(Dated: October 5, 2017)

We investigate effect of \(k\)-cubic spin-orbit interaction on electrical and thermoelectric transport properties of two-dimensional fermionic systems. We obtain exact analytical expressions of the inverse relaxation time (IRT) and the Drude conductivity for long-range Coulomb and short-range delta scattering potentials. The IRT reveals that the scattering is completely suppressed along the three directions \(\theta = (2n + 1)\pi/3\) with \(n = 1, 2, 3\). We also obtain analytical results of the thermopower and thermal conductivity at low temperature. The thermoelectric transport coefficients obey the Wiedemann-Franz law, even in the presence of \(k\)-cubic Rashba spin-orbit interaction (RSOI) at low temperature. In the presence of quantizing magnetic field, the signature of the RSOI is revealed through the appearance of the beating pattern in the Shubnikov-de Haas (SdH) oscillations of thermopower and thermal conductivity in low magnetic field regime. The empirical formulae for the SdH oscillation frequencies accurately describe the locations of the beating nodes. The beating pattern in magnetothermoelectric measurement can be used to extract the spin-orbit coupling constant.

I. INTRODUCTION

Two-dimensional (2D) systems of fermionic charge carriers (electron/hole) remain a test bed for spintronics related theoretical and experimental studies\(^1\). Experimental investigations reveal the presence of strong spin-orbit coupling (SOC) associated with 2D electron/hole gas in \(n\)-/\(p\)-doped GaAs/AlGaAs heterojunctions\(^2\),\(^3\), various topological insulating systems\(^4\), strained Ge/SiGe quantum wells, 2D electron gas in transition metal oxide interface like SrTiO\(_3\)/LaTiO\(_3\).

In two-dimensional electron gas (2DEG) formed at the III-V semiconductor heterostructures\(^2\) and in various topological insulating systems\(^4\), the RSOI is linear in momentum \(k\). Whereas, in \(p\)-doped III-V semiconductor heterojunctions such as AlGaAs/GaAs, strained-Ge/SiGe heterojunction\(^5\),\(^6\) and the interfaces of some transition metal oxides (e.g. SrTiO\(_3\)/LaTiO\(_3\))\(^7\)\(-10\), the RSOI is found to be cubic in momentum. It implies that the energy level splitting due to \(k\)-cubic SOI is \(2\alpha k^3\) with \(\alpha\) being the spin-orbit coupling constant. The \(k\)-cubic SOI arises due to the multi-orbital effects which can be seen in the subsequent discussion.

To describe the 2D hole gas (2DHG) in hole-doped AlGaAs/GaAs quantum well, we generally require a \(4 \times 4\) Luttinger Hamiltonian\(^11\),\(^12\) that describes the hole states \([3/2, \pm 3/2]\) and \([3/2, \pm 1/2]\). At very low temperature and low density only the lowest heavy hole (HH) subbands \([3/2, \pm 3/2]\) are occupied. The projection of \(4 \times 4\) Luttinger Hamiltonian onto the HH states leads to an effective \(k\)-cubic\(^13\),\(^14\) RSOI. On the other hand, in transition metal oxide, SrTiO\(_3\), the conduction bands originates from the \(3d\) orbitals of Ti ion. The atomic \(1s\)\(-s\) coupling splits the energy levels between \(yz\), \(xz\) and \(xy\) orbitals such that the lowest energy states for bulk SrTiO\(_3\) will now consist of fourfold degenerate bands, with total angular momentum \(J = 3/2\) \((m_j = \pm 3/2\) and \(\pm 1/2)\)\(^15\). The quantum confinement in the SrTiO\(_3\)/LaTiO\(_3\) further lifts this degeneracy such that the two-fold spin degenerate states \([3/2, \pm 3/2]\) becomes the lowest sub-bands which is for the \(xy\) orbital\(^17\),\(^16\). In all these two cases, the sub-bands \([3/2, \pm 3/2]\) is associated with the RSOI which is of the form \(H_R = \alpha(k^3\sigma \pm k^3\sigma)\), where \(k_\perp = k_x \pm ik_y\) and \(\sigma_\perp = \sigma_x \pm i\sigma_y\). The SOI associated with these sub-bands lift their two-fold spin degeneracy.

It is necessary to understand how the SOI affect the different electrical and magnetic transport properties. In the past few decades, several theoretical and experimental studies have been done on 2DHG with \(k\)-cubic RSOI to explore the effective mass\(^17\)\(-19\) effective Lande g-factor\(^20\), spin polarization\(^21\), spin rotation\(^22\) etc. The experimental and theoretical analyses of the spin Hall effect are presented in Refs.\(^23\)\(-28\). The effect of the RSOI to the Drude weight and optical conductivities\(^29\),\(^30\) in 2DHG has been thoroughly investigated. In the presence of a magnetic field normal to the 2D system, the \(k\)-cubic SOI of the charge carriers give rise to many noble phenomena such as weak anti-localization\(^8\),\(^31\) effect in low-field magnetoresistance\(^3\) and beating pattern at moderate magnetic field in various magnetotransport coefficients\(^3\),\(^32\).

