig=meig, x_nvc =TRUE)
```

This model assumes SNVC on  $x$  and constant coefficients on  $xconst$ . By default, the coefficient type (SNVC, SVC, NVC, or constant) on  $x$  is selected.

It is also possible to assume SNVCs on  $x$  and NVCs on  $xconst$  by specifying `xconst_nvc = TRUE` as follows:

```
res <- resf_vc(y=y,x=x,xconst=xconst,meig=meig, x_nvc =TRUE, xconst_nvc=TRUE)
```

```

```

By default, the coefficient type (SNVC, SVC, NVC, or constant) on x and those (NVC or const) on xconst are selected. The estimated SNVCs are plotted as follows:

```
plot_s(res,0)           # Spatially varying intercept
```

```
plot_s(res,1)           # SNVC on x[,1]
```

NVCs on xconst is plotted by specifying `xtype="xconst"` in the `plot_n` function, as below. The solid line denotes the estimated NVC, and the gray area denotes the 95% confidence interval:

```
plot_n(res,4,xtype="xconst")#NVC on xconst[,4]
```

```
plot_n(res,6,xtype="xconst")#NVC on xconst[,6]
```

These NVCs can also be plotted spatially as follows:

```
plot_s(res,4,xtype="xconst")#Spatial plot of NVC on xconst[,4]
```

```
plot_s(res,6,xtype="xconst")#Spatial plot of NVC on xconst[,6]
```

## 2.2.4 Models with group effects

**2.2.4.1 Outline** Two group effects are available in this package:

1. Spatially dependent group effects. Spatial dependence among groups is modeled instead of modeling spatial dependence among individuals.
2. Spatially independent group effects assuming independence across groups (usual group effects)

They are estimated in the `resf` and `resf_vc` functions. When considering both these effects, the `resf` function estimates the following model (if no NVC is assumed):

$$y_i = \sum_{k=1}^K x_{i,k} \beta_k + f_{MC}(g_{I(0)}) + \sum_{h=1}^H \gamma(g_{I(h)}) + \epsilon_i, \quad \epsilon_i \sim N(0, \sigma^2),$$

where  $g_{I(0)}, g_{I(1)}, \dots, g_{I(H)}$  represent group variables.  $f_{MC}(g_{I(0)})$  denotes spatially dependent group effects, while  $\gamma(g_{I(h)})$  denotes spatially independent group effects for the  $h$ -th group variable. On the other hand, the `resf_vc` function can estimate the following model considering these two effects (again, no NVC is assumed):

$$y_i = \sum_{k=1}^K x_{i,k} \beta_{i,k} + f_{MC}(g_{I(0)}) + \sum_{h=1}^H \gamma(g_{I(h)}) + \epsilon_i, \quad \beta_{i,k} = b_k + f_{MC,k}(g_{i(0)}), \quad \epsilon_i \sim N(0, \sigma^2),$$

Below, multilevel modeling, small area estimation, and panel data analysis are demonstrated.

**2.2.4.2 Multilevel model** Data often have a multilevel structure. For example, the school achievement of individual students changes depending on the class and school. A condominium unit price depends, not only on unit attributes, but also on building attributes. Multilevel modeling is required to explicitly consider the multilevel structure behind data and perform spatial regressions.

This section demonstrates the modeling considering the two group effects using the `resf` function. The data used are the Boston housing datasets that consist of 506 samples in 92 towns, which are regarded as groups.

To model spatially dependent group effects, Moran eigenvectors are defined by groups. This is done by specifying `s_id` in the `meigen` function using a group variable, which is the town name (`TOWNNO`), in this case, as follows:

```
xgroup<- boston.c[, "TOWNNO"]
coords<- boston.c[,c("LON", "LAT")]
meig_g<- meigen(coords=coords, s_id=xgroup)
```

When additionally estimating spatially independent group effects, the user needs to specify `xgroup` in the `resf` function by one or more group variables, as follows:

```
x      <- boston.c[,c("CRIM", "ZN", "INDUS", "CHAS", "NOX", "RM", "AGE")]
res    <- resf(y = y, x = x, meig = meig_g, xgroup = xgroup)
res
```

```
## Call:
## resf(y = y, x = x, xgroup = xgroup, meig = meig_g)
##

```

**2.2.4.3 Small area estimation** Small area estimation (SAE; Ghosh and Rao, 1994) is a statistical technique estimating parameters for small areas such as districts and municipality. SAE is useful for obtaining reliable small area statistics from noisy data. The `resf` and `resf_vc` functions are available for SEA (see as explained in Murakami 2020 for further detail).

The Boston housing datasets consist of 506 samples in 92 towns. This section estimates the standard housing price in the  $I$ -th towns by assuming the following model:

$$y_I = \hat{y}_I + \epsilon_I, \quad \epsilon_I \sim N(0, \frac{\sigma^2}{N_I})$$

where  $\hat{y}_I = \sum_{i=1}^{N_I} \frac{\hat{y}_i}{N_I}$ . This model decomposes the observed mean house price  $y_I$  in the  $I$ -th town into the standard price  $\hat{y}_I$  and noise  $\epsilon_I$ , which reduces as the number of samples in the  $I$ -th town increases. The standard price is defined by an aggregate of the predictors  $\hat{y}_i$  by individuals.

The above equation suggests that, if  $\hat{y}_i$  is predicted using the `resf` or `resf_vc` function and aggregated into the towns, we can estimate the standard house price. Here is a sample code for the individual level prediction:

