COMPATIBILITY OF QUASI-ORDERINGS AND VALUATIONS; A BAER-KRULL THEOREM FOR QUASI-ORDERED RINGS

SALMA KUHLMANN, SIMON MÜLLER

Abstract. In his work of 1969, Merle E. Manis introduced valuations on commutative rings. Recently, the class of totally quasi-ordered rings was developed in [11]. In the present paper, given a quasi-ordered ring \((R, \preceq)\) and a valuation \(v\) on \(R\), we establish the notion of compatibility between \(v\) and \(\preceq\), leading to a definition of the rank of \((R, \preceq)\).

Moreover, we prove a Baer-Krull Theorem for quasi-ordered rings: fixing a Manis valuation \(v\) on \(R\), we characterize all \(v\)-compatible quasi-orders of \(R\) by lifting the quasi-orders from the residue class domain to \(R\) itself.

1. Introduction

There have been several attempts to find a uniform approach to orders and valuations. In [2] for instance, Ido Efrat simply defined localities on a field to be either orders or valuations. S.M. Fakhruddin introduced the notion of (totally) quasi-ordered fields \((K, \preceq)\) and proved the dichotomy, that any such field is either an ordered field or else there exists a valuation \(v\) on \(K\) such that \(x \preceq y\) if and only if \(v(y) \leq v(x)\) ([11, Theorem 2.1]). Thus, Fakhruddin found a way to treat these two classes simultaneously. Inspired by this result, the second author of this paper established the said dichotomy for commutative ring with 1 ([11, Theorem 4.6]).

The aim of the present paper is to continue our study of quasi-ordered rings. To this end we consider important results from real algebra, which are also meaningful if the order is replaced by a quasi-order. The paper is organized as follows:

In section 2 we briefly recall ordered and valued rings, and give our definition of quasi-ordered rings (see Definition 2.6). Moreover, we quote the two theorems that we want to establish for this class (see Theorems 2.9 and 2.10).

Section 3 deals with the notion of compatibility between quasi-orders and valuations. Given a quasi-ordered ring \((R, \preceq)\), we first give a characterization of all Manis valuations (i.e. surjective valuations) \(v\) on \(R\) that are compatible with \(\preceq\) (see Theorem 3.12). In case where \(\preceq\) also comes from a Manis valuation, say \(w\), we will show that \(v\) is compatible with \(\preceq\) if and only if \(v\) is a coarsening of \(w\) (see Lemma 3.16), leading to a characterization of all the Manis coarsenings \(v\) of \(w\) (see Theorem 3.17). We conclude this section by developing a notion of rank of a quasi-ordered ring (see Definition 3.29).

In the fourth and final section we establish Baer-Krull Theorems for quasi-ordered rings (see Theorem 4.10 respectively Corollary 4.11, Theorem 4.12, Theorem 4.17). Once these are proven, we can not only generalize the classical Baer-Krull Theorem to ordered rings (see Corollary 4.19), but also characterize all Manis refinements \(w\) of a valued ring \((R, v)\), given that \(v\) is also Manis (see Corollary 4.25).

2. Preliminaries

Here we briefly introduce some basic results concerning valued, ordered and quasi-ordered rings. Moreover, we introduce the theorems, which we aim to establish for
quasi-ordered rings (see Theorems 2.8 and 2.10). Throughout this section let \( R \) always denote a commutative ring with 1.

**Definition 2.1.** (see [11 VI. 3.1]) Let \((\Gamma, +, \leq)\) be an ordered abelian group and \(\infty\) a symbol such that \(\gamma < \infty\) and \(\infty = \infty + \infty = \gamma + \infty = \gamma + \gamma\) for all \(\gamma \in \Gamma\).

A map \( v : R \to \Gamma \cup \{\infty\} \) is called a valuation on \( R \) if for all \( x, y \in R \):

\[
\begin{align*}
(V1) & \quad v(0) = \infty, \\
(V2) & \quad v(1) = 0, \\
(V3) & \quad v(xy) = v(x) + v(y), \\
(V4) & \quad v(x + y) \geq \min\{v(x), v(y)\}.
\end{align*}
\]

We always assume that \( \Gamma \) is the group generated by \( \{v(x) : x \in v^{-1}(\Gamma)\} \) and call it the value group of \( R \). We also denote it by \( \Gamma_v \). We call \( v \) trivial if \( \Gamma_v \) is trivial, i.e. if \( \Gamma_v = \{0\} \). The set \( q_v := \operatorname{supp}(v) := v^{-1}(\infty) \) is called the support of \( v \).

**Facts 2.2.**

1. An easy consequence of the axioms (V1) - (V4) is that \( q_v \) is a prime ideal of \( R \).

2. In general, \( v \) is not surjective, as \( v(R \setminus q_v) \) is not necessarily closed under additive inverses. However, if \( x \) is a unit, then \( v(x^{-1}) = -v(x) \).

