There has been a renewed interest to hydrodynamic phenomena in electron systems with a Dirac-like energy-momentum dispersion $v_F^2 = (p v)^2 + (m v^2)^2$. This subject was revived by studies in quantum criticality and holographic field theory [1] and outspread in research on two-dimensional (2D) conductors, e.g., graphene where the massless dispersion $m = 0$ is realized [2–14]. An experimental observation of a viscous electron flow in graphene has been recently reported [9]. Although not uncommon in plasmas [15], this type of transport is highly unusual in a solids. It may be possible only in a limited range of temperatures $T$ and chemical potentials $\mu$ in pristine samples where the combined rate of electron-impurity (ei) and electrons-phonon (ep) scattering $\Gamma_d = \Gamma_{ei} + \Gamma_{ep}$ is lower than the momentum-conserving electron-electron (ee) scattering rate $\Gamma_{ee}$ [16, 17]. The respective mean-free paths must obey the inequality $l_d \gg l_{ee}$. Under these conditions, the electron dynamics at frequencies $\omega \ll \Gamma_{ee}$ and momenta $q \ll k_F^{-1}$ is governed by collective variables that obey hydrodynamic equations [18].

The frequency range $\Gamma_d < \omega < \Gamma_{ee}$ may be as wide as several THz in graphene (see below). Therefore exploring electrodynamics of Dirac fluids may be worthwhile.

In this Letter we focus on the second-order ac conductivity, which controls nonlinear optical phenomena such as sum (difference) frequency generation and also photon drag. In the Supplemental material [19], we also discuss the third-order conductivity important for the Kerr effect. Prior work [20–28] has indicated that in graphene such effects may or may not [29] be stronger than in typical metals and semiconductors. We find significant differences of our results from what one obtains at frequencies $\omega > \Gamma_{ee}$ where the dynamics is described by the Boltzmann kinetic equation. The still higher frequency quantum regime (Fig. 1) is beyond the scope of our investigation.

Recall that the second-order conductivity is a third-rank tensor $\sigma_{ilm}^{(2)}(\mathbf{q}_1, \omega_1; \mathbf{q}_2, \omega_2)$ that describes the current of frequency $\omega_3 = \omega_1 + \omega_2$ and momentum $\mathbf{q}_3 = \mathbf{q}_1 + \mathbf{q}_2$ generated, to the order $O(E^2)$, to respond to an electric field

$$E(r, t) = E(q_1, \omega_1)e^{i\mathbf{q}_1\mathbf{r} - i\omega_1t} + E(q_2, \omega_2)e^{i\mathbf{q}_2\mathbf{r} - i\omega_2t} + \text{c.c.}$$

By convention, $\sigma_{ilm}^{(2)}$ is symmetrized, i.e., invariant under the interchange $(1 \leftrightarrow 2, l \leftrightarrow m)$. If the system preserves parity, which we assume to be the case, $\sigma_{ilm}^{(2)}$ must vanish if both $\mathbf{q}_1$, $\nu = 1, 2$ are zero. At small $\mathbf{q}_2$, relevant for optical/THz experiments, $\sigma_{ilm}^{(2)}$ should scale linearly with $\mathbf{q}_2$. In comparison, dissipative effects due to viscosity and heat conduction [17, 30], which scale as $|\mathbf{q}_2|^2$, are subleading: the fluid dynamics is approximately isentropic (ise) [18]. Below we show that in this regime the second-order conductivity has the universal form

$$\sigma_{ilm}^{(2)} = \frac{D_h^{(2)}}{\omega_1\omega_2\omega_3} \left( \frac{\omega_3}{\omega_1} q_1 d_{lm} + q_2 \delta_{lm} \right) + \left( \frac{1}{l} \right) \left( \frac{1}{m} \right),$$

for an arbitrary mass $m$, equilibrium charge density $\rho$, temperature $T$, and space dimension $d$. All the material-specific parameters are contained in the second-order spectral weight $D_h^{(2)}$, which we find to be equal to the derivative

$$D_h^{(2)} = \frac{1}{4\pi^2} \left( \frac{\partial |D_h|}{\partial \rho} \right)_{\text{ise}}$$

FIG. 1. A sketch of hydrodynamic, kinetic, and quantum domains in the frequency-momentum space. The collective modes of a massless fluid (plasmons and demons) are also shown, see text.
of the squared linear-response (i.e., Drude) spectral weight

$$D_h = \pi \frac{\varepsilon^2 n}{m^*}, \quad n \equiv \frac{\rho}{e}. \tag{4}$$

As stated above, these formulas hold for either massless or massive electrons. Conventional metals and semiconductors have a parabolic dispersion. This case is exemplified by the nonrelativistic limit $|\mu|, T \ll mv^2$ of our equations, yielding $m^* = m$. This result can also be understood as the consequence of Galilean invariance, which demands that the ee interactions affect the linear and nonlinear conductivities only in higher orders in $q$. This is why the effective mass $m^*$ in Eq. (S2) is equal to the bare mass $m$ and the leading $q$-linear terms of $\sigma_{ilm}^{(2)}$ [Eq. (S2)] are the same in hydrodynamic [15], kinetic [31], and quantum [32] domains. The equality of $m^*$ and $m$ does not hold if either $|\mu|$ or $T$ are comparable or larger than the energy gap $2mv^2$, e.g., in the case of graphene. (For linear conductivity at $T = 0$ this has been discussed at length [33–35].)

In the hydrodynamic regime of graphene, frequent collisions force electrons and holes to move together, causing cancellation of their partial currents. This enhances $m^*$ and reduces $D_h$ below its kinetic counterpart $D_k$ at all $T > 0$, see Fig. 2(a). Similarly, $D_h^{(2)}$ decreases with $T$ at fixed $\rho$ much faster in the hydrodynamic regime than in the previously studied kinetic one, see Fig. 2(b).

Let us now present a qualitative argument for Eq. (2). Consider the expansion of a given Fourier harmonic of the electric current $j_i^{(1)}(\mathbf{q}, \omega) = \frac{1}{2} \int j_i^{(1)}(\mathbf{q}, \omega) + j_i^{(2)}(\mathbf{q}, \omega) + \ldots$ in power series of the driving electric field $\mathbf{E}$. The first term is given by $j_i^{(1)}(\mathbf{q}, \omega) = \sigma_{ij}(\mathbf{q}, \omega) F_{ij}^{(1)}(\mathbf{q}, \omega)$ where $F_{ij}^{(1)}(\mathbf{q}, \omega) = E_i(\mathbf{q}, \omega) + \omega q_j$ is the driving force per unit charge and $\sigma_{ij}$ is the linear-response conductivity tensor. It suffices to consider the $\mathbf{q} \to 0$ limit in which $F_{ij}^{(1)} \to E_i$, $\sigma_{ij} \to \delta_{ij} \sigma$. The scalar $\sigma$ can be in general separated into the Drude pole

$$\sigma(q = 0, \omega) = \frac{1}{\pi} \frac{D_h}{i\omega + \Gamma_d} + \sigma_0, \quad \omega \ll \Gamma_{ee}. \tag{5}$$

Next, to the second order we expect $j_i^{(2)} = \sigma^{(1)} F_i^{(1)} + \sigma^{(2)} F_i^{(2)}$. Here $\sigma^{(1)} = (\partial \sigma / \partial \rho)^{(1)}$ and $\rho^{(1)}$ are the perturbations of the conductivity and charge density. The latter perturbation can be found from the continuity equation $(S23a)$, which gives $\rho^{(1)}(\mathbf{q}, \omega) = \mathbf{q} \cdot j^{(1)}(\mathbf{q}, \omega) / \omega$. Calculation of the second-order driving force $F_i^{(2)}$ is the difficult part of the problem. We glean the answer from the $\omega_1 = -\omega_2 \gg \omega_3$ case when it is equal to the sum of the pondermotive and Abraham forces [36]. The former is of order $(\omega_3^0)$, the latter is the leading $(\omega_3^1)$ correction. Following [36], Sec. 81, we find the real-space representation of the pondermotive force to be

$$F_i^{(2)}(\mathbf{r}) = \frac{i}{2} \partial_i \left[ \frac{\mathbf{E}(\mathbf{r}, \omega_1)}{\omega_2 - \omega} \frac{\partial \sigma(\omega_2)}{\partial \rho} \mathbf{E}(\mathbf{r}, \omega_2) + (1 \rightarrow 2) \right]$$

$$= -\frac{i}{2} \partial_i \left[ \frac{\mathbf{E}(\mathbf{r}, \omega_1)}{\omega_1} \frac{\partial \sigma(\omega_2)}{\partial \rho} \mathbf{E}(\mathbf{r}, \omega_2) + (1 \rightarrow 2) \right]. \tag{6}$$

The replacement of $\omega_2$ by $-\omega_1$ in the second line cannot be strictly justified if $\omega_3 \neq 0$. However, it is a natural way to ensure the triangular permutation symmetry of $\sigma_{ilm}^{(2)}$, which follows from the energy conservation [37] in the dissipationless limit $\Gamma_d, \sigma_0 \to 0$. Assembling all the terms of $j_i^{(2)}$, we can read off $\sigma_{ilm}^{(2)}$ and see it coincides with Eq. (2). One can verify that for a nonrelativistic electron gas our formulas agree with those in literature [15, 31].

The case of a Lorentz-invariant Dirac fluid can be studied rigorously. Proposed solid-state examples of such fluids [1] actually lack true Lorentz invariance. Their matter and field components have different limiting velocities, $v$ and $c$. However, if Coulomb interactions are weak, the approximate Lorentz invariance with velocity $v$ holds. In graphene this is so if the dielectric constant $\kappa$ of the environment is large, so that the interaction constant $\varepsilon^2 / (\hbar k v)$ is small. We will use relativistic hydrodynamics to derive $D_h$ and $D_h^{(2)}$ for this model and verify our key result (2).

Let us introduce two additional quantities. One is the flow velocity $\mathbf{u}$ that defines the electric current $j = \rho \mathbf{u}$. The other is the energy density $n_F = \gamma^2 W - P$ related to the pressure $P = P(\mu, T)$ and enthalpy density $W = W(\mu, T)$ at thermal equilibrium, $u = 0$ [18]. Here $\gamma \equiv 1/\sqrt{1 - (u/v)^2}$ and $n_F$ is referenced to the $\mu = T = u = 0$ state. Relativistic hydrodynamic equations admit many equivalent formulations [3–5, 18, 38], e.g.,

$$\partial_t \rho + \nabla \cdot j = 0, \tag{7a}$$

$$\partial_t n_F + \nabla \cdot (\gamma^2 W \mathbf{u}) = \mathbf{j} \cdot \mathbf{E}, \tag{7b}$$

$$(\gamma^2 m^* n) \nabla \cdot \mathbf{u} = \rho F_L - \frac{\mathbf{u}}{\gamma v^2} (\mathbf{j} \cdot \mathbf{E}) - \partial P, \tag{7c}$$

$$m^* = \frac{W}{\gamma v^2}, \quad F_L = E + \frac{1}{c} \mathbf{u} \times \mathbf{B}, \quad \nabla \times \mathbf{E} = -\frac{1}{c} \partial_t \mathbf{B}. \tag{7d}$$

The first pair is the charge continuity equation and the energy conservation equation sans the subleading viscous and
thermal conductivity terms. Equation (7d) for the Lorentz force \( \mathbf{F}_l \) includes the force from the ac magnetic field \( \mathbf{B} \) induced by \( \mathbf{E} \). (We assume that no static magnetic field is present.) This term is important if \( \mathbf{E} \)-field has a transverse component. Equation (S23c) is the relativistic Euler equation written in "covariant derivatives" \( \partial_i = \partial_t + (u_i/v^2)\partial_t \), \( \partial_t = \partial_t + \Gamma_d + u_i \partial_i \) with the scattering rate \( \Gamma_d \) accounting for momentum dissipation. We solve these equations for \( j \) perturbatively in \( \mathbf{E} \) to get the desired conductivities.

