ININCIDENCE RESULTS AND BOUNDS OF TRILINEAR AND QUADRILINEAR EXPONENTIAL SUMS

SIMON MACOURT

Abstract. We give a new bound on the number of collinear triples for two arbitrary subsets of a finite field. This improves on existing results which rely on the Cauchy inequality. We then use this to provide a new bound on trilinear and quadrilinear exponential sums.

1. Introduction

1.1. Set Up. For a prime $p$, we define $\mathbb{F}_p$ to be the finite field of $p$ elements. We also let $\mathbb{F}_p^* = \mathbb{F}_p/\{0\}$. We define the line

$$\ell_{a,b} = \{(x, y) \in \mathbb{F}_p^2 : y = ax + b\}$$

for some $(a, b) \in \mathbb{F}_p^2$. We let $\mathcal{A}, \mathcal{B} \subseteq \mathbb{F}_p$, with $|\mathcal{A}| = A$, $|\mathcal{B}| = B$ and $A \leq B$. We also define the number of incidences of any line with $\mathcal{A} \times \mathcal{B}$ to be

$$\iota_{\mathcal{A} \times \mathcal{B}}(\ell_{a,b}) = |\{(\mathcal{A} \times \mathcal{B}) \cap \ell_{a,b}\}|.$$ 

Furthermore for $\lambda, \mu \in \mathbb{F}_p^*$, we define the number of collinear triples $T_{\lambda, \mu}(\mathcal{A}, \mathcal{B})$ to be the number of solutions to

$$(a_1 - \lambda a_2)(b_1 - \mu b_2) = (a_1 - \lambda a_3)(b_1 - \mu b_3), \quad a_i \in \mathcal{A}, b_i \in \mathcal{B}, i = 1, 2, 3.$$ 

We define $T_{1,1}(\mathcal{A}, \mathcal{B}) = T(\mathcal{A}, \mathcal{B})$ and for $\mathcal{A} = \mathcal{B}$ we define $T(\mathcal{A}, \mathcal{A}) = T(\mathcal{A})$.

We also define the weighted trilinear exponential sums over sets $\mathcal{X}, \mathcal{Y}, \mathcal{Z} \subset \mathbb{F}_p$

$$T(\mathcal{X}, \mathcal{Y}, \mathcal{Z}; \rho, \sigma, \tau) = \sum_{x \in \mathcal{X}} \sum_{y \in \mathcal{Y}} \sum_{z \in \mathcal{Z}} \rho_{x,y} \sigma_{x,z} \tau_{y,z} e_p(axyz),$$

where $a \in \mathbb{F}_p^*$ and $\rho_{x,y}, \sigma_{x,z}, \tau_{y,z}$ are 2-dimensional weights that are bounded by 1.

2010 Mathematics Subject Classification. 11L07, 11T23.

Key words and phrases. exponential sum.
Similarly, we define the weighted quadrilinear exponential sums over sets \( W, X, Y, Z \subseteq \mathbb{F}_p \)

\[
T(W, X, Y, Z; \vartheta, \rho, \sigma, \tau) = \sum_{w \in W} \sum_{x \in X} \sum_{y \in Y} \sum_{z \in Z} \vartheta_{w, y, z} \rho_{w, z} \sigma_{w, y, z} \tau_{x, y, z} e_p(awxyz),
\]

where \( a \in \mathbb{F}_p^* \) and \( \vartheta_{w, y, z}, \rho_{w, z}, \sigma_{w, y, z}, \tau_{x, y, z} \) are 3-dimensional weights that are bounded by 1.

Throughout the paper we use the notation \( A \ll B \) to indicate \( |A| \leq c|B| \) for some absolute constant \( c \).

1.2. New Results. Our main result is the following theorem on the number of collinear triples.

**Theorem 1.1.** Let \( A, B \subseteq \mathbb{F}_p \) with \( |A| = A = |B| = B \) and \( \lambda, \mu \in \mathbb{F}_p^* \).

Then

\[
T_{\lambda, \mu}(A, B) = \frac{A^3 B^3}{p} \ll p^{1/2} A^2 B^{3/2} + AB^3.
\]

Using Lemma 2.6, which comes as a consequence of Theorem 1.1, we provide the following new bounds on trilinear and quadrilinear exponential sums.

**Theorem 1.2.** Let \( X, Y, Z \subseteq \mathbb{F}_p \) with \( |X| = X, |Y| = Y, |Z| = Z \), and \( X \geq Y \geq Z \). Then,

\[
T(X, Y, Z; \rho, \sigma, \tau) \ll p^{3/16} X^{13/16} Y^{7/8} Z^{7/8}.
\]

We compare the above the result with previous bounds in the following section. As an example, in the special case where \( X = Y = Z \) the bound from Theorem 1.2 is stronger than previous results for \( p^{1/2} < X < p^{5/9} \).