3. The subring \( R_v := \{x \in R : v(x) \geq 0\} \) of \( R \) is said to be the valuation ring of \( v \). The prime ideal \( I_v := \{x \in R : v(x) > 0\} \) of \( R \) is called the valuation ideal. If \( R \) is a field, \( R_v \) is a local ring with maximal ideal \( I_v \).

We conclude our introduction of valuations with a simple but very helpful lemma.

**Lemma 2.3.** Let \((R, v)\) be a valued ring and \( x, y \in R \) such that \( v(x) \neq v(y) \). Then \( v(x + y) = \min\{v(x), v(y)\} \).

**Proof.** Completely analogue as in the field case, see for instance [3 (1.3.4)]. \( \square \)

Let us now turn towards the notion of orders on rings. For the sake of convenience, they are usually identified with positive cones \( P \subset R \), where \( x \in P \) expresses that \( x \) is non-negative.

**Definition 2.4.** (see [10 p.29]) A positive cone of \( R \) is a subset \( P \subset R \) such that the following conditions are satisfied:

- \((P1)\) \( P \cup -P = R \),
- \((P2)\) \( P := P \cap -P \) is a prime ideal of \( R \), called the support of \( R \),
- \((P3)\) \( P \cdot P \subseteq P \),
- \((P4)\) \( P + P \subseteq P \).

**Definition 2.5.** (see [11 Definition 2.3]) Let \( \leq \) be a binary, reflexive, transitive and total relation on \( R \). Then \((R, \leq)\) is called an ordered ring if for all \( x, y, z \in R \):

\[
\begin{align*}
(O1) & \quad 0 < 1, \\
(O2) & \quad xy \leq 0 \Rightarrow x \leq 0 \lor y \leq 0, \\
(O3) & \quad x \leq y, \ 0 \leq z \Rightarrow xz \leq yz, \\
(O4) & \quad x \leq y \Rightarrow x + z \leq y + z.
\end{align*}
\]

The set of all orders of \( R \) is in 1 : 1 correspondence with the set of all positives cones of \( R \) via \( x \leq y \Leftrightarrow y - x \in P \). Note that if \( R \) is a field, then \((P2)\) yields that \( P = \{0\} \), which precisely means that the corresponding order \( \leq \) is anti-symmetric (and vice versa).
Recall from the introduction that some quasi-orders $\preceq$ of $R$ are induced by a valuation $v$ via $x \preceq y$ if and only if $v(y) \leq v(x)$. In this case all elements are non-negative. Hence, positive cones are inappropriate to deal with quasi-orders. So in order to compare ordered and quasi-ordered rings, it is necessary to stick to Definition 2.5. Hence, positive cones are inappropriate to deal with quasi-orders. So in order to compare ordered and quasi-ordered rings, it is necessary to stick to Definition 2.5.

Let us now have a closer look at quasi-ordered rings. As mentioned above, Fakhruddin developed a notion of quasi-ordered fields $(K, \preceq)$ and was able to show that quasi-ordered fields are either ordered fields or else $\preceq$ comes from a valuation as above (see [4, Theorem 2.1]). In [11], the second author of this paper generalized this result to commutative rings with 1, leading to the following result:

**Definition 2.6.** (see [11, Definition 3.2]) Let $R$ be a commutative ring with 1 and $\preceq$ a binary, reflexive, transitive and total relation on $R$. If $x, y \in R$, we write $x \sim y$ if $x \preceq y$ and $y \preceq x$, and we write $x \prec y$ if $x \preceq y$ but $y \not\preceq x$.

The pair $(R, \preceq)$ is called a **quasi-ordered ring** if for all $x, y, z \in R$:

1. $(QR1)$ $0 \prec 1$,
2. $(QR2)$ $xy \preceq 0 \Rightarrow x \preceq 0 \lor y \preceq 0$,
3. $(QR3)$ $x \preceq y, 0 \preceq z \Rightarrow xz \preceq yz$,
4. $(QR4)$ $x \preceq y, z \sim y \Rightarrow x + z \preceq y + z$,
5. $(QR5)$ If $0 \prec z$, then $xz \preceq yz \Rightarrow x \preceq y$.

We write $E_x$ for the equivalence class of $x$ w.r.t. $\sim$. $E_0$ is called the **support** of $\preceq$.

In [11, Theorem 4.6], the second author proved that a quasi-ordered ring $(R, \preceq)$ is either an ordered ring or a valued ring $(R, v)$ such that $x \preceq y \Leftrightarrow v(y) \leq v(x)$. Thus, via quasi-ordered rings, we can treat ordered and valued rings simultaneously.