The study of thermoelectricity is important since it directly yields the sign of the dominant charge carriers and provides information about the intrinsic charge carriers\(^33\)\(-36\). There have been detailed studies of the thermoelectricity in conventional 2DEG\(^37\),\(^38\). In Ref.\(^39\), a detailed theoretical study of the thermoelectricity in 2DEG with linear RSOI is given. The application of a magnetic field normal to the plane of the 2DEG/2DHG exhibits the Shubnikov–de Haas (SdH) oscillations in various thermoelectrical coefficients. The effect of RSOI on the oscillations of the thermopower and thermal conduc-
tivity has been well studied in the 2DEG\textsuperscript{39,40}. As a result of RSOI, they show beating pattern with the variation of magnetic field or Fermi energy. These beating patterns are due to the unequal spacing of Landau levels (LL’s) induced by the RSOI. The beating pattern of these oscillations gives a direct quantitative measurement of the strength of the RSOI.

In this work, we study the behavior of the electrical and thermoelectric transport properties of the 2D fermionic system with $k$-cubic RSOI. We study the energy dependence of inverse relaxation time (IRT) for two types of impurity potentials, Coulomb impurity potential and short-range impurity potential. These results are further used for investigating the carrier density and RSOI dependence of the Drude conductivity, thermopower and thermal conductivity. For non-zero magnetic field case, we study the effect of the RSOI on the various thermoelectric coefficients. The effect of the RSOI is reflected by the appearance of the beating pattern in thermoelectric coefficients at low magnetic field. The frequencies of SdH oscillations and the location of the beating nodes match very well with the empirical formulae given in Ref.\textsuperscript{32}.

This paper is organized as follows. In section II, the results of the inverse relaxation time, Drude conductivity, thermopower and thermal conductivity in zero magnetic field are presented. The results of the thermopower and thermal conductivity in the presence of quantizing magnetic field are given in section III. The conclusion of this paper is given in section IV.

II. 2D FERMIONIC SYSTEM IN ZERO MAGNETIC FIELD

The Hamiltonian describing the 2D fermionic system with $k$-cubic RSOI is given by

$$H = \frac{p_x^2}{2m^*} + \frac{i\alpha}{2\hbar^2}(\sigma_+ p^3_+ - \sigma_- p^3_-).$$

Here, $m^*$ is the effective mass of a fermion, $p_x = px + ip_y$, $\sigma_\pm = \sigma_x \pm i\sigma_y$, with $\sigma_{x,y}$ being the Pauli’s matrices and $\alpha$ measures the strength of the RSOI. The spin-split energy levels and their corresponding eigenstates are respectively given by

$$\varepsilon^\lambda_k = \frac{(\hbar k)^2}{2m^*} + \lambda \alpha k^3,$$

and

$$\psi^\lambda_k(r) = e^{ikr}/\sqrt{2\pi l^*} \phi^\lambda_k.$$  

Here, $\phi^\lambda_k$ is the spinor part of the wave function. Here, $\theta$ is the polar angle of the wave vector $\mathbf{k}$ and $T$ denotes the transpose.

The velocity operator is given by $\hat{\mathbf{v}} = \partial H/\partial \mathbf{p}$. The carrier velocity in each branch is given by $v^\lambda (\mathbf{k}) = \langle \mathbf{k}, \lambda | \hat{\mathbf{v}} | \mathbf{k}, \lambda \rangle = (\hbar k/m^* + 3\alpha k^2/\hbar)\mathbf{\hat{k}}$. The density of states of two spin-split energy levels are

$$D_\lambda(\varepsilon) = \frac{D_0}{1 + \lambda^2 k^2/\varepsilon^2}$$

where $D_0 = m^*/2\pi\hbar^2$, $k_a = \hbar^2/m^*\alpha$ and $k_\lambda(\varepsilon)$ is the root of $\hbar^2 k^2/2m^* + \lambda \alpha k^3 - \varepsilon = 0$. Note that $D_+ (\varepsilon) > D_-(\varepsilon)$ because $\varepsilon^+_{k_\lambda}$ is more steeper than $\varepsilon^+_{k}$.

For a given carrier density $n_c$, the exact expressions of the Fermi wave vectors and the Fermi energy are given in Ref.\textsuperscript{13} and can be rewritten in a more compact form as

$$\tilde{k}^\lambda_f = \left[ (\sqrt{1 - 16\pi n_c l^2_a} - 1)/8 + 3\pi n_c l^2_a \right]^{1/2}$$

$$\varepsilon_f = \frac{2\pi^2 (1 - 16\pi n_c l^2_a)}{(1 + \sqrt{1 - 16\pi n_c l^2_a})},$$

respectively. Here, $\tilde{k}^\lambda_f = k_f^\lambda/k_a$ is the dimensionless Fermi wave vector, $l_a = 1/k_a$ and $\varepsilon^0_f = \pi^2 n_c/m^*$ is the Fermi energy of charge carriers in a conventional 2D system.

For realistic samples, $n_c \leq 10^{17}$ m$^{-2}$ and $\alpha \leq 0.2$ eV-nm$^3$, one can easily check that $16\pi n_c l^2_a \leq 0.06 \ll 1$. In this limit, we have simple expressions of $k^\lambda_f$ and $\varepsilon_f$ as given by

$$k^\lambda_f \simeq \sqrt{3\pi n_c} - \lambda 2\pi n_c l^2_a$$

and

$$\varepsilon_f \simeq \varepsilon^0_f (1 - 12\pi n_c l^2_a).$$

The Fermi energy is reduced due to the presence of the spin-orbit coupling.

