On a topology property for the moduli space of Kapustin–Witten equations

Teng Huang

Abstract

In this article, we study the Kapustin–Witten equations on a closed, simply-connected, four-dimensional manifold which were introduced by Kapustin and Witten. We use the Taubes’ compactness theorem [24] to prove that if \((A, \phi)\) is a smooth solution of Kapustin–Witten equations and the connection \(A\) is close to a generic ASD connection \(A_\infty\), then \((A, \phi)\) must be a trivial solution. We also prove that the moduli space of the solutions of Kapustin–Witten equations is non-connected if the connections on the compactification of moduli space of ASD connections are all generic. At last, we extend the results for the Kapustin–Witten equations to other equations on gauge theory such as the Hitchin–Simpson equations and Vafa–Witten on a compact Kähler surface.

Keywords. Kapustin–Witten equations, Vafa–Witten equations, stable Higgs bundle, gauge theory

1 Introduction

Let \(X\) be an closed, oriented, smooth, four-dimensional manifold with a given Riemannian metric \(g\), and let \(P \rightarrow X\) be a principal \(G\)-bundle with \(G\) being a compact Lie group. We denote by \(\mathfrak{g}_P\) the adjoint bundle of \(P\) and by \(A_P\) the space of smooth connections on \(P\). On a 4-manifold \(X\) the Hodge star operator \(*\) takes 2-forms to 2-forms and we have \(*^2 = Id_{\Omega^2}\). The self-dual and anti-self-dual forms, we denoted \(\Omega^+\) and \(\Omega^-\) are defined to be the \pm eigenspace of \(*: \Omega^2 T^* X = \Omega^+ \oplus \Omega^-\).

The Kapustin–Witten equations are defined on a Riemannian 4-manifold given a principle bundle \(P\). For most present considerations, \(G\) can be taken to be \(SU(2)\) or \(SO(3)\). The equations require a pair \((A, \phi) \in A_P \times \Omega^1(X, \mathfrak{g}_P)\) satisfies

\[
F_A^+ - (\phi \wedge \phi)^+ = 0, \\
d_A^* \phi = 0, \quad (d_A \phi)^- = 0,
\]

Mathematics Subject Classification (2010): 58E15;81T13
where $F_A$ is the curvature two-form of the connection $A$, and superscripts “-” and “+” indicate taking the anti-self-dual part or self-dual part respectively. These equations were introduced by Kapustin and Witten [15]. The motivation is from the viewpoint of $\mathcal{N} = 4$ super Yang–Mills theory in four dimensions to study the geometric Langlands program [9, 11, 15] and [28, 29, 30, 31]. One also can see Gagliardo-Uhlenbeck’s article [8]. Note that the equation $d^*_A \phi = 0$ makes equations (1.1) an elliptic system after gauge fixing equation. Note also there are no solutions to Kapustin–Witten equations in the case of $p_1(P)$ is positive.

In mathematics, the analytic properties of solutions of Kapustin–Witten equations were discussed by Taubes [24, 25, 26] and Tanaka [21]. In [24], Taubes studied the Uhlenbeck style compactness problem for $SL(2,\mathbb{C})$ connections, including solutions to the above equations, on four-manifolds, see [25, 26]. In [21], Tanaka observed that equations on a compact Kähler surface are the same as Hitchin–Simpson’s equations [12, 18] and proved that the singular set introduced by Taubes for the case of Simpson’s equations has a structure of a holomorphic subvariety. In [13], the author proved that there exist a lower bounded for the $L^2$-norm of extra fields unless the connection is anti-self-dual under some mild conditions on $X, P, g, G$.

One always uses continuous method to construct the solutions of some gauge-theoretic equations. For example, Freed-Uhlenbeck and Taubes [6, 22] used this technical to constructed the ASD connections over a closed four-manifold. In this article, we suppose that the pair $(A_\infty + a, \phi)$ is a smooth solution of the Kapustitin–Witten equations, where $A_\infty$ is an anti-self-dual connection on $P$. Then, the pair $(A_\infty + a, \phi)$ satisfies the equations:

\[
d^+_{A_\infty} a + (a \wedge a)^+ - (\phi \wedge \phi)^+ = 0,
\]
\[
(d_{A_\infty} \phi + [a, \phi])^- = 0.
\]

We will show that if the connections are in a neighborhood of a generic anti-self-dual connection $A_\infty$, then the smooth solutions of Kapustitin–Witten equations on a closed four-manifold must be trivial solutions, i.e., $F^+_{A_\infty + a} = 0$ and $\phi = 0$.

**Theorem 1.1.** Let $X$ be a closed, oriented, simply-connected, four-dimensional manifold with a smooth Riemannain metric $g$, $P \to X$ be a principal $SU(2)$ or $SO(3)$-bundle with $p_1(P)$ negative. Suppose that there exist a generic ASD connection $A_\infty$ on $P$, i.e., $H^0_{A_\infty} = \ker d_{A_\infty}|_{\Omega^0(X, g_P)} = 0$ and $H^2_{A_\infty} = \ker d^+_{A_\infty}|_{\Omega^2+(X, g_P)} = 0$, then there is a positive constant $\delta = \delta(g, P, A_\infty)$ with following significance. If $(A, \phi)$ is a smooth solution of Kapustitin–Witten equations over $X$, then one of following must hold:

1. $F^+_A = 0$ and $\phi = 0$;
2. the pair $(A, \phi)$ satisfies

\[
dist(A, A_\infty) \geq \delta,
\]

where $dist(\cdot, \cdot)$ defined by

\[
dist(A, B) := \inf_{g \in G_P} \|g^*(A) - B\|_{L^2_1(X)}, \quad \forall A, B \in \mathcal{A}_P.
\]
Remark 1.2. We describe another result as follows which is a small variation of the result in [13]. Let the pair \((A, \phi)\) be a smooth solution of Kapustin–Witten equations. If \((A, \phi)\) is closed to \((A_{\infty}, 0)\) in \(L^2\)-topology, i.e., there exist a small enough constant \(\delta \in (0, 1)\) such that

\[
\inf_{g \in \mathcal{G}_P} \|g^*(A) - A_{\infty}\|_{L^2_P} + \|\phi\|_{L^2_P} \leq \delta,
\]

where \(A_{\infty}\) is a generic ASD connection, then \(A\) must be ASD and \(\phi\) identically zero. We should point out that the result is different to Theorem 1.1. We don’t make any assumptions on extra fields in theorem 1.1. The following case may happen: if the connection \(A\) tends to a generic ASD connection \(A_{\infty}\) in \(L^2\)-topology (under moduli gauge transformations), then the \(L^2\)-norm of extra field \(\|\phi\|_{L^2(X)}\) may tend to infinite. But thanks to a compactness theorem of Taubes, we observed that if \(\{(A_i, \phi_i)\}_{i \in \mathbb{N}}\) is a sequence of smooth solutions of Kapustin–Witten equations, then there exist a subsequence \(\Xi \subset \mathbb{N}\) such that the sequence \(\{\|\phi_i\|_{L^2(X)}\}_{i \in \Xi}\) is a bounded subsequence under some conditions, see Lemma 3.10. Using this useful observation, we could prove Theorem 1.1.

We define the gauge-equivariant map

\[
KW : \mathcal{A}_P \times \Omega^1(X, g_P) \to \Omega^{2+}(X, g_P) \times \Omega^{2-}(X, g_P),
\]

\[
KW(A, \phi) = (F^+_A - (\phi \wedge \phi)^+, (d_A \phi)^-).
\]

We denote by

\[
M_{KW}(P, g) := \{(A, \phi) \in \mathcal{A}_P \times \Omega^1(X, g_P) | KW(A, \phi) = 0\}/\mathcal{G}_P
\]

the moduli space of solutions of Kapustin–Witten equations. The moduli space \(M_{ASD}\) of all ASD connections can be embedded into \(M_{KW}\) via \(A_{\infty} \mapsto (A_{\infty}, 0)\), \(A_{\infty}\) is an ASD connection on \(P\). We also denote \(M_{ASD}\) by the compactification of moduli space of ASD connection.

Following the idea of Donaldson on [2] Section 4.2.1, we write \([A, \phi]\) for the equivalence class of a pair \((A, \phi)\), which is a point in the moduli space \(M_{KW}\). We set,

\[
\|(A_1, \phi_1) - (A_2, \phi_2)\|^2 = \|A_1 - A_2\|^2_{L^2_\Xi(X)} + \|\phi_1 - \phi_2\|^2_{L^2_\Xi(X)},
\]

is preserved by the action of \(\mathcal{G}_P\), so descends to define a distance function on \(M_{KW}\):

\[
dist([A_1, \phi_1], [A_2, \phi_2]) := \inf_{g \in \mathcal{G}_P} \|(A_1, \phi_1) - g^*(A_2, \phi_2)\|.
\]

Let the pair \((A, \phi)\) be a smooth solution of Decoupled Kapustin–Witten equations over a closed, simply-connected, four-manifold. We observe that if the connection \(A\) is irreducible, then the extra field \(\phi\) vanishes, see Theorem 3.4. Hence, we can denote by

\[
dist([A, \phi], M_{ASD}) := \inf_{g \in \mathcal{G}_P, A_{\infty} \in M_{ASD}} \|g^*(A, \phi) - (A_{\infty}, 0)\|
\]

\[
= \inf_{g \in \mathcal{G}_P, A_{\infty} \in M_{ASD}} \left(\|g^*(A) - A_{\infty}\|^2_{L^2_\Xi(X)} + \|\phi\|^2_{L^2_\Xi(X)}\right)^{1/2},
\]

the distance between \(M_{ASD}\) and \(M_{KW} \setminus M_{ASD}\).
Theorem 1.3. Let \( X \) be a closed, oriented, simply-connected, four-dimensional manifold with a smooth Riemannian metric \( g \), \( P \rightarrow X \) be a principal \( SU(2) \) or \( SO(3) \)-bundle with \( p_1(P) \) negative. Suppose that the connections in \( \mathcal{M}_{ASD}(P, g) \) are all generic, i.e., \( H^0_{A_{\infty}} = \ker d_{A_{\infty}}|_{\Omega^0(X, g_P)} = 0 \) and \( H^2_{A_{\infty}} = \ker d^*_A|_{\Omega^2+(X, g_P)} = 0 \) for any connection \( [A_{\infty}] \in \mathcal{M}_{ASD}(P, g) \), then there is a positive constant \( \delta = \delta(g, P) \) with following significance. If \( (A, \phi) \) is a smooth solution of Kapustin–Witten equations, then one of following must hold:

1. \( F^+_A = 0 \) and \( \phi = 0 \);
2. the pair \( (A, \phi) \) satisfies

\[
2\|\phi\|_{L^2}^2 \geq \|F^+_A\|_{L^2(X)} \geq \delta.
\]

In particular, there is a positive constant \( \tilde{\delta} = \tilde{\delta}(g, P) \) such that

\[
\text{dist}(A, M_{ASD}) := \inf_{g \in G_P, A_{\infty} \in M_{ASD}} \|g^*(A) - A_{\infty}\|_{L^2(X)} \geq \tilde{\delta},
\]

unless \( A \) is anti-self-dual with respect to \( g \).

We now take \( X \) to be a compact Kähler surface with Kähler form \( \omega \), and \( E \) to be a principal \( G \)-bundle over \( X \). Tanaka observed that the Kapustin–Witten equations are the same as Hitchin–Simpson equations. Furthermore, if \( A \) is an \( SU(N) \)-ASD connection on \( E \), then

\[
\ker d^*_A d_A|_{\Omega^2+(X, adE)} \cong \ker (\bar{\partial}_A \partial_A + \partial_A^* \bar{\partial}_A)|_{\Omega^0(X, adE)} \oplus \ker d_A|_{\Omega^0(X, adE)},
\]

see [14, Proposition 2.3] or [7, Chapter IV]. It’s difficult to addition certain mild conditions to ensure \( \ker (\bar{\partial}_A \partial_A + \partial_A^* \bar{\partial}_A)|_{\Omega^0(X, adE)} \) and \( \ker d_A|_{\Omega^0(X, adE)} \) vanish at some time. But one can see that \( \ker d_A|_{\Omega^0(X, adE)} = 0 \) is equivalent to the connection \( A \) is irreducible. It is convenient to introduce the \( c \)-generic metric which ensures the connections on the compactification of moduli space of ASD connections on \( E \), \( M(E, g) \), are irreducible, one also can see [7, Chapter IV].

Definition 1.4. Let \( X \) be a compact, connected, Kähler surface, \( c \) be a positive integer. We say that a Kähler metric \( g \) on \( X \) is \( c \)-generic if for every \( SU(2) \)-bundle \( E \) over \( X \) with \( c_2(E) \leq c \), there are no reducible ASD connections on \( E \).