The linear response has already been treated at length [1, 3–6, 12, 13, 38]. For massless particles, \( W = (d + 1)P = d\pi P \propto T^{d+1} \). The hydrodynamic Drude weight \( D_h = \pi P^2v^2/W \) [cf. Eqs. (S2) and (7d)] decreases as \( T^{-d−1} \) with \( T \), i.e., as \( T^{-3} \) in graphene. The usual, kinetic Drude weight \( D_k(\mu, T) = (g/2)(e/h)T\ln(2\cosh(\mu/2T)) \) where \( g = 4 \) is the number of Dirac cones [34] behaves differently. After some initial drop, \( D_k \) increases with \( T \) because of thermal excitation of carriers, see Fig. 2(a). The question how the opposite trends of \( D_h \) and \( D_k \) could be reconciled has not been given proper attention in prior literature. As a tentative answer, we suggest the interpolation formula:

\[
\sigma(q = 0, \omega) = \frac{1}{\pi} \frac{D_h}{\omega} + \frac{1}{\pi} \frac{D_k - D_h}{\omega + \Gamma_d + \Gamma_{ee}}.
\]

This formula can be derived from the Boltzmann kinetic equation with the ee scattering rate \( \Gamma_{ee} \) added to the collision integral [19]. Matching it with Eq. (5) at \( \omega \ll \Gamma_{ee} \), we deduce the parameter \( \sigma_0 = (D_k - D_h)/(\pi\Gamma_{ee}) \) therein [we assume \( \Gamma_d \ll \Gamma_{ee} \) [5]]. According to Eq. (S17), the effective Drude weight \( \pi \sigma_0 \Im \sigma \) as a function of \( \omega \) exhibits two plateaus, see Fig. 3, and \( \sigma \) as a function of \( T \) at fixed \( \omega \) may look like as sketched in Fig. 2(a). A quantitative theory of these crossover behaviors is a challenge for future work. Meanwhile, Fig. 3 indicates the existence of two separate frequency intervals where \( \Im \sigma(\omega) \gg \Re \sigma(\omega) \). In these intervals weakly damped collective modes are possible: sound waves [38] (or energy waves [39] or "demons" [22]) in the hydrodynamic regime and plasmons in the kinetic one, see also Fig. 1.

Let us move on to the second-order conductivity, ignoring the momentum dissipation for now, \( \Gamma_d \rightarrow 0 \). In the hydrodynamic regime we have two ways to derive \( \sigma_{im}^{(2)} \).

The quick one is via Eq. (2). The only unknown parameter is \( D_h^{(2)} \), which we can calculate from Eq. (3) applied to \( D_h = \pi P^2v^2/W \). This yields

\[
D_h^{(2)} = -\frac{1}{2} \frac{e^3 n}{m^2 v^2} (1 - C_{ise}),
\]

where

\[
C_{ise} = \frac{n}{W} \left( \frac{\partial P}{\partial n} \right)_{ise} = \frac{1}{m^2 v^2} \left( \frac{\partial P}{\partial n} \right)_{ise}
\]

is the dimensionless isentropic bulk modulus. Note that for massless electrons \( C_{ise} = 1/d \). The second derivation we can do is from hydrodynamic Eqs. (S23), which is more tedious [19] but gives the same result. This verifies the validity of our universal formula (2) for Dirac fluids.

Let us examine the \( T \)-dependence of the spectral weight \( D_h^{(2)} \). As one can anticipate, \( D_h^{(2)} \) rapidly decreases at high \( T \), e.g., \( D_h^{(2)} \propto T^{-2d−2} = T^{-6} \) for graphene. At \( T \rightarrow 0 \), Eq. (9) predicts \( D_h^{(2)} \rightarrow 2D_0^{(2)} \operatorname{sign} n \), where

\[
D_0^{(2)} = -\frac{g}{32\pi} \frac{e^3 v^2}{h^2}.
\]

It may seem unusual that \( D_h^{(2)} \) becomes doping-independent in this limit (except for the overall sign) but this can be rationalized by the dimensional analysis. Of course, at \( T = 0 \) the system must be in the kinetic not hydrodynamic regime. Surprisingly, in the kinetic regime of graphene, \( \sigma_{im}^{(2)} \) has a different tensorial structure:

\[
\sigma_{im}^{(2)} = \frac{D_k^{(2)}}{\omega_1 \omega_2 \omega_3} \Sigma_{ilmn}(\omega_1, \omega_2, \omega_3) + \left( \begin{array}{c} \pi \omega \operatorname{Re} \sigma \\ \pi \omega \operatorname{Im} \sigma \end{array} \right),
\]

\[
\Sigma_{ilmn} = -\left( 1 - \frac{3}{\omega_1} \delta_{il} \delta_{mn} - \frac{1}{\omega_1} \delta_{il} \delta_{nm} + \frac{3}{\omega_1} \delta_{lm} \delta_{in} \right).
\]

This result can be obtained from either the Boltzmann kinetic equation [27] or the semiclassical limit \( q \ll k_F, \omega \ll \varepsilon_F \) of the quantum random-phase approximation [24, 26, 28]. Here \( \varepsilon_F \) and \( k_F \) are the Fermi energy and momentum. Note that some of the related formulas in prior literature, e.g., Eq. (A.8) of [27] and Eq. (42) of [28] are valid only for response to a longitudinal \( \mathbf{E} \)-field. If \( \mathbf{curl} \mathbf{E} \neq 0 \), the correct result is obtained only if the induced \( \mathbf{B} \)-field is included [19, 24, 26]. When extended further [19], such calculations show that \( D_k^{(2)} = D_0^{(2)} \) at \( T = 0 \) and \( D_k^{(2)} \propto T^{-2} \) at high \( T \). Hence, \( D_h^{(2)} \) is twice larger than \( D_k^{(2)} \) at \( T = 0 \) but becomes smaller at high \( T \), see Fig. 2(b).
A direct experimental probe of the second-order spectral weight is the second harmonic generation (SHG), which corresponds to \( \omega_2 = \omega_1 = \omega \), \( \omega_3 = 2\omega_1 \), see Fig. S2(a). As explained above, the hydrodynamics predicts the SHG signal that is twice larger at low \( T \) and much smaller at high \( T \) compared to the standard kinetic theory [21, 23], see Fig. S2(b). The crossover from the kinetic regime to the hydrodynamic one would occur at temperature \( T^* \) such that \( \Gamma_{ee}(T^*) = \omega \). The measured SHG signal may look like as sketched by the dashed curve in Fig. S2(b).

Another effect controlled by \( \sigma_{ilm}^{(2)} \) is the photon drag (PD), the generation of a dc current in response to a monochromatic beam of frequency \( \omega \), see Fig. S2(a). (A recent work [40] studied a similar phenomenon for a surface plasmon playing the role of the incident beam.) To the second order in the in-plane field \( \mathbf{E}(\mathbf{q}, \omega) = (E_x, E_y) \) the PD is described by \( \sigma_{ilm}^{(2)} \) evaluated at \( \omega_2 = \omega_1 = \omega \), and \( \mathbf{q}_1 = -\mathbf{q}_2 = \mathbf{q} \). The PD in graphene has been previously studied in the kinetic regime [41–43]. It was shown that the dc current can be parametrized by three constants \( T_1, T_2 \) and \( \tilde{T}_1 \), which multiply the three Stokes parameters of the incident beam. Coefficients \( T_1 \) and \( T_2 \) quantify the linear PD, \( T_2 \) and \( \tilde{T}_1 \) characterize the circular PD. Instead of the Stokes parameters, we find it convenient to use the incident angle \( \theta \) and the \( E_y/E_x \) phase delay \( \psi \), so that \( E_x = E\cos\alpha \cos\theta \), \( E_y = E\sin\alpha \sin\theta \). Note that \( \alpha = 0 \) means s-polarization and \( \alpha = \pi/2 \) means s-polarization. For a beam with the in-plane momentum \( \mathbf{q} = (q_x, 0) \), the longitudinal and transverse current components are:

\[
\begin{align*}
\frac{j_x}{C_j} &= (T_1 + T_2) \cos^2\alpha \cos^2\theta + (T_1 - T_2) \sin^2\alpha, \\
\frac{j_y}{C_j} &= \cos\theta \sin 2\alpha (T_2 \cos \psi - 2\tilde{T}_1 \sin \psi),
\end{align*}
\]

where \( C_j = \frac{1}{2} q_x |E|^2 \), cf. Eq. (10) of [44]. To compute \( T_1, T_2 \) and \( \tilde{T}_1 \) for graphene in the hydrodynamic regime, we use the dissipative version of Eq. (2), which corresponds to retaining \( \Gamma_d \) in the Euler equation [S23c]. The resultant expression for \( \sigma_{ilm}^{(2)} \) at arbitrary \( \omega \) is ponderous [19]. We present only the formulas for the drag coefficients:

\[
T_1 = -3T_2, \quad T_2 = -\frac{4D_0^{(2)} \Gamma_d}{\omega(\omega^2 + \Gamma_d^2)}, \quad \tilde{T}_1 = 0. \quad (15)
\]

They are quite unlike those in the kinetic regime in which \( \tilde{T}_1 \) is nonzero, e.g.,

\[
\tilde{T}_1 = -\frac{48D_0^{(2)} \Gamma_d}{(\omega^2 + \Gamma_d^2)(\omega^2 + 4\Gamma_d^2)}. \quad (16)
\]

This expression, which is a particular case of a general formula given in [19, 41], assumes that the scattering rate \( \Gamma_d \) is due to short-range scatterers. The difference between the two regimes is illustrated in Fig. S2(c,d).

The following estimates suggest that the hydrodynamic regime \( \Gamma_d < \omega < \Gamma_{ee} \) could be fairly wide in ultra clean graphene where electrons are scattered primarily by acoustic phonons, \( \Gamma_{d} \approx \Gamma_{ep} \). The electron-phonon scattering rate \( \Gamma_{ep}(T_j, T, \theta) \) [44] is a function of the lattice temperature \( T_j \), electron temperature \( T \), and doping \( n \). From [45, 46] we estimate \( \Gamma_{ep}(150K, 150K, 2 \times 10^{12} \text{cm}^{-2}) \sim 0.3 \text{THz} \) On the other hand, \( \Gamma_{ee}(T, n) \) is a function of \( T \) and \( n \). (In the kinetic regime \( \omega \gg \Gamma_{ee} \), it may also depend on frequency.) Recent dc transport experiments [9] indicate \( \Gamma_{ee}(150K, 10^{12} \text{cm}^{-2}) \sim 0.5 \text{THz} \), so the hydrodynamic region is narrow. There are two possible schemes to diminish \( \Gamma_{ep} \) or enhance \( \Gamma_{ee} \). The first one is to reduce \( n \) to make electron gas non-degenerate, which should bring \( \Gamma_{ee} \) to the theoretical maximum [47] of \( 4(\omega^2/hcN)^2 T \sim 10 \text{THz} \). The other route is ultrafast pump-probe experiments [45] that can keep the lattice cold, perhaps, at \( T_1 \sim 30K \) but heat electrons to \( T \sim 3000K \).

The universal relation (3) between linear and nonlinear ac conductivities is the most important result of this Letter. Although we have used graphene as the example, this and our other formulas Eqs. (2), (9), etc., should apply as well to ultrapure metals and semiconductors [2, 11], to surface states of topological insulators and Weyl semimetals, provided they are in the hydrodynamic regime.