**Remark 2.7.**

1. If $(R, \preceq)$ is a quasi-ordered ring with $x \sim 0$ and $y \sim 0$, then $x + y \sim y$ (see [11, Lemma 3.6]). This result will be useful later on.
2. The support $E_0$ is a prime ideal of $R$ (see [11, Proposition 3.8]).
3. The “new” axiom $(QR5)$ is crucial for the dichotomy, see [11, Proposition 3.1]. Moreover, note that it easily implies $(QR2)$. Indeed, if $xy \preceq 0$ and $0 \prec x$, then $(QR2)$ yields $y \preceq 0$. However, we decided to keep axiom $(QR2)$ in order to preserve the analogy between ordered and quasi-ordered rings.
4. If $R$ is a field, then the axioms $(QR1)$ and $(QR2)$ can be replaced with the axiom $x \sim 0 \Rightarrow x = 0$, while $(QR5)$ becomes unnecessary. As a matter of fact, this is precisely how Fakhruddin introduced quasi-ordered fields in the first place (see [11, 2]).

Later on, we will also use the following variant of axiom $(QR5)$.

**Lemma 2.8.** Let $(R, \preceq)$ be a quasi-ordered ring and $x, y, z \in R$. If $x \sim 0$, then $xz \sim yz \Rightarrow x \sim y$.

**Proof.** For $0 \prec z$, this is the same as $(QR5)$. So suppose that $z \sim 0$. Then $0 \prec -z$. Thus, $(QR5)$ tells us $-x \sim -y$. Assume for a contradiction that $x \sim y$, without loss of generality $x \sim y$. By transitivity of $\sim$ we get either $x \sim -x, -y$ or $y \sim -x, -y$. If $y \sim -x, -y$, we obtain from $-x \preceq -y$ that $y - x \preceq 0$. If $x \sim 0$, then $(QR4)$ yields $y \preceq x$. Otherwise, the same follows from Remark 2.7(2). Hence, there is a contradiction anyway. So suppose that $x \sim -x, -y$. Then $-x \preceq -y$ implies $0 \preceq x - y$, and $-y \preceq -x$ implies $x - y \preceq 0$ via $(QR4)$. So $x - y \in E_0$, but then also $y - x \in E_0$ by the previous lemma. Thus, $y - x \sim 0$. From $(QR4)$ (if $x \sim 0$), respectively Remark 2.7(2) (if $x \sim 0$), we obtain $y \preceq x$, again a contradiction. $\Box$
We conclude this introductory section by recalling the Theorems 2.9 and 2.10 below, which we will establish for quasi-ordered rings in this paper. So let \((K, \leq)\) be an ordered field. Recall that a valuation \(v\) on \(K\) is said to be compatible with \(\leq\), if \(0 \leq x \leq y\) implies \(v(y) \leq v(x)\) (see for instance \[8, \text{Definition 2.4}\]). A subset \(S \subseteq K\) is convex (w.r.t. \(\leq\)) if from \(x \leq y \leq z\) and \(x, z \in S\) follows \(y \in S\).

**Theorem 2.9.** (see \[8, \text{Theorem 2.3 and Proposition 2.9}\] or \[3, \text{Proposition 2.2.4}\])

Let \((K, \leq)\) be an ordered field and let \(v\) be a valuation on \(K\). The following are equivalent:

1. \(v\) is compatible with \(\leq\),
2. the valuation ring \(K_v\) is convex,
3. the maximal ideal \(I_v\) is convex,
4. \(I_v < 1\),
5. \(\leq\) induces canonically via the residue map \(\varphi_v : K_v \rightarrow K_v := K_v/I_v, x \mapsto x + I_v\) an order \(\leq'\) on the residue field \(K_v\).

The fifth condition of the previous result is crucial for the second theorem, the so-called Baer-Krull Theorem (see \[3, \text{p.37}\]). Let \(K\) again be a field and \(v\) a valuation on \(K\) with value group \(\Gamma_v\). Note that \(\Gamma_v = \Gamma_v/2\Gamma_v\) is in a canonical way an \(\mathbb{F}_2\)-vector space. Hence, we find a subset \(\{\pi_i : i \in I\} \subset K\), such that \(\{v(\pi_i) : i \in I\}\) is an \(\mathbb{F}_2\)-basis of \(\Gamma_v\).