A. Drude conductivity and inverse relaxation time

Applying a weak DC electric field ($\mathbf{E} = E_x \mathbf{\hat{x}}$) along $x$-direction, the longitudinal current density becomes $J_x = \sigma_{xx} E_x$ with $\sigma_{xx}^1$ being the Drude conductivity. Using the semiclassical Boltzmann transport theory, the Drude conductivity\textsuperscript{41} at low temperature is given by

$$\sigma_{xx} = \frac{e^2}{(2\pi)^2} \sum_{\lambda} \int d^2k |\lambda\rangle |\langle \lambda | v_{\lambda} (k) | 2 \tau_{\lambda} (k) \left[ - \frac{\partial F_0 (\varepsilon_{\lambda})}{\partial \varepsilon_{\lambda}} \right]].$$

Here, $|\langle \lambda | v_{\lambda} (k) | 2 \tau_{\lambda} (k) \right]$ is the momentum relaxation time and $F_0 (\varepsilon_{\lambda}) = 1 + e^{\beta (\varepsilon_{\lambda} - \eta)}$ is the equilibrium Fermi distribution function with $\eta$ being the chemical potential and $\beta = (k_B T)^{-1}$.

After performing the integrals, the Drude conductivity at $T = 0$ is given by

$$\sigma_{xx} = \frac{e^2}{2\pi m^*} \sum_{\lambda} \tau_{\lambda} (k^\lambda_f) (k^\lambda_f)^2 (1 + \lambda^2 k^2_\lambda),$$

where $\tau_{\lambda} (k^\lambda_f)$ is the relaxation time at $k^\lambda_f$. This equation can be rewritten in a more compact form as

$$\sigma_{xx} = \frac{e^2}{2\pi m^*} \sum_{\lambda} \tau_{\lambda} (k^\lambda_f) (k^\lambda_f)^2 (1 + \lambda^2 k^2_\lambda),$$

where $k^\lambda_f = \tilde{k}^\lambda_f/k_a$ is the dimensionless Fermi wave vector, $l_a = 1/k_a$ and $\varepsilon^0_f = \pi^2 n_c/m^*$ is the Fermi energy of charge carriers in a conventional 2D system.

For realistic samples, $n_c \leq 10^{17}$ m$^{-2}$ and $\alpha \leq 0.2$ eV-nm$^3$, one can easily check that $16\pi n_c l^2_a \leq 0.06 \ll 1$. In this limit, we have simple expressions of $k^\lambda_f$ and $\varepsilon_f$ as given by

$$k^\lambda_f \simeq \sqrt{3\pi n_c} - \lambda 2\pi n_c l^2_a$$

and

$$\varepsilon_f \simeq \varepsilon^0_f (1 - 12\pi n_c l^2_a).$$

The Fermi energy is reduced due to the presence of the spin-orbit coupling.
where $\tau_{\lambda}(k_f)$ is the relaxation time evaluated at the Fermi contour.

Within the relaxation time approximation, the IRT \([1/\tau_{\lambda}(k)]\) for different energy levels ($\lambda$) is given by

$$\frac{1}{\tau_{\lambda}(\varepsilon_k)} = \int \frac{d^2k'}{(2\pi)^2} (1 - \cos \theta') W_{k,k'}^\lambda, \quad (9)$$

where $\theta'$ is the angle between the wave-vectors $k$ and $k'$ and $W_{k,k'}^\lambda$ is the intra-band transition probability of a charge carrier from the initial state $k$ to the scattered state $k'$ is given by

$$W_{k,k'}^\lambda = \frac{2\pi N_i}{\hbar} |\langle k, \lambda | U_\lambda(r) | k', \lambda \rangle|^2 \delta(\varepsilon_{k'} - \varepsilon_k). \quad (10)$$

Here $N_i$ is the number of static impurities present in the system and $U_\lambda(r)$ is circularly symmetric charge-impurity interaction potential. The delta function ensures the conservation of energy during the scattering process. The quantity $|\langle k, \lambda | U_\lambda(r) | k', \lambda \rangle|^2 = |U_\lambda(q)|^2 F(k,k')$, where $U_\lambda(q) = (2\pi)^{-1} \int d^2r e^{iqr} U_\lambda(r)$ is the impurity potential in $k$ space with $q = k - k'$ being the change in the wave vectors and $F(k,k') = |\phi^\dagger_{\lambda}(k')\phi_{\lambda}(k)|^2$ is the modulus square of the overlap of the spinors, which is given by

$$F(k,k') = |\phi^\dagger_{\lambda}(k')\phi_{\lambda}(k)|^2 = \frac{1 + \cos 3\theta'}{2}. \quad (11)$$

Equation (11) shows that the scattering is completely suppressed along the three directions $\theta' = (2n + 1)\pi/3$, with $n = 0, 1$ and $2$, irrespective of the type of impurity scattering potential. It is interesting to compare this result with that of the heavy holes in p-doped bulk III-V semiconductors, where only the back scattering is suppressed. For 2DHG, the complete suppression of scattering along two more directions ($\theta' = \pi/3, 5\pi/3$) is associated with the $k$-cubic nature of the spin-orbit coupling.

In realistic samples, the charge carriers scatter by different nature of impurities. Here we consider two different types of impurity potentials, namely, long-range screened Coulomb potential i.e. Yukawa-type potential and short-range ($\delta$-scatterer) scattering potential. We are neglecting phonon interaction with the charge carriers since we are restricted to study in the low temperature regime $T < 1 \text{ K}$ which is much less than the Bloch-Grünenisen temperature $T_{BG} \sim 5 - 10 \text{ K}$. In presence of both the independent scatterers, one can use Matthiessen’s rule, $1/\tau_{\text{tot}} = 1/\tau_{c} + 1/\tau_{s}$, to compute the total IRT ($1/\tau_{\text{tot}}$).