**LINEAR AC CONDUCTIVITY**

Drude weight and demons in the hydrodynamic regime

As shown in literature [1, 3–6, 12, 13, 38], the linear-response ac conductivity of a Dirac fluid at $q = 0$ is given by

$$\sigma(0, \omega) = \frac{D_h/\pi}{-i\omega + \Gamma_d} + \sigma_0, \quad (S1)$$

which is Eq. (5) of the main text. The hydrodynamic Drude weight that enters Eq. (S1) is

$$D_h = \frac{\pi e^2 n}{m^*}. \quad (S2)$$

At zero temperature the hydrodynamic mass $m^*$ is no different from the Fermi-liquid effective mass $m^* = \hbar k_F/v_F$, where $v_F$ is the Fermi velocity. Hence, $D_h$ is equal to the conventional (kinetic) Drude weight $D_k$. For example, for parabolic band, $m^*$ is simply the band mass $m$. For graphene with weak ee interactions,

$$D_h(T = 0) = \frac{g}{4} \frac{e^2 k_F v}{\hbar}, \quad (S3)$$

where $g = 4$ is the total spin-valley degeneracy [34].

As usual, at finite $q$, the conductivity becomes a tensor

$$\sigma_{ij}(q, \omega) = \sigma_L(q, \omega) \frac{q_i q_j}{q^2} + \sigma_T(q, \omega) \left( \delta_{ij} - \frac{q_i q_j}{q^2} \right). \quad (S4)$$

Neglecting two subleading dissipative effects [$\sigma_0$ in Eq. (S1) and viscous damping], the longitudinal conductivity $\sigma_L$ is given by [5, 38]

$$\sigma_L(q, \omega) = \frac{D_h/\pi}{-i\omega + \Gamma_d} - \frac{e^2 q^2}{m^*}. \quad (S5)$$

The longitudinal conductivity enters the equation for the dispersion of longitudinal collective modes. In 2D case, this equation reads [34]

$$q = \frac{i k \omega}{2 \pi \sigma_L(q, \omega)}. \quad (S6)$$

The longitudinal mode in the hydrodynamic regime has been variously referred to as the sound [38], the energy wave [5, 39], and finally, the demon [12], which is our preference here. Equations (S5) and (S6) imply that away from charge neutrality, $n \neq 0$, the dispersion of the demon varies from $\omega \propto \sqrt{q}$ at low $q$ to $\omega \approx v_d q$ at large $q$, see Fig. 1 of the main text. For neutral fluid, $D_h \to 0$, the demon dispersion is acoustic starting from $q = 0$. The (asymptotic) speed of the demon is given by $v_d = v \sqrt{C_{vis}}$ where $C_{vis}$ is the dimensionless isentropic bulk modulus [Eq. (10) of the main text or Eq. (S24) below]. For a degenerate Fermi gas

$$C_{vis} = \frac{n \hbar k_F v_F}{W/d}, \quad (S7)$$

where $W = n \varepsilon_F$ is the enthalpy density and $d$ is the space dimension; therefore,

$$C_{vis} = \frac{1}{d} \frac{\varepsilon_F}{\varepsilon_F}. \quad (S8)$$

For Dirac dispersion $\varepsilon_p^2 = (p v)^2 + (m v^2)^2$, the relation $\hbar k_F = \varepsilon_F v_F / v^2$ holds; thus,

$$C_{vis}(T = 0) = \frac{1}{d} \frac{v_F^2}{\varepsilon_F} \quad (S9)$$

and $v_d = v_F / \sqrt{d}$, same as the speed of the first sound in a neutral Fermi liquid. For graphene,

$$C_{vis} = \frac{1}{2} \quad (S10)$$

at any $T$ (see below). Therefore, $v_d = v / \sqrt{2}$ [5, 12, 38, 39].

**Interpolation formula for the ac conductivity**

In this Section we derive Eq. (8) of the main text, which smoothly connects the hydrodynamic and kinetic regimes of the linear-response theory. We start with the formula for the current

$$j = e \sum p f_p(t) \quad (S11)$$

in terms of the quasiparticle distribution function $f_p$ and velocity $v_p = \partial \varepsilon_p / \partial p$ as a function of momentum $p$. For simplicity of notations, all the other quantum numbers such as spin, valley, and band index are omitted. We use $\sum ...$ to denote the summation over these quantum numbers combined with the integration $\int d^2 p / (2\pi)^2$... over momentum. Let us assume that the electric field in the system is position-independent and directed along $x$, i.e., $E = \hat{x} E(t)$. We want to compute the current $j$ to the first order in $E(t)$. The result is different in the two regimes because the deviation $f_p - f_p^{(0)}$ of the distribution function from the equilibrium value $f_p^{(0)} = \left[ e^{(\varepsilon_p - \mu)/T} + 1 \right]^{-1}$ has different forms. It is proportional to $g_p = p x \partial_x f_p^{(0)}$ in the hydrodynamic limit but to $g_p = v_p \partial_p f_p^{(0)}$ in the kinetic limit. To obtain the desired interpolation, we postulate that in general, $f_p - f_p^{(0)}$ is a certain linear combination

$$f_p - f_p^{(0)} = a_p(t) g_p + a_p(t) g_p. \quad (S12)$$
To find the coefficients $a_v$ and $a_p$ we consider the Boltzmann kinetic equation
\[
(\partial_t + eE\partial_p) f_p = -\partial_t a_v g_v + \partial_t a_p g_p + eE g_v = \hat{I} [f_p].
\]  \hspace{1cm} (S13)

We further assume that the linearized collision operator $\hat{I}$ acts within the space of functions given by Eq. (S12) and is characterized by two parameters: $\Gamma_d$, the scattering rate due to disorder and phonons, and $\Gamma_{ee}$, the electron-electron (ee) scattering rate. Mode $g_v$ damped by both types of scattering but $g_p$ is immune to the ee one, which implies
\[
\hat{I}[g_p] = -\Gamma_d g_p, \quad \hat{I}[g_v] = -\left(\Gamma_d + \Gamma_{ee}\right) g_v + a_{pv} \Gamma_{ee} g_p.
\]  \hspace{1cm} (S14)

The condition that ee scattering conserves momentum fixes the coefficient $a_{pv} = D_h/(\pi \epsilon^2 n) = 1/m^* \text{[Eq. (S2)]}$, leading us to
\[
\partial_t a_v + eE = - (\Gamma_d + \Gamma_{ee}) a_v, \quad \partial_t a_p = - \Gamma_d a_p + \frac{\Gamma_{ee} m^*}{m} a_v.
\]  \hspace{1cm} (S15)

For $E(t) \propto e^{-i\omega t}$, the solution is
\[
a_v = \frac{eE}{-i \omega + \Gamma_d + \Gamma_{ee}}, \quad a_p = \frac{\Gamma_{ee} m^*}{-i \omega + \Gamma_d} a_v.
\]  \hspace{1cm} (S16)

Combining Eqs. (S11), (S12), and (S16), we get the linear conductivity
\[
\sigma(\omega) = \frac{j(\omega)}{E(\omega)} = \frac{1}{\pi} \frac{D_k - D_h}{-i \omega + \Gamma_d + \Gamma_{ee}} + \frac{1}{\pi} \frac{D_h}{-i \omega + \Gamma_d},
\]  \hspace{1cm} (S17)

which is Eq. (8) of the main text. Note that the obtained $\sigma(\omega)$ can be recast in the form of an extended Drude model [48]:
\[
\sigma(\omega) = \frac{1}{\pi} \frac{D_k}{-i \omega + M(\omega)}, \quad M(\omega) = \frac{1}{\tau(\omega)} - i \omega \lambda(\omega).
\]  \hspace{1cm} (S18)

The complex memory function $M(\omega)$ appearing in this equation is illustrated by Fig. S1. Both the effective scattering rate $1/\tau = \text{Re } M(\omega)$ and the mass renormalization factor $\lambda = - \text{Im } M(\omega)/\omega$ show step-like crossovers at the boundary $\omega = \Gamma_{ee}$ of the hydrodynamic and kinetic regimes.

SECOND-ORDER CONDUCTIVITY: GENERAL

The second-order nonlinear conductivity $\sigma^{(2)}_{ilm}$ determines the second-order current
\[
\begin{align*}
\jmath^{(2)}_l(\mathbf{q}, \omega) &= \int \frac{d\omega'}{(2\pi)^3} \sigma^{(2)}_{ilm}(\mathbf{q} - \mathbf{q}', \omega - \omega'; \mathbf{q}', \omega') \\
&\quad \times E_l(\mathbf{q} - \mathbf{q}', \omega - \omega') \langle \mathbf{q}', \omega' \rangle
\end{align*}
\]  \hspace{1cm} (S19)

in response to the total electric field $\mathbf{E}$ in the system. By convention, $\sigma^{(2)}_{ilm}(\mathbf{q}_1, \omega_1; \mathbf{q}_2, \omega_2)$ is chosen to be symmetrized, i.e., invariant under the interchange $(1 \leftrightarrow 2, l \leftrightarrow m)$. Expanded to the linear order in momenta, the second-order conductivity must have the form
\[
\sigma^{(2)}_{ilm} = \Sigma_{ilm}(\omega_1, \omega_2) q_{1l} + \left( \frac{1}{2} \frac{\gamma}{m} \right),
\]  \hspace{1cm} (S20)

where $\Sigma_{ilm}$ is some isotropic rank-4 tensor. Any such tensor is a linear combination of the following three:
\[
\begin{align*}
B^{1}_{ilm} &= \delta_{il} \delta_{nm}, \quad B^{2}_{ilm} = \delta_{im} \delta_{nl}, \quad B^{3}_{ilm} = \delta_{in} \delta_{lm}.
\end{align*}
\]  \hspace{1cm} (S21)

In other words, $\sigma^{(2)}_{ilm}$ is fully characterized by three functions $G_1$, $G_2$, and $G_3$ such that
\[
\Sigma_{ilm}(\omega_1, \omega_2) = \sum_{a=1}^{3} G_a(\omega_1, \omega_2) B^a_{ilm}.
\]  \hspace{1cm} (S22)

Below we derive $\sigma^{(2)}_{ilm}$ and show it has a different form in the hydrodynamic and the kinetic regimes.

SECOND-ORDER CONDUCTIVITY IN THE HYDRODYNAMIC REGIME

To derive $\sigma^{(2)}_{ilm}$ in the hydrodynamic regime we solve the equations
\[
\begin{align*}
\partial_t n + \partial_j j_l &= 0, \quad j_l = n u_l, \quad (S23a) \\
(\partial_t + \Gamma_E) n_E + \partial_j \left( \frac{1}{2} \gamma^2 W u_l \right) &= j_m E_m, \quad n_E = \gamma^2 W - P, \quad (S23b) \\
(\partial_t + \Gamma_d + u_k \partial_k) u_i &= \frac{1}{\gamma^2 W} \left( -\partial_j P - u_i \partial_j P + n E_l \right) \\
&\quad + \frac{n}{c} \epsilon_{ilk} u_t B_l - u_j j_m E_m. \quad (S23c)
\end{align*}
\]

These equations are the same as Eqs. (7) of the main text, except we added phenomenological energy dissipation rate $\Gamma_E$ in Eq. (S23b) and chose the units $e = v = 1$ to lighten the notations. Hence, the Lorentz factor in Eq. (S23c) is now $\gamma = 1/\sqrt{1 - \mathbf{u}^2}$. The derivation of Eqs. (S23) can be found...
in literature [3–5, 36, 38]. The definitions of pressure \(P\), energy density \(n_E\), and enthalpy density \(W\) deserve a comment. Whereas the current \(j\) is proportional to the actual charge density \(n\), the pressure \(P = P(n_0, n_{E0})\) is the equilibrium thermodynamic parameter, which is a function of the proper density \(n_0 = n/\gamma\) and the proper energy density \(n_{E0}\). The actual energy density is \(n_E\) [Eq. (S23b)] and the enthalpy density is \(W = n_{E0} + P\). Another key thermodynamic parameter is the dimensionless isentropic (ise) bulk modulus \(C_{ise}\).

