

SOME PROPERTIES OF ACCRETIVE OPERATORS IN LINEAR 2-NORMED SPACES

P.K. HARIKRISHNAN AND K.T. RAVINDRAN

ABSTRACT. In this paper we discuss some properties of resolvents of an accretive operator in linear 2-normed spaces, focusing on the concept of contraction mapping and the unique fixed point of contraction mappings in linear 2-normed spaces. Also, we establish the existence of solution of strong accretive operator equation in linear 2-normed spaces.

1. INTRODUCTION

The concept of 2- metric spaces, linear 2- normed spaces and 2-inner product spaces , introduced by S Gahler in 1963 , paved the way for a number of authors like, A White, Y J Cho, R Freese, C R Diminnie, to do work on possible applications of Metric geometry, Functional Analysis and Topology as a new tool. A systematic presentation of the recent results related to the Geometry of linear 2-normed spaces as well as an extensive list of the related references can be found in the book [1]. In [4] S Gahler introduced the following definition of linear 2-normed spaces. The study of accretive operators in various spaces has been done by the authors T Kato[6], Shih-sen Chang, Yeol Je Cho, Shin Min Kang [5]..

2. PRELIMINARIES

Definition 2.1 (4). Let X be a real linear space of dimension greater than 1 and $\|.,.\|$ be a real valued function on $X \times X$ satisfying the properties,

A1: $\|x, y\| = 0$ iff x and y are linearly dependent

A2: $\|x, y\| = \|y, x\|$

A3: $\|\alpha x, y\| = |\alpha| \|y, x\|$

A4: $\|x + y, z\| \leq \|x, z\| + \|y, z\|$

then the function $\|.,.\|$ is called a 2-norm on X . The pair $(X, \|.,.\|)$ is called a linear 2- normed space.

Some of the basic properties of 2-norms, they are non-negative and $\|x, y + \alpha x\| = \|x, y\| \forall x, y \in X$ and $\alpha \in \mathbb{R}$.

The most standard example for a linear 2 - normed space is $X = \mathbb{R}^2$ equipped with the following 2-norm,

$$\|x_1, x_2\| = \text{abs det} \begin{pmatrix} x_{11} & x_{12} \\ x_{21} & x_{22} \end{pmatrix} \text{ where } x_i = (x_{i1}, x_{i2}) \text{ for } i=1,2$$

Every linear 2-normed space is a locally convex TVS. In fact, for a fixed $b \in X$, $P_b(x) = \|x, b\|$ for $x \in X$ is a semi norm and the family $\{P_b; b \in X\}$ of semi norms generates a locally convex topology on X .

Definition 2.2 (1). Let $(X, \|.,.\|)$ be a linear 2- normed space, E be a subset of X then the closure of E is $\overline{E} = \{x \in X; \text{ there is a sequence } x_n \text{ of } E \text{ such that } x_n \rightarrow x\}$. We say, E is sequentially closed if $E = \overline{E}$.

2000 *Mathematics Subject Classification.* 41A65, 41A15.

Key words and phrases. Linear 2-normed spaces, sequentially closed, accretive operators, m-accretive operator, fixed point, sequentially continuous .

Definition 2.3 (1). Let $(X, \|\cdot, \cdot\|)$ be a linear 2- normed space, then the mapping $T : X \rightarrow X$ is said to be sequentially continuous if $x_n \rightarrow x$ implies $Tx_n \rightarrow Tx$.

Definition 2.4 (3). An operator $T : D(T) \subset X \rightarrow X$ is said to be accretive if for every $z \in D(T)$

$$\|x - y, z\| \leq \|(x - y) + \lambda(Tx - Ty), z\| \text{ for all } x, y \in D(T) \text{ and } \lambda > 0.$$

Definition 2.5 (3). An operator $T : D(T) \subset X \rightarrow X$ is said to be m-accretive if $R(I + \lambda T) = X$ for $\lambda > 0$.

Remark 2.6 (4). Every closed subset of a 2-Banach space is complete.