```
r_res <- resf(y=y, x=x, meig=meig_g, xgroup=xgroup)
pred <- predict0(r_res, x0=x, meig0=meig_g, xgroup0=xgroup)
pred$pred[1:5,]
```

```
##      pred      xb sf_residual  xgroup
## 1 23.70932 22.71407  -1.170482  2.165726
## 2 24.57615 22.21874  -1.390220  3.747633
## 3 30.58942 28.23201  -1.390220  3.747633
## 4 33.24998 28.19959  -1.493814  6.544205
## 5 33.62206 28.57167  -1.493814  6.544205
```

As shown above, the `predict0` function returns predicted values (`pred`), predicted trends (`xb`), predicted residual spatial components (`sf_residual`), and predicted group effects (`xgroup`). Then, these individual-level variables are aggregated into towns. Here is a code:

```
adat <- aggregate(data.frame(y, pred$pred), by=list(xgroup), mean)
adat[1:5,]
```

```
##  Group.1      y      pred      xb sf_residual  xgroup
## 1      0 24.00000 23.70932 22.71407  -1.170482  2.165726
## 2      1 28.15000 27.58279 25.22537  -1.390220  3.747633
## 3      2 32.76667 31.89132 26.84093  -1.493814  6.544205
## 4      3 19.42857 19.36679 18.51187  -1.576641  2.431558
## 5      4 16.71364 16.72781 17.10793  -1.416151  1.036033
```

The outputs are the predicted standard price (`pred`), trend (`xb`), spatially dependent group effects (`sf_residual`), and spatially independent group effects (`xgroup`) by town.

To map the result, spatial polygons for the towns are loaded and combined with our estimates:

```
require(dplyr)
b1      <- st_read(system.file("shapes/boston_tracts.shp",package="spData")[1])

## Reading layer `boston_tracts' from data source
##   `C:\Users\dmura\AppData\Local\R\win-library\4.3\spData\shapes\boston_tracts.shp'
##   using driver `ESRI Shapefile'
## Simple feature collection with 506 features and 36 fields
## Geometry type: POLYGON
## Dimension:      XY
## Bounding box:   xmin: -71.52311 ymin: 42.00305 xmax: -70.63823 ymax: 42.67307
## Geodetic CRS:   NAD27

boston.tr2  <- b1 %>% group_by(TOWNNO) %>% summarize() #dissolve
boston.tr2$id <- 1:(dim(boston.tr2)[1])
boston.tr3  <- merge(boston.tr2, adat, by.x="TOWNNO", by.y="Group.1", all.x=TRUE)
```

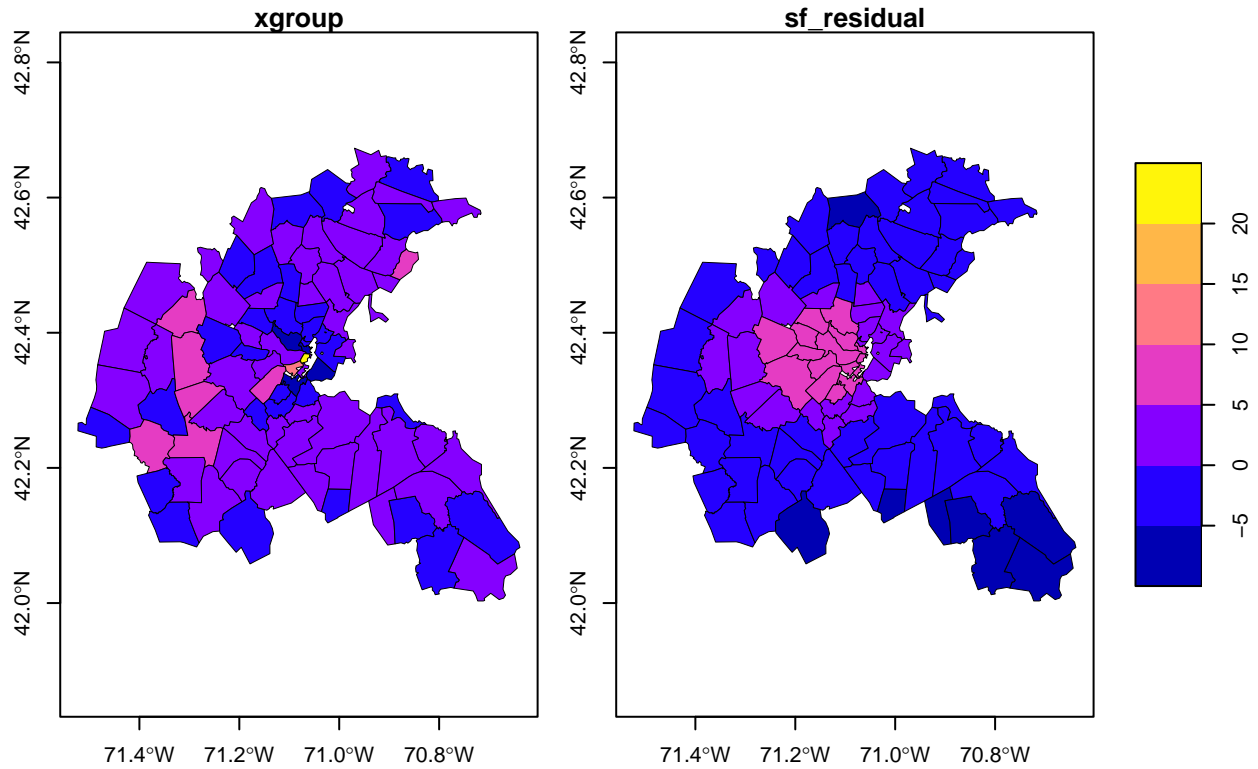

Here are the maps of our estimates. “y” denotes the observed mean prices, and “pred” denotes our predicted standard price. While they are similar, there are some differences in towns with high housing prices.