If we suppose that the Kähler metric \( g \) is \( c \)-generic, we could deform the connection \( A \in \mathcal{A}^{1,1} \) which obeys \( \|A_\omega F_A\|_{L^2(X)} \leq \varepsilon \) to an other connection \( A_{\infty} \) satisfies \( A_\omega F_{A_{\infty}} = 0 \), where \( \varepsilon \) is a suitable sufficiently small positive constant, see Theorem 4.8. Even though, the connection \( A_{\infty} \) may be not an ASD connection, but the \( (0, 2) \)-part \( F_{A_{\infty}}^{0,2} \) of the curvature \( F_{A_{\infty}} \) would estimated by \( A_\omega F_A \). We then extend the results of Kapustin–Witten equations to the Hitchin–Simpson equations case.

Theorem 1.5. Let \( X \) be a compact, Kähler surface with a smooth Kähler metric \( g \), \( E \) be a principal \( SU(2) \)-bundle with \( c_2(E) = c \) positive. Suppose that \( g \) is a \( c \)-generic metric in the sense of Definition 1.4 then there is a positive constant \( C = C(g, E) \) with following significance. If the Higgs pair \( (A, \theta) \in \mathcal{A}^{1,1}_E \times \Omega^{1,0}(X, adE) \) is a smooth solution of Hitchin-Simpson equations, then one of
following must hold:
(1) $\Lambda \omega F_A = 0$, or
(2) the Higgs field $\theta$ satisfies
\[ \|\theta\|_{L^2(X)} \geq C. \]
Furthermore, if $X$ is also simply-connected, then the curvature $F_A$ obeys
\[ \|\Lambda \omega F_A\|_{L^2(X)} \geq \tilde{C} \]
for a positive constant $\tilde{C} = \tilde{C}(g, P)$ unless $\Lambda \omega F_A = 0$.

We denote by
\[ M_{HS} := \{(A, \phi) \in \mathcal{A}_{E,1} \times \Omega^{1,0}(X, adE) \mid \Lambda \omega (F_A + [\theta, \theta^*]) = 0, \bar{\partial}_A \theta = \theta \wedge \theta = 0\} / G_E \]
the moduli space of solutions of Hitchin-Simpson equations. In [12], Hitchin proved that if the bundle $E$ is a rank-2 bundle of odd degree over a Riemannian surface of genus $g > 1$, then the moduli space of stable Higgs bundle is connected and simply connected, see [12, Theorem 7.6]. Following Theorem 1.5, it implies that the moduli space of stable Higgs bundle on a simply-connected Kähler surface with a generic Kähler metric is not connected. It is different from the Riemannian surface case, see Corollary 4.13.

**Remark 1.6.** If the principal $G$-bundle $P \to X$ over the closed manifold $X$ with $p_1(P) = 0$, the solutions $(A, \phi)$ of the Kapustin–Witten equations are flat $G_C$-connections with moment map condition:
\[ F_A - \phi \wedge \phi = 0, \]
\[ d_A \phi = 0, \]
\[ d^*_A \phi = 0. \]

The [2, Proposition 2.2.3] shows that the gauge-equivalence classes of flat $G$-connections over a connected manifold, $X$, are in one-to-one correspondence with the conjugacy classes of representations $\rho : \pi_1(X) \to G$. If $X$ is also a simply-connected manifold, i.e., $\pi_1(X)$ is trivial, then the representations $\rho$ must be a trivial representation. It is no sense to consider Kapustin–Witten equations on a principal $G$-bundle with $p_1(P) = 0$ over a simply-connected four-manifolds.

The organization of this paper is as follows. In section 2, we first recall gauge theory in 4-dimensional manifolds. We also discuss the elliptic deformation complex and Kuranishi model for the Kapustin–Witten equations. In section 3, we recall a vanishing theorem for the extra fields of the decoupled Kapustin–Witten equations. Using an optimal inequality proved by Donaldson, we observe that the $L^2$-norm of extra fields of non-trivial solutions of Kapustin–Witten equations have a positive lower bounded. Thanks to Taubes’ compactness theorem [24], we observe that if $(A_i, \phi_i)$ is a sequence solutions of Kapustin–Witten equations and the connection $A_i$ converges to an irreducible ASD connection $A_\infty$ in $L^2_1$ (under moduli gauge transformations), then the sequence $\{\|\phi_i\|_{L^2(X)}\}$ has a bounded subsequence. At last, we obtain our main result: if the connection $A$ is closed to a
**generic** ASD connection $A_{\infty}$, then $(A, \phi)$ must be a trivial solution. In section 4, we extend the above results to the global case. We will prove that if the connections on the compactification of moduli space of ASD connections, $\tilde{M}_{ASD}$, are **generic**, then $\|F_A^+\|_{L^2(X)}$ must has a uniform positive lower bounded. In particular, the subspace of anti-self-dual solutions is not connected to the space of Kapustin–Witten equations. We also given some four-manifolds $X$ with Riemannian metric $g$ and principle $SO(3)$-bundles $P \to X$ ensure that the connections on $\tilde{M}_{ASD}$ are **generic**. At last, we construct a gluing theorem for the connection $A$ which obeys $\|\Lambda_\omega F_A\|_{L^2(X)} \leq \varepsilon$, see Theorem 4.8. We then extend the results for the Kapustin–Witten equations to other coupled equations for pairs such as the Hitchin–Simpson equations and Vafa–Witten on compact Kähler surface with a smooth $c$-**generic** Kähler metric $g$.

## 2 A neighborhood of an ASD connection

### 2.1 Yang-Mills theory on 4-manifolds

Let $X$ be an oriented, closed, smooth, Riemannian 4-manifold, $P \to X$ be a principal $G$-bundle with $G$ being a compact Lie group. The Hodge star operator gives an endomorphism of $\Omega^2$ with property $*^2 = I_{\Omega^2}$. We denote by $\Omega^{2,+}$ and $\Omega^{2,-}$ the eigenvalues of $+1$ and $-1$. A 2-form in $\Omega^{2,+}$ (or in $\Omega^{2,-}$) is called self-dual (or anti-self-dual). Decomposing the curvature $F_A$ of a connection $A$ according to the decomposition $\Omega^2 = \Omega^{2,+} \oplus \Omega^{2,-}$ of the 2-forms into self-dual and anti-self-dual parts. An ASD connection $A$ on $P$ naturally induces the Yang–Mills complex

$$\Omega^0(X, g_P) \xrightarrow{d_A} \Omega^1(X, g_P) \xrightarrow{d_A^+} \Omega^{2,+}(X, g_P).$$

The $i$-th cohomology group $H^i_A$ of this complex if finite dimensional and the index $d = h^0 - h^1 + h^2$ ($h^i = \text{dim} H^i_A$) is given by $c(G)\kappa(P) - \text{dim} G(1 - b_1 + b^+)$. $H^0_A$ is the Lie algebra of the stabilizer $\Gamma_A$, the group of gauge transformation of $P$ fixing by $A$. We call a connection is **generic** when $H^0_A = 0$ and $H^2_A = 0$. We denote $M_{gen}$ the subset of $M_{ASD}$ of **generic** ASD connections on $P$. $M_{gen}$ becomes a smooth manifold whose tangent space is $H^1_A$. $M_{gen}$ consists exactly of all singular points and we have two types according to either case (1) in which $A$ is irreducible $H^0_A = 0$ but $H^2_A \neq 0$ or case (2) in which $A$ is reducible $H^0_A \neq 0$. So if the anti-self-dual connections $[A] \in M_{ASD}$ are all **generic**, the moduli space $M_{ASD}$ is a smooth manifold. Furthermore, We call an ASD connection is **regular** when $H^2_A = 0$.

Now we will present the Kuranishi complex associated to the Kapustin–Witten equations, see [13 section 3.1]. Tanaka obtained an analogous Kuranishi complex to the Vafa–Witten equations [16,19]. Let $(A, \phi) \in \mathcal{A}_P \times \Omega^1(X, g_P)$ be a smooth solution to the Kapustin–Witten equations. Then, the infinitesimal deformation at $(A, \phi)$ is given by the following:

$$0 \to \Omega^1(X, g_P) \xrightarrow{d_A^{(A,\phi)}} \Omega^1(X, g_P) \oplus \Omega^1(X, g_P) \xrightarrow{d_A^{(A,\phi)}} \Omega^{2,-}(X, g_P) \oplus \Omega^{2,+}(X, g_P) \to 0,$$
where the map \( d^0_{(A,\phi)} \) and \( d^1_{(A,\phi)} \) are defined for \( \xi \in \Omega^0(X, g_P) \) and \((a, b) \in \Omega^1(X, g_P) \oplus \Omega^1(X, g_P)\) by
\[
d^0_{(A,\phi)}(\xi) = (-d_A \xi, [\xi, \phi]), \\
d^1_{(A,\phi)}(a, b) = ((d_A b + [a, \phi])^-, (d_A a + [b, \phi])^+).
\]
We compute
\[
d^1_{(A,\phi)} \circ d^0_{(A,\phi)}(\xi) = ([\xi, (d_A \phi)^-], [\xi, (F_A + \phi \wedge \phi)^+]).
\]
Thus the pair \((A, \phi)\) satisfies Kapustin–Witten equations if and only if \( d^1_{(A,\phi)} \circ d^0_{(A,\phi)} = 0 \). We can define the homology groups: \( H^0_{(A,\phi)} = \ker d^0_{(A,\phi)} \), \( H^1_{(A,\phi)} = \frac{\ker d^1_{(A,\phi)}}{\text{Im} d^0_{(A,\phi)}} \) and \( H_2^{(A,\phi)} = \text{Coker} d^1_{(A,\phi)}. \) We denote the isotropy group of the pair \((A, \phi)\) as \( \Gamma_{(A, \phi)} = \{ u \in G_P | u^*(A, \phi) = (A, \phi) \}. \) Recall that \( H^0_{(A,\phi)} \) is the Lie algebra of the stabilizer of \((A, \phi)\) and \( H^1_{(A,\phi)} \) is the form tangent space. The dual complex is:
\[
0 \to \Omega^{2-}(X, g_P) \oplus \Omega^{2+}(X, g_P) \xrightarrow{d^1_{(A,\phi)*}} \Omega^1(X, g_P) \oplus \Omega^1(X, g_P) \xrightarrow{d^0_{(A,\phi)*}} \Omega^0(X, g_P) \to 0.
\]
where
\[
d^1_{(A,\phi)*}(a, b') = (d^* A b' - *[\phi, a'], d^* A a' + *[\phi, b']), \\
d^0_{(A,\phi)*}(a, b) = (-d^* A a + *[\phi, b]).
\]

**Proposition 2.1.** The map \( KW(A, \phi) \) has an exact quadratic expansion given by
\[
KW(A + a, \phi + b) = KW(A, \phi) + d^1_{A,\phi}(a, b) + \{(a, b), (a, b)\},
\]
where \( \{(a, b), (a, b)\} \) is the symmetric quadratic form given by
\[
\{(a, b), (a, b)\} := ([a, b]^-, (a \wedge a + [b, b])^+).
\]

Given fixed \((A_0, \phi_0)\), we look for solutions to the inhomogeneous equation \( KW(A_0 + a, \phi_0 + b) = \psi_0 \). By Proposition 2.1 this equation is equivalent to
\[
d^1_{A_0,\phi_0} + \{(a, b), (a, b)\} = \psi_0 - KW(A_0, \phi_0).
\]
To make this equation elliptic, it’s nature to impose the gauge-fixing condition
\[
d^0_{(A_0,\phi_0)*}(a, b) = \zeta.
\]
If we define
\[
D_{(A_0,\phi_0)} := d^0_{(A_0,\phi_0)*} + d^1_{(A_0,\phi_0)*}, \\
\psi = \psi_0 - KW(A_0, \phi_0).
\]
then the elliptic system can be rewritten as
\[
D_{(A_0,\phi_0)} + \{(a, b), (a, b)\} = (\zeta, \psi).
\]
Local interior estimates for the elliptic system (2.2) are consider in [5] equation 3.2 in the context of \( PU(2) \) monopoles. This is also considered similarly for the Vafa-Witten equations in [16].
2.2 An inequality for the connections near an ASD connection

Let $A_\infty$ be a fixing ASD connection on $P$, any connection $A$ can be written uniquely as

$$A = A_\infty + a$$

with $a \in \Omega^1(X, g_P)$. In [1], Donaldson proved that the connection $A$ can be written as

$$A = \tilde{A}_\infty + d_{A_\infty}^+ u,$$

where $\tilde{A}_\infty$ is also an ASD connection and $u \in \Omega^{2+}(X, g_P)$, i.e., the connection $A$ satisfies

$$- d_{A_\infty}^+ d_{A_\infty}^+ u + (d_{A_\infty}^+ u \wedge d_{A_\infty}^+ u)^+ - (a \wedge d_{A_\infty}^+ u)^+ + F_A^+ = 0$$

(2.3)

when the connection $A_\infty$ is regular and $a$ is small enough in $L^2$-norm. The operator $d_A^+ d_A^+$ is an elliptic self-adjoint operator on the space of $L^2$ sections of $\Omega^{2+}TX \otimes g_P$. It is a standard result that the spectrum of $d_A^+ d_A^+$ is discrete, and the lowest eigenvalue is nonnegative.