3. MAIN RESULTS

Consider an accretive operator $T : D(T) \subset X \rightarrow X$ then for $\lambda > 0$, $(I + \lambda T)^{-1}$ exists. We have, $T : D(T) \rightarrow R(T)$ then $(I + \lambda T)$ is onto. Let $x_1, x_2 \in D(T)$ with $(I + \lambda T)x_1 = (I + \lambda T)x_2$ implies $(x_1 - x_2) + \lambda(Tx_1 - Tx_2) = 0$ implies $\|(x_1 - x_2) + \lambda(Tx_1 - Tx_2), z\| = 0$ for every $z \in X$. Since T is accretive, we have $\|x_1 - x_2, z\| \leq 0$ for every $z \in X$ implies $\|x_1 - x_2, z\| = 0$ for every $z \in X$ implies $x_1 - x_2 = 0$ implies $x_1 = x_2$. So $(I + \lambda T)$ is one-one. Hence for $\lambda > 0$, $(I + \lambda T)^{-1}$ exist.

Definition 3.1. Let $(X, \|\cdot, \cdot\|)$ be a linear 2- normed space then an operator T on X is said to be non expansive if for each $x, y \in D(T)$, $\|Tx - Ty, z\| \leq \|x - y, z\|$ for every $z \in X$. T is said to be expansive if for each $x, y \in D(T)$, $\|Tx - Ty, z\| > \|x - y, z\|$ for every $z \in X$.

Proposition 3.2. Let $(X, \|\cdot, \cdot\|)$ be a linear 2- normed space and $T : D(T) \subset X \rightarrow X$ be an operator. If $(I + \lambda T)$ is expansive for all $\lambda > 0$ then T is accretive.

Proof: The proof is immediate from the definition 3.1.

Remark 3.3. If T is an accretive operator on a 2-normed space X then $(I + \lambda T)^{-1}$ is non expansive.

Definition 3.4. Let $(X, \|\cdot, \cdot\|)$ be a linear 2- normed space E be a non empty subset of X and $e \in E$ then E is said to be e-bounded if there exists some $M > 0$ such that $\|x, e\| \leq M$ for all $x \in E$. If for all $e \in E$, E is e-bounded then E is called a bounded set.

Let $(X, \|\cdot, \cdot\|)$ be a linear 2- normed space and T be an m-accretive operator on X . For $n=1,2,3,\dots$, Define the resolvent of T as, $J_n(x) = (I + n^{-1}T)^{-1}(x)$ and the Yosida approximation $T_n(x) = n(I - J_n)(x)$ for all $x \in X$ and $\lambda > 0$.

Proposition 3.5. Let $(X, \|\cdot, \cdot\|)$ be a linear 2- normed space and T be a m-operator then

- (i) $\|J_n x - J_n y, z\| \leq \|(x - y), z\|$
- (ii) $\|T_n x - T_n y, z\| \leq 2n\|(x - y), z\|$ for all $x, y \in X$

Proof:

(i) Since T is accretive in X , we have $(I + \alpha T)^{-1}$ is non expansive implies for each $x, y \in D(T)$, $\|(I + \alpha T)^{-1}x - (I + \alpha T)^{-1}y, z\| \leq \|x - y, z\|$ for every $z \in X$

Take $\alpha = 1/n$ then $\alpha > 0$. So $\|J_n x - J_n y, z\| \leq \|(x - y), z\|$.

(ii) We have for each $x, y \in D(T)$,

$$\begin{aligned} \|T_n x - T_n y, z\| &= \|n(I - J_n)x - n(I - J_n)y, z\| \\ &= \|n(x - y) + n(J_n x - J_n y), z\| \\ &\leq n\|x - y, z\| + n\|J_n x - J_n y, z\| \\ &\leq n\|x - y, z\| + n\|x - y, z\| \\ &= 2n\|x - y, z\| \end{aligned}$$

for all $z \in X$

Proposition 3.6. Let $(X, \|\cdot, \cdot\|)$ be a linear 2- normed space and E be a non empty bounded subset of X and $T : E \rightarrow E$ be an accretive operator then there exists some $M > 0$ and for $x \in E$, $\|T_n x, z\| \leq M$ for all $z \in E$.

Proof: Let $x \in E$ then

$$T_n x = n(x - J_n x) = n(J_n(J_n^{-1}x) - J_n x) = n(J_n(I + n^{-1}T)x - J_n x)$$

So, by Proposition 3.5 (i);

$$\|T_n x, z\| = \|n(J_n(I + n^{-1}T)x - J_n x), z\| \leq n\|(I + n^{-1}T)x - x, z\| = \|Tx, z\| \leq M$$

for all $z \in E$

Proposition 3.7. Let $(X, \|\cdot, \cdot\|)$ be a linear 2- normed space and E be a non empty bounded subset of X and $T : E \rightarrow E$ be an accretive operator . If $x \in \overline{E}$ then $J_n x \rightarrow x$.