```
boston.tr4 <- boston.tr3[order(boston.tr3$id),]
plot(boston.tr4[,c("y", "pred")], lwd=0.3, axes=TRUE, key.pos=4)
```

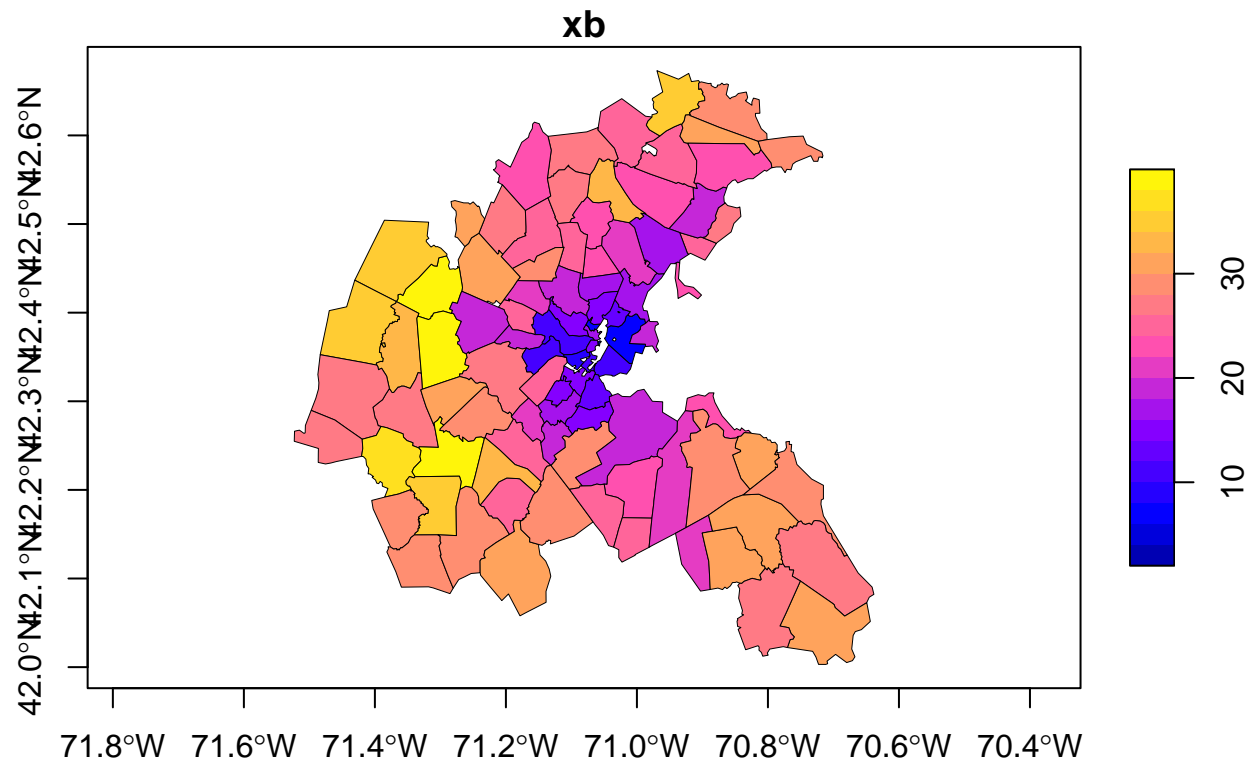

Here are the elements of the predicted values. The maps below show that each element explains different things to each other:

```
plot(boston.tr4[,c("xgroup", "sf_residual")], lwd=0.3, axes=TRUE, key.pos=4)
```

```
plot(boston.tr4[, "xb"], lwd=0.3, axes=TRUE, key.pos=4, nbreaks=20)
```

Note that the `resf_vc` function is also available for SVC model-based SAE. Here is a sample code:

```
rv_res <- resf_vc(y=y, x=x, meig=meig_g, xgroup=xgroup, x_sel=FALSE)
```

```

**2.2.4.4 Longitudinal/panel data analysis** The `resf` and `resf_vc` functions are also available for longitudinal or panel data analysis with/without S(N)VC (see Yu et al., 2020). Although this section takes `resf` as an example, `resf_vc` function-based panel analysis is implemented in the same way.

