Abstract

As is known, an elementary excitation of a many-particle system with boundaries is not characterized by a definite momentum. We obtain the formula for the quasimomentum of an elementary excitation for a one-dimensional system of \( N \) spinless point bosons under zero boundary conditions (BCs). In this case, we use the Gaudin’s solutions obtained with the help of the Bethe ansatz. We have also found the dispersion laws of particle-like and hole-like excitations under zero BCs. They coincide with the known dispersion laws obtained for periodic BCs.

1 Introduction

The theory of point bosons [1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16] based on the Bethe ansatz is a valuable part of the physics of many-particle systems, since the system of equations for quasimomenta \( k_j \) can be solved exactly at any coupling constant \( \gamma \), and the thermodynamic quantities can be determined from the Yang–Yang equations [5] at any temperature. This allows one to test the solutions for real nonpoint bosons, the equations for which can rarely be solved (we call “nonpoint” the bosons, for which the interatomic potential \( U(|x_j - x_l|) \) has a nonzero radius).

In the present work, we will study a one-dimensional (1D) system of spinless point bosons in the exactly solvable approach, based on the Bethe ansatz. For the real systems the boundary conditions (BCs) are closer to the zero ones \( (\Psi(x_1, \ldots, x_N) = 0 \) on the boundaries), than to periodic BCs. Therefore, it is of importance to find the ground-state energy and the dispersion law under zero BCs. The ground state was already studied [6, 17], but the dispersion law was not found. To find the dispersion law, it is necessary to determine the energy of a quasiparticle from Bethe equations and to obtain a formula for the quasimomentum of a quasiparticle. These problems will be considered in the present work. The main difficulty consists in obtaining the formula for the quasimomentum, because the ordinary method with the use of the operator of momentum fails under zero BCs.

Under periodic BCs, a quasiparticle possesses the momentum [3, 17, 15, 18, 19, 20]

\[
p = \sum_{i=1}^{N} (\hat{k}_i - k_i),
\]

where \( k_i \) are the solutions for the ground state, \( \hat{k}_i \) are the solutions for the state with one quasiparticle, and we set \( \hbar = 1 \). This definition of the momentum of a quasiparticle is self-consistent: the thermodynamic velocity of sound \( (v^th_s = \sqrt{m^{-1} \partial P/\partial \rho}, \rho = -\partial E_0/\partial L) \) coincides with the microscopic one \( (v^{mic}_s = \partial E(p)/\partial p|_{p \to 0}) \) [3].
Under zero BCs, the quasimomentum of a quasiparticle was obtained similarly to (1) [17, 21]:
\[ p = \sum_{i=1}^{N} (|k_i| - |k_i|). \] (2)
However, in such approach the equality \( v^{th} = v^{mic} \) is strongly violated [17]. Below we will define the quantity \( p \) in such a way that this difficulty disappears. Using the formula for \( p \), we will find the dispersion law of quasiparticles.