**Definition 2.2.** For $A_\infty \in M_{ASD}$, define

$$\mu(A_\infty) := \inf_{v \in \Omega^{2+}(X, g_P) \setminus \{0\}} \frac{\|d_{A_\infty}^+ v\|^2}{\|v\|^2},$$

is the lowest eigenvalue of $d_{A_\infty}^+ d_{A_\infty}^+$.

One can see that an ASD connection $A_\infty$ is regular, i.e., $\mu(A_\infty) > 0$. The Sobolev norms $L^p_{k,A}$, where $1 \leq p < \infty$ and $k$ is an integer, with respect to the connections defined as:

$$\|u\|_{L^p_{k,A}(X)} := \left( \sum_{j=0}^k \int_X |\nabla_j^A u|^p dvol \right)^{1/p}, \forall u \in L^p_{k,A}(X, g_P),$$

where $\nabla_j^A := \nabla_A \circ \ldots \circ \nabla_A$ (repeated $j$ times for $j \geq 0$).

**Theorem 2.3.** ([2] Proposition 22) Let $X$ be a closed, four-dimensional, smooth Riemannian manifold with a smooth Riemannian metric, $G$ be a compact Lie group, $P$ be a smooth principal $G$-bundle over $X$. If there is a $C^\infty$ ASD connection $A_\infty$ on $P$ that is regular, then there is constant $\sigma = \sigma(\mu(A_\infty), g, G) \in (0, 1]$ with the following significance. If $A := A_\infty + b$ is a smooth connection on $P$ obeying

$$\|\nabla b\|_{L^2(X)} + \|b\|_{L^2(X)} \|F_{A_\infty}\|_{L^4(X)} \leq \sigma,$$

then there exist a solution $a := d_{A_\infty}^+ u \in \Omega^1(X, g_P)$ where $u \in \Omega^{2+}(X, g_P)$ to Equation (2.3). In fact, the connection $\tilde{A}_\infty := A - a$ is an anti-self-dual connection on $P$. Further, there exist a constant $C = C(\mu(A_\infty), g, G) \in (0, \infty)$ such that

$$\|\nabla_A a\|_{L^2(X)} \leq C \|F_A^+\|_{L^2(X)} + \|F_{A_\infty}\|_{L^4} \|F_A^+\|_{L^{4/3}}.$$

$$\|a\|_{L^2(X)} \leq C \|F_A^+\|_{L^{4/3}(X)}.$$

This theorem 2.3 by follows the method of proof of [22] Theorem 2.2 ] applied to equation $F^+(A + d_{A_\infty}^+ u) = 0$. 

Teng Huang
3 Non-existence solutions on a neighborhood of a generic ASD connection

3.1 Decoupled Kapustin–Witten equations

Definition 3.1. Let $G$ be a compact Lie group, $P$ be a principal $G$-bundle over a closed, smooth four-manifold $X$ with a smooth Riemannian metric $g$. The decoupled Kapustin–Witten equations on $P$ over $X$ are the equations require a pair $(A, \phi) \in \mathcal{A}_P \times \Omega^1(X, g_P)$ satisfies

\[
F_A^+ = 0, \quad (\phi \wedge \phi)^+ = 0, \\
d_A^\ast \phi = 0, \quad d_A \phi^- = 0.
\]

Lemma 3.2. If a pair $(A, \phi)$ is a smooth solution of decoupled Kapustin–Witten equations, then the extra field $\phi$ also obeys

\[
\phi \wedge \phi = 0, \quad d_A \phi = 0.
\]

Proof. At first, we observe that $\int_X tr(\phi \wedge \phi \wedge \phi \wedge \phi) = 0$, hence

\[
\|\phi \wedge \phi\|_{L^2(X)}^2 = 2\|\phi \wedge \phi^+\|_{L^2(X)}^2 = 0,
\]

i.e., $\phi \wedge \phi = 0$. Following the identity $(d_A \phi)^- = 0$, i.e., $d_A \phi = *d_A \phi$, we obtain that

\[
d_A^\ast d_A \phi = - * [F_A, \phi].
\]

Hence take the $L^2$ inner of above identity with $\phi$ and integrable by parts, we obtain

\[
\|d_A \phi\|_{L^2(X)}^2 = - \int_X tr([F_A, \phi] \wedge \phi) = \int_X tr(F_A \wedge [\phi \wedge \phi]) = 0,
\]

i.e., $d_A \phi = 0$. We complete the proof of this lemma.

We recall a vanishing theorem on the extra fields of decoupled Kapustin–Witten equations. The prove is similar to Vafa–Witten equations \cite{16} Theorem 4.2.1. At first, we recall a useful lemma proved by Donaldson \cite{2}, Lemma 4.3.21.

Lemma 3.3. If $A$ is an irreducible $SU(2)$ or $SO(3)$ ASD connection on a bundle $P$ over a simply connected four-manifold $X$, then the restriction of $A$ to any non-empty open set in $X$ is also irreducible.

Theorem 3.4. (\cite{13} Theorem 2.9) Let $X$ be a closed, simply-connected, smooth, oriented, Riemannian four-manifold, $P \to X$ be an $SU(2)$ or $SO(3)$ principal bundle. Suppose that $(A, \phi)$ is a solution of the decoupled Kapustin–Witten equations. If $A$ is irreducible, then the extra fields $\phi$ vanishes.
Proof. We denote $Z^c$ by the complement of the zero of $\phi$. By unique continuation of the elliptic equation $(d_A + d^*_A)\phi = 0$, $Z^c$ is either empty or dense. Since $\phi \wedge \phi = 0$, $\phi$ has at most rank one. The Lie algebra of $SU(2)$ or $SO(3)$ is three-dimensional, with basis $\{\sigma^i\}_{i=1,2,3}$ and Lie brackets $\{\sigma^i, \sigma^j\} = 2\varepsilon_{ijk}\sigma^k$. In a local coordinate, we can set $\phi = \sum_{i=1}^{3} \phi_i \sigma^i$, where $\phi_i \in \Omega^1(X)$. We then have

$$0 = \phi \wedge \phi = 2(\phi_1 \wedge \phi_2)\sigma^3 + 2(\phi_3 \wedge \phi_1)\sigma^2 + 2(\phi_2 \wedge \phi_3)\sigma^1,$$

i.e.,

$$0 = \phi_1 \wedge \phi_2 = \phi_3 \wedge \phi_1 = \phi_2 \wedge \phi_3. \tag{3.1}$$

On $Z^c$, $\phi$ is non-zero, then without loss of generality we can assume that $\phi_1$ is non-zero. From (3.1), there exist functions $\mu$ and $\nu$ such that

$$\phi_2 = \mu \phi_1 \text{ and } \phi_3 = \nu \phi_1.$$

Hence we would re-written $\phi$ to

$$\phi = \phi_1(\sigma^1 + \mu \sigma^2 + \nu \sigma^3) = \phi_1(1 + \mu^2 + \nu^2)^{1/2} \sqrt{\frac{\sigma^1 + \mu \sigma^2 + \nu \sigma^3}{1 + \mu^2 + \nu^2}}.$$

Then on $Z^c$ write $\phi = \xi \otimes \omega$ for $\xi \in \Omega^0(Z^c, \mathfrak{g}_P)$ with $\langle \xi, \xi \rangle = 1$, and $\omega \in \Omega^1(Z^c)$. We compute

$$0 = d_A(\xi \otimes \omega) = d_A \xi \wedge \omega - \xi \otimes d\omega,$$

$$0 = d^*_A(\xi \otimes \omega) = d_A \xi \wedge *\omega - \xi \otimes d * \omega.$$

Taking the inner product with $\xi$ and using the consequence of $\langle \xi, \xi \rangle = 1$ that $\langle \xi, d_A \xi \rangle = 0$, we get $d\omega = d^* \omega = 0$. It follows that $d_A \xi \wedge \omega = 0$ and $d_A \xi \wedge *\omega = 0$. Since $\omega$ is nowhere zero along $Z^c$, we must have $d_A \xi = 0$ along $Z^c$. Therefore, $A$ is reducible along $Z^c$. However according to Lemma 3.3, $A$ is irreducible along $Z^c$. This is a contradiction unless $Z^c$ is empty. Therefore $Z = X$, so $\phi$ identically zero. \hfill $\square$

### 3.2 A bounded property of extra fields

In this section, we will proved that the extra fields have a lower positive bounded if the connections on the neighborhood of a regular ASD connection. The result has a direct proof by using the Kuranishi model for the moduli space of Kapustin–Witten solutions around the pair $(A_\infty, 0)$, where $A_\infty$ is an ASD connection. Our proof employs a Weizenböck formula, the idea could extends to the cases of Kapustin–Witten equations and Vafa–Witten equations on Kähler surface. We need recall a bounded on $\|\phi\|_{L^\infty}$ in terms of $\|\phi\|_{L^2}$. The technique is analogy to Vafa–Witten equations case [16].

**Theorem 3.5.** ([13] Theorem 2.4) If the pair $(A, \phi)$ is a smooth solution of Kapustin–Witten equations over a closed, smooth, Riemannian four-manifold, then

$$\|\phi\|_{L^\infty(X)} \leq C\|\phi\|_{L^2(X)},$$

where $C = C(g)$ is a positive constant only depends on metric $g$. 

If we suppose that the connection \([A]\) is in a neighborhood of a regular ASD connection \([A_\infty]\), then the Theorem 2.3 which provides existence of an other ASD connection \(\tilde{A}_\infty\) on \(P\) and a Sobolev norm estimate for the distance between \(A\) and \(\tilde{A}_\infty\). Following the idea in [13], we then have

**Proposition 3.6.** Let \(X\) be a closed, oriented, smooth, four-dimensional Riemannian manifold with Riemannian metric \(g\), \(P \to X\) be a principal \(G\)-bundle with \(G\) being a compact Lie group with \(p_1(P)\) negative. Suppose that \(A_\infty\) is an regular ASD connection on \(P\), i.e., \(\ker d^+_A|_{\Omega^{2,+(X,\mathcal{g}_P)}} = 0\), then there are positive constants \(\delta = \delta(g, A_\infty) \in (0, 1)\), \(C = C(g, A_0) \in [1, \infty)\) with following significance. If \((A, \phi)\) is a smooth solution of Kapustin–Witten equations and the connection \(A\) obeys

\[
\text{dist}(A, A_\infty) \leq \delta
\]

then either the extra field obeying

\[
\|\phi\|_{L^2} \geq C
\]

or \(A\) is anti-self-dual with respect to \(g\).

**Proof.** Following Theorem 2.3 it implies that for a suitable constant \(\delta\), the connection \(A\) can be written as \(A = \tilde{A}_\infty + a\), where \(\tilde{A}_\infty\) is also an ASD connection. Following the idea in [13], we have two integrable inequalities:

\[
\|\nabla A \phi\|^2_{L^2(X)} + \langle \text{Ric} \circ \phi, \phi \rangle_{L^2(X)} + 2 \|F^+_A\|^2_{L^2(X)} = 0,
\]

\[
\|\nabla \tilde{A}_\infty \phi\|^2_{L^2(X)} + \langle \text{Ric} \circ \phi, \phi \rangle_{L^2(X)} \geq 0.
\]

Combining the preceding inequalities gives

\[
0 \leq \|\nabla A_0 \phi\|^2_{L^2(X)} + \langle \text{Ric} \circ \phi, \phi \rangle_{L^2(X)}
\]

\[
\leq \|\nabla A \phi\|^2_{L^2(X)} + \langle \text{Ric} \circ \phi, \phi \rangle_{L^2(X)} + \|\nabla A \phi - \nabla \tilde{A}_\infty \phi\|^2_{L^2(X)}
\]

\[
\leq c \|a\|_{L^2(X)} \|\phi\|_{L^\infty(X)} - 2 \|F^+_A\|^2_{L^2(X)}
\]

\[
\leq (c \|\phi\|_{L^2(X)} - 2) \|F^+_A\|_{L^2(X)}.
\]

If \(\|F^+_A\|_{L^2(X)}\) is non-zero, thus \(\|\phi\|^2_{L^2(X)} \geq 2/c\). We complete the proof of this proposition. \(\square\)

### 3.3 Uhlenbeck type compactness of Kapustin–Witten equations

We now recall the work by Taubes on Uhlenbeck style compactness theorem of Kapustin–Witten equations on closed four-dimensional manifolds [24]. In [21], Tanaka also briefly describe the compactness theorem. Let \(X\) be a closed, oriented, smooth Riemannian four-manifold with Riemannian metric \(g\), \(P \to X\) be a principal \(G\)-bundle over \(X\) with \(G\) being \(SU(2)\) or \(SO(3)\). We consider a sequence solutions \(\{(A_i, \phi_i)\}\) of the Kapustin–Witten equations. We put \(r_i := \|\phi_i\|_{L^2(X)}\). In the case that \(\{r_i\}\) has a bounded subsequence, the Uhlenbeck compactness theorem with the Weizenböck formula deduces the following.
Theorem 3.7. ([27] Proposition 2.1) If \( \{r_i\} \) has a bounded subsequence, then
(1) there exist a principal bundle \( P_\Delta \to X \) and a pair \( (A_\Delta, \phi_\Delta) \in A_{P_\Delta} \times \Omega^1(X, g_{P_\Delta}) \) obeys the Kapustin-Witten equations;
(2) a finite set \( \Sigma \subset X \) of points, a subsequence \( \Xi \subset \mathbb{N} \) and a sequence \( \{g_i\}_{i\in \Xi} \) of automorphisms of \( P_\Delta|_X - \Sigma \) such that \( \{(g_i^*(A_i), g_i^*(\phi_i))\}_{i\in \Xi} \) converges to \( (A_\Delta, \phi_\Delta) \) in the \( C^\infty \) topology on compact subsets in \( X - \Sigma \).

