THE FACTORIZATION OF THE GIRY MONAD

KIRK STURTZ

Abstract. We construct a factorization of the Giry monad through the category of convex spaces, and show that, provided that no measurable cardinals exist, probability measures can be viewed as natural transformations. Using the adjunction of this factorization, we then show the category of Giry algebras is equivalent to the category of convex measurable spaces where the σ-algebra structure associated with a convex space satisfies an elementary property.

1. Introduction

In 1962, prior to the development of the theory of monads and their relationship with adjunctions, Lawvere[10] constructed what he called the category of probabilistic mappings, which is, up to an equivalence, the Kleisi category of the Giry monad, MeasΓ, where Meas is the category of measurable spaces and Γ denotes the Giry monad (Γ, η, µ). He also provided the adjunction between Meas and MeasΓ, whose composite yields the Giry monad. In 1982 Giry[6], using the theory of monads, formally defined what we now refer to as the Giry monad. Giry also defined a similar monad on a subcategory of Meas, consisting of those measurable spaces arising from Polish topological spaces, with the arrows in the category being continuous maps.

The Kleisi category MeasΓ is well known and used, by the science and engineering community, in modeling (regular) conditional probability theory[2]. For applications, MeasΓ is inadequate from the perspective that it is not a symmetric monoidal closed category (SMCC), and hence many basic constructions cannot be modeled within the framework of MeasΓ. Consequently other factorizations of the Giry monad, through categories with better categorical properties, are desirable so that scientist and engineers can naturally model problems in that category, permitting intuitive reasoning. Progress towards this goal has been made by several researchers. Doberkat[3, 4] has characterized the Giry-algebras on Polish measurable spaces using convex partitions on the spaces of all probability measures. Keimel[9] has characterized the case of compact ordered spaces, generalizing an earlier result due to Świrszcz[12], stating that the algebras over the category of compact Hausdorff spaces are the compact convex sets A embeddable in locally convex topological vector spaces with the barycenter maps as structure maps. In this paper we show, provided that no measurable cardinals exists, that the Giry monad factorizes through the category of convex spaces, Cvx, which in turn can be used to given an alternative characterization of the category MeasΓ in terms of convex spaces with a measurable structure. More specifically, we show that MeasΓ is equivalent to a full subcategory of the category of all convex measurable spaces CM, which we refer to as tame convex measurable spaces, tCM. The precise definition of both of these categories are given subsequently.

Key words and phrases. Convex spaces, Giry monad, Giry algebras, Isbell duality, dense subcategory, left-adequate subcategory, probability theory.
Recall the Giry monad \( \mathcal{G} \) is defined on objects by mapping a measurable space \( X \) to the measurable space \( \mathcal{G}(X) \) of all probability measures on \( X \), and has a natural convex structure defined on it by taking convex sums of probability measures. On arrows, \( X \xrightarrow{f} Y \), \( \mathcal{G}(f) \) is the pushforward map, sending a probability measure \( P \mapsto Pf^{-1} \), which is an affine map of convex spaces. These observations yield a functor \( \text{Meas} \xrightarrow{\mathcal{P}} \text{Cvx} \), where the functor \( \mathcal{P} \) is the same as \( \mathcal{G} \), but viewed as a functor into the category of convex spaces, \( \text{Cvx} \). To show that \( \mathcal{G} \) factorizes through \( \text{Cvx} \), it is necessary to find a right adjoint to \( \mathcal{P} \), \( \text{Cvx} \xrightarrow{\Sigma} \text{Meas} \), and then verify that \( \mathcal{G} = \Sigma \circ \mathcal{P} \). The most significant aspect in constructing this factorization resides in the construction of the counit of the adjunction, and it is this aspect which motivates using a dense subcategory of \( \text{Cvx} \) and Isbell conjugate duality to construct the counit.

The outline of the paper is as follows. After we discuss the necessary background material on convex spaces (§2), separable measurable spaces (§3), the symmetric monoidal closed category structure of both \( \text{Meas} \) and \( \text{Cvx} \) (§5), and define the functor \( \Sigma \) (§6), we discuss how Isbell conjugate duality can be used to construct the counit (§8). The construction of the counit is then developed within the framework of the Isbell conjugate functor pair, which are defined in terms of natural transformations (§9). The proof that the pair of functors \( \mathcal{P} \) and \( \Sigma \) form an adjoint pair which determine a factorization of the Giry monad then follows (§10). We conclude by showing the category \( \text{Meas}^{\mathcal{G}} \) is equivalent to the category \( \text{tCM} \).

### 2. Convex spaces

The category \( \text{Cvx} \) can be described in two equivalent ways. An axiomatic characterization of convex spaces is given by Gudder [7], who relates the axiomatic framework to the “convex operational” approach to quantum mechanics. The alternative characterization of \( \text{Cvx} \), as an algebraic theory, is given by Meng [11]. More explicitly, the category \( \text{Cvx} \) is the affine part of the algebraic theory of \( \mathcal{K} \)-modules, where \( \mathcal{K} \) is the rig \([0, \infty]\). This characterization immediately proves \( \text{Cvx} \) is complete, and a simple verification shows it is also cocomplete.

Let \( I = [0,1] \) with its natural convex structure. In the category \( \text{Cvx} \), the arrows \( A \xrightarrow{m} B \) are referred to as affine maps, and preserve convex sums,

\[
m((1-\alpha)a_1 + \alpha a_2) = (1-\alpha)m(a_1) + \alpha m(a_2) \quad \alpha \in I.
\]

For brevity, a convex sum is often denoted by

\[
a_1 +_\alpha a_2 \overset{\text{def}}{=} (1-\alpha)a_1 + \alpha a_2 \quad \alpha \in I.
\]

We make use of the result that every affine map \( \psi \in \text{Cvx}(I,A) \) can be characterized as a path map,

\[
\begin{array}{ccc}
I & \xrightarrow{\lambda_{a_1,a_2}} & A \\
\alpha & \mapsto & a_1 +_\alpha a_2
\end{array}
\]

A convex space \( A \) is called discrete whenever \( a_1, a_2 \in A \), the quantity \((1-\alpha)a_1 + \alpha a_2\) is constant for all \( \alpha \in (0,1) \). The set \( \mathbb{2} = \{0,1\} \) with the convex structure defined by

\[1\text{The affine part of the theory of } \mathcal{K}\text{-modules amounts to the restriction from taking all finite affine sums } \sum_{i=1}^{N} \alpha_i a_i, \text{ where } \alpha_i \in \mathcal{K} \text{ and } a_i \in A \text{ (an “affine space”) to only finite convex sums, } \sum_{i=1}^{N} \alpha_i = 1 \text{ of elements of a space. This is further explained in Meng’s thesis.}\]
\[(1 - \alpha)0 + \alpha1 = \begin{cases} 
0 & \text{for all } \alpha \in [0, 1) \\
1 & \text{otherwise} 
\end{cases}\]

is a discrete space. A convex space \(A\) is called \textit{geometric} if \(A\) can be embedded into a real vector space. The unit interval \(I\), with the embedding \(I \hookrightarrow \mathbb{R}\), makes it a geometric space. We make repeated use of the fact that there is a unique nonconstant affine map from \(I\) to \(2\), given by

\[
\begin{array}{c}
I \\
\alpha \mapsto \\
\end{array} \begin{array}{c}
2 \\
\epsilon_2 \\
\end{array} 
\begin{cases} 
0 & \text{for all } \alpha \in [0, 1) \\
1 & \text{for } \alpha = 1
\end{cases}.
\]

On the other hand, a routine computation shows there are no nonconstant affine maps \(2 \to I\). As we subsequently show, the category \(\text{Cvx}\) is a symmetric monoidal closed category (SMCC). Hence, letting \(B^A = \text{Cvx}(A, B)\), it follows from the preceding result that \(I^2 \cong I\). More generally, if \(B\) is any geometric space it follows that \(B^2 \cong B\). Further discussion and examples concerning discrete and geometric convex spaces can be found in Fritz\[5\], who uses the terminology “combinatorial” rather than “discrete”. It is worth emphasizing that most convex spaces are neither purely discrete or purely geometric, but a space having both discrete and geometric components.

Another property that \(\text{Cvx}\) has is the existence of a coseparator. Let \(\mathbb{R} = (-\infty, \infty)\) with the natural convex structure. This convex structure extends to \(\mathbb{R}_\infty = (-\infty, \infty]\), by defining for all \(r \in \mathbb{R}\),

\[
\alpha\infty + (1 - \alpha)r \overset{\text{def}}{=} \begin{cases} 
\infty & \text{for all } \alpha \in (0, 1] \\
r & \text{for } \alpha = 0
\end{cases}.
\]

\textbf{Lemma 2.1.} \textit{The object }\(\mathbb{R}_\infty\text{ is a coseparator in }\text{Cvx}.}\]

\textit{Proof.} See Borger and Kemp\[1\]. \hfill \Box

The property that makes the category \(\text{Cvx}\) convenient to work with is that it has a left-adequate (dense) subcategory consisting of a single object. Isbell’s original definition for a full subcategory \(\mathcal{C} \hookrightarrow \mathcal{A}\) to be left-adequate is that the “truncated” Yoneda functor, \(\mathcal{A} \overset{\mathcal{Y}}{\to} \text{Set}^{\text{op}}\), is still full and faithful. If we let \(\mathbb{I}\) denote the full subcategory of \(\text{Cvx}\) consisting of the single object \(I\), the left-adequacy of \(\mathbb{I}\) in \(\text{Cvx}\) is easy to prove directly.