It is defined by Eq. (10) of the main text:

\[
C_{ise} = \frac{n_0}{W} \left( \frac{\partial P}{\partial n_0} \right)_s = \frac{n_0}{W} \left( \frac{\partial P}{\partial n_0} \right)_{n_{E0}} + \left( \frac{\partial P}{\partial n_{E0}} \right)_{n_0} .
\] (S24)

The second equation in Eq. (S24) follows from the thermodynamic relation

\[
T\delta s_n = n_0^{-1} d n_{E0} - n_0^{-2} W d n_0
\]

for the quantity \(s_n = s/n_0\), with \(s = s(n_0, n_{E0})\) being the entropy density.

Suppose \(E(r, t) \propto e^{i \mathbf{q}_1 \cdot r - i \omega_1 t}\) and define \(\omega^+ = \omega + i \Gamma_d\). To the first order in \(E\) we obtain, for \(\Gamma_E = 0\):

\[
n^{(1)} = n_0^{(1)} = \frac{n_0}{\omega} q_m u_m^{(1)} , \quad n_{E0}^{(1)} = \frac{W}{\omega} q_m u_m^{(1)} , \quad \kappa_m^{(1)} = -i \omega^+ \frac{W}{n_0} u_m^{(1)} , \quad W^{(1)} = \frac{\partial W}{\partial n_0} n_0^{(1)} + \frac{\partial W}{\partial n_{E0}} n_{E0}^{(1)} = \frac{n_0}{W} \frac{\partial W}{\partial n_{E0}} + \frac{\partial W}{\partial n_0} , \quad \frac{W}{\omega} q_m u_m^{(1)} = (1 + C_{ise}) \frac{W}{\omega} q_m u_m^{(1)} , \quad P^{(1)} = \frac{\partial P}{\partial n_0} n_0^{(1)} + \frac{\partial P}{\partial n_{E0}} n_{E0}^{(1)} = \left( \frac{n_0}{W} \frac{\partial P}{\partial n_{E0}} + \frac{\partial P}{\partial n_0} \right) \frac{W}{\omega} q_m u_m^{(1)} = C_{ise} \frac{W}{\omega} q_m u_m^{(1)} .
\] (S25)

Now let us assume that the electric field consists of two plane waves:

\[
E(r, t) = E_1 e^{i (\mathbf{q}_1 \cdot r - \omega_1 t)} + E_2 e^{i (\mathbf{q}_2 \cdot r - \omega_2 t)} + c.c.
\] (S26)

To the second order in \(E\), various quantities of interest develop Fourier amplitudes of frequency and momenta \((\mathbf{q}_3, \omega_3) = (\mathbf{q}_1 + \mathbf{q}_2, \omega_1 + \omega_2)\). These amplitudes are given by

\[
n^{(2)} = O(\mathbf{q}^2 u) , \quad n_{E0}^{(2)} = \frac{\omega_2}{\omega_3} W u_{11} u_{21}^{(1)} + (1 \rightarrow 2) + O(\mathbf{q}^2) , \quad W^{(2)} = -W u^2 = \frac{i \Gamma_d - \omega_1}{\omega_3} W u_{11} u_{21}^{(1)} + (1 \rightarrow 2) + O(\mathbf{q}^2) , \quad P^{(2)} = \frac{n_0}{W} \frac{\partial P}{\partial n_0} n_0^{(2)} + \frac{\partial P}{\partial n_{E0}} n_{E0}^{(2)} + \frac{1}{2} \left\{ \left[ n_0^{(1)} \right]^2 \frac{\partial \omega^+}{\partial n_0^2} + 2 n_1^{(1)} n_0^{(1)} \frac{\partial^2 P}{\partial n_0 \partial n_{E0}} + \left[ n_{E0}^{(1)} \right]^2 \frac{\partial^2 P}{\partial n_{E0}^2} \right\} = -\frac{1}{2} n_0 u_{11}^{(1)} u_{21}^{(1)} \frac{\partial P}{\partial n_{E0}} + \frac{i \Gamma_d - \omega_1}{\omega_3} W u_{11} u_{21}^{(1)} + (1 \rightarrow 2) + O(\mathbf{q}^2) = -C_{ise} + \frac{2i \Gamma_d}{\omega_3} \frac{\partial P}{\partial n_{E0}} W u_{11} u_{21}^{(1)} + O(\mathbf{q}^2) .
\] (S27)

From Eq. (S23c) and the Faraday law \(\epsilon_{ikl} \partial_k E_l = -c^{-1} \partial_t B_i\) we obtain

\[
(\partial_t + \Gamma_d + u_k \partial_k) u_i = \frac{n}{\gamma^2 W} \hat{A}_{ij} (-i \partial_i) E_j - \frac{1}{\gamma^2 W} (\partial_i P + u_j \partial_i P) - \frac{1}{\gamma^2 W} u_j f m E_m , \quad (S28)
\]

\[
\hat{A}_{ij}(\mathbf{k}, \omega) = \left( 1 - \frac{k_m u_m}{\omega} \right) \delta_{ij} + \frac{k_i u_j}{\omega} .
\] (S29)

Keeping only the terms linear in \(q\), we find

\[
-i \omega_1 u_{12}^{(2)} = -i q_{21} \frac{\omega^+}{\omega_1} u_{21}^{(1)} - \frac{n_0}{W} \left( \frac{q_{2m}}{\omega_2} u_{1m}^{(1)} u_{21}^{(1)} + \frac{q_{21}}{\omega_2} u_{11}^{(1)} u_{m2}^{(1)} \right) + \left( \frac{n}{W} \right) \left[ E_{21}^{(1)} - \left( \frac{i}{2} q_{31} p^{(2)} - i \omega_1 p_{11}^{(1)} u_{21}^{(1)} \right) + (1 \rightarrow 2) \right] = -i q_{21} u_{1m}^{(1)} u_{21}^{(1)} - \frac{\Gamma_d}{\omega_2} q_{2m} u_{1m}^{(1)} u_{21}^{(1)} + \frac{\Gamma_d}{\omega_2} q_{21} u_{11}^{(1)} u_{m2}^{(1)} + i C_{ise} q_{31} u_{1m}^{(1)} u_{21}^{(1)} + i C_{ise} q_{31} u_{11}^{(1)} u_{m2}^{(1)} + \frac{\partial P}{\partial n_{E0}} \frac{\Gamma_d}{\omega_3} q_{31} u_{1m}^{(1)} u_{21}^{(1)} + (1 \rightarrow 2) .
\] (S30)
The current to the second order in field is

$$j^{(2)}_i = n^{(1)}u^{(1)}_i + n^{(0)}u^{(2)}_i$$

$$= n_0 \left( \frac{\omega_n^*}{\omega_1^3} q_{1i} u^{(1)}_{1i} u^{(1)}_{2i} + q_{2i} u^{(1)}_{1i} u^{(1)}_{2m} - \frac{i\Gamma_d}{\omega_2} q_{2m} u^{(1)}_{1i} u^{(1)}_{2i} + \frac{i\Gamma_d}{\omega_2} q_{2i} u^{(1)}_{1m} u^{(1)}_{2m} \right) - C_{\text{ise}} \frac{\omega_n^*}{\omega_1} q_{1m} u^{(1)}_{1m} u^{(1)}_{2i} - C_{\text{ise}} q_{2m} u^{(1)}_{1i} u^{(1)}_{2m} - \frac{1}{2} C_{\text{ise}} q_{3i} u^{(1)}_{1m} u^{(1)}_{2m} + \frac{\partial P}{\partial n_{E0}} \frac{i\Gamma_d}{\omega_3} q_{3i} u^{(1)}_{1m} u^{(1)}_{2m} \right) + (1 \rightarrow 2)$$

$$= n_0 \left( \frac{\omega_n^*}{\omega_1^3} q_{1i} \delta_{iv} + \frac{\omega_n^*}{\omega_2} q_{2i} \delta_{iv} + \frac{\omega_n^*}{\omega_1} q_{2i} \delta_{iv} - C_{\text{ise}} \frac{\omega_n^*}{\omega_1} q_{1m} \delta_{iv} - C_{\text{ise}} \frac{\omega_n^*}{\omega_2} q_{2i} \delta_{iv} - C_{\text{ise}} q_{2i} \delta_{iv} - C_{\text{ise}} q_{1i} \delta_{iv} - C_{\text{ise}} q_{3i} \delta_{iv} \right)$$

$$- \frac{i\Gamma_d}{\omega_2} q_{2i} \delta_{iv} - \frac{i\Gamma_d}{\omega_2} q_{2i} \delta_{iv} + \frac{i\Gamma_d}{\omega_1} q_{2i} \delta_{iv} + \frac{i\Gamma_d}{\omega_1} q_{2i} \delta_{iv} + \frac{\partial P}{\partial n_{E0}} \frac{2i\Gamma_d}{\omega_3} \omega_{3i} (\delta_{iv}) u^{(1)}_{1m} u^{(1)}_{2m} \right)$$

$$= n_0 \left( \frac{\omega_n^*}{\omega_1^3} \left( \frac{1}{1 - C_{\text{ise}}} \left( \frac{\omega_n^*}{\omega_1} q_{1i} \delta_{iv} + \frac{\omega_n^*}{\omega_2} q_{2i} \delta_{iv} + \frac{\omega_n^*}{\omega_1^3} q_{1i} \delta_{iv} + \delta_{iv} \right) \right) \right) + \frac{\partial P}{\partial n_{E0}} \left( \frac{2q_{3i}}{\omega_3} q_{3i} \delta_{iv} \right) \left( \delta_{iv} \right) u^{(1)}_{1m} u^{(1)}_{2m} \right)$$

$$= \left( \frac{1}{1 - C_{\text{ise}}} \left( \frac{\omega_n^*}{\omega_1} q_{1i} \delta_{iv} + \frac{\omega_n^*}{\omega_2} q_{2i} \delta_{iv} + \frac{\omega_n^*}{\omega_1} q_{1i} \delta_{iv} + \delta_{iv} \right) \right) \right) + \frac{\partial P}{\partial n_{E0}} \left( \frac{2q_{3i}}{\omega_3} q_{3i} \delta_{iv} \right) \left( \delta_{iv} \right) u^{(1)}_{1m} u^{(1)}_{2m} \right)$$

Hence, the second-order conductivity is

$$\sigma_{ilm}^{(2)} = \frac{D^{(2)}_h}{\omega_1^3 \omega_2^3 \omega_3^3} \left( \frac{\omega_n^*}{\omega_1} q_{1i} \delta_{il} + q_{1i} \delta_{il} + i\Gamma_d \left( \frac{q_{1i}}{\omega_1} + \frac{\partial P}{\partial n_{E0}} \frac{2q_{1i}}{\omega_3 \omega_1} \right) \delta_{il} - \frac{q_{1m} \delta_{il}}{\omega_1} \right) \right) + \left( \frac{1}{d} \right)$$

Here we added the neglected earlier energy dissipation rate $\Gamma_E$ in one of the terms in Eq. (S33). In principle, $\Gamma_E$ should appear in more than one place. However, we assume that $\Gamma_E$ is very small and its sole role is to resolve the indeterminacy of the ratio $q_{3i}/\omega_3$ in the context of the photon drag problem where $q_{3i}, \omega_3 \to 0$. The second-order spectral weight appearing in Eq. (S33) is

$$D^{(2)}_h = -\frac{e^3 n^3 \nu^4}{2W^2} (1 - C_{\text{ise}}) = -\frac{e^3 n^3 \nu^4}{2m^2} (1 - C_{\text{ise}})$$

where we restored physical units and replaced $n_0$ by $n$, $n_{E0}$ by $n_E$ to simplify notations. Let us discuss the value of $D^{(2)}_h$ in representative cases, assuming ee interaction corrections to pressure and enthalpy density are negligible. The result for particles with a parabolic dispersion can be obtained taking the nonrelativistic limit, in which $P = (2/7)(nE - nm\nu^2)$ and $W = nmv^2$. This gives

$$D^{(2)}_h = \frac{-1 e^3 n}{2m^2}, \quad \frac{\partial P}{\partial n_{E0}} = \frac{2}{d}, \quad C_{\text{ise}} \ll 1$$