**Yukawa-type impurity potential:** First, we consider long-range screened Coulomb potential as $U_\lambda(r) = U_0e^{-k_\lambda r}/r$, where $k_\lambda$ is the Thomas-Fermi (TF) screening wave vector and $U_0 = Ze^2/4\pi\epsilon$ with $Ze$ being ionic charge, $\epsilon$ being the dielectric constant of the system. The TF screening wave vectors can be calculated using the standard relation $k_\lambda^2 = Z e^2 D_\lambda(\varepsilon_f)/(2\epsilon)$ and are given by $k_\lambda^2 = [a_B/(1 + \lambda 3k_\lambda^2)]^{-1}$ with $a_B = 4\pi\epsilon k^2/(Ze^2m^*)$ being the effective Bohr radius. The Fourier transform of this potential is $U_\lambda(q) = 2\pi U_0/(\sqrt{k_\lambda^2 + q^2})$ with $q^2 = 4k^2\sin^2\theta'/2$ and now $W_{k,k'}^\lambda$ is given by

$$W_{k,k'}^\lambda = \frac{4\pi^3 n_i U_0^2}{\hbar} \left(1 + \cos 3\theta'\right) \left(k_\lambda^2 + q^2\right) \delta(\varepsilon_{k'} - \varepsilon_k).$$

Here, $n_i = N_i/\Omega$ is the impurity density. On further simplifications, the IRT for different energy levels can be written as

$$\frac{\tau_0}{\tau_{\lambda}(k)} = \frac{D_\lambda(k)}{D_0} \int_0^{2\pi} \left(1 - \cos \theta'\right)(1 + \cos 3\theta')d\theta' \left(k_\lambda^2 + q^2\right) \frac{1}{\sin^2(\theta'/2)} \quad (12)$$

where $\tau_0^\epsilon = m^*/\pi\hbar n_i$ and $k_B = 1/a_B$. The IRT is thus directly proportional to the density of states $D_\lambda(k)$ and the impurity density as expected. After performing the angular integral, we get exact analytical expressions of $\tau_{\lambda}(k)$ as given by

$$\frac{\tau_0}{\tau_{\lambda}(k)} = \frac{D_\lambda(k) \pi k_B^2}{2D_0} \left[2k^6 + 3k^4(k_\lambda^2)^2 + 4k^2(k_\lambda^4)^4 + (k_\lambda^6)^6 \right. \left. - \sqrt{4k^2 + (k_\lambda^4)^2}\{k^4 + 2(k_\lambda^4)^2 + (k_\lambda^2)^4\}\right]. \quad (13)$$

In the limit of small $k$,

$$\frac{\tau_0}{\tau_{\lambda}(k)} \approx \frac{2\pi}{\lambda 3k/\hbar}\left[1 - \frac{3(k/k_\lambda)^2}{1 + \lambda 3k/k_\lambda}\right].$$

The exact expression of the Drude conductivity at very low temperature can easily be obtained using Eqs. (13) and (5) into Eq. (8).

**FIG. 1:** Plots of $1/\tau_{\lambda}$ vs energy $E$ for long-range impurity potential for different values of $\alpha$: $\alpha = \alpha_0 = 0.05$ eV nm$^3$ (dashed-blue), $\alpha = 2\alpha_0$ (dotted-dashed-red) and $\alpha = 3\alpha_0$ (solid-black).
Let us consider TF limit ($k^2 \gg k^2_{\alpha}$) before presenting the numerical results of the IRT and Drude conductivity. In the TF limit, Eq. (12) is simplified to

$$\frac{\tau_0^*}{\tau_\alpha(k)} = \frac{2\pi}{1 + \lambda \beta k^2/k_{\alpha}}.$$  

On the other hand, Eq. (8) in the TF limit is simplified as $\sigma_{xx} = 2\pi n_e e^2 \tau/m^*$, independent of $\alpha$.

It would be interesting to compare this result with that of conventional 2DEG with $k$-linear RSOI $H_{\text{so}} = \alpha_1 (\sigma_{xx} \rho_+ - \sigma_{xx} \rho_-)/(2h)$. Here, $\alpha_1$ is the strength of RSOI. Following the similar steps, we obtain

$$\frac{\tau_0^*}{\tau_\alpha(k)} = \frac{2\pi}{1 + \lambda \beta k^2/k_{\alpha}}$$

$$\tau_\alpha(k) = \frac{2\pi}{1 + \lambda \beta k^2/k_{\alpha}} \int_0^{2\pi} \frac{(1 - \cos \theta')(\cos^2 \theta'/2)}{1 + 4(k/k_{\alpha})^2 \sin^2 \theta'/2}$$

$$\tau_\alpha(k) = \frac{\pi \alpha}{|k + \lambda k_{\alpha}|}$$

where $k_{\alpha} = m\alpha_1/h^2$. In the limit of small $k$,

$$\frac{\tau_0^*}{\tau_\alpha(k)} \approx \frac{2\pi}{1 + \lambda \beta k^2/k_{\alpha}}$$

Note that the inverse relaxation time goes to zero at $k = 0$ for linear RSOI case but remains finite for cubic RSOI case.