\textbf{Lemma 2.2.} \textit{The restricted Yoneda map }\(\text{Cvx} \overset{\mathcal{Y}}{\to} \text{Set}^{\text{op}}\text{ is an embedding.}\]

\textit{Proof.} Faithful Since the object \(1\) is a separator in \(\text{Cvx}\) it suffices to show that for any two distinct points \(a_1, a_2 \in A\), the resulting two natural transformations,

\[
\text{Cvx}(\bot, 1) \xrightarrow{\mathcal{Y}(a_1) = \text{Cvx}(\bot, a_1)} \text{Cvx}(\bot, A) \\
\text{Cvx}(\bot, 1) \xrightarrow{\mathcal{Y}(a_2) = \text{Cvx}(\bot, a_2)} \text{Cvx}(\bot, A)
\]

are distinct. These two natural transformations are (the names of) the constant “path maps” in \(A\), defined at component \(I\) by

\[
\begin{array}{c}
1 \\
\overset{\gamma_{a,a}^\uparrow}{\longrightarrow} \\
\end{array} \text{Cvx}(I, A)
\]
The two maps, \( \gamma_{a_1,a_1} \) and \( \gamma_{a_2,a_2} \), because the existence of the coseparator, \( \mathbb{R}_\infty = (-\infty, \infty] \), implies there is an affine map \( A \xrightarrow{m} \mathbb{R}_\infty \) such that \( m(a_1) \neq m(a_2) \). Consequently, the resulting set map \( A^I \xrightarrow{m^I} \mathbb{R}_\infty^I \), defined by composition with \( m \), distinguishes the map \( \gamma_{a_1,a_1} \) from \( \gamma_{a_2,a_2} \).

**Full** Suppose that \( \alpha \in \text{Nat} \left( \text{Cvx}(\_1), \text{Cvx}(\_A) \right) \). At component \( I \) we have the naturality requirement that the \( \text{Cvx} \)-diagram on the left-hand side of

\[
\begin{array}{ccc}
1 & \xrightarrow{\alpha_1} & A^I \\
\alpha_1 & & \downarrow \text{component } I \\
A^I & \xrightarrow{\gamma_{a_1,a_2}} & A^I
\end{array}
\]

commutes, for all \( \lambda \in \text{Cvx}(I, I) \). Consequently it follows that \( \alpha_1(\_1) \) must be a path map in \( A \), and the diagram on the right-hand side shows the path map must be a constant path map in \( A \). Therefore we conclude that every natural transformation \( \alpha \in \text{Nat}(\text{Cvx}(\_1), \text{Cvx}(\_A)) \) arises from a point of \( A \), \( \alpha = \text{Cvx}(\_a) = \mathcal{Y}(a) \).

1-1 on objects If \( A \) and \( B \) are distinct objects in \( \text{Cvx} \) then \( \text{Cvx}(\_A) \neq \text{Cvx}(\_B) \) since at component \( I \) it follows elementarily that the set of all path maps on \( A \) and \( B \) are distinct, \( A^I \neq B^I \).

For purposes of constructing the factorization of the Giry monad, we consider the truncated Yoneda embedding with the base category \( \text{Set} \) replaced by \( \text{Cvx} \), and augment the category \( \mathbb{I} \) with the discrete convex space \( 2 \), to obtain the embedding \( \text{Cvx} \hookrightarrow \text{Cvx}^{\text{cop}} \), where \( C \) is the full subcategory of \( \text{Cvx} \) consisting of the two objects, \( 2 \) and \( I \). It is clear, using the method of the proof as above, that replacing \( \text{Set} \) with \( \text{Cvx} \) and enlarging the exponent category still yields an embedding \( \text{Cvx} \hookrightarrow \text{Cvx}^{\text{cop}} \).

3. **The property of separability in Meas**

Given a measurable space \( X \), define an equivalence relation on \( X \) by

\[
x \sim y \iff x \in U \iff y \in U \forall U \in \Sigma_X.
\]

We say \( X \) is a separated measurable space if for any two points \( x, y \in X \), there is some \( U \in \Sigma_X \) with \( x \in U \) and \( y \notin U \). This definition is based upon the corresponding terminology used in point set topology. The equivalent categorical definition follows from

**Lemma 3.1.** A measurable space \( X \) is a separated measurable space iff 2 is a coseparator for the space \( X \).

**Proof.** Using the fact 1 is a separator for \( \text{Meas} \), the points \( x_1, x_2 \in X \) are separated if and only if there exist a characteristic map \( X \xrightarrow{\chi_U} 2 \) distinguishing the two points, for some measurable set \( U \) in \( X \).

---

\(^2\)If \( A \neq B \) because there exist a point \( a \in A \) and \( a \notin B \), or vice-versa, then one clearly has a constant path in \( A \) which is not in \( B \). On the other hand, if \( A = B \) and only the convex structure is different, then \( A^I \neq B^I \) because there exist two points \( a_1, a_2 \in A \) such that the path map \( \gamma_{a_1,a_2} \in A^I \) is distinct from \( \gamma_{a_1,a_2} \in B^I \).
Given any space $X$ let $X_s$ denote the equivalence classes $X$ under the relation $\sim$, and
\[
X \xrightarrow{q_X} X_s \\
x \mapsto [x]
\]
the set map sending each point to its equivalence class, and endow the set $X_s$ with the largest $\sigma$-algebra such that $q_X$ is a measurable function.

**Lemma 3.2.** The space $X_s$ is a separated measurable space.

*Proof.* Suppose $[x], [y] \in X_s$ are two distinct points in the quotient space. Then there exist a measurable set $U \in \Sigma_X$ such that $x \in U$ and $y \in U^c$. These two measurable sets, $U$ and $U^c$, partition $X$ such that every element in $U$ is separated from every point of $U^c$. The image of these two measurable sets, $q_X(U)$ and $q_X(U^c)$, partition $X_s$ into two sets since $q_X$ is surjective. Both $q_X(U)$ and $q_X(U^c)$ are measurable sets since $X_s$ has the final $\sigma$-algebra with regard to the surjective map $q_X$. Thus $[x] \in q_X(U)$ while $[y] \in q_X(U^c) = q_X(U^c)$, and hence $q_X(U)$ separates $[x]$ and $[y]$ in $X_s$. \hfill $\square$

**Lemma 3.3.** For $X \overset{f}{\to} Y$ a measurable map, the induced function $X_s \overset{f_s}{\to} Y_s$ mapping $[x] \mapsto [f(x)]$ is well defined and measurable. Hence the **Meas**-diagram
\[
\begin{array}{ccc}
X & \xrightarrow{f} & Y \\
q_X \downarrow & & \downarrow q_Y \\
X_s & \xrightarrow{f_s} & Y_s
\end{array}
\]
commutes.

*Proof.* Well-defined: Suppose $x_1 \sim x_2$ then $f(x_1) \sim f(x_2)$ in $Y$ are nonseparated because the existence of a $V \in \Sigma_Y$ such that $f(x_1) \in V$ and $f(x_2) \notin V$ would then yield the contradiction that $x_1 \sim x_2$ since $f^{-1}(V) \in \Sigma_X$ and $x_1 \in f^{-1}(V)$ while $x_2 \notin f^{-1}(V)$.

Thus we have $f(x_1) \sim f(x_2)$ in $Y$ and $[f(x_1)] = [f(x_2)]$ in $Y_s$. Hence $f_s$ is well-defined, and the diagram given in the Lemma commutes at the set theoretic level.

Measurability: If $W \subset \Sigma_{Y_s}$ then $q_Y^{-1}(W) \in \Sigma_Y$, and hence $f^{-1}(q_Y^{-1}(W)) \in \Sigma_X$. Since the **Set**-diagram
\[
\begin{array}{ccc}
X & \xrightarrow{q_X} & \Sigma_Y \\
q_X \downarrow & \downarrow q_Y \circ f \\
X_s & \xrightarrow{f_s} & Y_s
\end{array}
\]
commutes and the two maps $q_X$ and $q_Y \circ f$ are measurable, it follows that $f_s$ is measurable since $\Sigma_{X_s}$ has the largest $\sigma$-algebra such that $q_X$ is measurable, i.e., $q_X^{-1}\left(f_s^{-1}(W)\right) = f^{-1}(q_Y^{-1}(W)) \in \Sigma_X$ implies $f_s^{-1}(W)$ is measurable. \hfill $\square$

This result implies that the quotient space construction is functorial, yielding a functor $S$ to the full subcategory consisting of all the separated measurable spaces, $\textbf{Meas}_s$. The inclusion of this subcategory into $\textbf{Meas}$ then yields
Lemma 3.4. The inclusion functor is right adjoint to $S$,

$$\text{Meas} \xrightarrow{\mathcal{S}} \text{Meas}_s \quad S \dashv \iota$$

The proof of this follows directly from the definition of the induced function on the quotient space. It follows from the definition of the subcategory $\text{Meas}_s$ that the object $2$ is a coseparator in $\text{Meas}_s$.

In $\text{Meas}$ function spaces are defined by

$$Y^X = (\text{Meas}(X,Y), \Sigma_{ev}^{Y^X})$$

where $\Sigma_{ev}^{Y^X}$ is the $\sigma$-algebra generated by all the point evaluation maps $Y \xrightarrow{ev} Y$, sending $f \mapsto f(x)$. We refer to the $\sigma$-algebras generated by the evaluation maps as evaluation $\sigma$-algebras, and context permitting, denote the evaluation $\sigma$-algebra as just $\Sigma_{ev}$.

Lemma 3.5. If $X, Y \in \text{ob} \text{Meas}_s$ then the function space $Y^X$ is a separated measurable space.

Proof. If $f, g \in Y^X$ are two distinct points, then there exist a point $x \in X$ such that $f(x) \neq g(x)$. Since $Y$ is separated there exist a $V \in \Sigma_Y$ such that $f(x) \in V$ while $g(x) \notin V$. Consequently the evaluation map $ev_x$ serves the purpose of separating the maps $f$ and $g$ since $f \in ev_x^{-1}(f^{-1}(V))$ while $g \notin ev_x^{-1}(f^{-1}(V))$. □

4. Factorizing the Giry monad using separability

The unit of the Giry monad, which sends each point to a Dirac measure, $x \mapsto \delta_x$, is in general, not an injective mapping because if $x_1, x_2 \in X$ are nonseparable, then $\delta_{x_1} = \delta_{x_2}$. However the unit of the Giry monad, restricted to the subcategory $\text{Meas}_s$, is injective.

The functor $\text{Meas} \xrightarrow{\mathcal{P}} \text{Cvx}$, which we defined previously as $\mathcal{P}(X) = \mathcal{G}(X)$ and $\mathcal{P}(f) = \mathcal{G}(f)$, with both objects and arrows viewed as lying in $\text{Cvx}$ rather than $\text{Meas}$, factors through the subcategory $\text{Meas}_s$.

$$\text{Meas} \xrightarrow{\mathcal{P}} \text{Cvx} \quad \text{Meas}_s \xrightarrow{\mathcal{P}|} \text{Cvx}$$

As a result of this property we write $\mathcal{P}(X)$ rather than $\mathcal{P}|(X_s)$.