To illustrate this, we use a panel data of 48 US states from 1970 to 1986, which is published in the `plm` package (Croissant and Millo, 2008). Because our approach uses spatial coordinates by default, we added center spatial coordinates (`px` and `py`) to the panel data. Here is the code:

```
require(plm)
require(spData)

data(Produc, package = "plm")
data(us_states)
us_states2 <- data.frame(us_states$GEOID, us_states$NAME, st_coordinates(st_centroid(us_states)))
names(us_states2)[3:4] <- c("px", "py")
us_states3 <- us_states2[order(us_states2[,1]), ][-8,]
us_states3$state <- unique(Produc[,1])
pdat0 <- na.omit(merge(Produc, us_states3[, c(3:5)], by="state", all.x=TRUE, sort=FALSE))
pdat <- pdat0[order(pdat0$state, pdat0$year),]
pdat[1:5,]
```

```
##   state year region      pcap      hwy      water      util      pc      gsp      emp

## 5   5.5 -86.82797 32.78034
```

Following a vignette of the plm package, this section uses logged gross state product as explained variables (y) and logged public capital stock (log\_pcap), logged private capital stock (log\_pc), logged labor input measured by the employment in non-agricultural payrolls (log\_emp), and unemployment rate (unemp) as covariables.

```
y <- log(pdat$gsp)
x <- data.frame(log_pcap=log(pdat$pcap), log_pc=log(pdat$pc),
               log_emp=log(pdat$emp), unemp=pdat$unemp)
```

Because spatial coordinates are defined by states, Moran eigenvectors must be extracted by state by specifying s\_id in the meigen function, as follows:

```
coords<- pdat[,c("px", "py")]
s_id <- pdat$state
meig_p<- meigen(coords,s_id=s_id) # Moran eigenvectors by states
```

Currently, the following spatial panel models are available: pooling model (no group effects); individual random effects model (state-level group effects); time random effects model (year-level group effects); and two-way random effects model (state and year-level group effects). All these models consider residual spatial dependence. Here are the codes implementing these models:

```
pmod0 <- resf(y=y,x=x,meig=meig_p) # pooling model

xgroup<- pdat[,c("state")]
pmod1 <- resf(y=y,x=x,meig=meig_p,xgroup=xgroup) # individual model

xgroup<- pdat[,c("year")]
pmod2 <- resf(y=y,x=x,meig=meig_p,xgroup=xgroup) # time model

xgroup<- pdat[,c("state","year")]
pmod3 <- resf(y=y,x=x,meig=meig_p,xgroup=xgroup) # two-way model
```

Among these models, the two-way model indicates the smallest BIC. The output is summarized as

```
pmod3

## Call:
## resf(y = y, x = x, xgroup = xgroup, meig = meig_p)
##

## year_1973  0.021939489 0.010275153  2.1351982
## year_1974 -0.009861104 0.009674704 -1.0192668
```

For validation, the same panel model (but without spatial dependence) is estimated using the plm function:

```
pm0 <- plm(log(gsp) ~ log(pcap) + log(pc) + log(emp) + unemp,
           data = pdat, effect="twoways", model="random")
pm0
```

```
##
## Model Formula: log(gsp) ~ log(pcap) + log(pc) + log(emp) + unemp
##
## Coefficients:
## (Intercept)  log(pcap)      log(pc)    log(emp)      unemp
```

```
## 2.3634993 0.0178529 0.2655895 0.7448989 -0.0045755
```

```
s_g_plm <- ranef(pm0, "individual")  
t_g_plm <- ranef(pm0, "time")
```

The coefficient estimates are similar. The plots below compare estimated group effects. Estimated state-level effects have differences because our models consider residual spatial dependence, while plm does not (by default). Time effects are quite similar.

```
plot(s_g_plm, s_g[,1], xlab="plm", ylab="resf")  
abline(0, 1, col="red")
```

```
plot(t_g_plm, t_g[,1], xlab="plm", ylab="resf")  
abline(0, 1, col="red")
```

## 2.3 Spatial prediction

This package provides functions for ESF/RE-ESF-based spatial interpolation minimizing the expected prediction error (just like kriging). RE-ESF approximates a Gaussian process or the kriging model, which has actively been used for spatial prediction, and ESF is a special case (Murakami and Griffith, 2015). Because ESF and RE-ESF impose approximations, they are faster for very large samples.

In this tutorial, the Lucas housing price data with sample size being 25,357 is used. In the prediction, “price” is used as the explained variable, and “age,” “rooms,” “beds,” and “year” are used as covariates.

```
require(spData)
data(house)
dat0 <- st_as_sf(house)
dat <- data.frame(st_coordinates(dat0), dat0[,c("price", "age", "rooms", "beds", "syear")])
```

A total of 20,000 randomly selected samples are used for model estimation, and the other 5,357 samples are used for accuracy evaluation. The code below creates the data for observation sites (coords, y, x) and for unobserved sites (coords0, y0, x0):

```
samp <- sample(dim(dat)[1], 20000)
coords<- dat[samp, c("X", "Y")]
y <- log(dat[samp, "price"])
x <- dat[samp, c("age", "rooms", "beds", "syear")]

coords0<- dat[-samp, c("X", "Y")]
y0 <- log(dat[-samp, "price"]) # for validation
x0 <- dat[-samp, c("age", "rooms", "beds", "syear")]
```

The prediction is done in two steps: (1) evaluation of Moran eigenvectors at prediction sites using the `meigen0` function; (2) prediction using the `predict0` function. Below is a sample code based on the `resf` function:

```

start.time1<-proc.time()##### For CP time evaluation
meig      <- meigen_f(coords)
meig0     <- meigen0( meig=meig, coords0=coords0 )
mod       <- resf( y = y, x = x, meig = meig )
pred0     <- predict0( mod = mod, x0 = x0, meig0=meig0 )
end.time1<- proc.time()##### For CP time evaluation

```

Note that the first and last lines are just for computing time evaluation. NVCs are considered if adding NVC=TRUE in the resf function. The meigen\_f function is used for fast computation.