In the massless case, one finds $P = nE/d$ and $W = (1 + 1/d)nE$, so that

$$D^{(2)}_h = \frac{-d(d - 1) e^3 n^3 \nu^4}{2(d + 1)^2 n_{E0}^2}, \quad \frac{\partial P}{\partial n_{E0}} = \frac{1}{d}, \quad C_{\text{ise}} = \frac{1}{d}$$

Taking $d = 2$ for graphene, we get

$$D^{(2)}_h = \frac{-e^3 n^3 \nu^4}{9n_{E0}^2}$$

$$D^{(2)}_h (T = 0) = -\frac{g}{16\pi} \frac{e^3 \nu^2}{\hbar^2} \equiv 2D^{(2)}_0$$

Functions $G_1$, $G_2$, and $G_3$ [Eq. (S22)] corresponding to Eq. (S33) are

$$G_1 = \frac{D^{(2)}_h}{\omega_1 \omega_2 \omega_3} \left( \frac{1}{1 - C_{\text{ise}}} \frac{i\Gamma_d}{\omega_1} \right),$$

$$G_2 = \frac{D^{(2)}_h}{\omega_1 \omega_2 \omega_3} \left( \frac{\omega_n^*}{\omega_1} \right),$$

$$G_3 = \frac{D^{(2)}_h}{\omega_1 \omega_2 \omega_3} \left[ 1 + \frac{i\Gamma_d}{\omega_1} \left( \frac{1}{1 - C_{\text{ise}}} \frac{1}{\omega_1} + \frac{\partial P}{\partial n_{E0}} \frac{2}{\omega_3 \omega_1 + i\Gamma_E} \right) \right].$$

In the collisionless limit $\Gamma_d \to 0$, these formulas simplify to

$$G_1, G_2, G_3 = \frac{D^{(2)}_h}{\omega_1 \omega_2 \omega_3} \left( \frac{1}{\omega_1}, \frac{1}{\omega_1 \omega_2 \omega_3} \right),$$

while Eq. (S33) reduces to

$$\sigma_{ilm}^{(2)} = \frac{D^{(2)}_h}{\omega_1 \omega_2 \omega_3} \left( \frac{\omega_n^*}{\omega_1} q_{1i} \delta_{il} + \frac{\omega_n^*}{\omega_2} q_{2m} \delta_{il} \right) + \frac{\partial P}{\partial n_{E0}} \frac{2q_{3i}}{\omega_3} q_{3i} \delta_{il} \delta_{il} \right),$$

which is equivalent to Eq. (2) of the main text.

SECOND-ORDER CONDUCTIVITY IN THE KINETIC REGIME

The kinetic regime corresponds to the frequency range $\Gamma_{ee} \ll \omega \ll \epsilon_F$. The linear and nonlinear conductivities in this regime can be computed by solving the Boltzmann kinetic equation

$$\left[ \partial_t + \mathbf{v} \cdot \nabla + \left( \mathbf{E} \cdot \frac{\mathbf{v}}{c} \mathbf{B} \right) \partial_\mathbf{p} \right] f = I[f].$$

(S42)
In this section, we again set $e = 1$ and suppress the subscripts $p$ in $v_p$ and $f_p$. One should not confuse the quasiparticle velocity $v$ at finite $p$, a vector, with $v$, the limiting velocity at $p = \infty$, a scalar.

The magnetic-field term in Eq. (S42) can be expressed with the help of the kernel

$$A_{il} (k, \omega) = \left(1 - \frac{k_m v_m}{\omega}\right) \delta_{il} + \frac{k_i v_j}{\omega}, \quad (S43)$$

similar to Eq. (S29), leading to

$$\left[ \partial_t + v_l \partial_t + A_{il} (-i \partial, i \partial) E_j \partial_{p_i} \right] f = \hat{I} [f]. \quad (S44)$$

The second-order current we want to compute is

$$j_l (q_3, \omega_3) = \sum v_i f^{(2)} (q_3, \omega_3). \quad (S45)$$

To do this we need to specify the collision integral $\hat{I} [f]$.

**Nonconserving relaxation-time approximation**

It is useful to consider first the approximation $\hat{I} [f] = -\Gamma (f - f^{(0)})$, with $\Gamma$ being an energy-independent relaxation rate. This is probably the simplest model one can study. However, one should keep in mind that this approximation is flawed because it may not conserve the particle number.

Assuming the electric field is composed of two plane waves [Eq. (S26)], we expand $f$ to the first and second order in field:

$$f^{(1)} (q_v, \omega_v) = -i E_2 m v_m \delta_{k} f^{(0)}, \quad v = 1, 2, \quad (S46)$$

$$f^{(2)} (q_3, \omega_3) = -i E_1 A_1 (q_1, \omega_1) \delta_{p_a} f^{(1)} (q_2, \omega_2) + (1 \rightarrow 2). \quad (S47)$$

Hence, the second-order conductivity is

$$\sigma^{(2)}_{ilm} = -\sum A_{il} (q_1, \omega_1) \frac{v_i}{\omega_3 - v_j q_3 j} \delta_{p_a} \frac{v_m}{\omega_2 - v_k q_2 k} \partial_{k} f^{(0)} + \left(\frac{1}{i} \frac{2}{i} \frac{1}{m}\right). \quad (S48)$$

The evaluation of this expression for Dirac electrons in graphene is tedious but straightforward. The final result is

$$\sigma^{(2)}_{ilm} = \frac{D_{2}^{(2)} (x, y, z)}{\omega_1 \omega_2 \omega_3} \left[ (q_3 - \frac{\omega_1}{2 \omega_2} q_2 - \frac{\omega_2}{2 \omega_1} q_1) \delta_{ilm} + \delta_{i l} \right], \quad (S49)$$

Its collisionless limit $\Gamma \rightarrow 0$ is

$$\sigma^{(2)}_{ilm} = \frac{D_{2}^{(2)} (x, y, z)}{\omega_1 \omega_2 \omega_3} \left[ -2 - \frac{\omega_2}{\omega_1}, 2 + 3 \frac{\omega_2}{\omega_1}, 2 - \frac{\omega_2}{\omega_1} \right]. \quad (S50)$$

which implies [cf. Eq. (S22)]

$$(G_1, G_2, G_3) = \frac{D^{(2)}_{k}}{\omega_1 \omega_2 \omega_3} \left( -2 - \frac{\omega_2}{\omega_1}, 2 + 3 \frac{\omega_2}{\omega_1}, 2 - \frac{\omega_2}{\omega_1} \right). \quad (S51)$$

The second-order spectral weight in these equations is

$$D^{(2)}_{k} = D_{0}^{(2)} \left( 2 f^{(0)} - 1 \right) = D_{0}^{(2)} \text{tanh} \left( \frac{\mu}{2T} \right), \quad (S52)$$

where [Eq. (S38)]

$$D_{0}^{(2)} = -\frac{g}{32 \pi} \frac{e^3 \nu^2}{h^2}. \quad (S53)$$

In the limit of $T \rightarrow 0$, we have $D^{(2)}_{k} = D_{0}^{(2)} \text{sign}(\mu)$. At $T \gg \mu$, the asymptotic behavior of the chemical potential is $\mu \propto n/T$, see, e.g., Supplemental material of Ref. 12. Therefore, $D^{(2)}_{k} \propto n/T^2$ as mentioned in the main text. However, at high $T$, an interband contribution to $\sigma^{(2)}_{ilm}$, not included in our semiclassical approach, may become important.

**Multiple relaxation-time approximation**

Let us assume now that the collision operator $\hat{I} [f]$ is linear and diagonal in the angular momentum basis, so that
the Boltzmann equation can be written as
\[ \hat{L} f = -E_j A_{ij} \partial_{p_i} f, \quad \hat{L} = \hat{L}_0(\omega) + \mathbf{v} \cdot \partial, \quad (S54) \]
where \( \hat{L}_0 \) is the operator
\[ \hat{L}_0 = \sum_{l=-\infty}^{\infty} (\partial_l + \Gamma_l) \hat{l} / (l! \quad (S55) \]
and \( \Gamma_l \) is the scattering rate for the angular momentum \( l \). This rate may depend on the quasiparticle energy \( \varepsilon \). The model conserves the number of particles if \( \Gamma_0 = 0 \). The action of \( \hat{L}_0 \) can be written in terms of the complex frequencies
\[ \omega_{\nu}^{(m)} = \omega_{\nu} + i \Gamma_{\nu}, \quad \nu = 1, 2, 3. \quad (S56) \]
Instead of Eq. (S47) we now get a more complicated expression:
\[ f^{(2)} = L^{-1} E_j A_{ij} \partial_{p_i} \hat{L}^{-1} E_j A_{ij} \partial_{p_i} f^{(0)}. \quad (S57) \]
To calculate \( a_{lm}^{(2)}(q_1, \omega_1; q_2, \omega_2) \) we need the \( (q_3, \omega_3) \) Fourier harmonic of \( f^{(2)} \):

\[ f^{(2)} = \hat{L}^{-1} (q_3, \omega_3) E_{11} \left( \frac{1}{\omega_1} \partial_{p_1} - \frac{q_{1n}}{\omega_1} v_n \partial_{p_1} + \frac{q_{1n}}{\omega_1} v_1 \partial_{p_n} \right) \hat{L}^{-1} (q_2, \omega_2) E_{2m} v_m \partial_{\varepsilon} f^{(0)} + \left( \frac{1}{l} \times \frac{2}{m} \right). \quad (S58) \]

[The argument \( (q_3, \omega_3) \) of \( f^{(2)} \) is omitted.] For our purpose of computing the terms linear in gradients the expansion
\[ \hat{L}^{-1} = \hat{R} - \hat{R}(\mathbf{v} \cdot \partial) \hat{R}, \quad \hat{R} = \hat{L}_0^{-1} \quad (S59) \]
suffices. It yields
\[ f^{(2)} = E_{11} E_{2m} \left[ \hat{R}(\omega_3) \left( -\frac{1}{\omega_1} \partial_{q_{1n}} + \frac{1}{\omega_1} v_1 \partial_{p_1} \right) \hat{R}(\omega_2) - \hat{R}(\omega_3) i q_{3l} v_l \hat{R}(\omega_3) \partial_{p_l} \hat{R}(\omega_2) \right] \]
\[ - \hat{R}(\omega_3) \partial_{p_l} \hat{R}(\omega_2) i q_{2l} v_l \hat{R}(\omega_2) \right] v_m \partial_{\varepsilon} f^{(0)} + \left( \frac{1}{l} \times \frac{2}{m} \right). \quad (S60) \]

To do the summation over the angular directions, we expand all the variables in the angular momentum basis. To this end, we do a set of unitary transformations. For example, the velocity goes from \( \mathbf{v} = (v_x, v_y)^T = |v| (\cos \phi, \sin \phi)^T \) to \( (\tilde{v}_-, \tilde{v}_+)^T \):
\[ \left( \begin{array}{c} \tilde{v}_+ \\ \tilde{v}_- \end{array} \right) = \mathbf{U} \left( \begin{array}{c} v_x \\ v_y \end{array} \right) = \frac{|v|}{\sqrt{2}} \left( \begin{array}{c} M_+ \\ M_- \end{array} \right), \quad \mathbf{U} = \{ u_{mj} \} = \frac{1}{\sqrt{2}} \left( \begin{array}{c} 1 \\ -i \end{array} \right), \quad \mathbf{U}^\dagger = \{ \delta_{ij} \}, \quad M_m = e^{im\phi}, \quad m = \pm. \quad (S61) \]