The consequence of this is that in factorizing the Giry monad it suffices to consider factorizations through the subcategory $\text{Meas}_s$ since, by Lemma 3.4, the inclusion functor $\text{Meas}_s \hookrightarrow \text{Meas}$ is right adjoint to $S$, so that any adjunct pair $\mathcal{P} \dashv \Sigma$ between $\text{Meas}_s$ and $\text{Cvx}$ can be composed with the adjunction $S \dashv \iota_{\text{Meas}}$ to obtain the composite adjunction

$$\text{Meas} \xrightarrow{\mathcal{S}} \text{Meas}_s \xrightarrow{\mathcal{P}|} \text{Cvx} \quad (\mathcal{P} \circ \mathcal{S}) \dashv (\iota \circ \Sigma)$$

Factoring out the nonseparability associated with a space $X$ by the functor $\mathcal{S}$ allows us to work in $\text{Meas}_s$, and the two categories, $\text{Meas}_s$ and $\text{Cvx}$, have virtually identical categorical properties. They are both complete, cocomplete, have a separator and coseparator, and are symmetric monoidal closed categories (SMCC).
5. The SMCC structure of \textbf{Meas} and \textbf{Cvx}

The SMCC structure of both \textbf{Meas} and \textbf{Cvx} arise from the usual \textit{hom} tensor product construction, giving adjunctions, for every object in the category, \( \_ \otimes A \dashv \_^A \), which have the evaluation maps \( B^A \otimes B \xrightarrow{ev} B \) at each component specifying the counit of the adjunction \( \_ \otimes A \dashv \_^A \).

In \textbf{Meas}, for \( X, Y \in \text{ob} \textbf{Meas} \) the function spaces, denoted \( Y^X \), consist of the set \( \text{Meas}(X, Y) \) endowed with the smallest-\( \sigma \)-algebra such that all of the evaluation maps, \( \text{Meas}(X, Y) \xrightarrow{ev_{x,y}} Y \) are measurable. We denote the \( \sigma \)-algebra generated by the evaluation maps by \( \Sigma_{ev} \), or just \( \Sigma \) when the context make it clear, and refer to this \( \sigma \)-algebra as the evaluation \( \sigma \)-algebra.

In constructing the monoidal structure so as to obtain a symmetric monoidal closed category, the tensor product \( Y^X \otimes_{\text{Meas}} X \) is the cartesian product \( Y^X \times X \) endowed with the final \( \sigma \)-algebra (largest \( \sigma \)-algebra) such that all the constant graph maps become morphisms in the respective category.

\begin{center}
\begin{tikzcd}
Y^X \arrow{r}{\Gamma_x} \arrow{d}[swap]{ev_x} & Y^X \otimes_{\text{Meas}} X \arrow{d}{ev_{x,y}} \arrow{dl}[swap]{\Gamma_f} & X \arrow{d}[swap]{f} \\
Y & & Y
\end{tikzcd}
\begin{tikzcd}
B^A \arrow{r}{\Gamma_a} \arrow{d}[swap]{ev_a} & B^A \otimes_{\text{Cvx}} A \arrow{d}{ev_{a,b}} \arrow{dl}[swap]{\Gamma_m} & A \arrow{d}[swap]{m} \\
B & & B
\end{tikzcd}
\end{center}

\text{DIAGRAM 1. The construction of the two tensor products are chosen so that the constant graph maps become morphisms in the respective category.}

are measurable. This tensor product structure then makes the evaluation maps \( ev_{x,y} \) measurable functions, so that \textbf{Meas} is a SMCC.

In \textbf{Cvx} the function spaces \( B^A = \text{Cvx}(A, B) \) have the pointwise convex structure determined by the convex structure of \( B \), and the tensor product \( B^A \otimes_{\text{Cvx}} A \) is constructed by taking the smallest congruence relation on the free tensor product space, \( \mathcal{F}(B^A \times A) \), such that all the constant graph maps \( \{ \Gamma_a \}_{a \in A} \) and \( \{ \Gamma_m \}_{m \in B^A} \) become affine maps. This tensor product makes \textbf{Cvx} a SMCC using the same argument as that used in \textbf{Meas}.

The unit interval has a natural convex structure, and associating the Borel \( \sigma \)-algebra with \( I \), it is also a measurable space. Recalling that the Borel \( \sigma \)-algebra is generated by the intervals of the form \([0, u)\) shows that the \( \sigma \)-algebra generated by the Boolean subobjects of \( I \) coincides with the standard Borel \( \sigma \)-algebra \( \mathcal{B}, \Sigma I = (I, \mathcal{B}) \).

Finally we note that any measurable space \( X \) specifies a convex space \( I^X = \text{Meas}(X, I) \) using the pointwise construction, \((f +_\alpha g)(x) = f(x) +_\alpha g(x)\). Similiarly one obtains the convex space \( 2^X = \text{Meas}(X, 2) \).

6. The measurable structure of a convex space

Given any convex space \( A \) let \( \Sigma_A \) be the initial \( \sigma \)-algebra on the underlying set \( A \) generated by the set of all the affine maps \( \text{Cvx}(A, 2) \) and \( \text{Cvx}(A, I) \). Note that any affine map \( A \rightarrow I \)
determines a map \( A \to 2 \) by composition with \( I \xrightarrow{\varepsilon_2} 2 \),

\[
\begin{array}{cc}
A & \to 2 \\
\downarrow m & \downarrow \chi_{m^{-1}(1)} \\
2 & \to 2
\end{array}
\]

but there are affine maps \( A \to 2 \) which do not “lift” to an affine map \( A \to I \). For example, taking \( A = 2 \) and the affine map \( 2 \xrightarrow{id} 2 \), there exist no section of \( \varepsilon_2 \). When \( A \xrightarrow{\chi_V} 2 \) is an affine map, it follows that both \( V \) and its complement, \( V^c \), are convex subobjects of \( A \). Such a subobject \( V \hookrightarrow A \) is called a Boolean subobject of \( A \).

Given any affine map \( A \xrightarrow{m} B \) between convex spaces the map \((A, \Sigma_A) \xrightarrow{m} (B, \Sigma_B)\) is measurable since the generating maps for \( \Sigma_B \) become generating maps for \( \Sigma_A \) upon precomposition with \( m \). This construction specifies a functor \( \text{Cvx} \xrightarrow{\Sigma} \text{Meas} \).

Note that the Borel \( \sigma \)-algebra on \( I \) coincides with \( \Sigma_I \) since the identity map on \( I \) lies in the generating set for \( \Sigma_I \).

The functor \( \Sigma \) endows a convex space with the following nice property.

**Lemma 6.1.** For every convex space \( A \), the measurable space \((A, \Sigma_A)\) is a separated measurable space.

**Proof.** Let \( a_1, a_2 \in A \) be a pair of distinct points. Since \( \mathbb{R}_\infty \) is a coseparator in \( \text{Cvx} \), there exist an affine map \( A \xrightarrow{m} \mathbb{R}_\infty \) separating the pair, say \( m(a_1) < m(a_2) \). The \text{Meas}-diagram

\[
\begin{array}{cccc}
m^{-1}(\langle -\infty, m(a_2) \rangle) & \xrightarrow{\kappa_1} & \Sigma A & \xleftarrow{\kappa_2} & m^{-1}(\langle m(a_2), \infty \rangle) \\
\downarrow m_1 & & \uparrow \Sigma m & & \downarrow m_2 \\
\langle -\infty, m(a_2) \rangle & \to & \Sigma \mathbb{R}_\infty & \to & \langle m(a_2), \infty \rangle \\
\downarrow \chi_{\langle m(a_2), \infty \rangle} & & \downarrow 1 & & \downarrow 2 \\
0 & \to & 1 & & \to 2
\end{array}
\]

shows that \( m^{-1}(\langle m(a_2), \infty \rangle) \) is a measurable set which separates the pair of elements, \( \{a_1, a_2\} \). Thus \( \Sigma A \) is a separable measurable space. \[\square\]

Abusing notation, we subsequently refer to \( \Sigma \) as the functor \( \text{Cvx} \xrightarrow{\Sigma} \text{Meas} \).

For \( A \) a convex space, let us denote \( \Gamma_{\Sigma A} \overset{\text{def}}{=} \text{Meas}(\Sigma A, I) \), and \( I^A \overset{\text{def}}{=} \text{Cvx}(A, I) \). Both \( \Gamma_{\Sigma A} \) and \( I^A \) are convex spaces under the pointwise construction, and using the functor \( \Sigma \) both of these spaces become measurable spaces and we have the measurable inclusion map \( I^A \hookrightarrow \Gamma_{\Sigma A} \). On the other hand we can also endow these spaces with the evaluation \( \sigma \)-algebra, which is the initial \( \sigma \)-algebra generated by the point evaluation maps,

\[
\begin{array}{ll}
\Gamma_{\Sigma A} \xrightarrow{\text{ev}_{\Sigma}} I & \text{ and } \\
I^A \xrightarrow{\text{ev}} I
\end{array}
\]

Since the evaluation maps are affine maps, it readily follows that evaluation \( \sigma \)-algebra is a sub \( \sigma \)-algebra of the \( \sigma \)-algebra determined by the functor \( \Sigma \).
7. The integral as an affine map using the convex tensor product

A functional \( I^X \xrightarrow{P} I \) is called weakly averaging when, for all constant functions \( \overline{u} \in I^X \) with value \( u = \overline{u}(x) \in I \) for all \( x \in X \), \( P \) satisfies \( P(\overline{u}) = u \). This terminology is taken from Sets for Mathematics \([7]\) which specifically address the double dualization process and subfunctors thereof into objects with extra structure. When a functional is both affine and weakly averaging it is referred to as a weakly averaging affine functional.

For any convex space \( A \) and probability measure \( \hat{P} \in G(\Sigma A) \) one obtains the weakly averaging affine functional given by the (Lebesgue) integral of the measurable function \( \Sigma A \xrightarrow{f} I \),

\[
\begin{array}{c}
\int_A f d\hat{P} \\
\end{array}
\]

(1)

We refer to such functionals, arising from a probability measure, as probability functionals. Since these probability functionals are affine they trivially becomes measurable when we apply the functor \( \Sigma \).