2 Initial equations

Consider \( N \) spinless point bosons placed on a closed (or open) line of length \( L \). The Schrödinger equation for such system reads
\[ - \sum_{j} \frac{\partial^2}{\partial x_j^2} \Psi + 2c \sum_{i<j} \delta(x_i - x_j) \Psi = E \Psi. \] (3)
We use the units with \( \hbar = 2m = 1 \). Under periodic BCs for each of the domains \( x_1 \leq x_2 \leq \ldots \leq x_N \) a solution of the Schrödinger equation is the Bethe ansatz [2, 6]
\[ \psi_{\{k\}}(x_1, \ldots, x_N) = \sum_{P} a(P) e^{i \sum_{l=1}^{N} k_{P_l} x_l}, \] (4)
where \( k_{P_l} \) is one of \( k_1, \ldots, k_N \), and \( P \) means all permutations of \( k_l \). Under zero BCs the solution is a superposition of counter-waves [6, 11]:
\[ \Psi_{\{|k|\}}(x_1, \ldots, x_N) = \sum_{\{\epsilon\}} C(\epsilon_1, \ldots, \epsilon_N) \psi_{\{k\}}(x_1, \ldots, x_N), \] (5)
where \( k_j = \epsilon_j |k_j|, \epsilon_j = \pm 1 \). Under any BCs the energy of the system is
\[ E = k_1^2 + k_2^2 + \ldots + k_N^2. \] (6)
Under periodic BCs, \( k_j \) satisfy the Lieb–Liniger equations [2]. These equations are usually written in the Yang–Yang form [5]
\[ Lk_i = 2\pi I_i - 2 \sum_{j=1}^{N} \arctan \frac{k_i - k_j}{c}, \quad i = 1, \ldots, N. \] (7)
We will use the Lieb–Liniger equations in the Gaudin’s form [6] [11]:
\[ Lk_i = 2\pi n_i + 2 \sum_{j=1}^{N} \arctan \left( \frac{c}{k_i - k_j} \right)_{j \neq i}, \quad i = 1, \ldots, N, \] (8)
where \( n_i \) are integers. For the ground state of the system, \( n_i = 0 \) for all \( i = 1, \ldots, N \). The systems of equations (7) and (8) are equivalent [6] [11]. In this case, \( I_i = n_i + i - \frac{N+1}{2} \).

Under zero BCs, \( k_j \) satisfy the Gaudin’s equations [6] [11]:
\[ L|k_i| = \pi n_i + \sum_{j=1}^{N} \left( \arctan \frac{c}{|k_i| - |k_j|} + \arctan \frac{c}{|k_i| + |k_j|} \right)_{j \neq i}, \quad i = 1, \ldots, N, \] (9)
where \( n_i \) are integers, \( n_i \geq 1 \) [11] [22]. The ground state corresponds to \( n_i = 1 \) for all \( i \). We denote \( \rho = N/L, \gamma = c/\rho \).
Equations (8) has the unique real solution \( \{ k_i \} \) \([7]\), and equations (9) have the unique real solution \( \{|k_i|\} \) \([22]\). The positivity of all \(|k_i|\) was not proved in \([22]\), but it is corroborated by the direct numerical solution of system \((9)\).

The quasiparticles are commonly described with the help of the Yang–Yang \(I_i\)-numbering \((7)\). Below we will introduce the quasiparticles with the help of the Gaudin’s \(n_i\)-numbering \((8), (9)\), since this way is simpler, is more physical \([23]\), and allows one to sight the Bose properties of quasiparticles \([16, 17]\). These two ways of introduction of quasiparticles are equivalent. For example, under periodic BCs, the “particle” \(\{I_i\} = (1 - \frac{N + 1}{2}, \ldots, N - 1 - \frac{N + 1}{2}, N - \frac{N + 1}{2} + j)\) with the help of the \(n_i\)-numbering is written as \(\{n_i\} = (0, \ldots, 0, j)\).

In the \(n_i\)-language, the “hole” \(\{I_i\} = (1 - \frac{N + 1}{2}, \ldots, N - 2 - \frac{N + 1}{2}, N - \frac{N + 1}{2}, N + 1 - \frac{N + 1}{2})\) is \(\{n_i\} = (0, \ldots, 0, 1, 1)\). A way of introduction of quasiparticles with the help of the \(n_i\)-numbering was proposed in \([17]\).

3 Definition of the quasimomentum of an elementary excitation

We now find how the quasimomentum of an elementary excitation can be determined under zero BCs. Under periodic BCs, the relation \([2]\)

\[
\sum_{j=1}^{N} \left( -i \frac{\partial}{\partial x_j} \right) \psi_{\{k\}}(x_1, \ldots, x_N) = \left( \sum_{j=1}^{N} k_j \right) \psi_{\{k\}}(x_1, \ldots, x_N)
\]

holds in the whole domain \(x_1, \ldots, x_N \in [0, L]\). Therefore, the system has the total momentum

\[
P = \sum_{j=1}^{N} k_j,
\]

and the momentum of a quasiparticle is given by formula \((11)\). Under zero BCs, the relation