**Theorem 1.3.** Let \( W, X, Y, Z \subseteq \mathbb{F}_p^* \) with \( |W| = W, |X| = X, |Y| = Y, |Z| = Z \) and \( W \geq X \geq Y \geq Z \). Then,

\[
T(W, X, Y, Z; \vartheta, \rho, \sigma, \tau) \ll p^{3/32} W^{29/32} X^{15/16} Y^{15/16} Z^{31/32}.
\]

Again, we give an example of when our bound is non-trivial by considering the special case \( W = X = Y = Z \) and note that the bound from Theorem 1.3 is stronger than all existing bounds for \( p^{1/2} < W < p^{13/24} \).
1.3. **Previous Results.** Recent results on $T(\mathcal{A}, \mathcal{B})$ have been given by using the Cauchy inequality on bounds for $T(\mathcal{A})$. For this reason previous bounds for $T(\mathcal{A}, \mathcal{B})$ are symmetric. We compare our result with that of Aksoy Yazici, Murphy, Rudnev and Shkredov [1, Proposition 5]

$$T(\mathcal{A}) \ll \frac{A^6}{p} + A^{9/2}$$

hence, by the Cauchy inequality,

$$T(\mathcal{A}, \mathcal{B}) \ll \left( \frac{A^3}{p^{1/2}} + A^{9/4} \right) \left( \frac{B^3}{p^{1/2}} + B^{9/4} \right) + AB^3.$$

We see that for $A = B$ our new bound is stronger for $A > p^{1/2}$. More generally, our new bound is stronger when $AB^3 > p^2$. We also compare our result to that of Murphy, Petridis, Roche-Newton, Rudnev and Shkredov [8, Theorem 10]

$$T(\mathcal{A}) \ll \frac{A^6}{p} + A^{7/2}p^{1/2}$$

hence, by the Cauchy inequality,

$$T(\mathcal{A}, \mathcal{B}) \ll \left( \frac{A^3}{p^{1/2}} + A^{7/4}p^{1/4} \right) \left( \frac{B^3}{p^{1/2}} + B^{7/4}p^{1/4} \right) + AB^3.$$  

We see that our bound is equal to the above result for $A = B$, and stronger otherwise. We also mention that [7] gives a bound on collinear triples over subgroups.

Trilinear sums have been estimated by Bourgain and Garaev [4]. Variations and improvements have been made since, see [2, 3, 5, 6, 9]. More recently Petridis and Shparlinski [10] have given new bounds on weighted trilinear and quadrilinear exponential sums. We compare our bound on trilinear sums to [10, Theorem 1.3]

$$T(\mathcal{X}, \mathcal{Y}, \mathcal{Z}; \rho, \sigma, \tau) \ll p^{1/8}X^{7/8}Y^{29/32}Z^{29/32}.$$  

We see that our new bound, Theorem 1.2, improves that of Petridis and Shparlinski [10] for $XY^{1/2}Z^{1/2} \geq p$. Our bound from Theorem 1.2 is stronger than that of the triangle inequality

$$T(\mathcal{X}, \mathcal{Y}, \mathcal{Z}; \rho, \sigma, \tau) \ll XYZ$$

for $XY^{2/3}Z^{2/3} > p$. Similarly, it is stronger than the classical bound on bilinear sums, from Lemma 3.1,

$$T(\mathcal{X}, \mathcal{Y}, \mathcal{Z}; \rho, \sigma, \tau) \ll p^{1/2}X^{1/2}Y^{1/2}Z$$

for $XY^{6/5}Z^{-2/5} \leq p$. Letting $X = Y = Z$ we see that under these conditions Theorem 1.2 is stronger than previous bounds for $p^{1/2} < 1.3. **Previous Results.** Recent results on $T(\mathcal{A}, \mathcal{B})$ have been given by using the Cauchy inequality on bounds for $T(\mathcal{A})$. For this reason previous bounds for $T(\mathcal{A}, \mathcal{B})$ are symmetric. We compare our result with that of Aksoy Yazici, Murphy, Rudnev and Shkredov [1, Proposition 5]

$$T(\mathcal{A}) \ll \frac{A^6}{p} + A^{9/2}$$

hence, by the Cauchy inequality,

$$T(\mathcal{A}, \mathcal{B}) \ll \left( \frac{A^3}{p^{1/2}} + A^{9/4} \right) \left( \frac{B^3}{p^{1/2}} + B^{9/4} \right) + AB^3.$$

We see that for $A = B$ our new bound is stronger for $A > p^{1/2}$. More generally, our new bound is stronger when $AB^3 > p^2$. We also compare our result to that of Murphy, Petridis, Roche-Newton, Rudnev and Shkredov [8, Theorem 10]

$$T(\mathcal{A}) \ll \frac{A^6}{p} + A^{7/2}p^{1/2}$$

hence, by the Cauchy inequality,

$$T(\mathcal{A}, \mathcal{B}) \ll \left( \frac{A^3}{p^{1/2}} + A^{7/4}p^{1/4} \right) \left( \frac{B^3}{p^{1/2}} + B^{7/4}p^{1/4} \right) + AB^3.$$  

We see that our bound is equal to the above result for $A = B$, and stronger otherwise. We also mention that [7] gives a bound on collinear triples over subgroups.