The outputs shown below include predicted values (pred), predicted trend (xb), and predicted residual spatial component (sf\_residuals).

```
pred0$pred[1:5,]
```

```

##      pred      xb sf_residual
## 5  11.81208 11.34347  0.4686106
## 11 11.62800 11.19501  0.4329969
## 15 11.38538 10.89625  0.4891365
## 16 11.77415 11.36873  0.4054135
## 21 11.08661 10.67609  0.4105252

```

```
pred      <- pred0$pred[,1]
```

On the other hand, here is a code for a spatial prediction based on an S(N)VC model:

```

start.time2<-proc.time()##### For CP time evaluation
meig      <- meigen_f(coords)
meig0     <- meigen0( meig=meig, coords0=coords0 )
mod2      <- resf_vc( y = y, x = x, meig = meig )

```

```

## [1] "----- Iteration 1 -----"
## [1] "1/5"
## [1] "2/5"
## [1] "3/5"
## [1] "4/5"
## [1] "5/5"
## [1] "BIC: 13501.483"
## [1] "----- Iteration 2 -----"
## [1] "1/5"
## [1] "2/5"
## [1] "3/5"
## [1] "4/5"
## [1] "5/5"
## [1] "BIC: 13147.54"
## [1] "----- Iteration 3 -----"
## [1] "1/5"
## [1] "2/5"
## [1] "3/5"
## [1] "4/5"
## [1] "5/5"
## [1] "BIC: 13144.252"
## [1] "----- Iteration 4 -----"
## [1] "1/5"
## [1] "2/5"
## [1] "3/5"

```

```
## [1] "4/5"
## [1] "5/5"
## [1] "BIC: 13144.219"
## [1] "----- Iteration 5 -----"
## [1] "1/5"
## [1] "2/5"
## [1] "3/5"
## [1] "4/5"
## [1] "5/5"
## [1] "BIC: 13144.219"
## [1] "----- Iteration 6 -----"
## [1] "1/5"
## [1] "2/5"
## [1] "3/5"
## [1] "4/5"
## [1] "5/5"
## [1] "BIC: 13144.219"
```

```
pred02 <- predict0( mod = mod2, x0 = x0, meig0=meig0 )
end.time2<- proc.time()##### For CP time evaluation
```

NVCs are considered by adding NVC=TRUE in the resf\_vc function. Here are the output variables:

```
pred02$pred[1:5,]
```

```
##      pred      xb sf_residual
## 5  11.68471 11.64464 0.04006557
## 11 11.57193 11.54166 0.03027240
## 15 11.41369 11.36237 0.05131992
## 16 11.61277 11.57533 0.03744066
## 21 11.13501 11.09377 0.04124334
```

```
pred2 <- pred02$pred[,1]
```

The root mean squared prediction error (RMSPE) and the computational time of the spatial regression model (resf) are as follows:

```
sqrt(sum((pred-y0)^2)/length(y0))#rmse
```

```
## [1] 0.3509916
```

```
(end.time1 - start.time1)[3]#computational time (second)
```

```
## elapsed
##      8.8
```

while those of the SVC model (resf\_vc) are as follows:

```
sqrt(sum((pred2-y0)^2)/length(y0))#rmse
```

```
## [1] 0.3385873
```

```
(end.time2 - start.time2)[3]#computational time (second)
```

```
## elapsed
##    131.33
```

The results suggest that both models are available for large samples. It is also demonstrated that while the spatial regression model is faster than the SVC model, the SVC model is slightly more accurate. The actual values (y0) and predicted values (pred/pred2) are compared below:

```
par(mfrow=c(1,2))
plot(y0,pred);abline(0,1,col="red")
plot(y0,pred2);abline(0,1,col="red")
```

(RE-)ESF considers a limited number of eigenvectors, which limits the model flexibility. Because of that, (RE-)ESF suffers from a degeneracy/over-smoothing problem that decreases modeling accuracy for large samples. The `addlearn_local` function is useful to address this problem. This function estimates an improved SVC model by aggregating/averaging the pre-estimated SVC model (i.e., `mod2`) with local SVC models that are estimated by k-means-based spatial clusters each of which contains roughly 600 samples (see Murakami et al., 2023). Unlike the `resf_vc` and/or `besf_vc` function, the improved SVC model considers not only (global) eigenvectors but also local eigenvectors; the resulting model accurately captures local patterns even from very large samples.