Proof: Let $x \in E$ then $\|x - J_n x, z\| = n^{-1}\|T_n x, z\| \leq n^{-1}M$ for some $M > 0$ and for all $z \in E$.

ie; $\|x - J_n x, z\| \rightarrow 0$ as $n \rightarrow \infty$ implies $J_n x \rightarrow x$

If $x \in \overline{E}$ then there exists a sequence $\{x_m\} \in E$ such that $x_m \rightarrow x$. Since $x_m \in E$ we have $J_n(x_m) \rightarrow x_m$.

We have, for all $z \in E$

$$\begin{aligned} \|J_n x - x, z\| &= \|J_n x - J_n(x_m) + J_n(x_m) - x_m + x_m - x, z\| \\ &\leq \|J_n x - J_n(x_m), z\| + \|J_n(x_m) - x_m, z\| + \|x_m - x, z\| \\ &\leq \|x - x_m, z\| + \|J_n(x_m) - x_m, z\| + \|x_m - x, z\| \rightarrow 0 \text{ as } n \rightarrow \infty \end{aligned}$$

Hence $J_n x \rightarrow x$.

Definition 3.8. Let $(X, \|\cdot, \cdot\|)$ be a linear 2- normed space then the mapping $T : X \rightarrow X$ is said to be a contraction if there exists some $k \in (0, 1)$ such that $\|Tx - Ty, z\| \leq k\|x - y, z\|$ for all $x, y, z \in X$.

Lemma 3.9. Let $(X, \|\cdot, \cdot\|)$ be a linear 2- normed space then every contraction $T : X \rightarrow X$ is sequentially continuous.

Proof: Since T is a contraction, there exists some $k \in (0, 1)$ such that $\|Tx - Ty, z\| \leq k\|x - y, z\|$ for all $x, y, z \in X$.

Let $\{x_n\}$ be a sequence in X such that $x_n \rightarrow x$.

Then, $\|Tx_n - Tx, z\| \leq k\|x_n - x, z\| \rightarrow 0$ as $n \rightarrow \infty$ implies $Tx_n \rightarrow Tx$. So T is sequentially continuous.

Next lemma proves the analogues of Banach fixed point theorem in Linear 2-normed spaces.

Lemma 3.10. Let $(X, \|\cdot, \cdot\|)$ be a linear 2- normed space and E be a non empty closed and bounded subset of X . Let $T : E \rightarrow E$ be a contraction then T has a unique fixed point on X .

Proof: Since T is a contraction, there exists some $k \in (0, 1)$ such that

$$\|Tx - Ty, z\| \leq k\|x - y, z\| \text{ for all } x, y, z \in X.$$

We have, $\|T^2 x - T^2 y, z\| = \|T(Tx) - T(Ty), z\| \leq k\|Tx - Ty, z\| \leq k^2\|x - y, z\|$ for all $z \in E$. Similarly $\|T^n x - T^n y, z\| \leq k^n\|x - y, z\|$ for all $z \in E$.

Let $x_0 \in E$ then construct a sequence depending on x_0 .

Let $x_1 = Tx_0, x_2 = Tx_1, x_3 = Tx_2, \dots, x_n = Tx_{n-1}$ then $x_1 = Tx_0, x_2 = T^2 x_0, x_3 = T^3 x_0, \dots, x_n = T^n x_0$.

We show that $\{x_n\}$ is a Cauchy sequence in E . Let $m, n > 0$ with $m > n$. Take $m = n + p$ then for any $z \in E$,

$$\|x_n - x_m, z\| = \|x_n - x_{n+p}, z\|$$

$$\begin{aligned}
&= \|(x_n - x_{n+1}) + (x_{n+1} - x_{n+2}) + x_{n+2} - \dots + (x_{n+p-1} - x_{n+p}), z\| \\
&\leq \|x_n - x_{n+1}, z\| + \|x_{n+1} - x_{n+2}, z\| + \dots + \|x_{n+p-1} - x_{n+p}, z\| \\
&= \|T^n x_0 - T^n x_1, z\| + \|T^{n+1} x_0 - T^{n+1} x_1, z\| + \dots + \|T^{n+p-1} x_0 - T^{n+p-1} x_1, z\| \\
&\leq k^n \|x_0 - x_1, z\| + k^{n+1} \|x_0 - x_1, z\| + \dots + k^{n+p-1} \|x_0 - x_1, z\| \\
&\leq k^n \|x_0 - x_1, z\| (1 + k + k^2 + \dots) = \left(\frac{k^n}{1-k}\right) \|x_0 - x_1, z\|
\end{aligned}$$