**Theorem 2.10.** (Baer-Krull Theorem for ordered fields; see \[8, \text{Theorem 2.2.5}\])

Let \(K\) be a field and \(v\) a valuation on \(K\). Moreover, let \(\mathcal{X}(K)\) and \(\mathcal{X}(Kv)\) denote the set of all orderings on \(K\), respectively \(Kv\). There exists a bijective map \(\psi : \{\leq \in \mathcal{X}(K) : \leq\text{ is }v\text{-compatible}\} \rightarrow \{-1, 1\}^I \times \mathcal{X}(Kv)\), described as follows: given an ordering \(\leq\) in the domain of \(\psi\), let \(\eta_{\leq} : I \rightarrow \{-1, 1\}\), where \(\eta_{\leq}(i) = 1 \iff 0 \leq \pi_i\). Then the map \(\leq \mapsto (\eta_{\leq}, \leq')\) is the above bijection, where \(\leq'\) denotes the order on \(Kv\) from Theorem 2.9(5).

3. **Compatibility between quasi-orders and valuations**

The aim of this section is to prove an analogue of Theorem 2.9 for quasi-ordered rings. First we convince ourselves that for this end, we have to restrict our attention to surjective valuations (see Example \[8, \text{Example 3.10}\]), also called Manis valuations. Then we establish that the conditions (1) - (3) and (5) from the said theorem are equivalent for quasi-ordered rings, if \(v\) is Manis (see Theorem 3.12). This gives rise to a characterization of all Manis valuations \(v\) on \(R\), which are coarser than \(v\) (see Theorem 3.17). Afterwards, we prove that \(I_v < 1\) is no equivalent condition anymore, no matter of which of the two kinds the quasi-order is (see Examples \[8, \text{Example 3.10}\] and \[8, \text{Example 3.20}\]). Furthermore, we show that Theorem 2.9 holds to the full extend, if we additionally demand that \(v\) is local (see Lemma 3.24). We conclude this section by establishing the notion of rank of a quasi-ordered ring (see Definition 3.29).

**Notation 3.1.** We use the following notation for the rest of this section:

1. Let \(R\) always denote a commutative ring with 1. If a quasi-order \(\preceq\) on \(R\) (see Definition 2.6) is induced by some valuation \(v\) on \(R\), we also write \(\preceq_w\) instead of \(\preceq\) and call it a **proper quasi-order** (p.q.o). Note that a quasi-order \(\preceq\) comes from a valuation if and only if \(-1 < 0\). The symbol \(\leq\) is reserved for orders.

2. If \(v\) is a valuation on \(R\), we write \(q_v := \text{supp}(v) := v^{-1}(\infty)\) for its **support** and \(\Gamma_v\) for its **value group** (see Definition 2.1). Moreover, we denote by \(R_v := \{x \in R : v(x) \geq 0\}\) the **valuation ring** of \(v\), by \(I_v := \{x \in R : v(x) < 0\}\) the **initial ideal** of \(v\), and by \(\mathcal{X}(v) := \{\leq \in \mathcal{X}(K) : \leq\text{ is }v\text{-compatible}\} \rightarrow \{-1, 1\}^I \times \mathcal{X}(Kv)\), described as follows: given an ordering \(\leq\) in the domain of \(\psi\), let \(\eta_{\leq} : I \rightarrow \{-1, 1\}\), where \(\eta_{\leq}(i) = 1 \iff 0 \leq \pi_i\). Then the map \(\leq \mapsto (\eta_{\leq}, \leq')\) is the above bijection, where \(\leq'\) denotes the order on \(Kv\) from Theorem 2.9(5).
A BAER-KRULL THEOREM FOR QUASI-ORDERED RINGS

5

v(x) > 0} the valuation ideal, and by \( U_v := R_v \setminus I_v := \{ x \in R : v(x) = 0 \} \).

Last but not least, \( R_v := R_v / I_v \) denotes the residue class domain of \( v \) and \( \varphi_v : R_v \to R_v, x \mapsto x + I_v \) the residue map.

**Definition 3.2.** Let \((R, \preceq)\) be a quasi-ordered ring. A valuation \( v \) on \( R \) is said to be compatible with \( \preceq \) (or \( \preceq \)-compatible), if for all \( y, z \in R \):

\[ 0 \preceq y \preceq z \Rightarrow v(z) \leq v(y). \]

In general, we cannot expect that Theorem 2.9 holds even for ordered rings, as the following basic example shows:

**Example 3.3.**

1. Consider the map \( v : \mathbb{Z}[X] \to \mathbb{Z} \cup \{\infty\}, f = \sum_{i \in \mathbb{N}} a_i X^i \mapsto -\deg f \). It is easy to verify that \( v \) is a valuation on \( R \). We can extend the unique order on \( \mathbb{Z} \) to \( \mathbb{Z}[X] \) by declaring \( 0 \preceq f :\iff 0 \preceq f(0) \). Note that \( R_v = \mathbb{Z} \) and \( I_v = \{0\} \), so obviously the conditions (4) and (5) of Theorem 2.9 are satisfied. However, the inequalities \( 0 \preceq X \preceq 0 \) yield that neither \( I_v \) nor \( R_v \) is convex with respect to \( \preceq \). Moreover, we have \( 0 \preceq X + 1 \preceq 1 \), but \( v(X + 1) = -1 < 0 = v(1) \), so (1) is also not satisfied.