Here is a sample code for the model aggregation and prediction after the model aggregation:

```
start.time3<-proc.time() ##### For CP time evaluation
mod3      <- addlearn_local(mod=mod2, meig0 = meig0, x0 = x0)
```

```
## [1] "----- Aggregating 36 local sub-models -----"
## [1] "1/36"
## [1] "2/36"
## [1] "3/36"
## [1] "4/36"
## [1] "5/36"
## [1] "6/36"
## [1] "7/36"
## [1] "8/36"
## [1] "9/36"
## [1] "10/36"
## [1] "11/36"
```

```
## [1] "12/36"
## [1] "13/36"
## [1] "14/36"
## [1] "15/36"
## [1] "16/36"
## [1] "17/36"
## [1] "18/36"
## [1] "19/36"
## [1] "20/36"
## [1] "21/36"
## [1] "22/36"
## [1] "23/36"
## [1] "24/36"
## [1] "25/36"
## [1] "26/36"
## [1] "27/36"
## [1] "28/36"
## [1] "29/36"
## [1] "30/36"
## [1] "31/36"
## [1] "32/36"
## [1] "33/36"
## [1] "34/36"
## [1] "35/36"
## [1] "36/36"
```

```
pred3      <- mod3$pred0[,1]
end.time3  <- proc.time() ##### For CP time evaluation
```

The resulting RMSE is confirmed to be smaller than mod2, which is before the model aggregation:

```
sqrt(sum((pred3-y0)^2)/length(y0)) #rmse
```

```
## [1] 0.3128213
```

```
(end.time3 - start.time3)[3] #computational time (second)
```

```
## elapsed
## 215.62
```

While the `addlearn_local` function requires an additional computation time, it can be paralleled by specifying `parallel = TRUE`. The accuracy difference between the models with/without the model aggregation/averaging increases as the sample size increases. This `addlearn_local` function is especially recommended for larger samples.

The `addlearn_local` function is also useful to improve SVC coefficient estimation accuracy as demonstrated in Murakami et al. (2023). See Section 6.3 for further detail.

### 3 Non-Gaussian spatial regression models

This package is now available for modeling a wide variety of non-Gaussian data including count data. Unlike the conventional generalized linear model (GLM), the implemented model estimates the most likely data distribution (i.e., probability density/mass function) without explicitly specifying the data distribution (see Murakami et al., 2021). See Murakami (2021) or `vignette_spmoran(nongaussian).pdf`, which is another vignette in the same GitHub page <https://github.com/dmuraka/spmoran> for details on how to implement it.

## 4 Spatially filtered unconditional quantile regression

While the usual (conditional) quantile regression (CQR) estimates the influence of  $x_k$  on the  $\tau$ -th conditional quantile of  $y$ ,  $q_\tau(y|x_k)$ , the unconditional quantile regression estimates the influence of  $x_k$  on the “unconditional” quantile of  $y$ ,  $q_\tau(y)$  (Firpo et al., 2009).

Suppose that  $y$  and  $x_k$  represent land price and accessibility, respectively. UQR estimates the influence of accessibility on land price by quantile; it is interpretable and useful for hedonic land price analysis, for example. By contrast, this interpretation does not hold for CQR because it estimates the influence of accessibility on conditional land prices (land price conditional on explanatory variables). Higher conditional land price does not mean higher land price; rather, it means overprice relative to the price expected by the explanatory variables. Therefore, CQR has difficulty in its interpretation, in some cases, including hedonic land price modeling.

The spatial filter UQR (SF-UQR) model (Murakami and Seya, 2019), which is implemented in this package, is formulated as

$$q_\tau(y_i) = \sum_{k=1}^K x_{i,k} \beta_{k,\tau} + f_{MC,\tau}(s_i) + \epsilon_{i,\tau}, \quad \epsilon_{i,\tau} \sim N(0, \sigma_\tau^2),$$

This model is a UQR considering spatial dependence.

The `resf_qr` function implements this model. Below is a sample code. If `boot=TRUE` in `resf_qr`, a semiparametric bootstrapping is performed to estimate the standard errors of the regression coefficients. By default, this function estimates models at 0.1, 0.2, ..., 0.9 quantiles.

```
y      <- boston.c[, "CMEDV" ]
x      <- boston.c[,c("CRIM","ZN","INDUS", "CHAS", "NOX","RM", "AGE")]
coords<- boston.c[,c("LON","LAT")]
meig   <- meigen(coords=coords)
res    <- resf_qr(y=y,x=x,meig=meig, boot=TRUE)
```

```
## [1] "----- Complete: tau=0.1 -----"
## [1] "----- Complete: tau=0.2 -----"
## [1] "----- Complete: tau=0.3 -----"
## [1] "----- Complete: tau=0.4 -----"
## [1] "----- Complete: tau=0.5 -----"
## [1] "----- Complete: tau=0.6 -----"
## [1] "----- Complete: tau=0.7 -----"
## [1] "----- Complete: tau=0.8 -----"
## [1] "----- Complete: tau=0.9 -----"
```

Here is a summary of the estimation result:

```
res

## Call:
## resf_qr(y = y, x = x, meig = meig, boot = TRUE)
##

The estimated coefficients can be visualized using the `plot_qr` function, as below. The numbers 1 to 5 specify which coefficients are plotted (1: intercept). In each panel, solid lines are estimated coefficients, and gray areas are their 95% confidence intervals.