Let \( I^{(\Sigma A)}|_{w.a.} \) denote the restriction of the function space \( I^{(\Sigma A)} \), viewed in \( \mathbb{Cvx} \), consisting of the set of all probability functionals on the convex space \( A \). For every measurable function \( \Sigma A \xrightarrow{f} I \) the evaluation function

\[
\begin{array}{c}
\int_A f d\hat{P} \\
\end{array}
\]

is an affine function by the pointwise convex structure on the function space \( I^{\Sigma A} \). Using the SMCC structure of \( \mathbb{Cvx} \) we obtain the commutative \( \mathbb{Cvx} \)-diagram

\[
\begin{array}{ccc}
I^{(\Sigma A)}|_{w.a.} & \xrightarrow{\Gamma f} & I^{\Sigma A} \\
\downarrow & & \downarrow \\
I & \xrightarrow{P} & \int_A f d\hat{P} \\
\end{array}
\]

where, for all convex sums \( \{\alpha_i\}_{i=1}^n \),

\[
\int_A \left( \sum_{i=1}^n \alpha_i (P_i \otimes f_i) \right) \overset{def}{=} \sum_{i=1}^n \alpha_i \int_A f_i d\hat{P}_i,
\]

This “integral map”, \( \int_A \), is the restriction of the evaluation map to the subspace \( I^{(\Sigma A)}|_{w.a.} \otimes \mathbb{Cvx} I^{\Sigma A} \rightarrow I^{\Sigma A} \otimes \mathbb{Cvx} \).

Upon application of the functor \( \Sigma \) we obtain the above diagram viewed in \( \mathbb{Meas} \).

8. Isbell Conjugate Duality applied to the factorization problem

As noted in the introduction, the problem of factorizing the Giry monad through \( \mathbb{Cvx} \) is, for all intents and purposes, the problem of constructing the natural transformation defining the counit for the pair of functors, \( P \) and \( \Sigma \). Our methodology to construct the counit is motivated by the observation that the full subcategory \( \mathcal{C} \) of \( \mathbb{Cvx} \) consisting of the two objects, the unit interval and the discrete space \( \mathbb{2} \), is left-adequate in \( \mathbb{Cvx} \), as shown in \([2]\) The two objects of \( \mathcal{C} \) also have a natural measurable structure, given by the discrete \( \sigma \)-algebra for the
discrete convex space 2, and the Borel-σ-algebra on I, and hence are objects lying in Meas. There is also an evident functor Meas ↠ (Cvx)\(\text{op}\) given by \(\hat{Y}(X) = U(\text{Meas}(X, I))\), defined at the two component of C by forgetting the measurable structure of the function spaces, and viewing the resulting sets, \(2^X = \text{Meas}(X, 2)\) and \(I^X = \text{Meas}(X, I)\), as convex spaces with the convex structure defined pointwise using the convex structure of 2 and I\(\text{op}\). The functor \(\hat{Y}\) is, in general, not full because for any measurable space \(X\), a probability measure \(\hat{P} \in G(X)\) determines an affine map \(I^X \xrightarrow{\hat{P}} I\) defined by the integral, \(f \mapsto \int_X f \, d\hat{P}\). Since \((\hat{Y}(1 \xrightarrow{x} X))(I) = I^X \xrightarrow{\text{ev}_2} I\), corresponding to the Dirac measure \(\delta_x \in G(X)\), it follows that \(\hat{Y}\) is not full. However the functor \(\hat{Y}\) is faithful on Meas since for any two points \(x_1, x_2 \in X\), the two evaluation maps, \(\{I^X \xrightarrow{\text{ev}_2} I\}_{i=1}^2\), are distinct.

As noted in §4, any factorization of the Giry monad can be factored through the subcategory Meas, and hence for purposes of constructing the counit of the desired factorization \(P \dashv \Sigma\), it suffices to consider an adjunction between Meas and Cvx as illustrated in the diagrams in §4.

Isbell conjugate duality leads us to consider the Cat-diagram

\[
\begin{array}{ccc}
\text{Cvx}^{\text{op}} & \xrightarrow{\mathcal{O}} & (\text{Cvx})^{\text{op}} \\
\mathcal{O} & \downarrow \mathcal{S}_{\text{spec}} & (\text{Cvx})^{\text{op}} \\
\mathcal{P} \downarrow & \hat{Y} \downarrow & \mathcal{O} \dashv \mathcal{S}_{\text{spec}} \\
\text{Cvx} & \sim \overline{\overline{\text{Meas}}} & \text{Meas}_s
\end{array}
\]

Subsequently, abusing notation, we write \(\mathcal{P}\) rather than its restriction \(\mathcal{P}|\). The scheme we use to construct the counit \(\mathcal{P} \circ \Sigma \Rightarrow \text{id}_{\text{Cvx}}\) is to compare the two parallel functors from Meas to Cvx,

\[
\begin{array}{ccc}
\text{Cvx}^{\text{op}} & \xrightarrow{\mathcal{S}_{\text{spec}}} & (\text{Cvx})^{\text{op}} \\
\text{ev}_2 \downarrow & \mathcal{S}_{\text{spec}} \circ \hat{Y} \downarrow & \mathcal{O} \dashv \mathcal{S}_{\text{spec}} \\
\text{Cvx} & \sim \mathcal{P} \sim \text{Meas}_s
\end{array}
\]

where \(\text{ev}_2\) is the functor of evaluation at component \(2 \in C\). We show there is a natural isomorphism between these two functors (Theorem 9.6 below), and hence upon composition

\[\text{Formally, we should write } \hat{Y}(X) = U(\text{Meas}(X, \Sigma)), \text{ where the functor } \Sigma \text{ is some functor } \text{Cvx} \rightarrow \text{Meas} \text{ assigning these two objects their natural measurable structure. However, we adopt the convention that, unless otherwise stated, function spaces will always be viewed as a convex structure unless specifically noted otherwise.}\]

\[\text{Isbell conjugate duality, using the functor category } V^{\text{op}}, \text{ can be applied using any symmetric monoidal closed category } V, \text{ which is complete and cocomplete, as the base, provided } C \text{ is enriched over } V.\]
with the functor $\Sigma$ we obtain the natural transformation

$$ev_2 \circ (Spec \circ \hat{Y} \circ \Sigma) \xrightarrow{\hat{\epsilon}} id_{Cvx}$$

where $\hat{\epsilon}$ arises from some basic properties of the $Spec$ functor, and the various composite functors with $Spec$, which we now proceed to describe.

9. Properties of the $Spec$ functor

Let $\hat{X}$ denote the image of the functor $\hat{Y}$ applied to a measurable space $X$, so that at the two component of $C$, $2^X = \mathcal{U}(\text{Meas}(X, 2))$ and $I^X = \mathcal{U}(\text{Meas}(X, I))$, these spaces are viewed as convex spaces. Similarly, let $\hat{I}$ denote the functor $\text{Cvx}(I, \_)$ $\inob (\text{Cvx}^\text{C})$. We have

$$(ev_2 \circ Spec \circ \hat{Y} \circ \Sigma)(A) = Spec(\Sigma A)[2] = Nat(\Sigma A, 2)$$

Evaluation at component $I \in C$ yields $Nat(\Sigma A, I^2)$. However $I^2 \cong I$ because $2$ is a discrete convex space while $I$ is a geometric convex space. Consequently, if $\alpha \in Spec(\Sigma A)[2]$ then by naturality we have the commutative $\text{Cvx}$-diagram

$$\begin{array}{ccc}
\Sigma A & \xrightarrow{\alpha} & 2^\Sigma A \\
\epsilon_2 \downarrow & & \downarrow \epsilon_2 \\
2^\Sigma A & \xrightarrow{\alpha_2} & 2^2
\end{array}$$

so that the image of $\alpha_2$ is two-valued, taking the value of one of the two constant maps, $\overline{0}$ and $\overline{1}$. In other words, the identity map $2 \xrightarrow{id_2} 2$ does not lie in the image of $\alpha_2$ since there are no affine maps $2 \xrightarrow{\gamma} I$ such that $\epsilon_2 \circ \gamma = id_2$. (Note that the twist function $2 \xrightarrow{tw} 2$, which interchanges $0$ and $1$, is not an affine map.) Hence it follows that

$$Spec(\Sigma A)[2] \cong Nat(\Sigma A, \_).$$

Lemma 9.1. If $\alpha \in Spec(\Sigma A)[2]$ then it satisfies the two properties

1. For every constant function $\overline{u} \in I^X$ with value $u \in I$,

$$\alpha_1(\overline{u}) = u$$

2. For every $v \in I$ and every $f \in I^X$,

$$\alpha_1(v \cdot f) = v \alpha_1(f).$$

Proof. The naturality condition of $\alpha$ requires that for all $\gamma_{u,v} \in I$, and all $f \in I^X$, that the $\text{Cvx}$-diagram

$$\begin{array}{ccc}
I^X & \xrightarrow{\alpha_1} & I \\
\gamma_{u,v} \downarrow & & \downarrow \gamma_{u,v} \\
I^X & \xrightarrow{\alpha_1} & I
\end{array}$$

$$\begin{array}{ccc}
f & \xrightarrow{\alpha_1} & \alpha_1(f) \\
\gamma_{u,v} \circ f \mapsto \alpha_1(\gamma_{u,v} \circ f) = \gamma_{u,v} \circ \alpha_1(f)
\end{array}$$
commutes.

To prove (1), consider the constant path map $\gamma_{u,v} \in \text{Cvx}(I,I)$. The naturality condition yields

$$\alpha_I(\gamma_{u,v} \circ f) = \gamma_{u,v} \circ \alpha_I(f).$$

To prove (2), consider the “scaling” path map $\gamma_{0,v}$. The naturality condition yields

$$\alpha_I(v \cdot f) = \gamma_{0,v} \circ \alpha_I(f) = v \cdot \alpha_I(f).$$

The extension is unique because if $\hat{\alpha}_I$ and $\hat{\beta}_I$ are two extensions of $\alpha_I$ then, for every $U \in \Sigma_X$, since $\chi_U \in I^X \subset \mathbb{R}^X$, it follows that

$$\hat{\alpha}_I(\chi_U) = \alpha_I(\chi_U) = \hat{\beta}_I(\chi_U).$$

Because the set of all characteristic functions $\{\chi_U\}_{U \in \Sigma_X}$ forms a spanning set for the set of all simple measurable functions on $X$, it follows that $\hat{\alpha}_I$ and $\hat{\beta}_I$ must agree everywhere. In other words, the extension is completely specified by the values $\{\alpha_I(\chi_U)\}_{U \in \Sigma_X}$.