2. Let \( p \) be a prime number and \( v \) the \( p \)-adic valuation on the integers \( \mathbb{Z} \), i.e. if \( x = p^r a_1 \ldots a_n \) in the unique prime factorization, then \( v(x) = r \) (see [3 (1.3.1)]). Moreover, let \( \leq \) denote the unique order on \( \mathbb{Z} \). Then \( R_v = \mathbb{Z} \) is convex, so (2) holds. However, it is easy to see that all the other conditions of Theorem 2.9 are not satisfied.

As a matter of fact, for a quasi-ordered ring \((R, \preceq)\) and a valuation \( v \) on \( R \), in general none of the conditions from Theorem 2.9 is equivalent to another. We do get the following tabular of implications, where

<table>
<thead>
<tr>
<th>( \Rightarrow )</th>
<th>(1)</th>
<th>(2)</th>
<th>(3)</th>
<th>(4)</th>
<th>(5)</th>
</tr>
</thead>
<tbody>
<tr>
<td>(1)</td>
<td>√</td>
<td>√</td>
<td>√</td>
<td>√</td>
<td></td>
</tr>
<tr>
<td>(2)</td>

<td>√</td>
<td></td>
</tr>
</tbody>
</table>

**Proof.** We first show that (1) implies (2) and (3). So let \( 0 \preceq y \preceq z \) with \( z \in R_v \). Then (1) yields \( v(z) \leq v(y) \). Therefore \( v(y) \in R_v \). The same arguments for \( I_v \) instead of \( R_v \). In order to show that (1) implies (4) and (5), it suffices to show that (2) implies the two of them.

Condition (2) obviously implies (4). It also implies (5) as we will not use the Manis property in the proof of the respective implication in Theorem 3.12.
In Example 5.3(ii), we have already seen that (2) implies none of the other conditions. We now show that it does not imply (2), and hence also not (1). Let \( v \) be the trivial valuation on \( \mathbb{Z} \). Extend to \( \mathbb{Z}[X] \) with \( \gamma = -1 \). Let \( w \) be the \( p \)-adic valuation on \( \mathbb{Z} \). Extend to \( \mathbb{Z}[X] \) with \( \gamma = 1 \). Then (3) holds, because
\[
0 < w(x) \Rightarrow x = 0 \Rightarrow y = 0 \Rightarrow 0 < v(y),
\]
where the first implication follows by definition of \( v \) and the second one by (3).

However, (2) does not hold. Choose \( a = 1 \) and \( b = X \). Then \( w(a) = 0 \leq w(b) = 1 \) and \( 0 \leq v(a) = 1 \), but \( v(b) = -1 < 0 \).

Condition (4) implies nothing even if \( v \) is Manis, as we will see in Example 5.19 and 5.20. (5) implies (4): Assume \( 1 \preceq x \) for some \( x \in I_v \). Then \( 1 \preceq x \) but in quasi-ordered rings it holds \( 0 \prec 1 \), a contradiction. Therefore \( I_v \prec 1 \). The fact that (5) does not imply any of the other conditions follows from Example 5.3(i). \( \square \)

Such counterexamples can be prevented by demanding surjectivity of the valuation \( v \). Recall that valuations on fields are automatically surjective. Contrary, in the ring case, \( v(R[q_v]) \) is not necessarily closed under additive inverses, as \( R \) is not necessarily closed under multiplicative inverses (see Facts 2.2). Surjectivity will be frequently exploited later on, as it mitigates the lack of multiplicative inverses.

**Definition 3.4.** (see [9, p.193]) Let \( v \) be a valuation on \( R \). Then \( v \) is said to be a Manis valuation, if \( v \) is surjective.

We now turn towards the proof of Theorem 2.9 for quasi-ordered rings. This requires some preliminaries.

**Definition 3.5.** Let \((R, \preceq)\) be a quasi-ordered ring and \( S \subseteq R \) a subset of \( R \). Then \( S \) is said to be convex, if \( x \preceq y \preceq z \) and \( x, z \in S \) implies \( y \in S \).

The following lemma simplifies convexity in a usual manner and holds particularly for the valuation ring \( R_v \) and its prime ideal \( I_v \), as \( v(x) = v(-x) \) for all \( x \in R \).

**Lemma 3.6.** Let \((R, \preceq)\) be a quasi-ordered ring. A subset \( S \subseteq R \) with \( 0 \in S \) and \( S = -S \) is convex, if and only if \( 0 \preceq y \preceq z \) and \( z \in S \) implies \( y \in S \).