**Short-range disorder:** Now we consider short-range impurity potential for disorder taken as $U(r) = U_\alpha \sum_i \delta(r - r_i)$, where $U_\alpha$ is the strength of the zero-range impurity potential having dimension of energy times area and $r_i$ is the position vector of the $i$-th impurity. Here the Fourier transformation of this potential is simply $U(q) = U_\alpha$ and

$$W_{k,k'}^\lambda = \frac{\pi n_0 U^2}{\hbar} (1 + \cos 3\theta') \delta(\varepsilon^2_k - \varepsilon^2_{k'})$$

**Numerical Results and Discussion:** Here we present plots of $1/\tau_\alpha$ and $\sigma_{xx}$ given by Eqs. (8.13,15 and 17). For numerical calculations, we restrict ourselves to 2DHG and set $m^* = 0.41 m_0$ with $m_0$ being the free electron mass, $\epsilon = 12.8$, $n_i = 2 \times 10^{12}$ m$^{-2}$ and we will scale the RSOI strength in units of $\alpha_0$. Note that the system

![FIG. 2: Plots of IRT as a function of energy for delta scatterer for three different values of $\alpha$: $\alpha = \alpha_0$ (dashed-blue), $\alpha = 2\alpha_0$ (dotted-dashed-red) and $\alpha = 3\alpha_0$ (solid-black).](image)

![FIG. 3: Plots of the Drude conductivity for long-range Coulomb impurity potential. Left panel: $\sigma_{xx}$ vs $n_c$ (in units of $n_0 = 1 \times 10^{15}$ m$^{-2}$) for $\alpha = \alpha_0$ (dashed-blue), $\alpha = 2\alpha_0$ (dotted-dashed-red) and $\alpha = 3\alpha_0$ (solid-black). Right panel: $\sigma_{xx}$ vs $\alpha$ for $n_c = 5n_0$ (solid-black), $n_c = 3n_0$ (dotted-dashed-red) and $n_c = n_0$ (dashed-blue). The upper insets show the exponent $\delta_\alpha$ and $\delta_\alpha$.](image)
is far away from the TF limit for the chosen parameters here.

We present IRT versus energy for three different values of \( \alpha \) in Fig. (1) and Fig. (2) for long-range and short range impurity potentials, respectively. It is interesting to note that the difference \( \Delta(1/\tau(\varepsilon)) = 1/\tau_-(\varepsilon) - 1/\tau_+(\varepsilon) \) decreases with the increase of energy \( \varepsilon \) for long-range impurity potential and increases with \( \varepsilon \) for short-range scattering potential.

In Fig. (3) and Fig. (4), we present the variations of the Drude conductivity with \( n_c \) and \( \alpha \) for long-range and short-range scattering potentials, respectively. In both the cases, the Drude conductivity decreases with increasing \( \alpha \) and increases with increasing carrier density. The effective exponents \( (\delta_n, \delta_\alpha) \) of the carrier density and \( \alpha \) dependence of the Drude conductivity can be obtained from the relation \( \delta_q = d \log \sigma_{xx}/d \log q \), where \( q = n_c, \alpha \). The exponent \( \delta_n \) versus \( n_c \) and \( \delta_\alpha \) versus \( \alpha \) are shown in the upper inset of Fig. (3) and Fig. (4), respectively. The density dependence of the Drude conductivity is no longer linear for both type of impurity potentials since \( \delta_n \) deviates from unity. For long-range potential and large density, \( \delta_n < 1 \). On the other hand, \( \delta_\alpha \) is always less than one for short-range impurity potential. The exponent \( \delta_\alpha \) is always negative for both type of potentials.

![Figure 4: Plots of the Drude conductivity for short-range impurity potential. Left panel: \( \sigma_{xx} \) vs \( n_c \), for \( \alpha = \alpha_0 \) (dashed-blue), \( \alpha = 2\alpha_0 \) (dotted-dashed-red) and \( \alpha = 3\alpha_0 \) (solid-black). Right panel: \( \sigma_{xx} \) vs \( \alpha \), for \( n_c = 5n_0 \) (solid-black), \( n_c = 3n_0 \) (dotted-dashed-red) and \( n_c = n_0 \) (dashed-blue). We have scaled down \( \sigma_{xx} \) as \( \sigma_{xx}/1.35 \) (solid-black) and scaled up \( \sigma_{xx} \) as \( 2.5\sigma_{xx} \) (dashed-blue). The upper insets show the exponent \( \delta_n \) and \( \delta_\alpha \).](image)

**B. Thermoelectric coefficients**

In the linear response regime, electric current density \( \mathbf{J}' \) and thermal current density \( \mathbf{U} \) in response to the combined effects of uniform electric field \( \mathbf{E} \) and temperature gradient \( \nabla T \) are written as

\[
\mathbf{J} = \mathcal{L}^{11}\mathbf{E} + \mathcal{L}^{12}(-\nabla T)
\]

and

\[
\mathbf{U} = \mathcal{L}^{21}\mathbf{E} + \mathcal{L}^{22}(-\nabla T).
\]

Here, the transport coefficients are \( \mathcal{L}^{11} = \mathcal{L}^{(0)}, \mathcal{L}^{12} = -\mathcal{L}^{(1)}/e, \mathcal{L}^{21} = -\mathcal{L}^{(1)}/e \) and \( \mathcal{L}^{22} = \mathcal{L}^{(2)}/e^2T \), where the different integrals \( \mathcal{L}^{(\rho)} \) are defined as

\[
\mathcal{L}^{(\rho)} = \frac{e^2}{4\pi^2} \sum_\lambda \int d^2k \, \tau_\lambda(k) \, v_k^2 \, (\varepsilon_k^\lambda - \eta)^\rho \left(-\frac{\partial f}{\partial \varepsilon_k}\right)^{20}
\]

The thermopower (Seebeck coefficient) is defined as \( S = \nabla V/\nabla T \), where \( \nabla V \) is the voltage gradient developed due to the thermal gradient \( \nabla T \). Under an open circuit condition, the thermopower (Seebeck coefficient) and thermal conductivity are defined as \( (\mathcal{L}^{11})^{-1}\mathcal{L}^{12} \) and \( \kappa = \mathcal{L}^{22} - \mathcal{L}^{21}S \), respectively.