\[
\sum_{j=1}^{N} \left( -i \frac{\partial}{\partial x_j} \right) \Psi_{|k|}(x_1, \ldots, x_N) = f(|k_1|, \ldots, |k_N|) \Psi_{|k|}(x_1, \ldots, x_N)
\]

is not satisfied. Therefore, the system has no definite momentum. To find the formula for the quasimomentum of an excitation, we use the following property. It is known that the momentum (quasimomentum) of a quasiparticle is quantized by the law \(p_j = \hbar 2\pi j/L\) \((j = \pm 1, \pm 2, \ldots)\) under periodic BCs \([24]\) and \(p_j = \hbar \pi j/L\) \((j = 1, 2, \ldots)\) under zero BCs \([25, 26]\). Starting from these relations, one can guess the formula for the momentum (quasimomentum).

Consider a periodic system. Equations (8) yield

\[
\sum_{j=1}^{N} k_j = \frac{2\pi}{L} \sum_{j=1}^{N} n_j.
\]

It is seen that the quantity \(P = \sum_{j=1}^{N} k_j\) is quantized in the same way as the momentum of an ensemble of quasiparticles \([24]\). Therefore, it is natural to identify \(P\) with the total momentum of the system (in the reference system, where the center of masses is at rest).

We obtain that \(P_0 = \sum_{j=1}^{N} k_j = 0\) for the ground state and \(P_1 = \sum_{j=1}^{N} k_j = 2\pi r/L\) for the state with one particle-like excitation \((n_i \leq N - 1 = 0, n_N = r \neq 0)\). The momentum of a particle-like excitation

\[
p = P_1 - P_0 = \sum_{i=1}^{N} (k_i - k_i) = \frac{2\pi n_N}{L} = \frac{2\pi r}{L}
\]

(13)
corresponds to formula (11) and to momentum quantization \( p_j = \hbar 2\pi j/L \). We have solved system (8) numerically, found the energies of the ground and excited states, and obtained that the equality \( v_s^{th} = v_s^{mic} \) holds with high accuracy: for \( \rho = 1 \) and \( \gamma = 0.1, 1, 10 \), the equality \( v_s^{th} = v_s^{mic} \) holds with an error of \( \lesssim 0.02\% \). This error is caused by the inaccuracy of a numerical method and by the finiteness of the system (the equality \( v_s^{th} = v_s^{mic} \) must be exact in the thermodynamic limit and may be violated for not large \( N, L \)).

We now consider the system under zero BCs. Relation (9) yields

\[
\sum_{j=1}^{N} |k_j| = \frac{\pi}{L} \sum_{j=1}^{N} n_j + \frac{1}{L} \sum_{i,j=1}^{N} \arctan \frac{C}{|k_i| + |k_j|} |_{j\neq i}.
\]

Introduce the quantity

\[
P(\{|k_i|\}) = \sum_{j=1}^{N} |k_j| - \frac{1}{L} \sum_{i,j=1}^{N} \arctan \frac{C}{|k_i| + |k_j|} |_{j\neq i},
\]

then relations (14) and (15) yield

\[
P(\{|k_i|\}) = \frac{\pi}{L} \sum_{j=1}^{N} n_j.
\]

Since \( P(15), (16) \) is quantized similarly to the quasimomentum of the ensemble of quasiparticles for an interacting system with zero BCs \(26\), it is natural to identify \( P(15), (16) \) with this quasimomentum. It is essential that the quasiparticles are introduced for a system of point bosons in such a way that the total number of quasiparticles \( \leq N \) (the same limitation exists also for a system of nonpoint bosons \(23\)). This limitation agrees with (16). The smallest quasimomentum of the system corresponds to the ground state:

\[
P_0 = P(n_i \leq N = 1) = \frac{\pi}{L} \sum_{j=1}^{N} 1 = \frac{\pi N}{L} = \pi \rho.
\]