**Proof.** The implication \( \Rightarrow \) is trivial. So suppose that the right hand side holds and let \( x \preceq y \preceq z \) with \( x, z \in S \). If \( 0 \preceq y \), it follows immediately by assumption that \( y \in S \). So suppose that \( y \prec 0 \). Then \( x \preceq y \prec 0 \). We will show \( 0 \prec -y \preceq -x \). Note that \( -x \in S \) because \( S = -S \). Hence, we obtain \( -y \in S \), but then also \( y \in S \).

Clearly \( 0 \prec -x, -y \) by axiom (QR4) and the fact that \( E_0 \) is an ideal (see Remark 2.7(2)). It remains to show that \( -y \preceq -x \). Assume for a contradiction \( -x \prec -y \). Note that \( y \prec 0 \prec -x, -y \), therefore \( -x \prec y \) and \( y \npreceq -y \). Via (QR4), it follows from \( x \preceq y \) that \( 0 \preceq y - x \) and from \( -x \preceq -y \) that \( y - x \preceq 0 \). Thus, \( y - x \in E_0 \). This implies \( -y \sim -x \) (see Remark 2.7(2)), a contradiction. \( \square \)

The most difficult part of the proof will be to show that if \( v \) is a \( \preceq \)-compatible valuation on \( R \), then \( \preceq \) induces a quasi-order on the residue class domain \( R_v \). For that purpose we want to exploit convexity of \( I_v \).

**Lemma 3.7.** Let \((R, \preceq)\) be a quasi-ordered ring, \( v \) a valuation on \( R \) such that \( I_v \) is convex, and \( u \in U_v \).

1. If \( c \in I_v \), then \( c \npreceq u \).
2. If \( 0 \nprec u \), then \( 0 \nprec u + c \) for all \( c \in I_v \).
3. If \( u \nprec 0 \), then \( u + c \nprec 0 \) for all \( c \in I_v \).

**Proof.**
(1) Assume $c \sim u$. Then $c \preceq u \preceq c$ and convexity of $I_v$ yields $u \in I_v$, a contradiction.

(2) Assume that $0 \prec u$ but $0 \not\sim u + c$ for some $c \in I_v$. Then $0 \prec u$ and $u + c \preceq 0$. Note that this implies $c \not\in E_0$, as otherwise $u \sim u + c$ (see Remark 2.7(1)). Hence, we obtain $u \preceq -c$. So it holds $0 \prec u \preceq -c$. Convexity of $I_v$ yields $u \in I_v$, a contradiction.

(3) Assume $0 \preceq u + c$ for some $c \in I_v$. Then $u \prec 0 \preceq u + c$. It remains to show that $-u \not\sim u + c$. Then $0 \prec -u \preceq c$ and one may conclude by convexity of $I_v$. So assume for a contradiction that $-u \preceq u + c$. From Lemma 2.3 follows $u + c \in U_v$, so (1) yields that $-c \not\sim u + c$. Thus, one obtains $-u - c \preceq u$. Now note that $0 \prec -u \in U_v$. So (2) yields $0 \prec -u - c$. Therefore $0 \prec -u - c \preceq u \prec 0$, a contradiction. This finishes the proof.

Moreover, we require a couple of results that Fakhruddin established in the more specific setting of quasi-ordered fields (see [4]).

**Lemma 3.8.** Let $(R, \preceq)$ be a quasi-ordered ring and $x \in R$. Then $x \sim -x$ if and only if $0 \preceq x, -x$.

**Proof.** Just as in the case of quasi-ordered fields, see [4] Lemma 3.1].

**Lemma 3.9.** Let $(R, \preceq)$ be a quasi-ordered ring and $x, y \in R$. If $x \sim y$, then $x \sim -y$ or $0 \sim x - y$.

**Proof.** If $x, y \sim 0$, then $x \sim -y$, as $E_0$ is an ideal. So suppose that $x, y \sim 0$, and assume that $x \sim -y$. We show $0 \sim x - y$. Note that $y \preceq x \sim -y$. Therefore $0 \preceq x - y$. Moreover, $x \preceq y \sim x \sim -y$, so $y \sim -y$, and therewith $x - y \preceq 0$. Thus, $0 \sim x - y$.

**Corollary 3.10.** Let $(R, \preceq)$ be a quasi-ordered ring. Then $\sim$ is preserved under multiplication, i.e. if $x, y, a \in R$ such that $x \sim y$, then $ax \sim ay$.