Assuming \( \mathbf{E} = E_x \hat{x} \) and \( \nabla T = (\nabla_x T) \hat{i} \), we need to evaluate x-component of the transport coefficients \( (\mathcal{L}^{ij}) \) with \( i, j = 1, 2 \) for evaluation of thermopower and thermal conductivity. In the low-temperature limit \( (k_B T \ll \varepsilon_f) \), the transport coefficients are obtained as

\[
\mathcal{L}^{11}_{xx} = \frac{e^2}{4\pi^2} \sum_\lambda \tau_\lambda(\varepsilon_f) \left[2\varepsilon_f + \lambda\alpha(k_f^\lambda)^3 \right]
\]

\[
\mathcal{L}^{12}_{xx} = \pi \left(\frac{e k_B T}{\hbar}\right) \frac{2}{12} \sum_\lambda \tau_\lambda(\varepsilon_f) \left[1 + \lambda \delta_{k_f^\lambda} \right]
\]

\[
\mathcal{L}^{22}_{xx} = \frac{1}{12\tau} \left(\frac{\pi k_B T}{\hbar}\right)^2 \sum_\lambda \tau_\lambda(\varepsilon_f) \left[2\varepsilon_f + \lambda\alpha(k_f^\lambda)^3 \right]
\]

Here, we consider the relaxation time \( \tau_\lambda(\varepsilon_f) \) calculated for either Coulomb-type or short-range impurity potential or both the scattering potentials. We immediately see the ratio of transport coefficients obey the Wiedemann-Franz law, \( \mathcal{L}^{22}_{xx}/\mathcal{L}^{11}_{xx} = \frac{\pi k_B T}{3e^2} \), at very low temperature. Therefore, the Wiedemann-Franz law holds even in the presence of k-cubic RSIO.

Using Eqs. (21) and (22), the thermopower can be written as

\[
S_{xx} = \frac{\pi^2 k_B k_B T}{2e} \varepsilon_f \sum_\lambda \tau_\lambda(\varepsilon_f) \left[1 - \frac{1}{3(1 + \lambda \delta_{k_f^\lambda})} \right] \left[1 + \lambda\alpha(k_f^\lambda)^3/2\varepsilon_f \right]
\]

Let us analyze the characteristics of the thermopower and the thermal conductivity numerically and comparing with the value obtained by the low temperature approximation. For numerical calculation, the value of relaxation time \( \tau_\lambda \) is taken from Eq. (13) for long-range Coulomb scattering. The variation of the exact values of \( S_{xx} \) (using Eq. (20) in the definition of \( S_{xx} \)) with respect to \( n_c \) for different strength of RSIO is shown in Fig. (5).
The exact numerical results match very well with the approximate results [Eq. (24)] shown by green dots in Fig. (5). The insets show the exponents $\nu_n = \frac{d \log S_{xx}}{d \log n_c}$ and $\nu_\alpha = \frac{d \log S_{xx}}{d \log \alpha}$.

The variation of the thermal conductivity with respect to $n_c$ for two different RSOI’s strength is shown in Fig. (6). It is easy to see that the RSOI diminishes the thermopower only at higher carrier density. It is an increasing function of the carrier density and there are not much significant variations of the thermal conductivity with $\alpha$.

III. 2D FERMIONS IN PRESENCE OF QUANTIZING MAGNETIC FIELD

In the presence of a quantizing magnetic field $\mathbf{B} = B \hat{z}$, the Hamiltonian in Eq. (1) changes to\(^{43,45}\)

$$H = \frac{\mathbf{P}^2}{2m^*} + \frac{i\alpha}{2\hbar^3}(P_x^3\sigma_+ - P_y^3\sigma_-) - \frac{3}{2}g^* \mu_B \mathbf{\sigma} \cdot \mathbf{B}.$$  \hspace{1cm} (25)

Here, $\mathbf{P} = \mathbf{p} - e\mathbf{A}$ with $\mathbf{A}$ being the vector potential, $P_x = P_x \pm iP_y$, $g^*$ is the effective Lande-g factor and $\mu_B$ is the Bohr magneton. We choose the Landau gauge $\mathbf{A} = xB\hat{y}$ so that $k_y$ is a good quantum number. The Landau levels in units of $\hbar \omega_c$ with $\omega_c = eB/m^*$ being cyclotron frequency, are given by

$$\tilde{\xi}_n = n - 1 + \lambda\sqrt{\tilde{\xi}^2_{n_0} + \tilde{\xi}^2_{A0}}.$$  \hspace{1cm} (26)