Analysis for the case that \( \{r_i\} \) has no bounded subsequences was the bulk of [24, Theorem 1.1].

Theorem 3.8. ([27] Proposition 2.2) If \( \{r_i\} \) has no bounded subsequence. There exists in this case the following data:
(1) A finite set \( \Theta \subset X \) and a closed, nowhere dense set \( Z \subset X - \Theta \),
(2) a real line bundle \( \mathcal{I} \to X - (Z \cup \Theta) \),
(3) a section \( v \) of \( \mathcal{I} \otimes T^*X|_{X - (Z \cup \Theta)} \) with \( dv = d^*v = 0 \), the norm of \( v \) extends over the whole of \( X \) as a bounded \( L_2 \) function. In addition,
a) The extension of \( |v| \) is continuous on \( X - \Theta \) and its zero locus is the set \( Z \).
b) Let \( U \) denote an open set in \( X - \Theta \) with compact closure. The function \( |v| \) is Hölder continuous on \( U \) with Hölder exponent that is independent of \( U \) and of the original sequence \( \{(A_i, \phi_i)\}_{i=1,2,...} \).
c) If \( p \) is any given point in \( X \), then the function \( \text{dist}(\cdot, p)^{-1}|\nabla v| \) extends to the whole of \( X \) as an \( L_2 \) function.
(4) A principal G-bundle \( P_\Delta \) over \( X - (Z \cup \Theta) \) and a connection \( A_\Delta \) of \( P_\Delta \) with \( d_{A_\Delta}^*F_{A_\Delta} = 0 \).
(5) An isometric \( A_\Delta \) covariantly constant homorphism \( \sigma_\Delta : \mathcal{I} \to \mathfrak{g}_P \).

In addition, there exist a subsequence \( \Xi \subset \mathbb{N} \) and a sequence of automorphisms \( g_i : P_\Delta \to P|_{X - (Z \cup \Theta)} \) such that
(i) \( \{g_i^*(A_i)\}_{i\in \Xi} \) converges to \( A_\Delta \) in the \( L^2_\Sigma \) topology on compact subset in \( X - (Z \cup \Theta) \) and
(ii) The sequence \( \{r_i^{-1}g_i^*(\phi_i)\} \) converges to \( v \otimes \sigma_\Delta \) in \( L^2_\Sigma \) topology on compact subset in \( X - (Z \cup \Theta) \) and \( C^0 \) topology on \( X - \Theta \). Moreover, the sequence \( \{r_i^{-1}\phi_i\}_{i\in \Xi} \) is pointwise bounded and it converges in the \( L^2 \) topology on \( X \) to \( |v| \).

As was the case for Uhlenbeck theorem, the number of elements in \( \Theta \) only dependent on the first Pontrjagin class \( p_1(P) \). In particular, \( \Theta \) is empty if the first Pontrjagin class of \( p_1(P) = 0 \). As for the structure of the above \( Z \), Taubes proved that \( Z \) has the Hausdorff dimension at most 2, see [24].

For a sequence of connections \( \{A_i\} \) on \( P \), Tanaka defined a set \( S(\{A_i\}) \) as follows:
\[
S(\{A_i\}) := \bigcap_{r \in (0, \rho)} \{ x \in X : \liminf_{i \to \infty} \int_{B_r(x)} |F_{A_i}|^2 \geq \varepsilon_0 \},
\tag{3.2}
\]
where \( \varepsilon_0 \) is a positive constant is defined as in [20]. This set \( S(\{A_i\}) \) describes the singular set of a sequence of connections \( \{A_i\} \). In [20], Tanaka observed that under the particular circumstance where the connections are non-concentrating and the limiting connection is non-locally reducible, one obtains an \( L^2 \)-bounded on the extra fields. We extend the idea used by Tanaka for Vafa–Witten equations (see [20, Theorem 1.3]) to the Kapustin–Witten equations case.
Theorem 3.9. Let $X$ be a closed, oriented, 4-dimensional manifold with a smooth Riemannian metric $g$, $P \to X$ be a principal $G$-bundle with $G$ being $SU(2)$ or $SO(3)$. If $\{(A_i, \phi_i)\}$ is a sequence of smooth solutions of Kapustin–Witten equations with $S(\{A_i\})$ being empty, then there exists subsequence $\Xi \subset \mathbb{N}$ and a sequence of gauge transformations $\{g_i\}_{i \in \Xi}$ such that $\{g_i(A_i)\}_{i \in \Xi}$ converges weakly in the $L^2$-topology. If the limit is not locally reducible, then there exists a positive number $C$ such that $\int_X |\phi_i|^2 \leq C$ for all $i \in \Xi$, and $\{(g_i^*(A_i), g_i^*(\phi_i))\}_{i \in \Xi}$ converges in the $C^\infty$-topology to a pair that obeys the Kapustin–Witten equations.

We then have a useful lemma as follows.

Lemma 3.10. Let $X$ be a closed, oriented, simply-connected, 4-dimensional manifold with a smooth Riemannian metric $g$, $P \to X$ be a principal $G$-bundle with $G$ being $SU(2)$ or $SO(3)$. If $\{(A_i, \phi_i)\}$ is a sequence of smooth solutions of Kapustin–Witten equations such that

$$dist(A_i, A_\infty) \to 0, \text{ as } i \to \infty,$$

where $A_\infty$ is an irreducible ASD connection on $P$, then there exist a subsequence $\Xi \subset \mathbb{N}$ such that the sequence $\{r_i := \|\phi_i\|_{L^2(X)}\}_{i \in \Xi}$ is a bounded subsequence.

Proof. For the sequence of $\{A_i\}_{i \in \mathbb{N}}$ on $P$, one can see $S(\{A_i\}) = \emptyset$, where $S(\{A_i\})$ defined in as in equation (3.2). Following [19, Theorem 1.3], there exist a subsequence $\Xi \subset \mathbb{N}$ and a sequence of gauge transformations $g_i(A_i)_{i \in \Xi}$ converges weakly in the $L^2$-topology, we denote the limit connection by $\tilde{A}_\infty$. Under our assumption on the sequence $\{A_i\}_{i \in \mathbb{N}}$, there exist a gauge transformation $g_\infty$ such that $g_\infty(A_\infty) = \tilde{A}_\infty$. Hence $\tilde{A}_\infty$ is also not locally reducible, since the locally reducible connection on simply-connected manifold is also reducible, see [20, Appendix B]. At last, following Theorem 3.9 it implies that there exist a positive number $C$ such that $\|\phi_i\|_{L^2(X)} \leq C$ for all $i \in \Xi$. \qed

Proof of Theorem 1.1. We suppose that the pair $(A, \phi)$ is a smooth solution of Kapustin–Witten equations and $A$ is not ASD with respect to metric $g$. If we suppose that the constant $\delta$ does not exist, we may choose a sequence $\{(A_i, \phi_i)\}_{i \in \mathbb{N}}$ of solutions of Kapustin–Witten equations on $P$ such that $dist(A_i, A_\infty) \to 0$ as $i \to \infty$, then following Proposition 3.6 and Lemma 3.10, there exists a subsequence $\Xi \subset \mathbb{N}$ and two positive constants $C, c$, such that

$$c \leq \|\phi_i\|_{L^2(X)} \leq C.$$

Following the compactness Theorem 3.7, there exist a pair $(A_\Delta, \phi_\Delta) \in \mathcal{A}_{P_\Delta} \times \Omega^1(X, g_{P_\Delta})$ that obeys the Kapustin–Witten equations and there has a subsequence $\Xi' \subset \Xi$ and a sequence $\{g_i\}_{i \in \Xi'}$ of automorphisms of $P_\Delta$ such that $\{(g_i^*(A_i), g_i^*(\phi_i))\}_{i \in \Xi'}$ converges to $(A_\Delta, \phi_\Delta)$ in the $C^\infty$ topology on $X$. Thus the extra field $\phi_\Delta$ also has a lower positive bounded:

$$\|\phi_\Delta\|_{L^2(X)} \geq \lim inf \|\phi_i\|_{L^2(X)} \geq c.$$
But on the other hand, under our initial assumption regarding the sequence \( \{A_i\}_{i \in \mathbb{N}} \), we have \([A_\Delta] \equiv [A_\infty] \). Thus the connection \( A_\Delta \) is also irreducible, following the vanishing Theorem [3,4] it implies that the extra field \( \phi_\Delta = 0 \). This contradicts \( \|\phi_\Delta\|_{L^2(X)} \) has a uniform positive lower bound. The preceding argument shows that the desired constant \( \delta \) exists. \( \square \)

3.4 A bounded property of curvatures

In this section, we extend the proof method of Theorem 1.1 to global case. We suppose that the connections \([A_\infty] \in \overline{M}_{ASD} \) are all regular, i.e., \( \ker d^+_{A_\infty}\mid_{\Omega^2+(X,\mathbb{G}_P)} = 0 \). Following the result in [4 Section 3], one know that the connections on

\[
B_\varepsilon(P,g) := \{ A \in A_P : \|F_A^+\|_{L^2(X)} \leq \varepsilon \}
\]

also obey \( \ker d^+_{A_\infty}\mid_{\Omega^2+(X,\mathbb{G}_P)} = 0 \) for suitable constant \( \varepsilon \).

**Proposition 3.11.** Let \( G \) be a compact Lie group, \( P \to X \) be a principal \( G \)-bundle over a closed, connected, four-dimensional manifold \( X \) with a smooth Riemannian metric \( g \). Suppose that the connections on \( \overline{M}_{ASD} \) are all regular, i.e., \( \ker d^+_{A_\infty}\mid_{\Omega^2+(X,\mathbb{G}_P)} = 0 \) for any connection \([A_\infty] \in \overline{M}_{ASD} \), then there are positive constants \( \varepsilon = \varepsilon(P,g) \) and \( \mu = \mu(P,g) \) such that

\[
\mu(A) \geq \mu, \quad [A] \in \mathcal{B}_\varepsilon(P,g).
\]

where \( \mu(A) \) is as in Definition 2.2.

We then recall a result of extra fields \( \phi \) which proved by author [13].

**Theorem 3.12.** Assume the hypotheses of Proposition 3.11. Suppose that the connections on \( \overline{M}_{ASD} \) are all regular, i.e., \( \ker d^+_{A_\infty}\mid_{\Omega^2+(X,\mathbb{G}_P)} = 0 \) for any connection \([A_\infty] \in \overline{M}_{ASD} \), then there is a positive constant \( c = c(P,g) \) with following significance. If \((A,\phi)\) is a smooth solution of Kapustin–Witten equations, then the extra field \( \phi \) obeys

\[
\|\phi\|_{L^2(X)} \geq c,
\]

unless \( A \) is anti-self-dual with respect to \( g \).

Now, we begin to consider a sequence smooth solutions \( \{(A_i,\phi_i)\}_{i \in \mathbb{N}} \) of Kapustin–Witten equations. If we suppose that \( \|\phi_i\|_{L^2(X)} \) has no bounded subsequence, following the compactness theorem [3,8] proved by Taubes, we only know that the connection \( A_\Delta \) has harmonic curvature. Moreover if we suppose that \( F_{A_i}^+ \) converge to zero in \( L^2 \)-topology, then we can claim that \( A_\Delta \) is an anti-self-dual connection on the complement of \( Z \cup \Theta \cup \Sigma \).

**Corollary 3.13.** Let \( \{(A_i,\phi_i)\}_{i \in \mathbb{N}} \) be a sequence smooth solutions of Kapustin–Witten equations, set \( r_i := \|\phi_i\|_{L^2(X)} \). Suppose that \( \{F_{A_i}^+\}_{i \in \mathbb{N}} \) converge to zero in \( L^2 \)-topology and the sequence \( \{r_i\}_{i=1,2,...} \) has no bounded subsequence. Let \( Z, \Theta \) and \( I \) be as described in Theorem 3.8 so that \( \sigma_\Delta \) and \( A_\Delta \) are defined over \( X - (Z \cup \Theta \cup \Sigma) \). Then the connection \( A_\Delta \) is anti-self-dual connection on \( P_\Delta \).
Before the proof of Corollary 3.13 we should recall a key a compactness theorem due to Sedlacek, see [17] Theorem 4.3 or [8] Theorem 35.17.