Trilinear sums have been estimated by Bourgain and Garaev [4]. Variations and improvements have been made since, see [2, 3, 5, 6, 9]. More recently Petridis and Shparlinski [10] have given new bounds on weighted trilinear and quadrilinear exponential sums. We compare our bound on trilinear sums to [10, Theorem 1.3]

$$T(\mathcal{X}, \mathcal{Y}, \mathcal{Z}; \rho, \sigma, \tau) \ll p^{1/8}X^{7/8}Y^{29/32}Z^{29/32}.$$  

We see that our new bound, Theorem 1.2, improves that of Petridis and Shparlinski [10] for $XY^{1/2}Z^{1/2} \geq p$. Our bound from Theorem 1.2 is stronger than that of the triangle inequality

$$T(\mathcal{X}, \mathcal{Y}, \mathcal{Z}; \rho, \sigma, \tau) \ll XYZ$$

for $XY^{2/3}Z^{2/3} > p$. Similarly, it is stronger than the classical bound on bilinear sums, from Lemma 3.1,

$$T(\mathcal{X}, \mathcal{Y}, \mathcal{Z}; \rho, \sigma, \tau) \ll p^{1/2}X^{1/2}Y^{1/2}Z$$

for $XY^{6/5}Z^{-2/5} \leq p$. Letting $X = Y = Z$ we see that under these conditions Theorem 1.2 is stronger than previous bounds for $p^{1/2} <
We give another example for when our bound is non-trivial. Setting $X = p^{2/3}, Y = Z = p^{2/5}$ we obtain from Theorem 1.2

$$T(X, Y, Z; \rho, \sigma, \tau) \ll p^{343/240} = XYZ^{-3/80}.$$

One can easily compare this with results from previous bounds and see our new bound is stronger. We also mention that our bound is strongest for $X$ much larger than $Y$. We finally mention the bound on unweighted trilinear sums due to Garaev [6]. We note that when our bound is stronger than that of Shparlinski and Petridis [10], it also outperforms that of Garaev [6].

Similarly, we compare our results on quadrilinear exponential sums to [10, Theorem 1.4]

\[(1.1) \quad T(W, X, Y, Z; \vartheta, \rho, \sigma, \tau) \ll p^{1/16}W^{15/16}(XY)^{61/64}Z^{31/32},\]

as well as that coming from the classical bound on bilinear sums,

\[(1.2) \quad T(W, X, Y, Z; \vartheta, \rho, \sigma, \tau) \ll p^{1/2}W^{1/2}X^{1/2}YZ.\]

For $W = X = Y = Z$ Theorem 1.3 is stronger than the classical bound and (1.1) for all $p^{1/2} < W < p^{13/24}$, in this range it is also stronger than the bound of Petridis and Shparlinski [10]. We give another example for when our bound is non-trivial. Setting $W = p^{2/3}, X = Y = Z = p^{3/8}$ we obtain from Theorem 1.3

$$T(W, X, Y, Z; \vartheta, \rho, \sigma, \tau) \ll p^{1355/768} = WXZ^{-7/256}.$$

We also mention that our bound is strongest for $W$ much larger than $X$.

2. Incidence Results

2.1. Preliminaries. In this section we use $\ell$ to indicate all possible lines.

We mention the following results.

**Lemma 2.1.** Let $A, B \in \mathbb{F}_p$ with $|A| = A, |B| = B$ and $\lambda, \mu \in \mathbb{F}_p^*$. Then

$$\sum_{\ell} t_{A \times B}(\ell_{a,b}) = \sum_{\ell} t_{A \times B}(\ell_{\lambda a, \mu b}) = pAB$$

and

$$\sum_{\ell} t_{A \times B}(\ell_{a,b})t_{A \times B}(\ell_{\lambda a, \mu b}) = A^2B^2 - AB^2 + pAB$$
Proof. The first result is clear since for each choice of \((x, y, u) \in \mathcal{A} \times \mathcal{B} \times \mathbb{F}_p\) there is a unique choice of \(v \in \mathbb{F}_p\). The second result we have

\[
\sum_{\ell} t_{\mathcal{A} \times \mathcal{B}}(\ell_{a,b}) t_{\mathcal{A} \times \mathcal{B}}(\ell_{\lambda a, \mu b})
\]

\[
= \sum_{(a_1, a_2, b_1, b_2) \in \mathcal{A}^2 \times \mathcal{B}^2} |\{(c, d) \in \mathbb{F}_p^2 : b_1 = ca_1 + d, b_2 = \lambda ca_2 + \mu d\}|.
\]

Now there are \(AB\) quadruples \((a_1, a_2, b_1, b_2) \in \mathcal{A}^2 \times \mathcal{B}^2\) with \((a_1, b_1) = (\lambda \mu^{-1} a_2, \mu^{-1} b_2)\) which define \(p\) pairs \((c, d) = (c, b_1 - ca_1)\). There are \(AB(B - 1)\) quadruples with \(b_1 \neq \mu^{-1} b_2\) and \(a_1 = \lambda \mu^{-1} a_2\) which do not define any pairs \((c, d)\), as they are parallel. The remaining

\[A^2B^2 - AB(B - 1) - AB = A^2B^2 - AB^2\]

quadruples define one pair \((c, d)\) each, as they are the non-parallel lines. \qed

We immediately have the following corollary.