We do the same transformation for the momentum-space derivatives:
\[ \tilde{\partial}_{p_m} = u_{mj} \partial_{p_j} = \frac{1}{\sqrt{2}} \left( \partial_{p_z} + i m \partial_{p_r} \right) = M_m \left( \partial_p + \frac{i m}{p} \partial_\phi \right), \quad m = \pm. \quad (S62) \]
To the electric fields and spatial momenta we apply a conjugate transformation, \( \tilde{E}_m = E_j U_j^{jm} \), \( \tilde{q}_m = q_j U_j^{jm} \), in order to leave the scalar products \( E_j v_j, E_i \partial_{p_i}, q_i v_i \) invariant. The net effect on Eq. (S60) is simply to add tildes for every variable. The second-order current becomes
\[ j_i = \sum \tilde{v}_i f^{(2)} = \tilde{E}_{11} \tilde{E}_{2m} \sum \tilde{v}_i \left[ \tilde{R}(\omega_3) \left( -\frac{1}{\omega_1} \tilde{q}_{1n} \tilde{v}_n \tilde{\partial}_{p_l} + \frac{1}{\omega_1} \tilde{v}_1 \tilde{q}_{1n} \tilde{\partial}_{p_n} \right) \tilde{R}(\omega_2) - \tilde{R}(\omega_3) i \tilde{q}_{3l} \tilde{v}_l \tilde{R}(\omega_3) \tilde{\partial}_{p_l} \tilde{R}(\omega_2) \right] \tilde{R}(\omega_2) \tilde{\partial}_{p_i} \tilde{R}(\omega_2) \]
\[ - \tilde{R}(\omega_3) \tilde{\partial}_{p_i} \tilde{R}(\omega_2) i \tilde{q}_{2l} \tilde{v}_l \tilde{R}(\omega_2) \right] \tilde{v}_m \partial_{\varepsilon} f^{(0)} + \left( \frac{1}{l} \times \frac{2}{m} \right) \quad (S63) \]

Only the terms of zero net angular momentum, i.e., \( i + n + l + m = 0 \) survive after the summation. Since \( i, n, l, m \) have values \( \pm 1 \), they have to appear in opposite-sign pairs. This constraint can be implemented with the help of the transformed rank-2
and rank-4 isotropic tensors

\[ \tilde{\delta}_{ij} \equiv U_{im} \delta_{mn} U_{jn}, \quad \{ \tilde{\delta}_{ij} \} = UU^T = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \tilde{\delta}_{inlm} = \delta_{in} \tilde{\delta}_{lm} + \tilde{\delta}_{il} \delta_{nm} + \tilde{\delta}_{ln} \delta_{im}. \]  

(S64)

The subsequent calculations are done for \( T = 0 \) where \( \partial_x f^{(0)} = -\delta (\epsilon - \epsilon_F) \). We obtain

\[
j_i = \frac{v_F^2}{16\pi} \frac{\tilde{E}_1 \tilde{E}_2 m}{\omega_3^3} \left\{ \begin{pmatrix} \tilde{q}_{1n} \\ \omega_3^3 \end{pmatrix} \right\} \left\{ \frac{1}{\omega_2^3} m(l - n) \tilde{\delta}_{inlm} - \frac{1}{\omega_2^3} \left( \tilde{q}_{3n} \frac{ml}{\omega_3^3} \tilde{\delta}_{m(1)} + \tilde{q}_{2n} \frac{l(m + n)}{\omega_2^3} \tilde{\delta}_{m(1)} \right) \tilde{\delta}_{inlm} - \frac{1}{\omega_2^3} \left( \tilde{q}_{3n} \frac{ml}{\omega_3^3} + \tilde{q}_{2n} \frac{l(m + n)}{\omega_2^3} \right) \tilde{\delta}_{inlm} \right\} \\
\quad + \frac{1}{\omega_2^3} \left\{ \frac{\tilde{q}_{3n} \epsilon_F}{\omega_3^3} \left( \frac{\delta_{m(1)} \omega_3^3 + \delta_{m(1)} \omega_3^3}{\omega_2^3} \right) \frac{\tilde{\delta}_{inlm}}{\tilde{\delta}_{inlm}} \right\} \\
\quad + \frac{\tilde{q}_{2n} \epsilon_F}{\omega_3^3} \left( \frac{\delta_{m(1)} \omega_3^3 + \delta_{m(1)} \omega_3^3}{\omega_2^3} \right) \frac{\tilde{\delta}_{inlm}}{\tilde{\delta}_{inlm}} \\
\quad + \frac{\tilde{q}_{1n}}{\omega_3^3} \left\{ \frac{1}{\omega_2^3} \left( \frac{\tilde{q}_{3n} \frac{ml}{\omega_3^3} \tilde{\delta}_{m(1)} + \tilde{q}_{2n} \frac{l(m + n)}{\omega_2^3} \tilde{\delta}_{m(1)} \right) \right\} \\
\quad + \frac{\tilde{q}_{2n}}{\omega_3^3} \left\{ \frac{1}{\omega_2^3} \left( \frac{\tilde{q}_{3n} \frac{ml}{\omega_3^3} + \tilde{q}_{2n} \frac{l(m + n)}{\omega_2^3} \right) \right\} \right\}
\]

(S65)

To convert back to the \((x, y)\) coordinates, one simply needs to drop the tildes everywhere. Therefore, the second-order nonlinear optical conductivity is

\[
\sigma_{ilm}^{(2)} = \frac{2 D_{ilm}^{(2)}}{\omega_2^3} \left\{ \begin{pmatrix} \tilde{q}_{1n} \\ \omega_2^3 \end{pmatrix} \right\} \left\{ \begin{pmatrix} 2 \\ \omega_2^3 \end{pmatrix} \left( -\delta_{in} \tilde{\delta}_{lm} + \tilde{\delta}_{il} \delta_{nm} + \tilde{\delta}_{ln} \delta_{im} \right) \right\} \\
\quad - \frac{\epsilon_F}{\omega_2^3} \left\{ \begin{pmatrix} \tilde{q}_{1n} \tilde{\delta}_{il} \delta_{nm} + \frac{1}{\omega_2^3} \left( \tilde{\delta}_{in} \tilde{\delta}_{lm} - \tilde{\delta}_{il} \delta_{nm} + \tilde{\delta}_{ln} \delta_{im} \right) \right\} \right\}
\]

(S66)
Completing the symmetrization step \( \{ \frac{1}{n} - \frac{1}{n'} \} \), we get the following:

\[
\sigma_{ilm}^{(2)} = \frac{2D_{i}^{(2)}}{\omega_{1}^{(1)} \omega_{2}^{(1)} \omega_{3}^{(1)}} \left\{ q_{3n} \left[ \frac{\omega_{1}^{(1)} + \omega_{2}^{(1)}}{\omega_{3}^{(2)}} \right] (\delta_{lmn} \delta_{in} + \delta_{i1n} \delta_{nm} + \delta_{inl} \delta_{im}) 
- \frac{\omega_{1}^{(1)} + \omega_{2}^{(1)}}{2\omega_{3}^{(2)}} i\epsilon \Gamma \left( \frac{\partial \Gamma_{1}}{\omega_{3}^{(1)}} + \frac{\partial \Gamma_{2}}{\omega_{3}^{(2)}} \right) (\delta_{lmn} \delta_{in} + \delta_{i1n} \delta_{nm} + \delta_{inl} \delta_{im}) 
- \frac{\omega_{1}^{(1)} + \omega_{2}^{(1)}}{\omega_{3}^{(0)}} i\epsilon \Gamma \left( \frac{\partial \Gamma_{1}}{\omega_{3}^{(1)}} + \frac{\partial \Gamma_{0}}{\omega_{3}^{(0)}} \right) \delta_{lmn} \delta_{in} \right\} 
+ q_{2n} \left( \frac{\omega_{1}^{(1)}}{\omega_{2}^{(0)}} \delta_{i1n} \delta_{nm} - \frac{\omega_{1}^{(1)}}{2\omega_{2}^{(0)}} (\delta_{lmn} \delta_{in} - \delta_{inl} \delta_{nm} - \delta_{i1n} \delta_{im}) i\epsilon \Gamma \left( \frac{\partial \Gamma_{1}}{\omega_{3}^{(1)}} + \frac{\partial \Gamma_{2}}{\omega_{3}^{(2)}} \right) \right) 
+ q_{1n} \left( \frac{\omega_{1}^{(1)}}{\omega_{2}^{(0)}} \delta_{i1n} \delta_{nm} - \frac{\omega_{1}^{(1)}}{2\omega_{2}^{(0)}} (\delta_{lmn} \delta_{in} - \delta_{inl} \delta_{nm} - \delta_{i1n} \delta_{im}) i\epsilon \Gamma \left( \frac{\partial \Gamma_{1}}{\omega_{3}^{(1)}} + \frac{\partial \Gamma_{2}}{\omega_{3}^{(2)}} \right) \right) \right\}. 
\]

The corresponding functions \( G_{1}, G_{2}, \) and \( G_{3} \) [Eq. (S22)] are

\[
G_{1} = \frac{2D_{0}^{(2)}}{\omega_{1}^{(1)} \omega_{2}^{(1)} \omega_{3}^{(1)}} \left\{ \frac{\omega_{1}^{(1)} + \omega_{2}^{(1)}}{2\omega_{3}^{(2)}} \left[ \frac{2 - i\epsilon \Gamma \left( \frac{\partial \Gamma_{1}}{\omega_{3}^{(1)}} + \frac{\partial \Gamma_{2}}{\omega_{3}^{(2)}} \right)}{\omega_{3}^{(1)}} \right] - \frac{2\omega_{1}^{(1)}}{\omega_{1}^{(1)}} - \frac{\omega_{2}^{(1)}}{\omega_{2}^{(2)}} \left[ 1 + i\epsilon \Gamma \left( \frac{\partial \Gamma_{2}}{\omega_{3}^{(1)}} + \frac{\partial \Gamma_{0}}{\omega_{3}^{(0)}} \right) \right] \right\}, 
\]

\[
G_{2} = \frac{2D_{0}^{(2)}}{\omega_{1}^{(1)} \omega_{2}^{(1)} \omega_{3}^{(1)}} \left\{ \frac{\omega_{1}^{(1)} + \omega_{2}^{(1)}}{2\omega_{3}^{(2)}} \left[ \frac{2 - i\epsilon \Gamma \left( \frac{\partial \Gamma_{1}}{\omega_{3}^{(1)}} + \frac{\partial \Gamma_{2}}{\omega_{3}^{(2)}} \right)}{\omega_{3}^{(1)}} \right] + \frac{\omega_{2}^{(1)}}{2\omega_{2}^{(2)}} \left[ 1 + i\epsilon \Gamma \left( \frac{\partial \Gamma_{1}}{\omega_{3}^{(1)}} + \frac{\partial \Gamma_{0}}{\omega_{3}^{(0)}} \right) \right] \right\}, 
\]

\[
G_{3} = \frac{2D_{0}^{(2)}}{\omega_{1}^{(1)} \omega_{2}^{(1)} \omega_{3}^{(1)}} \left\{ \frac{\omega_{1}^{(1)} + \omega_{2}^{(1)}}{2\omega_{3}^{(2)}} \left[ \frac{2 - i\epsilon \Gamma \left( \frac{\partial \Gamma_{1}}{\omega_{3}^{(1)}} + \frac{\partial \Gamma_{2}}{\omega_{3}^{(2)}} \right)}{\omega_{3}^{(1)}} \right] - \frac{2\omega_{1}^{(1)}}{\omega_{1}^{(1)}} - \frac{\omega_{2}^{(1)}}{\omega_{2}^{(2)}} \left[ 1 + i\epsilon \Gamma \left( \frac{\partial \Gamma_{2}}{\omega_{3}^{(1)}} + \frac{\partial \Gamma_{0}}{\omega_{3}^{(0)}} \right) \right] \right\}. 
\]