Here, $n \geq 3$, $\tilde{\xi}_0 = 3/2 - \chi$ with $\chi = 3g^*m^*/(4\hbar^2)$ and $\tilde{\xi}_{n\alpha} = \alpha \sqrt{8n(n-1)(n-2)}$. The dimensionless parameter $\alpha$ is defined as $\alpha = l_\alpha/l_c$ with $l_c = \sqrt{\hbar/eB}$ is the magnetic length. The corresponding eigenstates are given by

$$\psi_n^+(\mathbf{r}) = \frac{e^{i k_y y}}{\sqrt{L_y A_n}} \left( \phi_n(\tilde{x}) \right),$$  \hspace{1cm} (27)

and

$$\psi_n^-(\mathbf{r}) = \frac{e^{i k_y y}}{\sqrt{L_y A_n}} \left( -\phi_{n-3}(\tilde{x}) \right),$$  \hspace{1cm} (28)

where $\xi \equiv \{n, k_y\}$ is a set of two quantum numbers, $L_y$ is the system size along $y$-direction, $\tilde{x} = (x - x_c)/l_c$ with $x_c = k_y l_c^2$, $A_n = 1 + D_n^2$ with $D_n = \tilde{\xi}_{n\alpha}/(\tilde{\xi}_0 + \tilde{\xi}_{n0} + \sqrt{\tilde{\xi}^2_0 + \tilde{\xi}^2_{n\alpha}})$ and $\phi_n(x)$ is the $n$-th order oscillator wave function normalized to unity. The first three Landau levels ($n = 0, 1, 2$) do not get split by the RSOI. The Landau levels and the corresponding eigenstates for $n = 0, 1, 2$ are given by $\tilde{\xi}_n = n + 1/2 - \chi$ and

$$\psi_\xi(\mathbf{r}) = \frac{e^{i k_y y}}{\sqrt{L_y}} \phi_n(\tilde{x}) \left( \begin{array}{c} 1 \\ 0 \end{array} \right).$$  \hspace{1cm} (29)

A. Thermoelectric coefficients

In this section, we calculate various magnetothermo-electric coefficients. For spin-split systems, the various
transport coefficients in presence of magnetic field are given by

\[
S_{\mu\nu}^\lambda = \frac{1}{eT} \left[ (\mathcal{L}^{(0),\lambda})^{-1} \mathcal{L}^{(1),\lambda} \right]_{\mu\nu},
\]

\[
\kappa_{\mu\nu}^\lambda = \frac{e^2}{T} \left( \mathcal{L}_{\mu\nu}^{(2),\lambda} - eT(\mathcal{L}^{(1),\lambda} S^\lambda)_{\mu\nu} \right),
\]

with

\[
\mathcal{L}_{\mu\nu}^{(2),\lambda} = \int d\varepsilon \left[ \frac{-\partial f(\varepsilon)}{\partial \varepsilon} \right] (\varepsilon - \eta) \delta_{\mu\nu,\lambda}(\varepsilon).
\]

Here the indices \( \mu, \nu = x, y \) and \( \sigma_{\mu\nu,\lambda}(\varepsilon) \) is the zero-temperature energy-dependent conductivity. The above thermoelectric coefficients are obtained by generalizing the results of Refs. 37,38 for the case of spin-split systems. The total thermopower and thermal conductivities are \( S_{\mu\nu} = \sum_{\lambda} S_{\mu\nu}^\lambda \) and \( \kappa_{\mu\nu} = \sum_{\lambda} \kappa_{\mu\nu}^\lambda \), respectively. The transport of holes takes place only through a collisional mechanism because of the zero drift velocity.

The energy-dependent zero-temperature collisional and Hall conductivities are given\(^{32}\) as

\[
\sigma_{x\lambda,\lambda}^{\text{coll}}(\varepsilon) = -\frac{e^2}{\hbar} \frac{\Gamma}{4\pi^2} \left[ \sum_{n<3} I_n \delta(\varepsilon - \varepsilon_n) \delta_{\lambda,1} + \sum_{n\geq3} I_n^\lambda \delta(\varepsilon - \varepsilon_n^\lambda) \right],
\]

\[
\sigma_{yx,\lambda}^{\text{Hall}}(\varepsilon) = \frac{2e^2}{\hbar} \left[ \sum_{n=0}^{1} 2(n+1) \theta(\varepsilon - \varepsilon_n, \varepsilon_{n+1} - \varepsilon) \delta_{\lambda,1} + \left( \frac{P_{23}}{A_{2,3}^\lambda} \right)^2 \theta(\varepsilon - \varepsilon_2, \varepsilon_3^\lambda - \varepsilon) \right.
\]

\[
+ \left. 2 \sum_{n\geq3} \left( \frac{P_n^\lambda}{\Delta_n^\lambda} \right)^2 \theta(\varepsilon - \varepsilon_n^\lambda, \varepsilon_{n+1}^\lambda - \varepsilon) \right].
\]

Here \( I_n = 2n + 1 \), \( I_n^\lambda = \left[ (2n - 2 - \lambda^3)(D_n^\lambda + 1) + \lambda\delta/\Delta_n^\lambda \right] \), \( \theta(x, y) \) represents a double arguments Heaviside theta function which is 1 only if both \( x \) and \( y \) are positive otherwise zero,

\[
P_n^+ = \sqrt{n+1 + D_n D_{n+1}} \sqrt{n - 2 + 6\delta D_{n+1} \sqrt{2n(n-1)}},
\]

\[
P_n^- = \sqrt{n+1 + D_n D_{n+1}} \sqrt{n - 2 - 6\delta D_{n+1} \sqrt{2n(n-1)}},
\]

\[
P_{23}^+ = (\sqrt{3} + 12\delta D_3)/\sqrt{2A_3},
\]

\[
P_{23}^- = (\sqrt{3} D_3 - 12\delta)/\sqrt{2A_3},
\]

\[
\Delta_{2,3}^\lambda = 1/2 - \chi - \lambda \sqrt{(3/2 - \chi^2 + 48\delta^2},
\]