**Corollary 2.2.** Let \(\mathcal{A}, \mathcal{B} \in \mathbb{F}_p\) with \(|\mathcal{A}| = A, |\mathcal{B}| = B\) and \(\lambda, \mu \in \mathbb{F}_p^*\). Then

\[
\sum_{\ell} \left( t_{\mathcal{A} \times \mathcal{B}}(\ell_{\lambda a, \mu b}) - \frac{AB}{p} \right)^2 \leq pAB.
\]

We need an analogue of [8, Lemma 9]. First we recall [8, Theorem 7].

**Lemma 2.3.** Let \(\mathcal{A}, \mathcal{B} \subset \mathbb{F}_p\) with \(|\mathcal{A}| = A \leq |\mathcal{B}| = B\) and let \(L\) be a collection of lines in \(\mathbb{F}_p^2\). Assume that \(A|L| \leq p^2\). Then the number of incidences \(I(P, L)\) between the point set \(P = \mathcal{A} \times \mathcal{B}\) and \(L\) is bounded by

\[
I(P, L) \ll A^{3/4}B^{1/2}|L|^{3/4} + |P| + |L|.
\]

We define \(L_{N_{\lambda, \mu}}\) to be the collection of lines that are incident to between \(N\) and \(2N\) points, that is

\[
L_{N_{\lambda, \mu}} = \{\ell_{\lambda a, \mu b} \in L : N < t_{\mathcal{A} \times \mathcal{B}}(\ell_{\lambda a, \mu b}) \leq 2N\}
\]

for \(\lambda, \mu \in \mathbb{F}_p^*\). We then have the following lemma.

**Lemma 2.4.** Let \(\mathcal{A}, \mathcal{B} \subset \mathbb{F}_p\) with \(|\mathcal{A}| = A \leq |\mathcal{B}| = B\), \(\lambda, \mu \in \mathbb{F}_p^*\) and let \(2AB/p \leq N \leq A\) be an integer greater than 1. Then

\[
|L_{N_{\lambda, \mu}}| \ll \min \left( \frac{pAB}{N^2}, \frac{A^3B^2}{N^4} \right).
\]
Proof. Since $\tau_{A \times B}(\ell_{\lambda_a,\mu_b}) \geq 2AB/p$, for $\tau_{A \times B}(\ell_{\lambda_a,\mu_b}) \in L_{N_{\lambda,\mu}}$, we have

$$\tau_{A \times B}(\ell_{\lambda_a,\mu_b}) - AB/p \geq AB/p \geq N/2.$$ 

Therefore, using Lemma 2.2,

$$\frac{N^2}{4} |L_{N_{\lambda,\mu}}| \leq \sum_{\tau_{A \times B}(\ell_{\lambda_a,\mu_b}) \in L_{N_{\lambda,\mu}}} (\tau_{A \times B}(\ell_{\lambda_a,\mu_b}) - AB/p)^2$$

(2.1)

$$\leq \sum_{\ell} (\tau_{A \times B}(\ell_{\lambda_a,\mu_b}) - AB/p)^2$$

$$\leq pAB.$$ 

Now suppose $2AB/p \leq N < 2AB^{1/2}/p^{1/2}$. From (2.1)

$$|L_{N_{\lambda,\mu}}| \leq \frac{pAB}{N^2} < \frac{pAB}{N^2} \times \frac{4A^2B}{N^2p} = \frac{4A^2B^2}{N^4}.$$ 

We now suppose $N \geq 2AB^{1/2}/p^{1/2}$. Now $N \geq 2AB/p$ hence by (2.1) $L_{N_{\lambda,\mu}} \leq 4pAB/N^2 \leq p^2/A$. We can now apply Lemma 2.3 to obtain

$$N|L_{N_{\lambda,\mu}}| \ll A^{3/4}B^{1/2}|L_{N_{\lambda,\mu}}|^{3/4} + AB + |L_{N_{\lambda,\mu}}|.$$ 

We now observe when each term dominates, omitting the last term as it gives $N \leq 1$, to get

$$|L_{N_{\lambda,\mu}}| \ll \frac{A^3B^2}{N^4} + \frac{AB}{N}.$$ 

We now recall $N \leq A$, hence

$$|L_{N_{\lambda,\mu}}| \ll \frac{A^3B^2}{N^4}.$$ 

This completes the proof. \hfill \Box

We now need the following lemma.

Lemma 2.5. For $A, B \subset \mathbb{F}_p$ with $|A| = A < |B| = B$ and $\lambda, \mu \in \mathbb{F}_p^*$,

$$\sum_{\ell} \tau_{A \times B}(\ell_{a,b}) \left( \tau_{A \times B}(\ell_{\lambda_a,\mu_b}) - \frac{AB}{p} \right)^2 \ll p^{1/2}A^2B^{3/2}.$$ 