It follows the operator $\mathbb{R}^X \xrightarrow{\hat{\alpha}_I} \mathbb{R}$ is a linear operator of norm 1, and since $|\hat{\alpha}_I(f)| \leq ||\hat{\alpha}_I|| ||f|| = ||f||$, it follows that $\hat{\alpha}_I$ is a continuous linear map, and therefore its restriction to $I^X$, which coincides with $\alpha_I$, is also a continuous map. Consequently, we obtain

**Lemma 9.2.** Let $f, f_i \in I^X$ for all $i \in \mathbb{N}$. If $\{f_i\}_{i=1}^{\infty} \rightarrow f$ pointwise then every $\alpha \in \text{Spec}(\_X)[2]$ satisfies the property that

$$\lim_{N \rightarrow \infty} \{\alpha_I(f_i)\} = \alpha_I(f).$$

**Corollary 9.3.** Let $\alpha \in \text{Spec}(\_X)[2]$. If $\{U_i\}_{i=1}^{\infty}$ is a sequence of measurable sets in $X$ converging to $\emptyset$ then $\lim_{i=1}^{\infty} \{\chi_{U_i}\} = 0$.

**Proof.** Viewing the sequence $\{\chi_{U_i}\}_{i=1}^{\infty}$ in $I^X$, by Lemma 9.2 it follows that $\lim_{i=1}^{\infty} \{\alpha_I(\chi_{U_i})\} = 0$. Composition with $\epsilon_2$ which preserves the ordering then yields, using naturality, that $\lim_{i=1}^{\infty} \{\alpha_2(\chi_{U_i})\} = 0$.

**Lemma 9.4.** Let $X$ be a separated measurable space and $2^X \xrightarrow{\chi_X} 2$ be a weakly averaging affine measurable map. Then the Boolean subobject pair $\{\mathcal{V}, \mathcal{V}^c\}$ of $2^X$ satisfies the property that if $U \in \Sigma_X$ and $\chi_U \in \mathcal{V}$ then $\chi_{U^c} \in \mathcal{V}^c$. In other words, $\chi_{\mathcal{V}}(\chi_U) = 1$ if and only if $\chi_{\mathcal{V}^c}(\chi_U) = 0$. 

□
Suppose the contrary, that there exist a measurable set \( U \) in \( X \) such that \( \chi_V, \chi_U \in \mathcal{V} \). Then since \( \mathcal{V} \) is a Boolean subobject, for all \( \alpha \in (0, 1) \) it follows that the convex sum \( \chi_U + \alpha \chi_V \in \mathcal{V} \) because evaluation at any point in \( X \) gives either \( 1 + \alpha 0 = 0 \) or \( 0 + \alpha 1 = 0 \). But \( \mathcal{V} = \chi_V^{-1}(1) \), so the result that \( \mathcal{V} \) implies that \( \chi_V(0) = 1 \) which contradicts the hypothesis that \( \chi_V \) is weakly averaging. \( \square \)

**Lemma 9.5.** Let \( A \) be a convex space, and assume no measurable cardinals exist\(^5\). If \( \alpha \in \text{Spec}(\Sigma^A)2 \) then, at component \( 2, 2^{\Sigma^A} \xrightarrow{\alpha} 2 \) is an evaluation map, \( \alpha_2 = ev_a \) for a unique point \( a \in A \).

**Proof.** Consider the set \( \alpha_2^{-1}(1) = \{ \chi_U | \alpha_2(\chi_U) = 1 \} \).

Suppose, to obtain a contradiction, that \( \cap \alpha_2^{-1}(1) = \emptyset \). Using the hypothesis that no measurable cardinals exist, we can find a sequence of measurable sets \( \{U_i\}_{i=1}^\infty \) in \( X \), with each \( \chi_{U_i} \in \alpha_2^{-1}(1) \), such that \( \lim_{N \to \infty} \{\cap_{i=1}^N U_i\} = \emptyset \). By Corollary 9.3 it follows that \( \lim_{N \to \infty} \{\alpha_2(\chi_{\cap_{i=1}^N U_i})\} = 0 \). But for every \( N \in \mathbb{N} \), since each \( \chi_{U_i} \in \alpha_2^{-1}(1) \), it follows that \( \alpha_2(\chi_{\cap_{i=1}^N U_i}) = 1 \), and hence

\[
\lim_{N \to \infty} \{\alpha_2(\chi_{\cap_{i=1}^N U_i})\} = 1,
\]

yielding a contradiction. Thus we conclude that \( \alpha_2^{-1}(1) \neq \emptyset \).

The uniqueness follows from the property, given in Lemma 3.5, that \( \Sigma A \) is a separated measurable space. For let \( U_a \overset{\text{def}}{=} \bigcap_{\chi_{U_i} \in \alpha_2^{-1}(1)} U_i \)

and suppose that \( a_1, a_2 \in U_a \) with \( a_1 \neq a_2 \), and with the measurable set \( V \in \Sigma A \) separating the pair, with \( a_1 \in V \) while \( a_2 \in V^c \). By Lemma 9.4, either \( \chi_V \in \alpha_2^{-1}(1) \) or \( \chi_{V^c} \in \alpha_2^{-1}(1) \). Either choice contradicts the condition that every element \( a \in U_a \) satisfies \( \chi_{U_k}(a) = 1 \) for all \( \chi_{U_k} \in \alpha_2^{-1}(1) \).

\( \square \)

**Theorem 9.6.** For \( X \) any measurable space, we have a \( \text{Cvx} \)-isomorphism

\[
\text{Spec}(\Sigma^X)2 \cong \mathcal{P}(X),
\]

and this isomorphism is natural in \( X \).

**Proof.** By lemmas 9.1 and 9.2 each \( \alpha \in \text{Spec}(\Sigma^X)2 \), evaluated at \( \mathbf{I} \), satisfies the three basic properties of a probability functional \( \mathbf{I}^X \xrightarrow{\alpha} \mathbf{I} \), given by

1. \( \alpha(\mathcal{V}) = c \),
2. For all \( s \in \mathbf{I} \) we have \( \alpha(sf) = s\alpha(f) \), and
3. If \( \{f_i\}_{i=1}^N \to f \) pointwise (with each \( f_i \in \mathbf{I}^X \)), then \( \lim_{N \to \infty} \alpha(f_i) = \alpha(f) \).

Conversely, every probability functional determines an element \( \alpha \in \text{Spec}(\Sigma^X)2 \) at the component \( \mathbf{I} \), since it satisfies these three characteristic properties.

\(^5\)Measurable cardinals are sets \( X \) with a (large) cardinality \( \kappa \) such that there exist countably additive 0-1 measures \( 2^X \xrightarrow{\mathcal{F}} 2 \) with the property that \( \cap \mathcal{F}^{-1}(1) = \emptyset \) but for every subset \( S \subset \mathcal{F}^{-1}(1) \) of cardinality \( \gamma < \kappa \), \( \cap S \neq \emptyset \). A proof of the existence of measurable cardinals would require an extension of the ZFC axioms.
The naturality follows directly from the definitions of $\text{Spec}(\cdot \rightarrow) \mathbb{2} = \text{Nat}(\cdot \rightarrow, \cdot)$, and $\mathcal{P}(X)$. If $X \xrightarrow{f} Y$ is a measurable function then $\mathcal{P}(X \xrightarrow{f} Y)$ is the pushforward map of probability measures, mapping $P \in \mathcal{P}(X) \mapsto Pf^{-1} \in \mathcal{P}(Y)$. On the other hand, $\text{Spec}(\cdot \rightarrow) : \text{Spec}(\cdot \rightarrow) \to \text{Spec}(\cdot \rightarrow)$

\[ P \xrightarrow{\alpha} Pf^{-1} \in \mathcal{P}(Y) \]

where $(\alpha \circ f)_c = \alpha_c \circ c^f$ is the evaluation at any component $c \in \mathcal{C}$. That is, $\text{Spec}(\cdot \rightarrow)$ is the “pushforward map” constructed using the natural transformation $\beta$, as illustrated, for component $I$, in the $\mathbf{Cvx}$-diagram

\[
\begin{array}{ccc}
X & \xrightarrow{\alpha_I} & I \\
| f | & & | f | \\
Y & \xrightarrow{\alpha_I \circ f} & Y
\end{array}
\]

Since a natural transformation $\alpha \in \text{Spec}(\cdot \rightarrow) \mathbb{2}$ at component $I$ is a weakly averaging affine map, $I^X \xrightarrow{P} I$, this theorem can be stated as

Corollary 9.7. There is a natural isomorphism of convex spaces

\[
\mathcal{P}(X) \xrightarrow{\Phi_X} I^{(X)\text{wa}}
\]

given by mapping a probability measure $\hat{P} \in \mathcal{G}(X)$ to the weakly averaging affine map $I^X \xrightarrow{P} I$ specified by $P(f) = \int X f d\hat{P}$.

Proof. One can apply the above theorem directly. Here is a more direct proof. The map $\Phi_X$ is affine because the convex structure of $\mathcal{P}(X)$ is defined pointwise, so that

\[
\Phi_X(\hat{P} + \alpha \hat{Q})[f] = \int X f d(\hat{P} + \alpha \hat{Q}) = \int X f d\hat{P} + \alpha \int X f d\hat{Q} = \Phi_X(\hat{P})[f] + \alpha \Phi_X(\hat{Q})[f] = (\Phi_X(\hat{P} + \alpha \Phi_X(\hat{Q}))[f]
\]

The inverse map is specified, for all $U \in \Sigma_X$, by $\left(\Phi_X^{-1}(P)\right)[U] = P(\chi_U)$. A routine computation using the fact that the pushforward map of a probability functional, as illustrated in the proof of the Theorem, shows that $\Phi$ is a natural transformation. □

Using the SMCC structure of $\mathbf{Cvx}$, it follows that

Corollary 9.8. There is a natural $\mathbf{Cvx}$-isomorphism

\[
\begin{array}{ccc}
I^X & \xrightarrow{\hat{\Phi}_X} & \mathbf{Cvx}(\mathcal{P}(X), I) \\
\hat{P} & \xrightarrow{\int X f d\hat{P}} & \mathcal{P}(X) \xrightarrow{\hat{f}} I
\end{array}
\]
10. The adjunction between $\mathcal{P}$ and $\Sigma$

Viewing probability measures as natural transformations, we proceed to construct the counit required for the adjunction between $\mathcal{P}$ and $\Sigma$.