**Theorem 3.14.** Let $G$ be a compact Lie group and $P$ a principal $G$-bundle over a closed, smooth, oriented, four-dimensional Riemannian manifold $X$ with a Riemannian metric $g$. If $\{A_i\}_{i \in \mathbb{N}}$ is a sequence $C^\infty$ connection on $P$ and the sequence $\{F_{A_i}^+\}_{i \in \mathbb{N}}$ converges to zero in $L^2$-topology, then there exists

1. An integer $L$ and a finite set of points, $\Sigma = \{x_1, \ldots, x_L\} \subset X$, $\Sigma$ maybe empty,

2. A smooth anti-self-dual $A_\infty$ on a principal $G$-bundle $P_\infty$ over $X$ with $\eta(P_\infty) = \eta(P)$,

3. A subsequence $\Xi \subset \mathbb{N}$, we also denote by $\{A_i\}_{i \in \Xi}$, a sequence gauge transformation $\{g_i\}_{i \in \Xi}$ such that, $g_i^* (A_i)$ weakly converges to $A_\infty$ in $L^2_1$ on $X - \Sigma$, and $g_i^* (F_{A_i})$ weakly converges to $F_{A_\infty}$ in $L^2$ on $X - \Sigma$.

**Proof of Corollary 3.13** We can apply Theorem 3.14 to the sequence $\{A_i\}_{i \in \mathbb{N}}$. This yields a subsequence $\Xi \subset \mathbb{N}$, a sequence of gauge transformations $\{g_i\}_{i \in \Xi}$ and an anti-self-dual connection $A_\infty$ on a principal $G$-bundle $P_\infty$ which is the weakly $L^2_1$ limit of $\{g_i^* (A_i)\}_{i \in \Xi}$ over $X - \Sigma$, $\Sigma$ is the set of some points on $X$. If the sequence $r_i$ don’t has a bounded subsequence. Apply Theorem 3.8 to the subsequence $\{(A_i, \phi_i)\}_{i \in \Xi}$. Recall from Theorem 3.8 that $A_\Delta$ is the limit over compact subset of $X - (Z \cup \Theta)$ of gauge transformations of $\{A_i\}_{i \in \Xi}$. In particular, both $A_\infty$ and $A_\Delta$ are weakly $L^2_1$ limits over $X - (Z \cup \Theta \cup \Sigma)$ of gauge-equivalent connections. Since weakly $L^2_1$ limits preserve $L^2_2$ gauge equivalence, it follows that there exists a Sobolev-class $L^2_2$ gauge transformation $g_\Delta$ such that $g_\Delta^*(A_\Delta) = A_\infty$. Thus $A_\Delta$ is anti-self-dual on the complement of $Z \cup \Theta \cup \Sigma$.

The result due to Tanaka [19] Theorem 1.3 for the sequence $\{A_i\}_{i \in \mathbb{N}}$ obeys $\|F_{A_i}^+\|_{L^2(X)}$ converges to zero in $L^2$-topology will invalid, since $S(A_i)$ may be not empty. But we could prove a compactness theorem for a sequence solutions of Kapustin–Witten equations by using the Lemma 3.3.

**Proposition 3.15.** Let $X$ be a closed, oriented, simply-connected, four-dimensional manifold with a smooth Riemannian metric $g$, $P \to X$ be a principal $SU(2)$ or $SO(3)$-bundle with $p_1(P)$ negative. Suppose that the connections on $\tilde{M}_{ASD}(P,g)$ are irreducible. If $\{(A_i, \phi_i)\}_{i \in \mathbb{N}}$ is a sequence smooth solutions of Kapustin–Witten equations and the curvatures $F_{A_i}^+$ converge to zero in $L^2$-topology, then

1. An integer $L$ and a finite set of points, $\Sigma = \{x_1, \ldots, x_L\} \subset X$,

2. A subsequence $\Xi \subset \mathbb{N}$, we also denote by $\{A_i\}$, a sequence gauge transformation $\{g_i\}_{i \in \Xi}$ such that, $(g_i^* (A_i), g_i^* (\phi_i))$ converges to $(A_\infty, 0)$ in $C^\infty$ on $X - \Sigma$, where $A_\infty$ is an anti-self-dual connection on a principal $P_\infty$.

**Proof.** At first, we claim that the sequence $r_i := \|\phi_i\|_{L^2(X)}$ has a bounded subsequence. If not, the sequence $r_i$ don’t has a bounded subsequence. Following Theorem 3.8 we have $Z, \Theta$ and $\sigma_\Delta, \nu$ which described in Theorem 3.8 We define $\sigma_\infty := g_\Delta^*(\sigma_\Delta)$ over $X - (Z \cup \Theta \cup \Sigma)$, where $g_\Delta, \Sigma$ are as described in the proof of Corollary 3.13. Following Theorem 3.8 we then have

$$\nabla_{A_\infty} \sigma_\infty = \nabla_{A_\Delta} \sigma_\Delta = 0 \text{ on } X - (Z \cup \Theta \cup \Sigma).$$
Thus we have a section $s := v \otimes \sigma_\infty$ on $P_\infty|_{X - (Z \cup \Theta \cup \Sigma)}$ and one can see $v \otimes \sigma_\infty$ is non-zero all over $X - (Z \cup \Theta \cup \Sigma)$. We can rewrite $s$ to $s = \tilde{\sigma} \otimes \tilde{v}$, where $\tilde{\sigma} \in \Gamma(X - (Z \cup \Theta \cup \Sigma), g_{P_\infty})$ and $\tilde{v} \in \Omega^1(X - (Z \cup \Theta \cup \Sigma))$. We also setting $\langle \tilde{\sigma}, \tilde{\sigma} \rangle = 1$, thus $\langle d_{A_\infty} \tilde{\sigma}, \tilde{\sigma} \rangle = 0$ along $X - (Z \cup \Theta \cup \Sigma)$. In a direct calculate, we have

$$d_{A_\infty} \tilde{\sigma} \wedge \tilde{v} + \tilde{\sigma} \wedge d\tilde{v} = 0,$$

thus $d\tilde{v} = 0$. It follows that $d_{A_\infty} \tilde{\sigma} \wedge v = 0$. Since $\tilde{v}$ is nowhere zero along $X - (Z \cup \Theta \cup \Sigma)$, we must have $d_{A_\infty} \tilde{\sigma} = 0$. According to Lemma 3.3, $A$ is irreducible along a open set of $X - (Z \cup \Theta \cup \Sigma)$, then $\tilde{\sigma} = 0$. This contradict $s$ is non-zero on $X - (Z \cup \Theta \cup \Sigma)$. Hence we prove that the sequence $\{r_i\}_{i=1,2,...}$ must has a bounded subsequence. Then following the compactness theorem 3.7, there exist a pair $(A_\Delta, \phi_\Delta) \in \mathcal{A}_P \times \Omega^1(X, g_{P_\Delta})$ that obeys the Kapustin–Witten equations and there has a subsequence $\Xi' \subset \Xi$ and a sequence $(g_i)_{i \in \Xi'}$ of automorphisms of $P_\Delta$ such that $\{(g_i^*(A_i), g_i^*(\phi_i))\}_{i \in \Xi'}$ converges to $(A_\Delta, \phi_\Delta)$ in the $C^\infty$ topology on $X - \{x_1, \cdots, x_L\}$. Under the assumption of $\{A_i\}_{i \in \mathbb{N}}$, the connection $A_\Delta$ is an irreducible anti-self-dual connection, then the vanish theorem ensures $\phi_\Delta = 0$. \hfill \Box

**Proof of Theorem 1.3** Now we begin to proof Theorem 1.3. Suppose that the constant $\delta$ does not exist. We may choose a sequence of solutions $\{(A_i, \phi_i)\}_{i \in \mathbb{N}}$ of Kapustin–Witten equations such that $\|F_A^+\|_{L^2(X)} \to 0$. Following Proposition 3.15, there exist a subsequence $\Xi \subset \mathbb{N}$ and a sequence transformation $(g_i)_{i \in \Xi}$ such that $(g_i^*(A_i), g_i^*(\phi_i)) \to (A_\infty, 0)$ in $C^\infty$ over $X - \Sigma$, $\Sigma := \{x_1, \cdots, x_L\}$. There also exist a positive constant $C$, such that $\|\phi_i\|_{L^\infty(X)} \leq C$. We then have

$$\|\phi_i\|_{L^\infty(X)} \leq c \|\phi_i\|_{L^2(X)} \leq cC,$$

where $c = c(g)$ is a positive constant. Therefore

$$\lim_{i \to \infty} \int_X |\phi_i|^2 = \lim_{i \to \infty} \int_{X - \Sigma} |\phi_i|^2 + \lim_{i \to \infty} \int_{\Sigma} |\phi_i|^2 \leq cC \mu(\Sigma) = 0.$$

This contradict $\|\phi_i\|_{L^2(X)}$ has a uniform positive lower bound, see Theorem 3.12. The preceding argument shows that the desired constant $\delta$ exists.

If we denote by $A_\infty$ an ASD connection on $P$, then the curvature $F_A$ of a connection $A := A_\infty + a$ has an estimate

$$\|F_A^+\|_{L^2(X)} = \|(d_{A_\infty} a + a \wedge a)^+\|_{L^2(X)} \leq \|d_{A_\infty} a\|_{L^2(X)} + \|a \wedge a\|_{L^2(X)} \leq C(\|\nabla_{A_\infty} a\|_{L^2(X)} + \|a\|_{L^4(X)}^2) \leq C(\|a\|_{L^2_1(X)} + \|a\|_{L^4_1(X)}^2),$$

where $C = C(g)$ is a positive constant. If $\|a\|_{L^2_1(X)} \leq 1$, then

$$\|F_A^+\|_{L^2(X)} \leq 2C \|a\|_{L^2_1(X)}.$$

We also suppose that $A$ is not anti-self-dual with respect to $g$, then

$$\|a\|_{L^2_1(X)} \geq \frac{\delta}{2C},$$
where $\delta$ is the positive constant as above. So we can set $\tilde{\delta} := \min\{1, \frac{\delta}{2C}\}$, hence
\[
\text{dist}(A, M_{\text{ASD}}) := \inf_{g \in G, A_{\infty} \in M_{\text{ASD}}} \|g^*(A) - A_{\infty}\|_{L_2^2(X)} \geq \tilde{\delta}
\]
unless $A$ is ASD with respect to metric $g$.

\[\square\]

### 3.5 Some examples

In this section, we give some conditions on the topology of manifold, the metric of manifold and the topology of principle bundle to ensure that the connections on $\bar{M}_{\text{ASD}}$ are all \textit{generic}. For a compact four-manifold $X$, the compactification $\bar{M}_{\text{ASD}}(P, g)$ of $M_{\text{ASD}}(P, g)$ contained in the disjoint union
\[
\bar{M}_{\text{ASD}}(P, g) \subset \bigcup (M_{\text{ASD}}(P_l, g) \times \text{Sym}^l(X)). \tag{3.3}
\]

We denote by $\eta(P)$ the element in $H^2(X, \mathbb{R})$ which defined as \cite{17} Definition 2.1]. Following \cite{17} Theorem 5.5], every principal $G$-bundle, $M(P_l, g)$ over $X$ appearing in (3.3) has the property that $\eta(P_l) = \eta(P)$.

**Proposition 3.16.** Let $X$ be a closed, oriented, simply-connected, four-dimensional manifold with a generic Riemannian metric $g$, $P \to X$ be a principal $SU(2)$ or $SO(3)$-bundle with $p_1(P)$ negative. If $b^+(X) > 0$, then the connection $[A] \in M_{\text{ASD}}$ is irreducible.

**Proof.** If $G = SU(2)$ or $SO(3)$, $X$ is a simply-connected four-manifold and $b^+(X) > 0$, then following \cite[Corollary 4.3.15]{2} , the only reducible anti-self-dual connection on a principal $G$-bundle over $X$, is the product connection on the product bundle $P = X \times G$ if only if the anti-self-dual connection is flat connection, i.e., $p_1(P) = 0$. Hence under our assumption on $X, P, G$, then the anti-self-dual connection must be irreducible.

In Proposition \ref{3.16} we mean by \textit{generic metric} the metrics in a second category subset of the space of $C^k$ metrics for some fixed $k > 2$ (\cite Section 4] and [\cite Corollary 2]). It may reassure the reader to know that for all practical purposes one can work with an open dense subset of the smooth metrics, or even real analytic metrics.