Proof. We begin by splitting our sum over a parameter $\Delta$ which will be chosen later. We also observe that $\tau_{A \times B}(\ell_{\lambda_a,\mu_b}) \leq A$. We then find
a bound on
\[
\sum_{\ell_{A \times B}(\ell_{a,b}) \leq \Delta} \ell_{A \times B}(\ell_{a,b}) \left( \ell_{A \times B}(\ell_{\lambda a,\mu b}) - \frac{AB}{p} \right)^2
\]
\[
+ \sum_{\ell_{A \times B}(\ell_{a,b}) > \Delta, \ell_{A \times B}(\ell_{\lambda a,\mu b}) \leq \Delta} \ell_{A \times B}(\ell_{a,b}) \left( \ell_{A \times B}(\ell_{\lambda a,\mu b}) - \frac{AB}{p} \right)^2
\]
\[
+ \sum_{\ell_{A \times B}(\ell_{a,b}) > \Delta, \ell_{A \times B}(\ell_{\lambda a,\mu b}) > \Delta} \ell_{A \times B}(\ell_{a,b}) \left( \ell_{A \times B}(\ell_{\lambda a,\mu b}) - \frac{AB}{p} \right)^2 = I + II + III.
\]
By using Corollary 2.2 it is clear that \( I \leq \Delta pAB \). We also have
\[
II \leq \sum_{\ell_{A \times B}(\ell_{a,b}) > \Delta} \ell_{A \times B}(\ell_{a,b}) \left( \Delta - \frac{AB}{p} \right)^2.
\]
Using dyadic decomposition and Lemma 2.4 we obtain
\[
II \ll \left( \Delta - \frac{AB}{p} \right)^2 \sum_{k \geq 0} (2^k \Delta) |L_{2^k \Delta}|
\]
\[
\ll \left( \Delta - \frac{AB}{p} \right)^2 \sum_{k \geq 0} (2^k \Delta) \frac{A^3 B^2}{(\Delta 2^k)^4}
\]
\[
\ll \left( \Delta - \frac{AB}{p} \right)^2 \frac{A^3 B^2}{\Delta^3}.
\]
From (2.3), for \( \Delta > 2AB/p \), we have
\[
\sum_{\ell_{A \times B}(\ell_{a,b}) > 2AB/p} \ell_{A \times B}(\ell_{a,b}) \ell_{A \times B}(\ell_{\lambda a,\mu b})^2
\]
\[
\geq \sum_{\ell_{A \times B}(\ell_{a,b}) > 2AB/p} \ell_{A \times B}(\ell_{a,b}) \left( \ell_{A \times B}(\ell_{\lambda a,\mu b}) - \frac{AB}{p} \right)^2
\]
\[
+ \frac{3A^2 B^2}{p^2} \sum_{\ell_{A \times B}(\ell_{a,b}) > 2AB/p} \ell_{A \times B}(\ell_{a,b})
\]
\[
\geq \sum_{\ell_{A \times B}(\ell_{a,b}) > 2AB/p} \ell_{A \times B}(\ell_{a,b}) \left( \ell_{A \times B}(\ell_{\lambda a,\mu b}) - \frac{AB}{p} \right)^2 = III.
\]
We can now use dyadic decomposition and Lemma 2.4 to obtain
\[
\sum_{\substack{\ell_A \times B(\ell_{a,b}) \leq \Delta \\
\ell_A \times B(\ell_{a,b}) \leq \Delta}}\ell_A \times B(\ell_{a,b})^2 \cdot \ell_A \times B(\ell_{a,b})^2 \leq \sum_{k \geq 0} (2^k \Delta)^3 |L_{2^k \Delta}| \\
\leq \sum_{k \geq 0} (2^k \Delta)^3 \frac{A^3 B^2}{(\Delta 2^k)^4} \\
= \frac{A^3 B^2}{\Delta}.
\]

Therefore,
\[
\sum_{\ell} \ell_A \times B(\ell_{a,b}) \left( \ell_A \times B(\ell_{a,b}) - \frac{AB}{p} \right)^2 \leq \Delta pAB + II + \frac{A^3 B^2}{\Delta}.
\]

We choose \(\Delta = AB^{1/2}/p^{1/2}\) to get
\[
II \leq \frac{A^2 B}{p} \left( 1 - \frac{B^{1/2}}{p^{1/2}} \right) p^{3/2} B^{1/2} \\
= p^{1/2} A^2 B^{3/2}
\]

and
\[
\sum_{\ell} \ell_A \times B(\ell_{a,b}) \left( \ell_A \times B(\ell_{a,b}) - \frac{AB}{p} \right)^2 \leq p^{1/2} A^2 B^{3/2},
\]

assuming \(AB^{1/2}/p^{1/2} \geq \frac{2AB}{p}\). Otherwise \(p < 4B\), but then it is clear from Corollary 2.2 that
\[
\sum_{\ell} \ell_A \times B(\ell_{a,b}) \left( \ell_A \times B(\ell_{a,b}) - \frac{AB}{p} \right)^2 \leq pA^2 B \ll p^{1/2} A^2 B^{3/2}.
\]

This completes the proof. \(\square\)