**Lemma 10.1.** Provided that no measurable cardinals exist, for every convex space $A$, it follows that the map

$$Spec(\Sigma^A)[2] \xrightarrow{\hat{\alpha}^A} A$$

defined by mapping a natural transformation $\alpha$ to the unique element $a \in A$ such that $\alpha_2 = ev_a$, defines the components of a natural transformation

$$\epsilon_2 \circ Spec \circ \hat{\gamma} \circ \Sigma \xrightarrow{\epsilon} \text{id}_{\text{Cvx}}$$

where $ev_2$ is the evaluation of the functor at component $2 \in C$.

**Proof.** Every natural transformation $\alpha \in Spec(\Sigma^A)[2]$ evaluated at component $2$ is, by Lemma 9.5, an affine map, $\alpha \xrightarrow{2} \Sigma A \xrightarrow{\alpha} 2$, which is an evaluation map, $ev_a$ for a unique point $a \in A$. This defines the map $\hat{\epsilon}_A$, and, for $A \xrightarrow{m} B$ an affine map, we have the commutativity of the Cvx-diagram

$$Spec(\Sigma^A)[2] \xrightarrow{\hat{\epsilon}_A} A \xrightarrow{(\Sigma^A \xrightarrow{\alpha} \cdot)} \hat{\epsilon}_A(\alpha)$$

where $\alpha \in Spec(\Sigma^A)[2] = \text{Nat}(\Sigma^A, \cdot)$ and its “pushforward” along $m$ is the natural transformation $\alpha \circ \Sigma m \in Spec(\Sigma^B)[2] = \text{Nat}(\Sigma^B, \cdot)$. The evaluation of the latter map at component $2$ is therefore

$$2 \xrightarrow{\Sigma^A \circ \alpha = ev_{\hat{\epsilon}_A(\alpha)}^A} 2 \xrightarrow{\Sigma^B} 2 \xrightarrow{(ev_{\hat{\epsilon}_A(\alpha)} \circ \Sigma^m)} 2 \xrightarrow{\text{id}_{\text{Cvx}}} 2$$

where the equality on the diagonal map follows because the affine map $\alpha_2 \circ 2 \Sigma m = ev_{\hat{\epsilon}_A(\alpha)}$ is an evaluation map at the unique element $\hat{\epsilon}_B(\alpha \circ \Sigma m)$. Evaluation of that equation at any characteristic function $\chi_B \in 2 \Sigma B$ shows that $m(\hat{\epsilon}_A(\alpha)) = \hat{\epsilon}_B(\alpha \circ \Sigma m)$, thereby proving naturality. □

Every probability measure $\hat{P} \in \mathcal{G}(\Sigma A)$ specifies a weakly averaging affine functional $\Gamma^A \xrightarrow{P} \mathcal{I}$ using the integral, and by Theorem 9.6, every such functional is the $\mathcal{I}$-component of a natural transformation $\alpha \in Spec(\Sigma^A)[2]$. Thus the natural transformation $\hat{\epsilon}$, as defined above, can be characterized alternatively as in

**Lemma 10.2.** Provided no measurable cardinals exist, there is a natural transformation $\mathcal{P} \circ \Sigma \xrightarrow{\epsilon_A} \text{id}_{\text{Cvx}}$ defined by the component maps

$$\mathcal{P}(\Sigma A) \xrightarrow{\epsilon_A} A$$
sending a probability measure \( \hat{P} \) to the unique element \( a \in A \) such that the weakly averaging affine map \( \Sigma^A \xrightarrow{P} I \), defined by the integral, restricts to the evaluation map \( \Sigma^A \xrightarrow{ev} \).

**Theorem 10.3.** Assuming that no measurable cardinals exist, the functor \( P \) is left adjoint to \( \Sigma \), with the unit \( id_{\text{Meas}} \xrightarrow{\eta} \Sigma \circ P \) given at component \( X \) by \( \eta_X(x) = \delta_x \), and the counit specified by the map in Lemma 10.2.

**Proof.** The two natural transformations, \( (P \circ \Sigma) \xrightarrow{\epsilon} id_{\text{Cvx}} \) and \( id_{\text{Meas}} \xrightarrow{\eta} \Sigma \circ P \), together yield the required bijective correspondence. Given a measurable function \( f \):

\[
X \xrightarrow{\eta_X} \Sigma(P(X)) \xrightarrow{\Sigma(f)} \Sigma \circ P(\Sigma A) \xrightarrow{\epsilon} \Sigma A
\]

in \( \text{Meas} \)

\[
P(X) \xrightarrow{P(f)} \Sigma(P(X)) \xrightarrow{\epsilon_P(X)} P(X) \xrightarrow{\epsilon} \Sigma A \xrightarrow{\epsilon_A} A
\]

in \( \text{Cvx} \)

\[
P \sim \delta_P \xrightarrow{P} \Sigma P \xrightarrow{\epsilon_f} \Sigma A \xrightarrow{\epsilon_A} A
\]

where the bottom path, \( \hat{f} = \epsilon_A \circ P(f) \), yields \( \hat{f}(P) \), while the east-south path gives \( g(P) = g(\epsilon_P(X)(\delta_P)) \).

This adjunction, \( \langle P, \Sigma, \eta, \epsilon \rangle \), determines the monad \( \langle \Sigma \circ P, \eta, \Sigma \circ P \circ \epsilon \rangle \). It is evident, that the underlying sets and set functions of \( \Sigma \circ P \) and \( G \) coincide. Let us verify that the σ-algebras these two functors assign to a set of probability measures coincide. Let us denote the σ-algebra of the Giry monad on a the set \( \mathcal{G}(X) \) by \( \Sigma_{\mathcal{G}} \), which is specified as the initial σ-algebra on \( \mathcal{G}(X) \) induced by all the evaluation maps \( ev_U \), for all \( U \in \Sigma_X \). As defined
previously, the σ-algebra assigned by the functor Σ to \( \mathcal{P}(X) \) is denoted \( \Sigma_{\mathcal{P}(X)} \). Since the evaluation maps are affine maps into \( I \), it follows that \( \Sigma^X_{ev} \subseteq \Sigma_X \).

To prove the converse, let \( \mathcal{P}(X) \overset{m}{\to} I \) be an affine map. Using Corollary 9.8, \( m \) determines a measurable map \( X \overset{f_m}{\to} I \), which can be written as the pointwise limit of a sequence of simple measurable functions,

\[
f^i_m = \sum_{i=1}^{N_i} \alpha^i_j \chi_{U^i_j}.
\]

It follows that \( m \) can also be written as a pointwise limit since

\[
m(\hat{P}) = \int_X f_m d\hat{P} = \int_X \lim_j f^i_m d\hat{P} = \lim_j \{ \sum_{i=1}^{N_i} \alpha^i_j \int_X \chi_{U^i_j} d\hat{P} \} = \lim_j \{ \sum_{i=1}^{N_i} \alpha^i_j \hat{P}(U^i_j) \} = \lim_j \{ \sum_{i=1}^{N_i} \alpha^i_j \text{ev}_{U^i_j} \}[\hat{P}] \]

where the coefficients \( \alpha^i_j \) lie in an interval \( J \subseteq I \) whose length goes to zero as \( j \) tends to infinity. Since each of these functions \( f^i_m \) are measurable with respect to \( \Sigma^X_{ev} \) it follows that the (pointwise) limit function, given by \( m \), is also measurable with respect to \( \Sigma^X_{ev} \).

Since the σ-algebra of \( \mathcal{P}X \) is also generated by affine maps \( \mathcal{P}X \overset{m}{\to} 2 \) we must show these are also measurable with respect to \( \Sigma^X_{ev} \).

**Lemma 10.4.** Any affine map \( \mathcal{G}(X) \overset{m}{\to} 2 \) is measurable with respect to \( \Sigma^X_{ev} \).

**Proof.** Since \( \langle \mathcal{P}, \Sigma, \eta, \epsilon \rangle \) is an adjunction, with counit \( \epsilon \), we have the following commutative \( \text{Cvx} \)-diagram,

\[
\begin{array}{ccc}
\mathcal{G}^2(X) & \overset{\epsilon_{\mathcal{G}X}}{\longrightarrow} & \mathcal{G}(X) \\
\mathcal{G}(m) \downarrow & & \downarrow m \\
\mathcal{G}(2) & \overset{\epsilon_2}{\longrightarrow} & 2
\end{array}
\]

where we have used the fact that, as convex spaces, \( \mathcal{G}(X) = \mathcal{P}(X) \) and \( \mathcal{G}(m) = \mathcal{P}(m) \), as well as the \( \text{Cvx} \)-isomorphism between \( \mathcal{G}(2) \) and \( I \). Now \( \mathcal{G}(m) \), being an affine map into \( I \), is measurable by the argument preceding the Lemma, and \( \epsilon_2 \) is also a measurable map. Consequently we have

\[
m \circ \epsilon_{\mathcal{G}X} \circ \eta_{\mathcal{G}X} = \epsilon_2 \circ \mathcal{G}(m) \circ \eta_{\mathcal{G}X} = \text{id}_{\mathcal{G}X}
\]

where all the maps on the right hand side are \( \Sigma^X_{ev} \)-measurable. Hence \( m \) is measurable with respect to \( \Sigma^X_{ev} \). \( \square \)

Thus the reverse inequality \( \Sigma_{\mathcal{G}X} \subseteq \Sigma^X_{ev} \) also holds and we conclude that the σ-algebra given by the functor \( \Sigma \) coincides with that of the Giry monad construction.