**Proof.** The cases $0 \preceq a$ (axiom (QR3)) and $x, y$ in $E_0$ ($E_0$ is an ideal) are both trivial. So suppose that $0 \not\preceq a$ and $x, y \sim 0$. Then $0 \preceq -a$. The previous lemma gives rise to a case distinction. First suppose $0 \sim x - y$. Since $-x \sim 0$ it holds $-x \sim x - y$. Hence, $0 \sim x - y$ yields $-x \sim -y$. Since $0 \preceq -a$, axiom (QR3) yields $ax \sim ay$. Now suppose that $0 \sim x - y$. Then also $0 \sim y - x$. The previous lemma implies $x \sim -y$ and $y \sim -x$. Therefore $-y \sim x \sim -x$. Since $0 \preceq -a$, we obtain $ay = (-a)(-y) \sim (-a)(-x) = ax$.

**Lemma 3.11.** Let $(R, \preceq)$ be a quasi-ordered ring such that $0 \prec -1$. Then it holds $x + y \preceq \max\{x, y\}$ for all $x, y \in R$.

**Proof.** Basically as in the field case, see [4] Lemma 4.1]. Suppose that $x \preceq y$, and assume for a contradiction that $y \prec x + y$. Note that $0 \preceq 1$ by axiom (QR1). Lemma 3.8 implies $-1 \sim 1$, so the previous corollary yields $-r \sim r$ for all $r \in R$. It follows $-x \sim x \preceq y \prec x + y$. Particularly, $-y \sim x + y$, since $y \sim x + y$. So, by applying (QR4), we obtain $x + y \sim -x - y \preceq x \preceq y$, a contradiction.

Finally, we can prove the main theorem of this section:

**Theorem 3.12.** Let $(R, \preceq)$ be a quasi-ordered ring and let $v$ be a Manis valuation on $R$.

(a) The following are equivalent:

(1) $v$ is compatible with $\preceq$.
(2) $I_v$ is convex.

(3) $\preceq$ induces canonically via the residue map $x \mapsto x + I_v$ a quasi-order $\preceq$ with support $\{0\}$ on the residue class domain $R_v$.

Moreover, any of these conditions implies that $R_v$ is convex.

(b) If $v$ is non-trivial, then

(4) $R_v$ is convex

is equivalent to the conditions (1) – (3).

Proof.

(a) We first prove that (1) and (2) are equivalent. So suppose that (1) holds and let $0 \preceq y \preceq z$ with $z \in I_v$. Then (1) yields that $0 < v(z) \preceq v(y)$, and therefore $y \in I_v$. Now suppose that $I_v$ is convex and assume for a contradiction that there exist some $0 \preceq y \preceq z$ such that $v(y) < v(z)$. Note that $y \notin q_v$. Hence, since $v$ is Manis, we find some $0 \preceq a$ such that $v(a) = -v(y)$ (for if $a < 0$, then $0 \preceq -a$ and $v(a) = v(-a)$). Via axiom (QR3) follows $0 \preceq ay \preceq az$ with $v(ay) = 0$ and $v(az) = v(z) - v(y) > 0$, so $az \notin I_v$. This contradicts the convexity of $I_v$.

We continue by showing that (2) and (3) are equivalent. First suppose that (3) holds and let $0 \preceq y \preceq z$ be such that $v(y) \preceq v(z)$, this yields that $v(ay) = 0$ and $v(az) = v(z) - v(y) > 0$. Taking residues, it follows $0 \preceq ay \preceq az$. Since the support of $\preceq'$ is trivial, this yields that $\overline{ay} = 0$, contradicting $v(ay) = 0$, i.e. $ay \notin I_v$. Therefore, $y \in I_v$.

Now suppose that (2) holds. The quasi-order induced by the residue map is given by $x \preceq' y :\iff \exists c_1, c_2 \in I_v : x + c_1 \preceq y + c_2$.

First of all we verify that $\preceq'$ is well-defined. So assume that $x \preceq' y$ and let $x = x_1 + c_1$ and $y = y_1 + c_2$ for some $c_1, c_2 \in I_v$. There exist some $c_3, c_4 \in I_v$ such that $x + c_3 \preceq y + c_4$. But then $x_1 + (c_1 + c_3) \preceq y_1 + (c_2 + c_4)$, thus, $x \preceq' y$.

Evidently, $\preceq'$ is reflexive and total. Next we show transitivity. So assume that $x + c_1 \preceq y + c_2$ and $y + d_1 \preceq z + d_2$ for some $c_1, c_2, d_1, d_2 \in I_v$. We argue by case distinction. First suppose that $y \in U_v$. Assume for a contradiction that $x + c_1 \succ z + c_2$ for all $c_1, c_2 \in I_v$. In particular, $x + c_1 + d_1 - c_2 \succ z + d_2$. Note that $y + c_2 \in U_v$ and $d_1 - c_2 \in I_v$, so Lemma 3.7(1) yields $y + c_2 \sim d_1 - c_2$. So from the inequality $x + c_1 \preceq y + c_2$ follows

$$x + c_1 + d_1 - c_2 \preceq y + c_2 + d_1 - c_2 = y + d_1 \preceq z + d_2,$$

a contradiction.