2.2. Proof of Theorem 1.1. We can transform \(T_{\lambda,\mu}(A, B)\) to be the number of solutions of
\[
\frac{b_1 - \mu b_2}{a_1 - \lambda a_3} = \frac{b_1 - \mu b_3}{a_1 - \lambda a_2},
\]
by adding an error term of \(O(AB^3 + A^2 B^2)\) coming from the cases where \(a_1 = \lambda a_2 = \lambda a_3\), or \(a_1 = \lambda a_3\) and \(b_1 = \mu b_2\), or \(a_1 = \lambda a_2\) and \(b_1 = \mu b_3\). Then collecting our solutions for each \(c \in \mathbb{F}_p\),
\[
\frac{b_1 - \mu b_2}{a_1 - \lambda a_3} = \frac{b_1 - \mu b_3}{a_1 - \lambda a_2} = c
\]
and re-arranging and relabelling, we obtain
\[ b_1 - ca_1 = \mu b_2 - \lambda c a_2 = \mu b_3 - \lambda c a_3. \]
Therefore,
\[
T_{\lambda, \mu}(A, B) = \sum_{\ell} t_{A \times B}(\ell_{a, b}) t_{A \times B}(\ell_{\lambda a, \mu b})^2 + O(AB^3 + A^2B^2). \tag{2.2}
\]
As in [7, p. 6], we use the result \( X^2 = (X - Y)^2 + 2XY - Y^2 \) with \( X = t_{A \times B}(\ell_{\lambda a, \mu b}) \) and \( Y = AB/p \) and see
\[
\sum_{\ell} t_{A \times B}(\ell_{a, b}) t_{A \times B}(\ell_{\lambda a, \mu b})^2
= \sum_{\ell} t_{A \times B}(\ell_{a, b}) \left( t_{A \times B}(\ell_{\lambda a, \mu b}) - \frac{AB}{p} \right)^2
+ \frac{2AB}{p} \sum_{\ell} t_{A \times B}(\ell_{a, b}) t_{A \times B}(\ell_{\lambda a, \mu b}) - \frac{A^2B^2}{p^2} \sum_{\ell} t_{A \times B}(\ell_{a, b}).
\tag{2.3}
\]
We now apply Lemma 2.1 to obtain,
\[
\sum_{\ell} t_{A \times B}(\ell_{a, b}) t_{A \times B}(\ell_{\lambda a, \mu b})^2
= \sum_{\ell} t_{A \times B}(\ell_{a, b}) \left( t_{A \times B}(\ell_{\lambda a, \mu b}) - \frac{AB}{p} \right)^2 + \frac{A^3B^3}{p} - \frac{2A^3B^2}{p} + 2A^2B^2.
\]
Combining (2.2), (2.3) and Lemma 2.5 we complete the proof.

2.3. Consequences. We give some results that come as a consequence of Theorem 1.1, these are necessary for our proofs of Theorem 1.2 and Theorem 1.3.

We define \( D_{\lambda, \mu}(A, B) \) to be the number of solutions to
\[
(a_1 - \lambda a_2)(b_1 - \mu b_2) = (a_3 - \lambda a_4)(b_3 - \mu b_4)
\tag{2.4}
\]
for \((a_i, b_i) \in A \times B, i = 1, 2, 3, 4, \) and \(\lambda, \mu \in \mathbb{F}_p^*\). We also define \( T^*_{\lambda, \mu}(A, B) \) to be the number of solutions of
\[
(a_1 - \lambda a_2)(b_1 - \mu b_2) = (a_1 - \lambda a_3)(b_1 - \mu b_3) \neq 0
\]
and, similarly, \( D^*_{\lambda, \mu}(A, B) \) to be the number of solutions of
\[
(a_1 - \lambda a_2)(b_1 - \mu b_2) = (a_3 - \lambda a_4)(b_3 - \mu b_4) \neq 0.
\]
We also define \( D^*_{1,1}(A, B) = D^*(A, B), \ D_{1,1}(A, B) = D(A, B) \) and \( T^*_{1,1}(A, B) = T^*(A, B) \).
Lemma 2.6. Let $\mathcal{A}, \mathcal{B} \subset \mathbb{F}_p$ with $|\mathcal{A}| = A \leq |\mathcal{B}| = B$ and $\lambda, \mu \in \mathbb{F}_p^\ast$. Then

$$D_{\lambda,\mu}^*(\mathcal{A}, \mathcal{B}) \ll p^{1/2} A^3 B^{5/2} + \frac{A^4 B^4}{p}.$$  

Proof. We rearrange $D_{\lambda,\mu}^*(\mathcal{A}, \mathcal{B})$ so it is the number of solutions of

\[
\frac{b_1 - \mu b_2}{a_3 - \lambda a_4} = \frac{b_3 - \mu b_4}{a_1 - \lambda a_2} \neq 0.
\]

We define $J(\xi)$ to be the number of quadruples $(a_1, a, b_1, b) \in \mathcal{A}^2 \times \mathcal{B}^2$ with

\[
(2.5) \quad \frac{b - \mu b_1}{a - \lambda a_1} = \xi.
\]

We also let $J_{a,b}(\xi)$ be the number of pairs $(a, b) \in \mathcal{A} \times \mathcal{B}$ for which $(2.5)$ holds. Then by the Cauchy inequality, we have

\[
D_{\lambda,\mu}^*(\mathcal{A}, \mathcal{B}) = \sum_{\xi \in \mathbb{F}_p^\ast} J(\xi)^2 = \sum_{\xi \in \mathbb{F}_p^\ast} \left( \sum_{(a, b) \in \mathcal{A} \times \mathcal{B}} J_{a,b}(\xi) \right)^2 
\leq AB \sum_{\xi \in \mathbb{F}_p^\ast} \sum_{(a, b) \in \mathcal{A} \times \mathcal{B}} J_{a,b}(\xi)^2
= AB \sum_{(a, b) \in \mathcal{A} \times \mathcal{B}} \sum_{\xi \in \mathbb{F}_p^\ast} J_{a,b}(\xi)^2.
\]