**Lemma 10.5.** The multiplication natural transformations of the two monads, \( (\mathcal{G}, \eta, \mu) \) and \( (\Sigma \circ \mathcal{P}, \eta, \Sigma \epsilon_{\mathcal{P}X}) \), coincide

\[
\mu_X = \Sigma \epsilon_{\mathcal{P}X}.
\]
Proof. Recall the multiplication $\mu$ of the Giry monad is defined componentwise by

$$\mu_X(P)[U] = \int_{q \in \mathcal{G}(X)} ev_U(q) dP(q).$$

This definition for $\mu_X$ is the composite of the two measurable maps determining the east-south path of the Meas-diagram

$$\begin{array}{cccc}
X & \xrightarrow{\mu_X} & \mathcal{G}(X) & P \\
\downarrow{\chi_U} & \downarrow{\mathcal{G}(ev_U)} & \downarrow{ev_U} & \downarrow{ev_U} \\
\Sigma_{\mathcal{P}(X)} & \xrightarrow{\mu_2} & \mathcal{G}(2) & \Sigma_{\mathcal{P}(2)} \\
\downarrow{\Sigma_{\mathcal{P}(X)}} & \downarrow{\mathcal{G}(ev_U)} & \downarrow{ev_U} & \downarrow{ev_U} \\
\Sigma_{\mathcal{P}(2)} & \xrightarrow{\mu_2} & \mathcal{G}(2) & \Sigma_{\mathcal{P}(2)} \\
\end{array}$$

which commutes by naturality of $\mu$, where we have used the fact that $ev_U = \mathcal{G}(\chi_U)$. By the naturality of $\epsilon$, we also have

$$\begin{array}{cccc}
X & \xrightarrow{\Sigma_{\mathcal{P}(X)}} & \mathcal{G}(X) & P \\
\downarrow{\chi_U} & \downarrow{\mathcal{G}(ev_U)} & \downarrow{ev_U} & \downarrow{ev_U} \\
\Sigma_{\mathcal{P}(2)} & \xrightarrow{\mu_2} & \mathcal{G}(2) & \Sigma_{\mathcal{P}(2)} \\
\downarrow{\Sigma_{\mathcal{P}(X)}} & \downarrow{\mathcal{G}(ev_U)} & \downarrow{ev_U} & \downarrow{ev_U} \\
\Sigma_{\mathcal{P}(2)} & \xrightarrow{\mu_2} & \mathcal{G}(2) & \Sigma_{\mathcal{P}(2)} \\
\end{array}$$

Now use the fact that $\mu_2 = \Sigma_{\mathcal{P}(2)}$ to conclude that, for all $U \in \Sigma_X$ and all $P \in \mathcal{G}^2(X)$,

$$\mu_X(P)[U] = \mu_2(P ev_U^{-1}) = \Sigma_{\mathcal{P}(2)}(P ev_U^{-1}) = \Sigma_{\mathcal{P}(X)}(P)[U]$$

from which it follows that, for all $P \in \mathcal{G}^2(X)$ that $\mu_X(P) = \Sigma_{\mathcal{P}(X)}(P)$. This in turn implies the result that

$$\mu_X = \Sigma_{\mathcal{P}(X)}.$$  

$\Box$

Combining Lemmas 10.4 and 10.5 and the preceding remarks, we conclude that the two monads $(\mathcal{G}, \eta, \mu)$ and $(\Sigma \circ \mathcal{P}, \eta, \Sigma \epsilon)$ are equal, and consequently we obtain the result that

**Theorem 10.6.** The Giry monad $\mathcal{G}$ factors through the category of convex spaces via the adjunction $(\mathcal{P}, \Sigma, \eta, \epsilon)$.

11. **The category of convex measurable spaces**

Recall that a $\mathcal{G}$-algebra consist of a measurable space $(X, \mathcal{X})$, which we will often denote simply by $X$, and a measurable function

$$\begin{array}{ccc}
\mathcal{G}(X) & \xrightarrow{h} & X \\
\mu_X & & \downarrow{h} \\
\mathcal{G}(X) & \xrightarrow{h} & X \\
\end{array}$$

which satisfies (1) $h \circ \eta_X = id_X$, and (2) makes the Meas-diagram commute.
The factorization of the Giry monad using the adjunction \((\mathcal{P}, \Sigma, \eta, \epsilon)\) immediately yields

**Lemma 11.1.** For every convex space \(A\) the measurable function \(\Sigma \mathcal{P}(\Sigma A) \xrightarrow{\Sigma A} \Sigma A\) is a \(G\)-algebra.

*Proof.* The property \(\Sigma \epsilon_A \circ \eta_{\Sigma A} = id_{\Sigma A}\) is satisfied since \(\epsilon_A(\delta_a) = a\). By the naturality of \(\epsilon\), the \(\textbf{Cvx}\)-diagram on the left hand side

\[
\begin{array}{c c c c}
\mathcal{P} \Sigma \mathcal{P}(\Sigma A) & \xrightarrow{\epsilon_{\mathcal{P} \Sigma A}} & \mathcal{P} \Sigma A & \\
\mathcal{P} \Sigma \epsilon_A & \xrightarrow{\epsilon_A} & A & \\
\mathcal{P} \Sigma A & \xrightarrow{\epsilon_A} & A & \\
\end{array}
\]

commutes. Applying the functor \(\Sigma\) to this diagram, and using the property, given in Lemma 10.3, \(\mu_{\Sigma A} = \Sigma \epsilon_{\mathcal{P} \Sigma A}\), it follows that the \(\textbf{Meas}\)-diagram on the right also commutes. Hence the two properties for \(\Sigma \epsilon_A\) to be a \(G\)-algebra are satisfied. \(\square\)

**Corollary 11.2.** Let \(A\) be any convex space, and \(\mathcal{A}\) a \(\sigma\)-algebra on the underlying set of \(A\), denoted \(|A|\), such that \(\mathcal{A} \subseteq \Sigma A\). Then the restriction of \(\Sigma \epsilon_A\) along the inclusion map \((|A|, \mathcal{A}) \hookrightarrow \Sigma A\) is a \(G\)-algebra.

*Proof.* By Lemma 11.1 the square on the back side of the \(\textbf{Meas}\) diagram

\[
\begin{array}{c c c c}
\Sigma \mathcal{P} \Sigma \mathcal{P}(|A|, \mathcal{A}) & \xrightarrow{\Sigma \epsilon_{\mathcal{P} \Sigma \mathcal{P}(|A|, \mathcal{A})}} & \Sigma \mathcal{P}(|A|, \mathcal{A}) & \\
\Sigma \mathcal{P} \epsilon_{|A|} & \xrightarrow{\epsilon_{|A|}} & |A| & \\
\mathcal{P}(|A|, \mathcal{A}) & \xrightarrow{\epsilon_{|A|}} & (|A|, \mathcal{A}) & \\
\end{array}
\]

commutes. The top, bottom, and left and right hand side squares also commute where \((|A|, \mathcal{A}) \xrightarrow{\iota} \Sigma A\) is the inclusion map. Hence the front square also commutes, which shows, using Lemma 10.3 again, that \(\epsilon_{|A|}\) satisfies the property \(\mu_{(|A|, \mathcal{A})} \circ \iota \epsilon_{|A|} = G \epsilon_{|A|} \circ \epsilon_{|A|}\). Combined with the property that \(\epsilon_{|A|} \circ \eta_{(|A|, \mathcal{A})} = id_{(|A|, \mathcal{A})}\), it follows that \(\epsilon_{|A|}\) is a \(G\)-algebra. \(\square\)

We claim that every \(G\)-algebra can be obtained as the restriction \(\epsilon_{|A|}\), for some convex space.

**Lemma 11.3.** Every \(G\)-algebra \(G(X) \xrightarrow{h} X\) specifies a convex structure on \(X\) defined by

\[x_1 +_\alpha x_2 = h(\delta_{x_1} +_\alpha \delta_{x_2}).\]

*Proof.* Using the axiomatic definition of a convex space, as given in Gudder[7] Theorem 2.3, requires that the following three properties are satisfied: (1) \(x_1 +_\alpha x_2 = x_2 +_1 -\alpha x_1\) for all \(\alpha \in \mathbb{I}\), (2) \(x_1 +_0 x_2 = x_1\), and (3) for all \(\alpha \in [0, 1]\) and all \(\beta \in \mathbb{I}\), \((x_1 +_\alpha x_2) +_\beta x_3 = x_1 +_\alpha(\alpha +_\beta) x_3\). The verification of the first two properties are trivial. To prove the last property, first note that in \(G(X)\),

\[(\delta_{x_1} +_\alpha \delta_{x_2}) +_\beta \delta_{x_3} = \delta_{x_1} +_\alpha \beta (\delta_{x_2} +_\alpha(1 - \beta) \delta_{x_3}) \quad \forall \alpha \in [0, 1], \forall \beta \in [0, 1].\]
Now use the identity \( \mu_X \circ \eta_{\mathcal{G}(X)} = \text{id}_{\mathcal{G}(X)} \) to obtain
\[
(\delta_{x_1} + \alpha \delta_{x_2}) + \beta \delta_{x_3} = \mu_X(\eta_{\mathcal{G}(X)}((\delta_{x_1} + \alpha \delta_{x_2}) + \beta \delta_{x_3})) = \mu_X(\delta_{x_1} + \alpha \delta_{x_2} + \beta \delta_{x_3}) = h((\delta_{x_1} + \alpha \delta_{x_2}) + \beta \delta_{x_3}) = h((\delta_{x_1} + \alpha \delta_{x_2}) + \beta \delta_{x_3}).
\]

Now apply \( h \) to both sides of the equation, and use the property that \( h \circ \mathcal{G}h = h \circ \mu_X \), to obtain
\[
(\delta_{x_1} + \alpha \delta_{x_2}) + \beta \delta_{x_3} = (\delta_{x_1} + \alpha \delta_{x_2}) + \beta \delta_{x_3}.
\]

Similarly,
\[
h(\delta_{x_1} + \alpha \beta (\delta_{x_2} + \alpha(1-\beta) \delta_{x_3})) = h(\delta_{x_1} + \alpha \beta \delta_{x_2} + \alpha(1-\beta) \delta_{x_3})
\]

By equation 2 the last two equations are equal thereby proving condition (3). \( \square \)

Given any \( \mathcal{G} \)-algebra \( \mathcal{G}(X) \xrightarrow{h} X \), we denote the convex space with the induced convex structure on the set \( X \), as defined in Lemma 11.3, by \( X_h \).