```
plot_qr( res, 1 )
```

```
plot_qr( res, 2 )
```

```
plot_qr( res, 3 )
```

```
plot_qr( res, 4 )
```

```
plot_qr( res, 5 )
```

## CHAS

Standard errors and the scaled Moran coefficient ( $\text{Moran.I}/\max(\text{Moran.I})$ ), which is a measure of spatial scale by quantile, are plotted if `par = "s"` is added. Here are the plots:

```
plot_qr( res, par = "s" , 1 )
```

## spcomp\_SD

```
plot_qr( res, par = "s" , 2 )
```

## spcomp\_Moran.I/max(Mor

## 5 Low rank spatial econometric models

While ESF/RE-ESF and their extensions approximate Gaussian processes, this section explains low rank spatial econometric models approximating spatial econometric models (see Murakami et al., 2018).

### 5.1 Spatial weight matrix and their eigenvectors

The low rank models use eigenvectors and eigenvalues of a spatial connectivity matrix, which is called a spatial weight matrix or W matrix in spatial econometrics. The `weigen` function is available for the eigen-decomposition. Here is a code extracting the eigenvectors and eigenvalues from spatial polygons:

```
data( boston )
poly  <- st_read( system.file( "shapes/boston_tracts.shp", package = "spData" ) [ 1 ] )

## Reading layer `boston_tracts' from data source
## `C:\Users\dmura\AppData\Local\R\win-library\4.3\spData\shapes\boston_tracts.shp'
## using driver `ESRI Shapefile'
## Simple feature collection with 506 features and 36 fields
## Geometry type: POLYGON
## Dimension: XY
## Bounding box: xmin: -71.52311 ymin: 42.00305 xmax: -70.63823 ymax: 42.67307
## Geodetic CRS: NAD27

weig  <- weigen( poly )          ##### Rook adjacency-based W
```

By default, the `weigen` function returns a Rook adjacency-based W matrix. Other than that, knn-based W, Delaunay triangulation-based W, and user-specified W are also available.

## 5.2 Models

### 5.2.1 Low rank spatial lag model

The low rank spatial lag model (LSLM) approximates the following model:

$$y_i = \beta_0 + z_i + \epsilon_i \quad \epsilon_i \sim N(0, \sigma^2) \quad z_i = \rho \sum_{i \neq j}^N w_{i,j} z_j + \sum_{k \neq 1}^K x_{i,k} \beta_k + u_i \quad u_i \sim N(0, \tau^2)$$

where  $z_i$  is defined by the classical spatial lag model (SLM; see LeSage and Pace, 2009) with parameters  $\rho$  and  $\tau^2$ . Just like the original SLM,  $\rho$  takes a value between 1 and  $1/\lambda_N (< 0)$ . Larger positive  $\rho$  means stronger positive dependence.  $\tau^2$  represents the variance of the SLM-based spatial process (i.e.,  $z_i$ ), while  $\sigma^2$  represents the variance of the data noise  $\epsilon_i$ . Because of the additional noise term, the LSLM estimates are different from the original SLM, in particular if data is noisy.

The LSLM is implemented using the `lslm` function. Here is a sample code:

```
y      <- boston.c[, "CMEDV" ]
x      <- boston.c[, c("CRIM", "ZN", "INDUS", "CHAS", "NOX", "RM", "AGE")]
coords<- boston.c[, c("LON", "LAT")]
res    <- lslm( y = y, x = x, weig = weig, boot = TRUE )
```

```
## [1] "----- Complete:20/200 -----"
## [1] "----- Complete:40/200 -----"
## [1] "----- Complete:60/200 -----"
## [1] "----- Complete:80/200 -----"
## [1] "----- Complete:100/200 -----"
## [1] "----- Complete:120/200 -----"
## [1] "----- Complete:140/200 -----"
## [1] "----- Complete:160/200 -----"
## [1] "----- Complete:180/200 -----"
## [1] "----- Complete:200/200 -----"
```

If `boot=TRUE`, a nonparametric bootstrapping is performed to estimate the 95% confidence intervals for the  $\tau^2$  and  $\rho$  parameters and the direct and indirect effects, which quantify spill-over effects. Default is `FALSE`. Here is the output in which `{s_rho, sp_SE}` are parameters `{ $\rho, \tau^2$ }`:

```
res

## Call:
## lslm(y = y, x = x, weig = weig, boot = TRUE)

### 5.2.2 Low rank spatial error model

The low rank spatial error model (LSEM) approximates the following model:

$$y_i = \beta_0 + z_i + \epsilon_i \quad \epsilon_i \sim N(0, \sigma^2) \quad z_i = \sum_{k \neq 1}^K x_{i,k} \beta_k + e_i \quad e_i = \lambda \sum_{j \neq i}^N w_{i,j} e_j + u_i \quad u_i \sim N(0, \tau^2)$$

where  $z_i$  is defined by the classical spatial error model (SLM) with parameters  $\lambda$  and  $\tau^2$ . Just like the original SEM,  $\lambda$  takes a larger positive value in the presence of stronger positive dependence.  $\tau^2$  represents the variance of the SEM-based spatial process (i.e.,  $z_i$ ). As with LSLM, the LSEM estimates can be different from the original SEM if data is noisy.