1e; $\|x_n - x_m, z\| \leq \left(\frac{k^n}{1-k}\right) \|x_0 - x_1, z\|$ for all $z \in E$

Since E is bounded, there exists $M > 0$ such that $\|x_0 - x_1, z\| \leq M$ for all $z \in E$

So, $\|x_n - x_m, z\| \leq \left(\frac{k^n M}{1-k}\right)$ for all $z \in E$ implies $\|x_n - x_m, z\| \rightarrow 0$ as $n \rightarrow \infty$, since $k \in (0, 1)$ implies $\{x_n\}$ is a cauchy sequence in E, So $\{x_n\}$ converges to some x in E.

Since T is sequentially continuous, $Tx = \lim T x_n = \lim x_{n+1} = x$ as $n \rightarrow \infty$. Therefore T has a fixed point in E.

Now, we have to prove that such a fixed point is unique.

Let $y \in E$ with $y \neq x$ and $Ty \neq y$.

Assume that $Ty = y$ then $\|x - y, z\| = \|Tx - Ty, z\| \leq k \|x - y, z\|$ implies $k \geq 1$, a contradiction to $k \in (0, 1)$. So, $Ty \neq y$. Hence the fixed point of T is unique in E.

Definition 3.11. Let $(X, \|\cdot, \cdot\|)$ be a linear 2- normed space then the mapping $T : X \rightarrow X$ is said to be strong accretive if for every $z \in X$

$$\|(\lambda - k)(x - y), z\| \leq \|(\lambda - 1)(x - y) + (Tx - Ty), z\|$$

for all $x, y \in X$ and $\lambda > k$, and $k \in (0, 1)$.

Theorem 3.12. Let $(X, \|\cdot, \cdot\|)$ be a linear 2- normed space and E be a non empty closed and bounded subset of X. Let $T : E \rightarrow X$ be a strong accretive mapping. If $(I + T)(E) \supset E$ then the equation $Tx = \theta$ has a solution in E, where θ is the zero vector in X.

Proof: Since T is strong accretive implies

$$\|(\lambda - k)(x - y), z\| \leq \|(\lambda - 1)(x - y) + (Tx - Ty), z\|$$

for all $x, y \in X$ and $\lambda > k$, and $k \in (0, 1)$

Put $\lambda = 2$ then $\|(2 - k)(x - y), z\| \leq \|(x - y) + (Tx - Ty), z\|$

implies $|2 - k| \|(x - y), z\| \leq \|(I + T)(x) - (I + T)(y), z\|$

implies $\|(x - y), z\| \leq \frac{\|(I + T)(x) - (I + T)(y), z\|}{|2 - k|}$

Since $(I + T)(E) \supset E$ we get,

$x, y \in D[(I + T)^{-1}]$ implies $x = (I + T)^{-1}(u)$ and $y = (I + T)^{-1}(v)$ for some $u, v \in E$

So, $\|(I + T)^{-1}(u) - (I + T)^{-1}(v), z\| \leq \frac{\|u - v, z\|}{|2 - k|}$

ie; $(I + T)^{-1} : E \rightarrow E$ is a contraction mapping. By the Lemma 3.10 $(I + T)^{-1}$ has a fixed point x_0 in E. ie; $x_0 = (I + T)^{-1}(x_0)$ implies $x_0 = (I + T)(x_0)$ implies $Tx_0 = \theta$.

Hence, the equation $Tx = \theta$ has a solution in E.

Corollary 3.13. Let $(X, \|\cdot, \cdot\|)$ be a linear 2- normed space and E be a non empty closed and bounded subset of X. Let $T : E \rightarrow E$ be a strong accretive mapping. If $(I + T)(E) = E$ then $R(T) = E$.

Proof:

For any $p \in E$. Take $T_0 = T - p$

Since T is strong accretive we have,

$\|(\lambda - k)(x - y), z\| \leq \|(\lambda - 1)(x - y) + (Tx - Ty), z\|$ for all $x, y \in X$ and $\lambda > k$, and $k \in (0, 1)$

We have, T_0 is also strong accretive.

Therefore, by theorem 3.12, there exists $x_0 \in E$ such that $T_0(x_0) = \theta$ implies $Tx_0 - p = \theta$ implies $Tx_0 = p$ for every $p \in E$. Therefore, $R(T) = E$.