Setting the particle number relaxation rate \( \Gamma_{0} \) to zero, which is the physical case, we get

\[
G_{1} = \frac{2D_{0}^{(2)}}{\omega_{1}^{(1)} \omega_{2}^{(1)} \omega_{3}^{(1)}} \left\{ \frac{\omega_{1}^{(1)} + \omega_{2}^{(1)}}{2\omega_{3}^{(2)}} \left[ \frac{2 - i\epsilon \Gamma \left( \frac{\partial \Gamma_{1}}{\omega_{3}^{(1)}} + \frac{\partial \Gamma_{2}}{\omega_{3}^{(2)}} \right)}{\omega_{3}^{(1)}} \right] - \frac{2\omega_{1}^{(1)}}{\omega_{1}^{(1)}} - \frac{\omega_{2}^{(1)}}{\omega_{2}^{(2)}} \left[ 1 + i\epsilon \Gamma \left( \frac{\partial \Gamma_{2}}{\omega_{3}^{(1)}} + \frac{\partial \Gamma_{0}}{\omega_{3}^{(0)}} \right) \right] \right\}, 
\]

\[
G_{2} = \frac{2D_{0}^{(2)}}{\omega_{1}^{(1)} \omega_{2}^{(1)} \omega_{3}^{(1)}} \left\{ \frac{\omega_{1}^{(1)} + \omega_{2}^{(1)}}{2\omega_{3}^{(2)}} \left[ \frac{2 - i\epsilon \Gamma \left( \frac{\partial \Gamma_{1}}{\omega_{3}^{(1)}} + \frac{\partial \Gamma_{2}}{\omega_{3}^{(2)}} \right)}{\omega_{3}^{(1)}} \right] + \frac{\omega_{2}^{(1)}}{2\omega_{2}^{(2)}} \left[ 1 + i\epsilon \Gamma \left( \frac{\partial \Gamma_{1}}{\omega_{3}^{(1)}} + \frac{\partial \Gamma_{0}}{\omega_{3}^{(0)}} \right) \right] \right\}, 
\]

\[
G_{3} = \frac{2D_{0}^{(2)}}{\omega_{1}^{(1)} \omega_{2}^{(1)} \omega_{3}^{(1)}} \left\{ \frac{\omega_{1}^{(1)} + \omega_{2}^{(1)}}{2\omega_{3}^{(2)}} \left[ \frac{2 - i\epsilon \Gamma \left( \frac{\partial \Gamma_{1}}{\omega_{3}^{(1)}} + \frac{\partial \Gamma_{2}}{\omega_{3}^{(2)}} \right)}{\omega_{3}^{(1)}} \right] - \frac{2\omega_{1}^{(1)}}{\omega_{1}^{(1)}} - \frac{\omega_{2}^{(1)}}{\omega_{2}^{(2)}} \left[ 1 + i\epsilon \Gamma \left( \frac{\partial \Gamma_{2}}{\omega_{3}^{(1)}} + \frac{\partial \Gamma_{0}}{\omega_{3}^{(0)}} \right) \right] \right\}. 
\]

In the collisionless limit, \( \Gamma_{i} \to 0 \), these formulas reduce to Eq. (S51).

**THIRD-ORDER CONDUCTIVITY IN THE HYDRODYNAMIC REGIME**

The third-order ac conductivity \( \sigma_{ilmn}^{(3)}(q_1, \omega_1; q_2, \omega_2; q_3, \omega_3) \) is defined as

\[
\sigma_{ilmn}^{(3)}(q_1, \omega_1; q_2, \omega_2; q_3, \omega_3) = \frac{1}{(2\pi)^3} \int d^3q \delta(q_1 + q_2 + q_3 - q) \delta(\omega_1 + \omega_2 + \omega_3 - \omega) \times \sigma_{ilmn}^{(3)}(q_1, \omega_1; q_2, \omega_2; q_3, \omega_3) E_i(q_1, \omega_1) E_m(q_2, \omega_2) E_n(q_3, \omega_3). 
\]

Unlike the second-order conductivity, \( \sigma_{ilmn}^{(3)} \) can approach a nonzero value at \( q = 0 \) in inversion-symmetric systems. We will compute this value and disregard \( O(\lambda^2) \) nonlocal corrections. The calculation is simplified by the observation that Eqs. (S25) and (S27) yield \( n_1^{(1)} = n_1^{(0)} = n_E = W^{(1)} = P^{(1)} = \theta(q) \to 0 \) in this approximation. An alternative way to get the same result is to neglect spatial gradients in Eqs. (S23c), (S23b) and (S23a), after which the hydrodynamic equations reduce to

\[
(\partial_t + \Gamma q) u_i = \frac{1}{\gamma^2} \left[ nE_i - u_i \partial_P - u_i j j E_j \right], \quad \partial_t n_E = j j E_j = n u_j E_j, \quad \partial_t n = 0. 
\]
The last equation entails \( n = n^{(0)} \), and so \( j_i^{(3)} = n^{(0)} u_i^{(3)} \). The third-order velocity can be found from

\[
(\partial_t + \Gamma_d) u_i^{(3)} = -\frac{n}{(\gamma^2 W)^2} (\gamma^2 W)^{(2)} E_i - \frac{1}{\gamma^2 W} u_i^{(1)} \partial_t P^{(2)} - \frac{n}{\gamma^2 W} u_i^{(1)} u_i^{(3)} E_j, \tag{S76}
\]

Since \( \gamma^2 W = n_E + P \), we have

\[
(\gamma^2 W)^{(2)} = n_E^{(2)} + P^{(2)} = W \frac{\omega^+}{\omega} u_i^{(1)} u_i^{(1)} + \left[ \frac{\partial P}{\partial n_0} \left( -\frac{1}{2} n \right) + \frac{\partial P}{\partial n_{E0}} W \left( \frac{\omega^+}{\omega} - 1 \right) \right] u_i^{(1)} u_i^{(1)} + \text{perm.,} \tag{S77}
\]

where “perm.” stands for permutations among subscripts \( = i, j, k \), respectively. The equation for the Fourier amplitude \( u_3^{(3)}(\omega) \) of the combined frequency \( \omega = \omega_1 + \omega_2 + \omega_3 \) becomes

\[
(-i\omega + \Gamma_d) u_i^{(3)} = -\frac{n}{(\gamma^2 W)^2} E_i \left\{ W \frac{\omega^+}{\omega_1 + \omega_2} u_i^{(1)} u_i^{(2)} + \left[ \frac{\partial P}{\partial n_0} \left( -\frac{1}{2} n \right) + \frac{\partial P}{\partial n_{E0}} W \left( \frac{\omega^+}{\omega_1 + \omega_2} - 1 \right) \right] u_i^{(1)} u_i^{(2)} \right\} 
- \frac{1}{\gamma^2 W} u_i^{(1)} \partial_t \left\{ \left[ \frac{\partial P}{\partial n_0} \left( -\frac{1}{2} n \right) + \frac{\partial P}{\partial n_{E0}} W \left( \frac{\omega^+}{\omega_1 + \omega_2} - 1 \right) \right] u_i^{(1)} u_i^{(2)} \right\} 
- \frac{n}{\gamma^2 W} u_i^{(1)} \left\{ \left[ \frac{\partial P}{\partial n_0} \left( -\frac{1}{2} n \right) + \frac{\partial P}{\partial n_{E0}} W \left( \frac{\omega^+}{\omega_1 + \omega_2} - 1 \right) \right] u_i^{(1)} u_i^{(2)} \right\} 
- \frac{i}{W} \frac{\omega^+}{\omega_1} u_i^{(1)} u_i^{(1)} u_i^{(1)} \left\{ W \frac{\omega^+}{\omega_1 + \omega_2} + \left[ \frac{\partial P}{\partial n_0} \left( -\frac{1}{2} n \right) + \frac{\partial P}{\partial n_{E0}} W \left( \frac{\omega^+}{\omega_1 + \omega_2} - 1 \right) \right] u_i^{(1)} u_i^{(2)} \right\} 
- \frac{1}{W} \frac{\omega^+}{\omega_1} u_i^{(1)} u_i^{(2)} \partial_t \left\{ \left[ \frac{\partial P}{\partial n_0} \left( -\frac{1}{2} n \right) + \frac{\partial P}{\partial n_{E0}} W \left( \frac{\omega^+}{\omega_1 + \omega_2} - 1 \right) \right] u_i^{(1)} u_i^{(2)} \right\} 
- \frac{i}{W} \frac{\omega^+}{\omega_1 + \omega_2} \frac{\partial P}{\partial n_0} \left( \frac{1}{2} n \right) \left( \omega_1 + \omega_2 \right) + \frac{\partial P}{\partial n_{E0}} W(-i) \left( \omega_1 + \omega_2 \right) u_i^{(1)} u_i^{(2)} - \frac{i}{W} \frac{\omega^+}{\omega_1 + \omega_2} \frac{\partial P}{\partial n_0} \left( \frac{1}{2} n \right) \left( \omega_1 + \omega_2 \right) + \frac{\partial P}{\partial n_{E0}} W \left( \omega_1 + \omega_2 \right) u_i^{(1)} u_i^{(2)} \right\} 
- \frac{i}{W} \frac{\omega^+}{\omega_1 + \omega_2} + \frac{\partial P}{\partial n_0} \left( \frac{1}{2} n \right) \left( \omega_1 + \omega_2 \right) + \frac{\partial P}{\partial n_{E0}} W \left( \omega_1 + \omega_2 \right) u_i^{(1)} u_i^{(2)} \right\} 
- \frac{i}{W} \frac{\omega^+}{\omega_1 + \omega_2} + \frac{\partial P}{\partial n_0} \left( \frac{1}{2} n \right) \left( \omega_1 + \omega_2 \right) + \frac{\partial P}{\partial n_{E0}} W \left( \omega_1 + \omega_2 \right) u_i^{(1)} u_i^{(2)} \right\} 
- \frac{i}{W} \frac{\omega^+}{\omega_1 + \omega_2} + \frac{\partial P}{\partial n_0} \left( \frac{1}{2} n \right) \left( \omega_1 + \omega_2 \right) + \frac{\partial P}{\partial n_{E0}} W \left( \omega_1 + \omega_2 \right) u_i^{(1)} u_i^{(2)} \right\} 
- \frac{i}{W} \frac{\omega^+}{\omega_1 + \omega_2} + \frac{\partial P}{\partial n_0} \left( \frac{1}{2} n \right) \left( \omega_1 + \omega_2 \right) + \frac{\partial P}{\partial n_{E0}} W \left( \omega_1 + \omega_2 \right) u_i^{(1)} u_i^{(2)} \right\} \right\}. \tag{S78}
\]

Therefore,

\[
u_i^{(3)} = -\frac{1}{(\omega + \omega_1 + \omega_2) W} + \frac{\partial P}{\partial n_0} \left( \frac{1}{2} n \right) \omega_1 + \omega_2 + \omega_3 + \frac{\partial P}{\partial n_{E0}} W \left( \omega_1 + \omega_2 + \omega_3 + \omega_4 - \omega_1 - 1 \right) \omega_1 + \omega_2 + \omega_3 + \omega_4 \right\} u_i^{(1)} u_i^{(3)} \right\} \right\}. \tag{S79}
\]

(For brevity, we omitted “+ perm.” in the above equations.) In the dissipationless limit Eq. (S79) simplifies to [cf. Eq. (S24)]

\[
u_i^{(3)} = \frac{C_{\text{se}} - 1}{2} u_i^{(1)} u_i^{(2)} u_i^{(3)} + \text{perm.} \tag{S80}
\]

Therefore,

\[
u_i^{(3)} = \frac{D_{i}}{\omega_1^2 \omega_2 \omega_3} (\delta_{il} \delta_{mn} + \delta_{im} \delta_{ln} + \delta_{in} \delta_{lm}), \quad D_{i}^{(3)} = \frac{1 - C_{\text{se}}}{3!} \frac{n}{m^2 v^2}, \tag{S81}
\]

where \( e \) and \( v \) were restored.