**Proposition 3.17.** Let $X$ be a closed, oriented, simply-connected, four-dimensional manifold with a generic Riemannian metric $g$, $P \to X$ be a principal $SO(3)$-bundle with $p_1(P)$ negative. If $b^+(X) > 0$ and the second Stiefel-Whitney class $w_2(P) \neq 0$, then the connections $[A] \in \bar{M}_{\text{ASD}}$ are all \textit{generic}.

**Proof.** Under the hypothesis on this proposition, we know that the connections $[A] \in \bar{M}_{\text{ASD}}$ are all \textit{regular}, i.e., $\mu(A) > 0$ where $\mu(A)$ is as in Definition \ref{2.2} see \cite Corollary 3.9]. If $G = SO(3)$, following \cite Theorem 2.4] , we have $\eta(P) = w_2(P)$. We then obtain that if $w_2(P)$ is non-trivial, then every principal $G$-bundle, $M(P_l, g)$, over $X$ appearing in (3.3) has the property that $w_2(P_l)$ is
non-trivial. We would claim that the ASD connections on $M(P_l, g)$ are irreducible. Since an reducible ASD connection on $P_l$ ensures that the bundle $P_l$ is trivial bundle. This contradict $w_2(P_l) \neq 0$. By the similar method in Proposition 4.5 for any $[A] \in \overline{M}_{\text{ASD}}(P, g)$, we have $\lambda(A) > 0$, where $\lambda(A)$ is as in Definition 4.2, i.e., $[A]$ is irreducible. We complete the proof of this proposition.

Following Theorem 1.3 we then have

**Corollary 3.18.** Assume the hypothesis on Proposition 3.17. Suppose that $b^+(X) > 0$ and the second Stiefel-Whitney class $w_2(P) \neq 0$. There is a positive constant $\delta = \delta(P, g)$ with following significance. If the pair $(A, \phi)$ is a smooth solution of Kapustin-Witten equations, then one of following must hold:

1. $F_A^+ = 0$ and $\phi = 0$;
2. the pair $(A, \phi)$ satisfies 

$$2\|\phi\|^2_{L^2} \geq \|F_A^+\|_{L^2(X)} \geq \delta.$$ 

In particular, there is a positive constant $\bar{\delta} = \bar{\delta}(g, P)$ such that

$$\text{dist}(A, \overline{M}_{\text{ASD}}) := \inf_{g \in \mathcal{G}_P, A_\infty \in \overline{M}_{\text{ASD}}} \|g^*(A) - A_\infty\|_{L^2(X)} \geq \bar{\delta},$$

unless $A$ is anti-self-dual with respect to $g$.

## 4 Kähler surfaces

In this section, we now denote by $X$ a compact Kähler surface with a Kähler form $\omega$ and $E$ a principal $G$-bundle over $P$ with structure group $G$. We also set $d_A = \partial_A + \bar{\partial}_A$, $d_{\omega}^* = \partial_A^* + \bar{\partial}_A^*$ and $\phi = \sqrt{-1}(\theta - \theta^*)$, where $\theta \in \Omega^{1,0}(X, \text{ad}E)$. Thus, Tanaka observed that Kapustin-Witten equations on a closed Kähler surface are the same as Hitchin-Simpson’s equations, see [21, Proposition 3.1].

**Proposition 4.1.** Let $X$ be a closed Kähler surface, the Kapustin-Witten equations have the following form that asks $(A, \theta) \in \mathcal{A}_E \times \Omega^{1,0}(X, \text{ad}E)$ to satisfies

$$\bar{\partial}_A \theta = 0, \quad \theta \wedge \theta = 0,$$

$$F_A^{0,2} = 0, \quad \Lambda_\omega (F_A^{1,1} + [\theta \wedge \theta^*]) = 0.$$

Hence the bundle $E$ on $X$ is holomorphic and $\theta$ is a holomorphic section of $\text{End}(E) \otimes \Omega^{1,0}(X)$, i.e., the bundle $(E, \theta)$ is a Higgs bundle. Following the Kobayashi-Hitchin corresponding for Higgs bundle, see [12, 18], we know that the Higgs bundle $(E, \theta)$ is stable since the pair $(A, \phi)$ satisfies the Hitchin-Simpson equations.

### 4.1 Irreducible connections

In this section, we first recall a definition of irreducible connection on a principal $G$-bundle. Given a connection $A$ on a principal $G$-bundle $E$ over $X$. We can define the stabilizer $\Gamma_A$ of $A$ in the gauge group $\mathcal{G}_E$ by

$$\Gamma_A := \{ u \in \mathcal{G}_E| u^*(A) = A \},$$
On a topology property for the moduli space of Kapustin–Witten equations

one also can see [2, 6]. A connection \( A \) called reducible if the connection \( A \) whose stabilizer \( \Gamma_A \) is larger than the centre \( C(G) \) of \( G \). Otherwise, the connections are irreducible, they satisfy \( \Gamma_A \cong C(G) \). For the cases \( G = SU(2) \) or \( SO(3) \), it’s easy to see that a connection \( A \) is irreducible when it admits no nontrivial covariantly constant Lie algebra-value 0-form, i.e.,

\[
\ker d_A|_{\Omega^0(X, adE)} = 0.
\]

We can defined the least eigenvalue \( \lambda(A) \) of \( d^*_A d_A \) as follow .

**Definition 4.2.** For \( A \in \mathcal{A}_E \), define

\[
\lambda(A) := \inf_{v \in \Omega^0(X, adE) \setminus \{0\}} \frac{\|d_A v\|^2}{\|v\|^2}.
\] (4.1)

is the lowest eigenvalue of \( d^*_A d_A \).

By the similar method of the proof of [4, Proposition A.3] or [3, Proposition 35.14] , we would also show that the least eigenvalue \( \lambda(A) \) of \( d^*_A d_A \) with respect to connection \( A \) is \( L^p_{\text{loc}} \)-continuity \( 2 \leq p < 4 \).

**Proposition 4.3.** Let \( X \) be a closed, connected, oriented, smooth four-manifold with Riemannian metric, \( g \). Let \( \Sigma = \{x_1, x_2, \ldots, x_L\} \subset X \) \((L \in \mathbb{N}^+)\) and \( \rho = \min_{i \neq j} \text{dist}_g(x_i, x_j) \), let \( U \subset X \) be the open subset give by

\[
U := X \setminus \bigcup_{l=1}^L \bar{B}_{\rho/2}(x_l).
\]

Let \( G \) be a compact Lie group, \( A_0, A \) are \( C^\infty \) connections on the principal \( G \)-bundles \( E_0 \) and \( E \) over \( X \) and \( p \in [2, 4) \). There is an isomorphism of principal \( G \)-bundles, \( u : E \mid X \setminus \Sigma \cong E_0 \mid X \setminus \Sigma \), and identify \( E \mid X \setminus \Sigma \) with \( E_0 \mid X \setminus \Sigma \) using this isomorphism. Then \( \lambda(A) \) satisfies upper bound

\[
\sqrt{\lambda(A)} \geq \sqrt{\lambda(A_0)} - c\sqrt{L} \rho^{1/6}(\lambda(A) + 1) - cL \rho(\sqrt{\lambda(A)} + 1) - c_p \|A - A_0\|_{L^p(U)}(\lambda(A) + 1),
\]

and the lower bound,

\[
\sqrt{\lambda(A)} \leq \sqrt{\lambda(A_0)} + c\sqrt{L} \rho^{1/6}(\lambda(A_0) + 1) + cL \rho(\sqrt{\lambda(A_0)} + 1) + c_p \|A - A_0\|_{L^p(U)}(\lambda(A_0) + 1),
\]

where \( c \) is a positive constant depends on \( g, p \).

We now have the useful

**Corollary 4.4.** Let \( G \) be a compact Lie group and \( P \) a principal \( G \)-bundle over a closed, smooth, oriented, four-dimensional Riemannian manifold \( X \) with a Riemannian metric \( g \). If \( \{A_i\}_{i \in \mathbb{N}} \) is a sequence \( C^\infty \) connection on \( P \) and the sequence \( \{F^+_i\}_{i \in \mathbb{N}} \) converges to zero in \( L^2 \)-topology, then

\[
\lim_{i \to \infty} \lambda(A_i) = \lambda(A_\infty).
\]

where \( \lambda(A) \) is as in Definition 4.2.
Proof. The proof is similar to the least eigenvalue of operator $d_A^+d_A^{+*}|_{\Omega^{2,+}(X,adE)}$ with respect to connection $A$ (see [3] Corollary 35.16).

For a compact Kähler surface $X$ we have a moduli space of ASD connections $M(E, g)$. The compactification $\bar{M}(E, g)$ of $M(E, g)$ contained in the disjoint union

$$\bar{M}(E, g) \subset \cup(M(E_\ell, g) \times Sym^1(X)),$$

(4.2)

Following [2] Theorem 4.4.3, the space $\bar{M}(E, g)$ is compact.

**Proposition 4.5.** Let $X$ be a compact, Kähler surface with smooth Kähler metric $g$, $E$ be a principal $SU(2)$-bundle with $c_2(E) = c$ positive. Suppose that $g$ is a $c$-general Kähler metric, then there are positive constants $\varepsilon = \varepsilon(E, g)$ and $\lambda_0 = \lambda_0(E, g)$ with following significance. If $A$ is a connection on $E$ such that

$$\|F_A^+\|_{L^2(X)} \leq \varepsilon,$$

and $\lambda(A)$ is as in (4.1), then

$$\lambda(A) \geq \lambda_0.$$

**Proof.** If $g$ is $c$-generic metric, $\lambda(A) > 0$ for $[A] \in M(E_\ell, g)$ and $E_\ell$ is a principal $SU(2)$-bundle over $X$ appearing in the Uhlenbeck compactification. Since the function $\lambda(A), A \in \bar{M}(E, g)$ is continuous by Corollary 4.4 and $\bar{M}(E, g)$ is compact, there is a uniform positive constant $\lambda$ such that $\lambda(A) \geq \lambda$ for $[A] \in \bar{M}(E, g)$. Suppose that the constant $\varepsilon$ does not exist. We may then choose a minimizing sequence $\{A_i\}_{i \in \mathbb{N}}$ of connections on $E$ such that $\|F_{A_i}^+\|_{L^2(X)} \to 0$ and $\lambda(A_i) \to 0$ as $i \to \infty$. According to Corollary 4.4, $A_i$ converges to an ASD connection, $A_\infty$, on $L^1_{1, loc}(X)$. Then $\lim_{i \to \infty} \lambda(A_i) = \lambda(A_\infty) > 0$, contradicting our initial assumption regarding the sequence $\{A_i\}_{i \in \mathbb{N}}$. \qed

Fix an algebraic surface $S$ and an ample line bundle $L$ on $S$. For every integer $c$ we have defined the moduli space $\mathcal{M}_c(S, L)$ of $L$-stable rank two holomorphic vector bundles $V$ on $S$ and such that $c_1(V) = 0, c_2(V) = c$. Taubes [23] has shown that, if $X$ is an arbitrary closed 4-manifold and $g$ is any Riemannian metric on $X$, then the moduli space of all irreducible $g$-ASD connections on $P$ with $c_2(P) = c$ moduli gauge equivalence which denote by $\mathcal{M}(P_c, g)$ is nonempty if $c$ is sufficiently large. In the case of an algebraic surface $S$ and a Hodge metric corresponding to the ample line bundle $L$, similar existence results are due to Maruyama and Gieseker [10]. Friedman-Morgan ([7] Chapter IV, Theorem 4.7) given a very general result along these lines is the following:

**Theorem 4.6.** With $S$ and $L$ as above, for all $c \geq 2p_g + 2$, the modulis space $\mathcal{M}_c(S, L)$ is nonempty.

Next let us determine when a Hodge metric with Kähler form $\omega$ admits reducible ASD connections. Corresponding to such a connection is an associated ASD harmonic 1-form $\alpha$, well-defined up to $\pm 1$, representing an integral cohomology class, which by the description of $\Omega^{2,-}(X)$ is of type
(1, 1) and orthogonal to $\omega$. Thus Friedman-Morgan proved for an integer $c > 0$, there exist Hodge metric $g$ over $S$ is $c$-generic in the sense of Definition 1.4 (see [7, Chapter IV, Proposition 4.8]). For the convenience of readers, we give a detailed proof.

**Proposition 4.7.** Fix $c > 0$. Then there is an open dense subset $\mathcal{D}$ of the cone of ample divisors on $S$ such that if $g$ is a Hodge metric whose Kähler form lies in $\mathcal{D}$, $g$ is a $c$-generic metric in the sense of Definition 1.4.