Now

\[
\sum_{\xi \in \mathbb{F}_p^\ast} J_{a,b}(\xi)^2 = \|\{(a_1, a_2, b_1, b_2) \in \mathcal{A}^2 \times \mathcal{B}^2 : \frac{b - \mu b_1}{a - \lambda a_1} = \frac{b - \mu b_2}{a - \lambda a_2} \neq 0\}\|,
\]

hence

\[
D_{\lambda,\mu}^*(\mathcal{A}, \mathcal{B}) \leq AB T_{\lambda,\mu}^*(\mathcal{A}, \mathcal{B}) \leq AB \sum_{\ell} t_{\mathcal{A} \times \mathcal{B}}(\ell_{a,b}) t_{\mathcal{A} \times \mathcal{B}}(\ell_{\lambda a, \mu b})^2 
\ll p^{1/2} A^3 B^{5/2} + \frac{A^4 B^4}{p}.
\]

This concludes the proof. \[\square\]

Since the number of solutions for when $(2.4)$ is equal to 0 is $O(A^2 B^4 + A^3 B^3 + A^4 B^2)$ we get the following simple corollary.

Corollary 2.7. Let $\mathcal{A}, \mathcal{B} \subset \mathbb{F}_p$ with $|\mathcal{A}| = A \leq |\mathcal{B}| = B$ and $\lambda, \mu \in \mathbb{F}_p^\ast$. Then

$$D_{\lambda,\mu}(\mathcal{A}, \mathcal{B}) \ll p^{1/2} A^3 B^{5/2} + \frac{A^4 B^4}{p} + A^2 B^4.$$
3. Exponential Sums

3.1. Preliminaries. We recall the classical bound for bilinear exponential sums, see [4, Equation 1.4] or [6, Lemma 4.1].

Lemma 3.1. For any sets $\mathcal{X}, \mathcal{Y} \subseteq \mathbb{F}_p$ and any $\alpha = (\alpha_x)_{x \in \mathcal{X}}, \beta = (\beta_y)_{y \in \mathcal{Y}}$ with

$$\sum_{x \in \mathcal{X}} |\alpha_x|^2 = A \quad \text{and} \quad \sum_{y \in \mathcal{Y}} |\beta_y|^2 = B,$$

we have

$$\left| \sum_{x \in \mathcal{X}} \sum_{y \in \mathcal{Y}} \alpha_x \beta_y e_p(xy) \right| \leq \sqrt{pAB}.$$

We define $N(\mathcal{X}, \mathcal{Y}, \mathcal{Z})$ to be the number of solutions to

$$x_1(y_1 - z_1) = x_2(y_2 - z_2)$$

with $x_1, x_2 \in \mathcal{X}, y_1, y_2 \in \mathcal{Y}$ and $z_1, z_2 \in \mathcal{Z}$. We now recall [10, Corollary 2.4].

Lemma 3.2. Let $\mathcal{X}, \mathcal{Y}, \mathcal{Z} \subseteq \mathbb{F}_p^*$ with $|\mathcal{X}| = X, |\mathcal{Y}| = Y, |\mathcal{Z}| = Z$ and $M = \max(X, Y, Z)$. Then

$$N(\mathcal{X}, \mathcal{Y}, \mathcal{Z}) \ll \frac{X^2Y^2Z^2}{p} + X^{3/2}Y^{3/2}Z^{3/2} + MXYZ.$$

3.2. Proof of Theorem 1.2. We use Lemma 2.6 in the proof of [10, Theorem 1.3] to give a new bound on trilinear exponential sums. We pick up the proof of [10, Theorem 1.3] at equation (3.8), permuting the variables we obtain

$$T(\mathcal{X}, \mathcal{Y}, \mathcal{Z}; \rho, \sigma, \tau)^8 \ll pX^4Y^7Z^4K + X^8Y^8Z^6.$$

Now $K$ is simply $D^*(\mathcal{X}, \mathcal{Z})$ hence by Lemma 2.6

$$(3.1) \quad T(\mathcal{X}, \mathcal{Y}, \mathcal{Z}; \rho, \sigma, \tau)^8 \ll p^{3/2}X^{13/2}Y^7Z^7 + X^8Y^7Z^8 + X^8Y^8Z^6.$$

We then take 8th roots and compare with the classical bound on bilinear sums, Lemma 3.1, combined with the triangle inequality

$$T(\mathcal{X}, \mathcal{Y}, \mathcal{Z}; \rho, \sigma, \tau) \ll p^{1/2}X^{1/2}Y^{1/2}Z.$$

For our bound to be non-trivial

$$p^{3/16}X^{13/16}Y^{7/8}Z^{7/8} \leq p^{1/2}X^{1/2}Y^{1/2}Z,$$

or equivalently

$$X^{5/16}Y^{3/8}Z^{-1/8} \leq p^{5/16},$$
therefore,

\[ XY^{4/5} \leq p. \]

Now for \( XY^{4/5} \leq p \) we have

\[ XY^{7/8} Z \leq p^{3/16} X^{13/16} Y^{29/40} Z \leq p^{3/16} X^{13/16} Y^{7/8} Z^{7/8}. \]

Similarly,

\[ XYZ^{3/4} \leq p^{3/16} X^{13/16} Y^{34/40} Z^{3/4} \leq p^{3/16} X^{13/16} Y^{7/8} Z^{7/8}. \]

Hence our first term dominates over the non-trivial region. Furthermore, when our bound is trivial, i.e. for \( X^{5/16} Y^{3/8} Z^{-1/8} \leq p^{5/16} \),

\[ T(X, Y, Z; \rho, \sigma, \tau) \ll p^{1/2} X^{1/2} Y^{1/2} Z \ll p^{3/16} X^{13/16} Y^{7/8} Z^{7/8}. \]

This concludes the proof.