\[
\Delta_n^\lambda = -1 + \lambda \left( \sqrt{(3/2 - \chi^2 + 8n(n-1)(n-2)}\right) \pm \sqrt{(3/2 - \chi^2 + 8n(n-1)(n-2)}\Delta_n^\lambda.
\]
Using Eqs. (33), (34), the finite temperature $\mathcal{L}_{yy}^{(r)}$ and $\mathcal{L}_{yx}^{(r)}$ can be written as

$$
\mathcal{L}_{yy}^{(r)} = \frac{e^2}{h} \frac{\Gamma}{4\pi^2}\left\{\delta_{\lambda,1} \sum_{n<3} I_n(\varepsilon - \eta) \left[ - \frac{\partial f(\varepsilon)}{\partial \varepsilon} \right]_{\varepsilon_n} + \sum_{n} I_n^\lambda(\varepsilon - \eta) \left[ - \frac{\partial f(\varepsilon)}{\partial \varepsilon} \right]_{\varepsilon_n^\lambda} \right\} 
$$

and

$$
\mathcal{L}_{yx}^{(r)} = \frac{2e^2}{h} \left[ \delta_{\lambda,1} \sum_{n=0}^{1} 2(n + 1) \int_{\varepsilon_n}^{\varepsilon_{n+1}} (\varepsilon - \eta) \left[ - \frac{\partial f(\varepsilon)}{\partial \varepsilon} \right] d\varepsilon + \sum_{n=2}^{3} (P_n^\lambda \Delta_n^\lambda)^2 \int_{\varepsilon_n}^{\varepsilon_{n+1}} (\varepsilon - \eta) \left[ - \frac{\partial f(\varepsilon)}{\partial \varepsilon} \right] d\varepsilon \right].
$$

respectively.

Using Eq. (35, 36) in Eq. (30, 31), we compute the various thermoelectric coefficients numerically. For the numerical approach we have taken the value of various parameters, such as carrier density $n_c = 2n_0$, the effective mass $m^* = 0.41m_0$, RSOI strength $\alpha = \alpha_0$ and taking the temperature as low as $T = 0.1$ K.

The beating pattern formation of the thermopower and the thermal conductivity with respect to the applied magnetic field are shown in Fig. (7 - 8). The beating patterns are prominent for $B \leq 0.3$ T. The beating pattern arises due to the difference in the SdH oscillation frequencies ($f_\pm$) of two spin-split branches. The beating pattern in the oscillation of the thermopower and thermal conductivity can be modeled as $\cos(2\pi f_d/B) \cos(2\pi f_a/B)$. Here $f_d = (f_- - f_+)/2$ and $f_a = (f_- + f_+)/2$, where $f_\pm$ are the SdH oscillation frequencies. The expression of $f_\pm$ is taken from Ref. [32], which have been used to explain the beating pattern observed in the SdH oscillation of the collisional conductivity, i.e.

$$
f_\pm = \frac{m^*}{eB} \left[ \varepsilon + \sqrt{8q^2m^*\varepsilon f^3 \pm 4} \right].
$$

Note that the SdH frequencies $f_\pm$ are magnetic field dependent which is coming from the term $\varepsilon_0$. The non-appearance of beating patterns at moderate or high magnetic field is due to the magnetic field dependent frequencies $f_\pm$. With the help of Eq. (37) and by analyzing the oscillations, the location of each of the beating nodes are

$$
B_j = \phi_0 n_c \sqrt{\frac{32\pi n_c P^2_0}{(2j + 1)^2 - 16\varepsilon_0^2}},
$$

where $\phi_0 = h/e$ is the magnetic flux quantum and $j = 0, 1, 2, \ldots$. The values of $B_j$’s coincide with the nodes appearing in Fig. (7 - 8). In Fig. (8), the values of the corresponding $1/B_j$’s are marked with the vertical dashed lines. The number of oscillations between two successive nodes

$$
N_0 = \frac{1}{32\pi n_c P_0^2} \left[ \sqrt{(2j + 3)^2 - 16\varepsilon_0^2} - (2j + 1)^2 - \varepsilon_0^2 \right].
$$

To test correctness of Eq. (39), we count the number of oscillations between $B = 0.117$ T and $B = 0.152$ T, which is $N_0 = 8$. With the values of the different parameters (except $\alpha$) in Eq. (39), the value of RSOI becomes $\alpha = 0.0529$ eV-nm$^3 \approx \alpha_0$ which is the value that we have.
taken.

IV. SUMMARY

We have studied the effect of k-cubic Rashba spin-orbit interaction on electrical and magnetothermoelectric coefficients of a 2D fermions formed in different condensed matter systems. We obtained exact analytical expressions of the IRT and the Drude conductivity for long-range and short-range impurity potentials. Our study revealed that the scattering is completely blocked along three different angles $\theta' = (2n + 1)\pi/3$ ($n = 0, 1, 2$), irrespective of the type of impurity potentials. The IRT remains finite at $k \to 0$ in contrast to k-linear RSOI case. At zero magnetic field, we find that the RSOI diminishes the thermopower. However the thermal conductivity is an increasing function of the carrier density and there are not much significant variation with respect to the strength of RSOI. We have obtained analytical results of the thermopower and thermal conductivity at low temperature ($\varepsilon_f \gg k_B T$) using Sommerfeld’s expansion. The Wiedemann-Franz law remains valid even in the presence of RSOI.

For non-zero magnetic field, the signature of the RSOI is revealed through the beating pattern appeared in thermopower and thermal conductivity at low magnetic field regime. The empirical formula of the SdH oscillation frequencies allows us to carefully note the location of each node in the beating pattern of the oscillations. Magnetothermoelectric measurements can be used to determine the strength of the k-cubic Rashba SOI.