**Lemma 11.4.** Let \( \mathcal{G}(X) \xrightarrow{h} X \) be a \( \mathcal{G} \)-algebra. The map
\[
\mathcal{P}(X) \xrightarrow{\hat{h}} X_h
\]
defined pointwise, for all \( P \in \mathcal{P}(X) \), by \( \hat{h}(P) = h(P) \), is an affine map and factors uniquely through \( \epsilon_{X_h} \).

**Proof.** To show the function \( h \) is affine let \( P_1, P_2 \in \mathcal{G}(X) \), and \( \alpha \in I \). Using the associativity condition associated with the \( \mathcal{G} \)-algebra \( h \) we have the commutative Meas-diagram
\[
\begin{array}{ccc}
\mathcal{G}^2(X) & \xrightarrow{\mathcal{G}h} & \mathcal{G}(X) \\
\mu_X \downarrow & & \downarrow h \\
\mathcal{G}(X) & \xrightarrow{h} & X \\
\end{array}
\]

\[
\begin{array}{ccc}
P_1 + \alpha P_2 & & \delta_{h(P_1)} + \alpha \delta_{h(P_2)} \\
\alpha \delta_{P_1} + \beta \delta_{P_2} & \xrightarrow{\delta_{h(P_1)} + \alpha \delta_{h(P_2)}} & \delta_{h(P_1)} + \alpha \delta_{h(P_2)} \\
\end{array}
\]

By the definition of the convex structure on \( X_h \), the right hand term in the equality expression in the lower right is \( h(\delta_{h(P_1)} + \alpha \delta_{h(P_2)}) = h(P_1) + \alpha h(P_2) \), from which we conclude \( \hat{h} \) is affine.

The property that \( \hat{h} \) factors through \( \epsilon_{X_h} \) follows using the adjunction \( \mathcal{P} \dashv \Sigma \). The map \( \epsilon_{X_h} \) is a universal arrow from the functor \( \mathcal{P} \) to the object \( X_h \), and hence the affine map \( \hat{h} \) factors uniquely through \( \epsilon_{X_h} \),

\[
\begin{array}{ccc}
(X, \Sigma_{X_h}) & \xrightarrow{\mathcal{P}(\Sigma X_h)} & X_h \\
\downarrow \epsilon_{X_h} & & \downarrow \hat{h} \\
(X, \mathcal{X}) & \xrightarrow{\mathcal{P}((X, \mathcal{X}))} & X_h \\
\end{array}
\]

in Meas \quad \text{in Cvx}

where, in the left hand diagram, we have used the fact \( \Sigma X_h = (|X_h|, \Sigma_{X_h}) = (X, \Sigma_{X_h}) \). The adjunct to the affine map \( \hat{h} \) is the “inclusion” map \( \iota(x) = x \) because \( \epsilon_{X_h}(\delta_x) = x \), and \( h \) is a \( \mathcal{G} \)-algebra so that \( h(\delta_x) = x \), and hence \( \hat{h}(\delta_x) = x \).
Since the adjunct to the affine map \( \hat{h} \) is the inclusion map \((X, \mathcal{X}) \hookrightarrow (X, \Sigma_{X_h})\), we can restate the property that \( \hat{h} \) factors through \( \epsilon_{X_h} \) as

**Corollary 11.5.** If \( \mathcal{G}(X) \xrightarrow{h} X \) is a \( \mathcal{G} \)-algebra then \( \mathcal{X} \subseteq \Sigma_{X_h} \).

**Corollary 11.6.** If \( \mathcal{G}(X) \xrightarrow{h} X \) is a \( \mathcal{G} \)-algebra then, up to an isomorphism, \( h \) is the pullback of \( \Sigma\epsilon_{X_h} \) along the inclusion map \((X, \mathcal{X}) \hookrightarrow \Sigma_{X_h}\).

Proof. The pullback of \( \Sigma\epsilon_{X_h} \) along the inclusion map \( X \hookrightarrow \Sigma_{X_h} \) gives the pullback square in the above \text{Meas}-diagram. By Lemma 11.4 it follows that \( \Sigma\epsilon_{X_h} \circ \mathcal{G} \iota = \Sigma\hat{h}, \) and hence (pointwise) we have \( \iota \circ h = \Sigma\epsilon_{X_h} \circ \mathcal{G} \iota \). Hence \( h \) is, up to isomorphism, the pullback of \( \Sigma\epsilon_{X_h} \) along \( \iota \). \(\square\)

We now proceed to give an alternative characterization of the category \text{Meas}^G.

Let \textbf{CM} denote the category of convex measurable spaces with the objects \((A, \mathcal{A})\) consisting of a convex spaces \( A \) with a \( \sigma \)-algebra structure \( \mathcal{A} \) on the underlying set of \( A \). The arrows in this category, \((A, \mathcal{A}) \xrightarrow{f} (B, \mathcal{B})\) are functions which are affine maps with respect to the convex structure, and also a measurable map with respect to the given \( \sigma \)-algebras. The objects \((A, \mathcal{A})\) in \textbf{CM} satisfying the additional property that \( \mathcal{A} \) is a sub \( \sigma \)-algebra of \( \Sigma_A \), the \( \sigma \)-algebra determined by the functor \( \Sigma \), are called tame convex measurable spaces. The full subcategory of \textbf{CM} consisting of all the tame objects, called the category of tame convex measurable spaces, is denoted \textbf{tCM}.

There is a functor \( \text{Meas}^G \xrightarrow{\Psi} \textbf{tCM} \) mapping a \( \mathcal{G} \)-algebra \( \mathcal{G}(X) \xrightarrow{h} X \) to \((X_h, \mathcal{X})\), where \( \mathcal{X} \) is the given \( \sigma \)-algebra associated with the measurable space \( X \). By Corollary 11.6 the object \((X_h, \mathcal{X})\) is a tame convex measurable space. The functor \( \Psi \) maps a morphism of \( \mathcal{G} \)-algebras, say

\[
\begin{align*}
\mathcal{G}(X) \xrightarrow{Gf} \mathcal{G}(Y) \\
\downarrow h \quad \quad \quad \quad \downarrow g \\
X \xrightarrow{f} Y
\end{align*}
\]
to the function \( f \) which is affine with respect to the underlying convex structures, \( X_h \) and \( Y_g \), of \( X \) and \( Y \) respectively, since
\[
\begin{align*}
f(x_1 + \alpha x_2) &= f \circ h(\delta_{x_1} + \alpha \delta_{x_2}) \\
&= (g \circ Gf)(\delta_{x_1} + \alpha \delta_{x_2}) \\
&= g((\delta_{x_1} + \alpha \delta_{x_2}) \circ f^{-1}) \\
&= g(\delta_{f(x_1)} + \alpha \delta_{f(x_2)}) \\
&= f(x_1) + \alpha f(x_2)
\end{align*}
\]

The function \( f \) is also measurable since it is a morphism of \( G \)-algebras.

There is also a functor \( tCM \to \text{Meas} G \) defined on the objects by the mapping
\[
G(\langle |A|, A \rangle) \quad (A, A) \quad \epsilon_A \quad \epsilon_A \quad (\langle |A|, A \rangle)
\]
where \( \epsilon_A \) is the \( \text{Meas} \)-pullback of \( \Sigma \epsilon_A \) along the inclusion map \( (|A|, A) \hookrightarrow \Sigma A \). By Corollary 11.2, \( \epsilon_A \) is a \( G \)-algebra.

On arrows the functor \( \Phi \) is specified by mapping \( (A, A) \overset{f}{\to} (B, B) \) to the map of \( G \)-algebras
\[
\begin{array}{ccc}
G(\langle |A|, A \rangle) & \xrightarrow{Gf} & G(\langle |B|, B \rangle) \\
\epsilon_A & \downarrow & \epsilon_B \\
(\langle |A|, A \rangle) & \xrightarrow{f} & (\langle |B|, B \rangle)
\end{array}
\]

by viewing \( f \) as just a measurable function.

**Theorem 11.7.** The pair of functors \( \Phi \) and \( \Psi \)
\[
tCM \xrightarrow{\Phi} \text{Meas} G
\]
specify an equivalence between the two categories.

**Proof.** Let us first show that \( \Psi \circ \Phi \cong id_{tCM} \). On objects,
\[
(\Psi \circ \Phi)(A, A) = \Psi \left( G(\langle |A|, A \rangle) \right) = (\langle |A|, A \rangle_{\epsilon_A}, A)
\]
where \( \langle |A|, A \rangle_{\epsilon_A} = A \) follows from the definition of the convex structure on \( \langle |A|, A \rangle_{\epsilon_A} \), given by \( a_1 + \alpha a_2 = \epsilon_A(\delta_{a_1} + \alpha \delta_{a_2}) \), and the fact that \( \epsilon_A \) is, up to an isomorphism, just the pullback of \( \epsilon_A \) along the inclusion map \( (|A|, A) \hookrightarrow \Sigma A \). Hence \( \epsilon_A(\delta_{a_1} + \alpha \delta_{a_2}) = a_1 + \alpha a_2 \), as computed in \( A \).

On arrows the result \( (\Psi \circ \Phi)(f) = f \) is immediate since the arrows in \( tCM \) are affine measurable functions, and \( \Psi \) is a functor, i.e., \( \Psi(f) = f \) is an affine measurable map.
Let us now show that $\Phi \circ \Psi \cong id_{\text{Meas}^G}$. On objects we have

$$(\Phi \circ \Psi)((X, \mathcal{X})) \left( \int h \right) = \Phi((X_h, \mathcal{X}')) = \left( \int \epsilon_{X_h} \right) \cong \left( \int h \right)$$

On arrows, if $f$ is a morphism of $\mathcal{G}$-algebras as shown in expression 3, the result $\Phi \circ \Psi(f) = f$ is immediate because $\Psi(f)$ is the affine measurable map $(X_h, \mathcal{X}) \xrightarrow{f} (Y_g, \mathcal{Y})$, and applying $\Phi$ to this map just gives back the original morphism of $\mathcal{G}$-algebras. \hfill \square