The quasimomentum of a particle-like excitation is

\[
p_{r-1} = P(n_i \leq N-1 = 1, n_N = r) - P(n_i \leq N = 1) = \\
= \sum_{j=1}^{N} (|\hat{k}_j| - |k_j|) - \frac{1}{L} \sum_{i,j=1}^{N} \left( \arctan \frac{C}{|\hat{k}_i| + |\hat{k}_j|} - \arctan \frac{C}{|k_i| + |k_j|} \right) |_{j\neq i},
\]

where \( \{|\hat{k}_j|\} \) and \( \{|k_j|\} \) are solutions of Gaudin’s equations (9) for the states with one particle-like excitation and without quasiparticles, respectively. Relations (16), (18) yield

\[
p_{r-1} = \pi (r - 1)/L,
\]

where \( r \) is equal to the value of \( n_N \) for the state with one particle-like excitation: \( r = n_N = 2, 3, 4, \ldots; n_{j\leq N-1} = 1 \). We have obtained the quantity with the required law of quantization: \( p_j = \pi j/L \). The numerical analysis showed that the equality \( v_s^{th} = v_s^{mic} \) is satisfied with an error \( \lesssim 0.2\% \) for \( \rho = 1, \gamma = 0.1, 1, 10 \).

Thus, we have obtained the formula for the quasimomentum of a quasiparticle for the system under zero BCs. It would be of interest to clarify which operator corresponds to quasimomentum (15).
Let us find the dispersion law $E(p)$ of particle-like excitations for a system under zero and periodic BCs. Under zero BCs we are based on (19) and the formula for the energy of a quasiparticle is [3]

$$E = \sum_{i=1}^{N} (\dot{k}_i^2 - k_i^2). \quad (20)$$

Under periodic BCs we use formulae (13), (20). We find the solutions $\{\dot{k}_i\}$ and $\{k_i\}$ from Eqs. (8) under periodic BCs and from Eqs. (9) under zero BCs. In this case, $\{\dot{k}_i\}$ corresponds to the state with one quasiparticle ($n_i \leq N - 1 = 0$, $n_N = r$ for periodic BCs and $n_i \leq N - 1 = 1$, $n_N = r > 1$ for zero BCs), whereas $\{k_i\}$ corresponds to the ground state ($n_i \leq N = 0$ for periodic BCs and $n_i \leq N = 1$ for zero BCs). We have solved Eqs. (8), (9) numerically and determined the dispersion law $E(p)$ for zero and periodic BCs. As is seen from Fig. 1, the dispersion laws $E(p)$ under periodic and zero BCs coincide (a small difference $\lesssim 0.5\%$ is caused by the surface contribution $\Delta E(|p|) \sim E(|p|)/N > 0$ arising under zero BCs and by the error of a numerical method). The direct numerical solution of systems (8) and (9) indicates that the ground-state energy ($E_0$) under zero BCs exceeds $E_0$ under periodic BCs by only a small surface contribution $\Delta E \sim E_0/N$ [17]. For interacting nonpoint bosons, the picture is similar: at any repulsive interatomic potential, the values of $E_0$ and $E(p)$ of a 1D system under zero BCs [26] coincide with $E_0$ and $E(p)$ of the periodic system [24]. Moreover, for a 1D system of interacting bosons it was found in the harmonic-fluid approximation that the sound velocity is identical under periodic and zero BCs [25].

Figure 1: [Color online] Dispersion curves $E(p)$ calculated by numerical solving Eqs. (8) and (9) within the Newton method for $N = L = 1000$. 1) $\gamma = 1$: $E(p)$ of particle-like excitations under periodic BCs (open circles), under zero BCs (open triangles), and the Bogolyubov law [24] $E = \sqrt{p^4 + 4\gamma \rho^2 p^2}$ (crosses); 2) $\gamma = 10$: $E(p)$ of particle-like excitations under periodic BCs (circles), under zero BCs (triangles), the Bogolyubov law (stars), and the Girardeau’s law [1] $E = p^2 + 2\pi \rho |p|$ (squares); 3) $\gamma = 1.725$: $E(p)$ of hole-like excitations under periodic (open diamonds) and zero (diamonds) BCs.