### 3.3. Proof of Theorem 1.3

We use Lemma 2.6 in the proof of [10, Theorem 1.4] to give a new bound on weighted quadrilinear exponential sums. As in the proof of [10, Theorem 1.4], after permuting the variables, we have

\[
T(W, X, Y, Z; \vartheta, \rho, \sigma, \tau)^8 \ll (WXY)^6 Z^7 \sum_{\mu \in \mathbb{F}_p^*} \sum_{\lambda \in \mathbb{F}_p} J(\mu) \eta_{\mu} I(\lambda) e_p(\lambda \mu) + (WXZ)^8 Y^7,
\]

(3.2)

where \( I(\lambda) \) is the number of triples \((x_1, x_2, z) \in X^2 \times Z\) with \( z(w_1 - w_2) = \lambda \), \( J(\mu) \) is the number of quadruples \((w_1, w_2, y_1, y_2) \in W^2 \times Y^2\) with \((w_1 - w_2)(y_1 - y_2) = \mu\) and \( \eta_{\mu} \) is a complex number with \(|\eta_{\mu}| = 1\).

It is clear that

\[
\sum_{\mu \in \mathbb{F}_p^*} J(\mu)^2 = D^*(W, Y) \ll p^{1/2} W^{5/2} Y^3 + \frac{W^4 Y^4}{p}.
\]

We now use Lemma 3.2 to obtain

\[
\sum_{\lambda \in \mathbb{F}_p} I(\lambda)^2 \ll \frac{Z^2 X^4}{p} + Z^{3/2} X^3 + ZX^3 \ll \frac{X^4 Z^2}{p} + X^3 Z^{3/2}.
\]

We now apply the classical bound for bilinear sums, Lemma 3.1, to (3.2) to obtain

\[
T(W, X, Y, Z; \vartheta, \rho, \sigma, \tau)^8 \ll (WXY)^6 Z^7 \left(p^{1/4} W^{5/4} Y^{3/2} + \frac{W^2 Y^2}{p^{1/2}}\right) \left(p^{1/2} X^{3/2} Z^{3/4} + X^2 Z\right)
+
(WXZ)^8 Y^7.
\]
We compare the above bound with the classical bound on bilinear sums combined with the triangle inequality

\[ T(W, \mathcal{X}, \mathcal{Y}, \mathcal{Z}; \vartheta, \rho, \sigma, \tau)^8 \ll p^{4} W^{4} X^{4} Y^{8} Z^{8} \]

coming from Lemma 3.1. For our bound to be non-trivial we need

\[ p^{3/4} W^{29/4} X^{15/2} Y^{15/2} Z^{31/4} \leq p^{4} W^{4} X^{4} Y^{8} Z^{8} \]

That is,

\[ W^{13/4} X^{7/2} Y^{-1/2} Z^{-1/4} \leq p^{13/4}, \]

therefore, since \( Z \leq Y \leq X \)

\[ WX^{11/13} \leq p. \]

Now for \( WX^{11/13} \leq p, \)

\[ X^2 Z \leq p^{13/48} X^{3/2} Z \leq p^{13/32} X^{3/2} Z^{3/4} < p^{1/2} X^{3/2} Z^{3/4}. \]

Similarly,

\[ \frac{W Y^2}{p^{1/2}} \leq \frac{p^{3/4} W^{5/4} Y^2}{X^{33/52} p^{1/2}} \leq p^{1/4} W^{5/4} Y^{71/52} \leq p^{1/4} W^{5/4} Y^{3/2}. \]

Finally,

\[ (WX Z)^8 Y^7 \leq p^{3/4} W^{29/4} X^{383/52} Y^{7} Z^{8} \leq p^{3/4} W^{29/4} X^{15/2} Y^{7} Z^{8} \leq p^{3/4} W^{29/4} X^{15/2} Y^{15/2} Z^{31/4}. \]

Hence, for \( WX^{11/13} \leq p, \) after taking 8th roots

\[ T(W, \mathcal{X}, \mathcal{Y}, \mathcal{Z}; \vartheta, \rho, \sigma, \tau) \ll p^{3/32} W^{29/32} X^{15/16} Y^{15/16} Z^{31/32}. \]

However, for \( WX^{11/13} > p, \) then our bound is trivial and

\[ T(W, \mathcal{X}, \mathcal{Y}, \mathcal{Z}; \vartheta, \rho, \sigma, \tau) \ll p^{1/2} W^{1/2} X^{1/2} Y Z \ll p^{3/32} W^{29/32} X^{15/16} Y^{15/16} Z^{31/32}. \]

This completes the proof.