**Proof.** By standard argument, the set of $\omega$ in the ample cone which are orthogonal to an integral class $\alpha$ with $0 < -\alpha^2 \leq c$ is the intersection of the ample cone with a collection of hyperplanes in $H^2(S; \mathbb{R})$ which is locally finite on the ample cone. This result is immediate from this. \hfill $\square$

### 4.2 Approximate ASD connections

In this section, we will give a general criteria under which an approximate ASD connection $A \in \mathcal{A}_E^{1,1}$ can be deformation into an other approximate ASD connection $A_\infty$ which obeys the equation

$$\Lambda_\omega F_{A_\infty} = 0. \quad (4.3)$$

Let $A$ be a connection on a principal $G$-bundle over $X$. The equation (4.3) for a second connection $A_\infty := A + a$, where $a \in \Omega^1(X, adE)$ is a bundle valued 1-form, can be written as:

$$\Lambda_\omega (d_Aa + a \wedge a) = -\Lambda_\omega F_A. \quad (4.4)$$

We seek a solution of the equation (4.4) in the form

$$a = d_A^* s \otimes \omega = \sqrt{-1} (\partial_A s - \bar{\partial}_A s)$$

where $s \in \Omega^0(X, adE)$ is a section on $ad(E)$. Then equation (4.4) becomes to a second order equation:

$$- d_A^* d_A s + \Lambda_\omega (d_A s \wedge d_A s) = -\Lambda_\omega F_A. \quad (4.5)$$

For convenience, we define a map

$$B(u, v) := \frac{1}{2} \Lambda_\omega [d_A u \wedge d_A v].$$

It’s easy to check, we have the pointwise bound:

$$|B(u, v)| \leq C |\nabla_A u| |\nabla_A v|,$$

where $C$ is a uniform positive constant. We want to prove that if $\Lambda_\omega F_A$ is small in an appropriate sense, then there is a small solution $s$ to equation (4.5).
Theorem 4.8. Let $X$ be a compact Kähler surface with a Kähler metric $g$, $E$ a principal $SU(2)$-bundle over $X$. There are positive constants $\varepsilon = \varepsilon(E, g) \in (0, 1)$ and $\lambda = \lambda(E, g) \in (0, \infty)$ with following significance. If $A \in A^{1,1}_E$ obeys
\[ \|A \omega F_A\|_{L^2(X)} \leq \varepsilon, \]
\[ \lambda(A) \geq \lambda, \]
then there is a section $s \in \Omega^0(X, adE)$ such that the connection $A_\infty := A + \sqrt{-1}(\partial_A s - \bar{\partial}_A s)$ satisfies
(1) $\Lambda_\omega F_{A_\infty} = 0$
(2) $\|s\|_{L^2(X)} \leq C\|A \omega F_A\|_{L^2(X)}$,
(3) $\|F_{A_\infty}^0\|_{L^2(X)} \leq C\|A \omega F_A\|_{L^2(X)}^2$,
where $C = C(\lambda, g) \in [1, \infty)$ is a positive constant.

Now, we begin to prove Theorem 4.8. The method of proof Theorem 4.8 is based on Taubes’ ideas [22]. At first, suppose that $s$ and $f$ are sections of $adE$ with
\[ d_A^*d_A s = f, \text{ i.e., } \nabla_A^*\nabla_A s = f. \tag{4.6} \]
The first observation is

Lemma 4.9. If $\lambda(A) \geq \lambda > 0$, then there exists a unique $C^\infty$ solution to equation (4.6). Furthermore, we have
\[ \|s\|_{L^2(X)} \leq c\|f\|_{L^2(X)}, \]
\[ \|B(s, s)\|_{L^2(X)} \leq c\|f\|_{L^2(X)}^2, \]
where $c = c(\lambda, g)$ is a positive constant.

Proof. Since $\nabla_A^*\nabla_A$ is an elliptic operator of order 2, then for each $k \geq 0$, there is a positive constant $C_k$ so that for all section $v$ of $adE$, see [22] (A8),
\[ \|v\|_{L^2_k(X)} \leq C_k(\|\nabla_A^*\nabla_A v\|_{L^2_k(X)} + \|v\|_{L^2(X)}) \leq C_k(\|\nabla_A^*\nabla_A v\|_{L^2_k(X)} + \lambda^{-1}\|\nabla_A^*\nabla_A v\|_{L^2(X)}). \]

We take $v = s$ and $k = 0$, then
\[ \|s\|_{L^2(X)} \leq c\|\nabla_A^*\nabla_A s\|_{L^2(X)} \leq c\|f\|_{L^2(X)}, \]
where $c = c(\lambda, g)$ is a positive constant. By the Sobolev inequality in four dimension,
\[ \|B(s, s)\|_{L^2(X)} \leq C\|\nabla_A s\|_{L^2(X)}^2 \leq C\|\nabla_A s\|_{L^2(X)}^2 \leq c\|s\|_{L^2(X)}, \]
where $C$ is a positive constant. Hence we complete the proof of this lemma. \qed
Lemma 4.10. If $d^*_A d_A s_1 = f_1$, $d^*_A d_A s_2 = f_2$, then

$$
\|B(s_1, s_2)\|_{L^2(X)} \leq c \|f_1\|_{L^2(X)} \|f_2\|_{L^2(X)}.
$$

We can prove the existence of a solution of (4.5) by the contraction mapping principle. We write $s = (d^*_A d_A)^{-1} f$ and (4.5) becomes an equation for $f$ of the from

$$
f - S(f, f) = \Lambda_\omega F_A,
$$

where $S(f, g) := B((d^*_A d_A)^{-1} f, (d^*_A d_A)^{-1} g)$. By Lemma 4.10,

$$
\|S(f_1, f_1) - S(f_2, f_2)\|_{L^2(X)} = \|S(f_1 + f_2, f_1 - f_2)\|_{L^2(X)} \leq c \|f_1 + f_2\|_{L^2(X)} \|f_1 - f_2\|_{L^2(X)}.
$$

We denote $g_k = f_k - f_{k-1}$ and $g_1 = f_1$, then

$$
g_1 = \Lambda_\omega F_A, \quad g_2 = S(g_1, g_1)
$$

and

$$
g_k = S\left(\sum_{i=1}^{k-1} g_i, \sum_{i=1}^{k-1} g_i\right) - S\left(\sum_{i=1}^{k-2} g_i, \sum_{i=1}^{k-2} g_i\right), \quad \forall k \geq 3.
$$

It is easy to show that, under the assumption of $\Lambda_\omega F_A$, the sequence $f_k$ defined by

$$
f_k = S(f_{k-1}, f_{k-1}) + \Lambda_\omega F_A,
$$

starting with $f_1 = \Lambda_\omega F_A$, is Cauchy with respect to $L^2$, and so converges to a limit $f$ in the completion of $\Gamma(adE)$ under $L^2$.

Proposition 4.11. There are positive constant $\varepsilon \in (0, 1)$ and $C \in (1, \infty)$ with following significance. If the connection $A$ satisfies

$$
\|\Lambda_\omega F_A\|_{L^2(X)} \leq \varepsilon,
$$

then each $g_k$ exists and is $C^\infty$. Further for each $k \geq 1$, we have

$$
\|g_k\|_{L^2(X)} \leq C^{k-1} \|\Lambda_\omega F_A\|_{L^2(X)}^k.
$$

Proof. The proof is by induction on the integer $k$. The induction begins with $k = 1$, one can see $g_1 = \Lambda_\omega F_A$. The induction proof if completed by demonstrating that if (4.8) is satisfied for $j < k$, then it also satisfied for $j = k$. Indeed, since

$$
\|S\left(\sum_{i=1}^{k-1} g_i, \sum_{i=1}^{k-1} g_i\right) - S\left(\sum_{i=1}^{k-2} g_i, \sum_{i=1}^{k-2} g_i\right)\|_{L^2(X)}
$$

$$
\leq c \|\sum_{i=1}^{k-1} g_i + \sum_{i=1}^{k-2} g_i\|_{L^2(X)} \|g_{k-1}\|_{L^2(X)}
$$

$$
\leq 2c \sum_{i=1}^{k-1} \|g_i\|_{L^2(X)} \|g_{k-1}\|_{L^2(X)}
$$

$$
\leq \frac{2c}{1 - C\|\Lambda_\omega F_A\|_{L^2(X)}^2} C^{k-2} \|\Lambda_\omega F_A\|_{L^2(X)}^k.
$$
Now, we provide the constants $\varepsilon$ sufficiently small and $C$ sufficiently large to ensure that
\[ \| \Lambda_\omega F_A \|_{L^2(X)} \leq C^{-2}(C - 2\varepsilon), \]
i.e., \[ \frac{2\varepsilon}{1 - C\| \Lambda_\omega F_A \|_{L^2(X)}} \leq C, \]
hence we complete the proof of this proposition.

**Proof of Theorem 4.8** The sequence $g_k$ is Cauchy in $L^2$, the limit
\[ f := \lim_{i \to \infty} f_i \]
is a solution to (4.7). Using Lemma 4.9 and Proposition 4.11, we have
\[ \| s \|_{L^2(X)} \leq C \| f \|_{L^2(X)} \leq \frac{\| \Lambda_\omega F_A \|_{L^2(X)}}{1 - C\| \Lambda_\omega F_A \|_{L^2(X)}}, \]
we provide $\varepsilon$ and $C$ to ensure $C\varepsilon \leq \frac{1}{2}$, hence
\[ \| s \|_{L^2(X)} \leq 2\| \Lambda_\omega F_A \|_{L^2(X)}. \]
We denote $A_\infty := A + \sqrt{-1}(\partial_A s - \bar{\partial}_A s)$, then
\[ \| F_{A_\infty}^{0,2} \|_{L^2(X)} = \| - \sqrt{-1}\partial_A \bar{\partial}_A s - \bar{\partial}_A s \|_{L^2(X)} \]
\[ = \| \bar{\partial}_A s \|_{L^2(X)} \leq 2\| \bar{\partial}_A s \|_{L^2(X)} \]
\[ \leq c\| \nabla_A s \|_{L^2(X)} \leq C\| \Lambda_\omega F_A \|_{L^2(X)}, \]
where $c$ is a positive constant. We complete the proof of Theorem 4.8.

### 4.3 A topological property for the moduli space of stable Higgs bundles

In this section, we use the inequality in Theorem 4.8 to prove that the Higgs filed has a positive lower bounded if the Kähler metric $g$ is $c$-generic. Following Theorem 3.4, we have a vanishing result of Higgs fields as follows.

**Corollary 4.12.** Let $X$ be a closed Kähler surface with a smooth Kähler metric $g$, $E$ be a principal $SU(2)$-bundle with $c_2(E) = c$ positive. Suppose that $g$ is a $c$-generic metric in the sense of Definition 1.4. If the Higgs pair $(A, \theta)$ is a smooth solution of the equations: $\Lambda_\omega F_A = 0$, $[\theta \wedge \theta^*] = 0$, then the Higgs field $\theta$ vanishes.

**Proof Theorem 1.5** Let $(A, \theta) \in \mathcal{A}_E^{1,1} \times \Omega^{1,0}(X, \text{ad}E)$ be a smooth solution of Hitchin–Simpson equations. We denote $\phi = \sqrt{-1}(\theta - \theta^*) \in \Omega^1(X, \text{ad}E)$. Suppose that the constant $C$ does not exist. We may provide a positive constant $\varepsilon_0$ such that
\[ 0 < \| \Lambda_\omega F_A \|_{L^2(X)} \leq c\| \theta \|_{L^2(X)}^2 \leq c\varepsilon_0 < \varepsilon \]
where \( c = c(g) \) is a positive constant and \( \varepsilon \) is a constant as Proposition 4.8. Thus \( \lambda(A) > 0 \). Following Theorem 4.8, there exist a connection \( A_\infty \) which satisfies \( \Lambda \omega F_{A_\infty} = 0 \) and

\[
\| A - A_\infty \|_{L^2(X)} \leq c \| \Lambda \omega F_A \|_{L^2(X)}
\]

for some positive constant \( c = c(g, P) \). We have two integrable inequalities:

\[
\| \nabla_A \phi \|^2_{L^2(X)} + \langle \text{Ric} \circ \phi, \phi \rangle_{L^2(X)} + \| \Lambda \omega F_A \|^2_{L^2(X)} = 0,
\]

\[
\| \nabla_A \phi \|^2_{L^2(X)} + \langle \text{Ric} \circ \phi, \phi \rangle_{L^2(X)} + \| \Lambda \omega F_A \|^2_{L^2(X)} \geq 0.
\]

To obtain the second identity, we use the Weitzenböck formula [6] Equation (6.25):

\[
2d_{A_\infty}^* d_{A_\infty} + d_{A_\infty} d_{A_\infty}^* = \nabla_{A_\infty}^* \nabla_{A_\infty} + \text{Ric}(\cdot) + * [F_{A_\infty}^+, \cdot] = 0 \text{ on } \Omega^1(X, g_P).
\]

We also observe that \( \langle F_{A_\infty}^{0,2} + F_{A_\infty}^{2,0}, [\phi, \phi] \rangle_{L^2(X)} = 0 \) since \( [\phi, \phi] \in \Omega^{1,1}(X, adE) \).