We can compare our formula for the third-order ac conductivity in the hydrodynamic regime with other results in the literature for the case \( \omega_1 = \omega_2 = \omega_3 \), which corresponds to the third harmonic generation. This effect is controlled by the conductivity \( \sigma_{i1m0}^{(3)}(0, \omega_1; 0, \omega_2; 0, \omega_3) \). Applied to graphene at \( T = 0 \), our result for \( D_{i}^{(3)} \) is twice larger than the third-order spectral weight from the collisionless Boltz-
mann transport theory [23]. Compared to the linear response, the third-order current is suppressed by the small parameter $\xi = (eE|\omega|)^2$. At zero temperature, neglecting exchange-correlation corrections, $m^*v$ is just the Fermi momentum $p_F$, so that $\xi = (\delta p/p_F)^2$. The quantity $\delta p = -eE/\omega$ is equal by the order of magnitude to the change in electron momentum caused by the electric field during one half cycle of the sum-frequency oscillations, $\delta t \sim \pi/\omega$. The ratio of $\xi$ factors for a nonrelativistic and ultrarelativistic Dirac fluids is $\sim (v_F/v)^2 \ll 1$. This factor vanishes for a system with a parabolic dispersion corresponding to $v \rightarrow \infty$. Indeed, for such a system all nonlinearities at zero $q$ should be absent because of the Galilean invariance. On the other hand, the linear and second-order conductivities, $\sigma$ and $\sigma_{\text{lin}}$, do not show this contrasting behavior because they do not contain $v$ explicitly.

**APPLICATIONS AND SUMMARY**

**Photon drag**

The photon drag effect is the generation of dc current by a light incident on the sample. Unlike optical rectification and photogalvanic effect, the photon drag current is the result of the transfer of the linear momentum of photons $\mathbf{q}$ to free carriers [41]. This is why photon drag can appear only if $\mathbf{q} = \hat{x}q_x + \hat{y}q_y$ is not strictly normal to the $x$-$y$ plane of the sample, see Fig. S2(a). An alternative classical picture of the photon drag is the carrier drift in the crossed electric and magnetic fields of the electromagnetic wave, and so the photon drag is also sometimes referred to as the dynamical Hall effect. The drag current can have both longitudinal $j_x$ and transverse $j_y$ components. Let the in-plane component of the electric field be $\mathbf{E} = E_0 e^{i(qr-\omega t)} + c.c.$ where $E_0 = \hat{x}E_x + \hat{y}E_y$. The polarization of the incident wave in the $x$-$y$ plane is important. This polarization can be specified in terms of the Stokes parameters $s_0 = |E_x|^2 + |E_y|^2$, $s_1 = |E_x|^2 - |E_y|^2$, $s_2 = E_xE_y^* + E_yE_x^*$, and $s_3 = -i(E_xE_y^* - E_yE_x^*)$. From Eq. (S33), we can calculate the induced dc current components as [42]

$$j_x = 2\sigma_{\text{ph}}^{(2)}(\mathbf{q}, \omega; -\mathbf{q}, -\omega)E_yE_x^* + 2\sigma_{\text{ph}}^{(2)}(\mathbf{q}, \omega; -\mathbf{q}, -\omega)E_xE_y^*$$

$$T_1 = T_1(q_x)^2 + T_2(q_x)^2(\epsilon|E_x|^2 - |E_y|^2),$$

$$j_y = 2\sigma_{\text{ph}}^{(2)}(\mathbf{q}, \omega; -\mathbf{q}, -\omega)E_xE_y^* + 2\sigma_{\text{ph}}^{(2)}(\mathbf{q}, \omega; -\mathbf{q}, -\omega)E_yE_x^*$$

$$T_2 = T_2(q_y)^2(E_xE_y^* + E_yE_x^*) + T_1(q_z)(-i(E_xE_y^* - E_yE_x^*).$$

The coefficients $T_1$ and $T_2$ are as follows:

$$T_1 = 2\left(\hat{G}_1 + \hat{G}_2(\hat{G}_3), \quad T_2 = 2\left(\hat{G}_1 + \hat{G}_2\right),$$

where

$$\hat{G}_d(\omega) \equiv G_d(\omega, -\omega) - G_d(-\omega, \omega)$$

and $G_d$ are the functions introduced in Eq. (S22). For $\hat{T}_1$, we get

$$\hat{T}_1 = -i\left(G_1(\omega, -\omega) + G_1(-\omega, \omega)\right)$$

$$+ i\left(G_2(\omega, -\omega) + G_2(-\omega, \omega)\right).$$

For the hydrodynamic regime, we take $G_d(\omega, -\omega)$ from Eq. (S39) and obtain

$$T_1 = \left(-\frac{1}{1-C_{\text{ise}}} - 1\right) \frac{4D_{\text{h}}(2)}{\omega(\omega^2 + \Gamma_2^2)},$$

$$T_2 = \left(-\frac{1}{1-C_{\text{ise}}} - 1\right) \frac{4D_{\text{h}}(2)}{\omega(\omega^2 + \Gamma_2^2)},$$

$$\hat{T}_1 = 0.$$}

For the case of graphene, $C_{\text{ise}} = 1/2$, these equations give

$$T_1 = -3T_2, \quad T_2 = \frac{4D_{\text{h}}(2)}{\omega(\omega^2 + \Gamma_2^2)}, \quad \hat{T}_1 = 0.$$}

which is Eq. (15) of the main text.

In the kinetic regime, the photon drag coefficients are more complicated. Equations (S71)–(S73) for $G_d$ can be used to compute them for graphene at zero temperature. We get the following:

$$T_1 = 8D_{\text{h}}(2)\left(1 + \varepsilon_F\varepsilon_F\ln\Gamma_1\right) \frac{\left|\omega^2 + \Gamma_2^2\right| + \omega^2(1 + \Gamma_2^2/\Gamma_1)}{\omega\left|\omega^2 + \Gamma_2^2\right|},$$

$$T_2 = 8D_{\text{h}}(2)\left(1 + \varepsilon_F\varepsilon_F\ln\Gamma_1\right) \frac{\omega(\omega^2 + \Gamma_2^2)}{\omega\left|\omega^2 + \Gamma_2^2\right|},$$

$$\hat{T}_1 = -4D_{\text{h}}(2)\left(1 + \Gamma_2^2/\Gamma_1\right) \frac{\left|\omega^2 + \Gamma_2^2\right| + \omega^2(1 + \Gamma_2^2/\Gamma_1)}{\omega\left|\omega^2 + \Gamma_2^2\right|}. $$

 deformations of the Fermi surface obey the relations

$$\Gamma_2 = 2\Gamma_1, \quad \varepsilon_F\varepsilon_F\ln\Gamma_1 = 1.$$

When substituted into the general formulas above, followed
by the notation change $\Gamma_1 \rightarrow \Gamma_d$, these relations lead to Eq. (16) of the main text.

Instead of the Stokes parameters, we can use two angles $\psi$ and $\alpha$ such that $E_x = E \cos \alpha \cos \theta$, $E_y = E \cos \alpha \sin \theta$. Note that $\alpha = 0$ means p-polarization and $\alpha = \pi/2$ means s-polarization, see Fig. S2(a). The formulas for $j_x$ and $j_y$ become

$$j_x = \frac{1}{2} q_x |E|^2 \left[ (T_1 + T_2) \cos^2 \alpha \cos^2 \theta + (T_1 - T_2) \sin^2 \alpha \right],$$

$$j_y = \frac{1}{2} q_x |E|^2 \left[ \cos \theta \sin 2\alpha \left( T_2 \cos \psi - 2 \tilde{T}_1 \sin \psi \right) \right].$$

In the hydrodynamic regime where $\tilde{T}_1 = 0$, the transverse current $j_y$ has no component proportional to $\sin \psi$. However, $j_y$ does have such a component in the kinetic regime, as illustrated by Fig. S2(d). This distinction may be used to identify the two regimes in experiments.

**Second harmonic generation**

The second-harmonic generation (SHG) signal is proportional to the $(2\mathbf{q}, 2\omega)$ Fourier harmonic of the second-order ac current, which is given by [20]

$$j_x = \sigma^{(2)}_{xxy}(\mathbf{q}, \omega; \mathbf{q}, \omega) E_x^2 + \sigma^{(2)}_{xyx}(\mathbf{q}, \omega; \mathbf{q}, \omega) E_x E_y,$$

$$j_y = \sigma^{(2)}_{yxy}(\omega, \mathbf{q}, \omega, q) E_x E_y + \sigma^{(2)}_{yx}(\omega, q, \omega, q) E_x,$$

where

$$S_1 = G_1(\omega, \omega) + G_2(\omega, \omega) + 2G_3(\omega, \omega),$$

$$S_2 = G_1(\omega, \omega) + G_2(\omega, \omega).$$

Neglecting the damping, for graphene in the kinetic regime, we get

$$S_1 = \frac{2D^{(2)}_h}{\omega^3}, \quad S_2 = \frac{D^{(2)}_k}{\omega^3}.$$  \hspace{1cm} (S97)

In the hydrodynamic regime, we find

$$S_1 = \frac{2D^{(2)}_h}{\omega^3}, \quad S_2 = \frac{D^{(2)}_k}{\omega^3}.$$  \hspace{1cm} (S98)

This implies that SHG signal has the same polarization dependence in the hydrodynamic and kinetic regimes but the magnitude of the response is different because it is controlled by either $D^{(2)}_h$ or $D^{(2)}_k$. At zero temperature the ratio $D^{(2)}_h/D^{(2)}_k$ is equal to 2, but at high temperature it rapidly decreases, see Fig. S2(b). Experimentally, this difference may be observed as the electron temperature is increased and the system crosses over from the kinetic to the hydrodynamic regime at some $T^* = T^*(\omega)$. This crossover temperature is the solution of the equation $\Gamma_\sigma(T^*) = \omega$. As $T^*$ is approached from below, the SHG signal may increase, by up to a factor of two from its $T = 0$ value, as sketched by the dashed line in Fig. S2(b). When the temperature is raised beyond $T^*$, the system enters the hydrodynamic regime where the SHG signal should drop due to decreasing $D^{(2)}_h$. The transient states of high electron temperatures can be realized with intense photoexcitation.

**Summary tables for the second-order conductivity**

As we pointed out earlier, $\sigma^{(2)}_{lim}$ is fully characterized by three functions $G_1$, $G_2$, and $G_3$. Shown in Table I are $G_1$, $G_2$, $G_3$ and $T_1$, $T_2$, $\tilde{T}_1$ in different regimes and for different band dispersions. In addition, the same formulas in the clean limit are summarized in Table II.

Electron systems with parabolic dispersion is an interesting case. In such systems $\sigma^{(2)}_{lim}$ has the same form in the kinetic and hydrodynamic regimes but only in the absence of momentum dissipation. As mentioned in the main text, in this system the random-phase approximation (RPA) also gives the same $\sigma^{(2)}_{lim}$ to the linear order in $q$ in the absence of dissipation. In the diagrammatic derivation [32] of this

![Image S2](image-url)
RPA result only the “diamagnetic” terms contribute to $\sigma_{ilm}^{(2)}$. Those diamagnetic terms are all determined by the linear-response Drude weight. The “paramagnetic” term, that is, a single-loop diagram with three current vertices vanishes to the first order in $q$. This is superficially similar yet apparently unrelated to Furry’s theorem in quantum electrodynamics, which says that fermion loops with odd number of photon vertices vanish because of electron-positron symmetry. For Dirac electrons in graphene one may invoke Furry’s theorem to explain vanishing of the spectral weight at $\mu = 0$ [see Eq. (S52)]. However, in the case of interest, $\mu \neq 0$, the three-point current correlation function $[24, 26, 28]$ is finite. In fact, it is the diamagnetic contribution that vanishes, so that $\sigma_{ilm}^{(2)}$ is determined solely by this paramagnetic term.