We have also calculated the dispersion law of hole-like excitations. It is seen from Fig. 1 that the dispersion law is the same under zero and periodic BCs. Visually, it coincides with the dispersion law of holes obtained by Lieb [3]. Under zero BCs, holes correspond to the states with the following quantum numbers $n_j$: $n_{1 \leq j \leq l} = 1$, $n_{l < j \leq N} = 2$, where $l = 0, 1, \ldots, N - 2$. Under periodic BCs, holes are the states with $n_{1 \leq j \leq l} = 0$, $n_{l < j \leq N} = 1$ ($l = 0, 1, \ldots, N - 2$) and the states with $n_{1 \leq j \leq k} = -1$, $n_{k < j \leq N} = 0$ ($k = 2, 3, \ldots, N$). Formula (16) implies that the quasimomentum of a hole under zero BCs is $p = \pi(N - l)/L$;
the maximal quasimomentum is \( p^{\text{max}} = \pi N/L = \pi \rho \). Under periodic BCs the hole has momentum \((1), (12)\), which takes values from \( p^{\text{min}} = -2\pi \rho \) to \( p^{\text{max}} = 2\pi \rho \). The physical nature of holes was studied in works [3, 4, 23, 27, 28, 29, 30, 31].

We note that the formulae for the quasimomentum and the solutions for the dispersion laws, obtained above under zero BCs, are new results.

Interestingly, the dispersion law of particle-like excitations (Fig. 1) differs at \( \gamma = 1 \) from the Bogolyubov law only by 5%. In this case, the available criterion of applicability of the Bogolyubov model in the 1D case for zero and periodic BCs is as follows (at \( T = 0 \)) [26]:

\[
\frac{\sqrt{\gamma}}{2\pi} \ln \frac{N\sqrt{\gamma}}{\pi} \ll 1. \tag{21}
\]

According to (21), it should be \( \gamma \to 0 \), if \( N \to \infty \). But the solutions \( E_0 \) and \( E(p) \) for point bosons are close to the Bogolyubov solutions even at \( N \to \infty \), \( \gamma \sim 1 \) (as for periodic BCs, see [2, 3]); for zero BCs it was found [17] that the energy levels \( E(n_N) \) obtained in the limit \( N \to \infty \) coincide (with an error of 1%) with \( E(n_N) \) found by a direct numerical solving Eqs. (9) at \( N = 1000 \); therefore, the dispersion law \( E(p)|_{N=\infty} \) coincides with the above-found one \( E(p)|_{N=1000} \) and is close to the Bogolyubov law at \( \gamma \ll 1 \). We remark that the dispersion law at \( \gamma = 10 \) (see Fig. 1) is closer to the Bogolyubov law, than to the Girardeau’s one. Though it would be expected the contrary, since the Girardeau’s formula is exact at \( \gamma = +\infty \), whereas the Bogolyubov formula loses its meaning at such \( \gamma \). The reason for the applicability of the Bogolyubov solutions at not small \( \gamma \) is yet unclear.

It was obtained [17] that the dispersion laws of particle-like excitations under zero and periodic BCs are strongly different. However, this difference is unphysical: it arose because under zero BCs formula (2) was used instead of formula (18).

To our knowledge, only one point of the dispersion law \( E(p) \) was measured, at several values of \( \gamma \), for a 1D system of point bosons in a trap [32]. The question is, how to measure the dispersion law in a system with zero boundary conditions? Apparently, this can be made with the help of an ordinary scattering. But we do not know how to pass from the Gaudin’s wave function (5) to a localized wave package with a definite momentum.

4 Conclusion

We have studied the properties of quasiparticles for a 1D system of spinless point bosons, by using the Gaudin’s numbering [6 11]. We have found the formula for the quasimomentum of a quasiparticle under zero boundary conditions. The analysis implies that the formula for the quasimomentum depends on the boundary conditions and can be obtained from the equations for \( k_j \). Moreover, we have calculated the dispersion law for particle-like and hole-like quasiparticles under zero boundary conditions.