Combining the preceding inequalities gives

\[
0 \leq \| \nabla_{A_\infty} \phi \|^2_{L^2(X)} + \langle \text{Ric} \circ \phi, \phi \rangle_{L^2(X)}
\]

\[
\leq \| \nabla_A \phi \|^2_{L^2(X)} + \langle \text{Ric} \circ \phi, \phi \rangle_{L^2(X)} + \| \nabla_A \phi - \nabla_{A_\infty} \phi \|^2_{L^2(X)}
\]

\[
\leq (c \| \phi \|^2_{L^2(X)} - 1) \| \Lambda \omega F_A \|^2_{L^2(X)}.
\]

for a positive constant \( c = c(g) \). If we provide \( C = 1/(2c) \) such that \( \| \phi \|^2_{L^2(X)} \leq C \), then \( \Lambda \omega F_A \equiv 0 \). Its contradiction to our initial assumption regarding the \( \Lambda \omega F_A \). The preceding argument shows that the desired constant \( \tilde{C} \) exists.

We also suppose \( X \) is simply-connected, if the constant \( \tilde{C} \) does not exist. We may choose a sequence \( \{(A_i, \theta_i)\}_{i \in \mathbb{N}} \) of Hitchin–Simpson equations such that \( \| \Lambda \omega F_{A_i} \|_{L^2(X)} \to 0 \). We set \( \phi_i := \sqrt{-1}(\theta_i - \theta^{*}_i) \). Following the idea of Theorem 1.3, the Proposition 3.13 implies that there exist a subsequence \( \Xi \in \mathbb{N} \) and a sequence transformation \( \{g_i\}_{i \in \Xi} \) such that \( g^*(A_i, g^*(\phi_i)) \to (A_\infty, 0) \) in \( C^\infty \) over \( X - \Sigma, \Sigma := \{x_1, \ldots, x_L\} \). We also have \( \lim_{i \to \infty} \int_X |\phi_i|^2 = 0 \). This contradict \( \| \phi_i \|^2_{L^2(X)} \) has a uniform positive lower bounded. The preceding argument shows that the desired constant \( \tilde{C} \) exists.

\[\square\]

**Corollary 4.13.** Let \( X \) be a compact, simply-connected, Kähler surface with a smooth Kähler metric \( g, E \) be a principal \( SU(2) \)-bundle over \( X \). Suppose that \( (E, \theta) \) is a stable Higgs bundle with \( c_2(E) = c \), then there is a positive integer \( c \) with following significance. If \( g \) is a \( c \)-generic metric in the sense of Definition 4.7, then the moduli space of stable Higgs bundle is non-connected.

**Proof.** Taubes [23] has shown that, if \( X \) is an arbitrary closed 4-manifold and \( g \) is any Riemannian metric on \( X, P \) be a \( SU(2) \)-bundle with \( c_2(E) = c \) sufficiently large, then there exist an irreducible ASD connection on \( P \). The moduli space \( M_{\text{ASD}}(E, g) \) is non-empty under our conditions. Since the map \( (A, \theta) \mapsto \| \theta \|_{L^2} \) is continuous, then the moduli space \( M_{\text{HS}} \) is not connected.

\[\square\]

Following Proposition 4.7 and Corollary 4.13 we have
Corollary 4.14. Let $S$ be a compact, simply-connected, algebraic surface with a Hodge metric $g$, $(E, \theta)$ be a Higgs bundle over $X$. There is an open dense subset $D$ of the cone of ample divisor on $S$ and a positive integer $c$ with following significance. If the Kähler form of $g$ lies in $D$ and $(E, \theta)$ is stable with $c_2(E) = c$, then the moduli space of stable Higgs bundle is non-connected.

4.4 Vafa-Witten equations

We next consider analogue of the Hitchin–Simpson equations, called Vafa–Witten equations \cite{27}. Let $X$ be a closed, oriented, smooth, four-manifold, $E$ be a principal $G$-bundle with $G$ being a compact Lie group over $X$. We denote by $A$ a connection on $E$, $B$ a section of the associated bundle $\Omega^2(X, adE)$ and $\gamma$ a section of $adE$. A triple $(A, B, \gamma)$ is a solution of Vafa–Witten equations if $(A, B, \gamma)$ satisfies

$$F_A^+ + [B.B] + [B, \Gamma] = 0, \quad d_A^+ B + d_A \Gamma = 0,$$

(4.9)

where $[B.B] \in \Gamma(X, \Omega^2(X, adE))$ is defined through the Lie brackets of $adE$ and $\Omega^2$, see \cite[Appendix A]{16}. We take $X$ to be a compact Kähler surface with Kähler form $\omega$. In a local orthonomal coordinates, we can write $B = \beta - \beta^* + B_0 \omega$, where $\beta \in \Omega^2(X, adE)$, $B_0 \in \Omega^0(X, adE)$ and $\gamma = C - \sqrt{-1} B_0$, one can see \cite[Chapter 7]{16} for details. We have

Theorem 4.15. (\cite[Theorem 7.1.2]{16}) On a compact Kähler surface, the Vafa–Witten equations (4.9) have the following form that asks $(A, \beta, \gamma) \in A^{1,1}_E \times \Omega^2(X, adE) \times \Omega^0(X, adE)$ to satisfies

$$\sqrt{-1} \omega \wedge F_A + \frac{1}{2} [\beta \wedge \beta^*] = 0,$$

$$\overline{\partial}_A \beta = d_A \gamma = 0,$$

$$[\gamma, \gamma^*] = [\gamma, \beta + \beta^*] = 0.$$

\quad (4.10)

Mares also discussed a relation between the existence of a solution to the equations and a stability of vector bundles, see \cite{16,19}.

Definition 4.16. For any $\beta \in \Omega^2(X, End E) \cong \Omega^0(Hom(E, E \otimes K))$, we say that a subbundle $E' \subset E$ is $\beta$-invariant, if

$$\beta(E') \subset E' \otimes K.$$

A holomorphic bundle $E$ is $\beta$-stable (semi-stable) if all $\beta$-invariant holomorphic subbundle $E' \subset E$ satisfies

$$\mu(E') = \frac{\text{deg}(E')}{\text{rank} E'} < (\leq) \mu(E) = \frac{\text{deg}(E)}{\text{rank} E}.$$

We also recall a bound on $\|\beta\|_{L^\infty}$ in terms of $\|\beta\|_{L^2}$. One can see \cite{16} for detail.

Theorem 4.17. Let $X$ be a compact, Kähler surface with a smooth Kähler metric $g$, $E$ a principal $G$-bundle over $X$ with $G$ being a compact Lie group. If the pair $(A, \beta, \gamma)$ is a smooth solution of Equations (4.10), there is a positive constant $C = C(g)$ such that

$$\|\beta\|_{L^\infty(X)} \leq C \|\beta\|_{L^2(X)}.$$
We extend the idea of Hitchin–Simpson equations to the case of the Vafa–Witten equations on the compact Kähler surface with a \( c \)-generic Kähler metric.

**Theorem 4.18.** Let \( X \) be a compact, Kähler surface with a smooth Kähler metric \( g \), \( E \) be a principal \( SU(2) \)-bundle with \( c_2(E) = c \) positive. Suppose that \( g \) is a \( c \)-generic metric in the sense of Definition (1.4), then there is a positive constant \( C = C(g, P) \) with following significance. If the triple \( (A, \beta, \gamma) \in \mathcal{A}^{1,1} \times \Omega^{2,0}(X, adE) \times \Omega^0(X, adE) \) satisfies equations (4.10), then one of following must hold:

1. \( \Lambda_\omega F_A = 0 \), or
2. the extra field \( \beta \) satisfies
   \[ \|\beta\|_{L^2(X)} \geq C. \]

**Proof.** For \( (A, \beta, \gamma) \) is a solution of equations (4.10), we denote \( \beta_0 := \beta - \beta^* \in \Omega^{2,0}(X, adE) \), hence \( d_A^+ \beta_0 = * (\partial_A \beta - \partial_A \beta) = 0 \). Suppose that the constant \( C \) does not exist. We may provide a positive constant \( \varepsilon_0 \) such that
   \[ 0 < \|\Lambda_\omega F_A\|_{L^2(X)} \leq c \|\beta\|_{L^2(X)}^2 \leq c \varepsilon_0 < \varepsilon \]
where \( c = c(g) \) is a positive constant and \( \varepsilon \) is a constant as Proposition 4.5. Thus \( \lambda(A) > 0 \). Following Theorem 4.8, there exist a connection \( A_\infty \) such that
   \[ \|A - A_\infty\|_{L^2(X)} \leq c \|\Lambda_\omega F_A\|_{L^2(X)} \]
for a positive constant \( c = c(g, P) \). By the Weizenböck formula (6.26) in [6], we have two integrable identities:
   \[ \|\nabla_A \beta_0\|_{L^2(X)}^2 + \langle \left( \frac{1}{3} s - 2\omega^+ \right) \beta_0, \beta_0 \rangle_{L^2(X)} + \|\Lambda_\omega F_A\|_{L^2(X)}^2 = 0, \]
   \[ \|\nabla_{A_\infty} \beta_0\|_{L^2(X)}^2 + \langle \left( \frac{1}{3} s - 2\omega^+ \right) \beta_0, \beta_0 \rangle_{L^2(X)} + \left( F_{A_\infty}^{0,2} + F_{A_\infty}^{0,2} \alpha \right)_{L^2(X)} \geq 0. \]
We also observe that
   \[ \langle F_A^{0,2} + F_A^{0,2}, [\beta_0, \beta_0] \rangle_{L^2(X)} \leq c \|F_A^{0,2}\|_{L^2(X)} \|\beta_0\|_{L^2(X)}^2 \]
   \[ \leq c \|\Lambda_\omega F_A\|_{L^2(X)} \|\beta_0\|_{L^2(X)}^2, \]
for a positive constant \( c = c(g) \). Combing the preceding inequalities gives
   \[ 0 \leq \|\nabla_{A_\infty} \beta_0\|_{L^2(X)}^2 + \langle \left( \frac{1}{3} s - 2\omega^+ \right) \beta_0, \beta_0 \rangle_{L^2(X)} + \left( F_{A_\infty}^{0,2} + F_{A_\infty}^{0,2} \alpha \right)_{L^2(X)} \]
   \[ \leq \|\nabla_A \beta_0\|_{L^2(X)}^2 + \langle \left( \frac{1}{3} s - 2\omega^+ \right) \beta_0, \beta_0 \rangle_{L^2(X)} \]
   \[ + \|\nabla_A \beta_0 - \nabla_{A_\infty} \beta_0\|_{L^2(X)}^2 + c \|\Lambda_\omega F_A\|_{L^2(X)} \|\beta_0\|_{L^2(X)}^2 \]
   \[ \leq \|[A - A_\infty, \beta_0]\|_{L^2(X)}^2 + c \|F_A^{0,2}\|_{L^2(X)} \|\beta_0\|_{L^2(X)}^2 - \|\Lambda_\omega F_A\|_{L^2(X)}^2 \]
   \[ \leq (\|\beta_0\|_{L^2(X)}^2 - 1) \|\Lambda_\omega F_A\|_{L^2(X)}^2. \]
for a positive constant \( c = c(g) \). We provide \( \|\beta_0\|_{L^2(X)}^2 \leq 1/(2c) \), thus \( \Lambda_\omega F_A = 0 \). This contradicting our initial assumption regarding the \( \Lambda_\omega F_A \). The preceding argument shows that the desired constant \( C \) exists. \( \Box \)
We denote by
\[ M_{VW} := \{(A, \beta, \gamma) \in A^{1,1}_E \times \Omega^{2,0}(adE) \times \Omega^0(adE) \mid (A, \beta, \gamma) \text{ satisfies (1.10)}\}/G_E \]
the moduli space of solutions of Vafa–Witten equations. We apply a vanishing theorem of extra fields of Vafa–Witten equations due to Mare [16, Theorem 4.2.] to prove that

**Theorem 4.19.** Let \( X \) be a simply-connected, Kähler surface with a smooth Kähler metric \( g \), \( E \) be a principal \( SU(2) \) or \( SO(3) \)-bundle. Let the triple \((A, \beta, \gamma)\) be a solution of the decoupled Vafa–Witten equations:

\[
\begin{align*}
\Lambda_\omega F_A &= 0, \\
\bar{\partial} A \beta &= [\beta \wedge \beta^*] = 0, \\
d A \gamma &= [\gamma, \gamma^*] = [\gamma, \beta + \beta^*] = 0.
\end{align*}
\]

If \( A \) is an irreducible connection, then \( \beta = \gamma = 0 \).

Following the idea of Hitchin–Simpson equations, we also have

**Corollary 4.20.** Let \( X \) be a compact, simply-connected, Kähler surface with a smooth Kähler metric \( g \), \( E \) be a principal \( SU(2) \)-bundle. Suppose that \((E, \beta)\) is \( \beta \)-stable bundle with \( c_2(E) = c \), then there is a positive integer \( c \) with following significance. If \( g \) is a \( c \)-generic metric in the sense of Definition (1.4), then the moduli space of \( \beta \)-stable bundle is non-connected.