The `lsem` function estimates LSEM, as follows:

```
data(boston)
res <- lsem( y = y, x = x, weig = weig )
res

## Call:
## lsem(y = y, x = x, weig = weig)
##
## ----Coefficients-----

## 6 Modeling large samples

### 6.1 Eigen-decomposition

The `meigen` function implements an eigen-decomposition that is slow for large samples. For fast eigen-approximation, the `meigen_f` function is available. By default, this function approximates 200 eigenvectors; 200 is based on simulation results in Murakami and Griffith (2019a). The computation is further accelerated by reducing the number of eigenvectors. It is achieved by specifying `enum` by a number smaller than 200. While the `meigen` function took 243.8 seconds for 5,000 samples, the `meigen_f` took less than 1 second, as demonstrated below:

```
coords_test <- cbind( rnorm( 5000 ), rnorm( 5000 ) )
system.time( meig_test200 <- meigen_f( coords = coords_test ))[3]

## elapsed
##      0.22

system.time( meig_test100 <- meigen_f( coords = coords_test, enum=100 ))[3]

## elapsed
##      0.06

system.time( meig_test50 <- meigen_f( coords = coords_test, enum=50 ))[3]

## elapsed
##      0.05
```

On the other hand, the `weigen` function implements the ARPACK routine for fast eigen-decomposition by default. The computational times with 5,000 samples and `enum = 200` (default), 100, and 50 are as follows:

```

system.time( weig_test200  <- weigen( coords_test ))[3]

## elapsed
##    7.09

system.time( weig_test100  <- weigen( coords_test, enum=100 ))[3]

## elapsed
##   12.75

system.time( weig_test50   <- weigen( coords_test, enum=50 ))[3]

## elapsed
##    0.7

```

## 6.2 Parameter estimation

The basic ESF model is estimated computationally efficiently by specifying `fn = "all"` in the `esf` function. This setting is acceptable for large samples (Murakami and Griffith, 2019a). The `resf` and `resf_vc` functions estimate all the models explained above using a fast estimation algorithm developed in Murakami and Griffith (2019b). They are available for large samples (e.g., 100,000 samples). Although the SF-UQR model requires a bootstrapping to estimate confidential intervals for the coefficients, the computational cost for the iteration does not depend on sample size. Therefore, it is available for large samples too.

## 6.3 Sub-model aggregation for improved scalability in terms of accuracy

The spatial regressions implemented in this package rely on a low rank approximation (i.e., approximation that considers only a limited number of eigen-pairs). For large samples (e.g.,  $n > 5,000$ ), this approximation can lead to an degeneracy/over-smoothing of SVCs that decreases modeling accuracy. To address this problem, the `addlearn_local` function additionally learns local patterns in the SVCs by aggregating/averaging a model pre-estimated by the `resf_vc` or `besf_vc` function with local SVC models, which are defined by k-means-based spatial clusters each of which contains roughly 600 samples (see Murakami et al., 2023). The last line below is a sample example for the additional learning:

```

data(house)
dat0    <- st_as_sf(house)
dat0    <- dat0[dat0$yrbuilt>1950,]
dat     <- data.frame(st_coordinates(dat0),dat0[,c("price","age","rooms","beds","syear")])
coords  <- dat[,c("X","Y")];names(coords)<-c("px","py")
y       <- log(dat[, "price"])
x       <- dat[,c("age","rooms","beds","syear")]
meig    <- meigen_f(coords=coords)
res     <- resf_vc(y=y,x=x,meig=meig )

```

The `addlearn_local` function can be paralleled by specifying `parallel= TRUE`. The smaller error of `res2` over `res` confirms its better accuracy:

```
res$e # Before the adjustment
```

```
##
##          stat
## resid_SE    0.2992962
## adjR2(cond)  0.7007731
## rlogLik      -3351.2431146
## AIC          6726.4862292
## BIC          6815.4935080
```

The `plot_s` function is available to quickly visualize the estimated SVCs:

```
plot_s(res2,2)### coefficients on rooms
```

The `addlearn_local` function is also useful to improve predictive accuracy for large samples. See Section 2.3 for further detail.

## 6.4 For very large samples (e.g., $n > 100,000$ )

A computational limitation is the memory consumption of the `meigen` and `meigen_f` functions to store Moran eigenvectors. Because of the limitation, the `resf` and `resf_vc` functions are not available for very large samples (e.g., millions of samples). To overcome this limitation, the `besf` and `besf_vc` functions perform the same calculation as `resf` and `resf_vc` but without saving the eigenvectors in the memory. Besides, for fast computation, these functions perform a parallel model estimation (see Murakami and Griffith, 2019c).

Here is an example implementing a spatial regression model using the `besf` function and an SVC model using the `besf_vc` function:

```
data(house)
dat0 <- st_as_sf(house)
dat0 <- dat0[dat0$yrbuilt>1950,]
dat <- data.frame(st_coordinates(dat0),dat0[,c("price","age","rooms","beds","syear")])
coords<- dat[,c("X","Y")]
y <- log(dat[, "price"])
x <- dat[,c("age","rooms","beds","syear")]
res1 <- besf(y=y, x=x, coords=coords)
res1
```

```
## Call:
## besf(y = y, x = x, coords = coords)
##
## ----Coefficients-----

```

Roughly speaking, these functions are faster than the `resf` and `resf_vc` functions if the sample size is more than 100,000.

As with the `resf_vc` function, the `besf_vc` function can suffer from the degeneracy/over-smoothing problem. The `addlearn_local` function is useful to address this problem and improves SVC modeling accuracy:

```
res2b <- addlearn_local(res2)
```

```
## [1] "----- Aggregating 23 local sub-models -----"
```

```
res2b
```

```
## Call:
## addlearn_local(mod = res2)