If $y \in I_v$, then $y + c_2$ and $y + d_1 \in I_v$ By convexity and Lemma 3.7(2) and (3), this yields that $x$ is either a negative unit or in $I_v$, and that $z$ is either a positive unit or in $I_v$. We only have to consider the case where both elements are in the valuation ideal. But then $x + (z - x) \preceq z + 0$, and thus $x \preceq' z$.

Now we show that the support of $\preceq'$ equals $\{0\}$. So let $x \sim 0$ and assume for a contradiction that $x \in R_v \setminus I_v = U_v$. Then there exist $c_1, c_2 \in I_v$ such that $x + c_1 \preceq c_2$ and there exist $d_1, d_2 \in I_v$ such that $d_1 \preceq x + d_2$.

If $0 < x$, then $0 < x + c_1 \preceq c_2$ by Lemma 3.7(2), and we have $x + c_1 \in I_v$ by convexity, a contradiction. Likewise, if $x < 0$, then $d_1 \preceq x + d_2 < 0$ by Lemma 3.7(3), again contradicting the convexity.
It remains to check the axioms (QR1) and (QR3) - (QR5) (axiom (QR2) is omitted because of Remark 2.7(3)).

(QR1) Assume for a contradiction that $\overline{1} \not\preceq \overline{0}$. Then there exist $c_1, c_2 \in I_v$ such that $0 \prec 1 + c_1 \preceq c_2$ (Lemma 3.7(2)). Convexity of $I_v$ yields $1 + c_1 \in I_v$, and therefore $1 \in I_v$, a contradiction. Thus, $0 \prec \overline{1}$.

(QR3) We have to verify that $0 \not\preceq \overline{x}$ and $\overline{y} \not\preceq \overline{x}$ implies $\overline{xy} \not\preceq \overline{x}$. For $\overline{x} = 0$, there is nothing to show, so assume without loss of generality $x \notin I_v$. From $0 \not\preceq \overline{x}$ follows that there are some $c_1, c_2 \in I_v$ such that $c_1 \preceq x + c_2$. Applying Lemma 3.7(1) yields that $c_1 - c_2 \preceq x$. So convexity of $I_v$ gives us $0 \preceq x$. Moreover, $\overline{y} \not\preceq \overline{x}$ means $y + d_1 \preceq z + d_2$ for some $d_1, d_2 \in I_v$. (QR3) implies $xy + xd_1 \preceq xz + xd_2$, and therefore $\overline{xy} \not\preceq \overline{x}$.

(QR4) We have to prove that $\overline{x} \not\preceq \overline{y}$ and $\overline{y} \not\preceq \overline{x}$ yields $\overline{x + z} \not\preceq \overline{y + z}$. Let $c_1, c_2 \in I_v$ such that $x + c_1 \preceq y + c_2$. Note that $\overline{y} \not\preceq \overline{x}$ implies either $\forall e_1, e_2 : y + c_1 \preceq z + c_2$ or $\forall e_1, e_2 : y + c_1 \not\preceq z + c_2$. Either way, $z \not\preceq y + c_2$. But then $x + z + c_1 \preceq y + z + c_2$ by (QR4), i.e. $\overline{x + z} \not\preceq \overline{y + z}$.

(QR5) We have to show that if $0 \not\prec \overline{v}$, then $\overline{xy} \not\preceq \overline{v}$ implies $\overline{y} \not\preceq \overline{v}$. Note that if $ax \preceq ay$, then $x \preceq y$ by axiom (QR5), hence $\overline{x} \not\preceq \overline{y}$. So from now on assume that $ay \prec ax$. First we show that one may also assume that $x, y \in U_v$. Indeed, suppose that $\overline{x} = 0$ and assume for a contradiction that $\overline{y} \prec 0$. Then $\overline{xy} \preceq 0$ by axiom (QR3). But equality cannot hold because neither $a \in I_v$, nor $y \in I_v$. Thus, $\overline{xy} \preceq 0 = \overline{xy}$, contradicting the assumption. Now suppose that $\overline{y} = 0$ and assume for a contradiction that $0 \prec \overline{v}$. Then $\overline{xy} \preceq 0 = \overline{xy}$, again a contradiction. Hence, one may assume that both $x$ and $y$ lie in $U_v$. So from $\overline{xy} \preceq \overline{y}$ follows that there exists some $c \in I_v$ such that $ax \preceq ay + c$. Thus, it holds $ay \prec ax \preceq ay + c$. The rest of the proof is done by case distinction.

If $0 \prec -1$, then $0 \preceq -r$ for all $r \in R$ with $0 \preceq r$ by (QR3). This yields that all elements are non-negative. Particularly, since $ay$ is a unit and $I_v$ is convex, it holds $a \prec ay$ (otherwise $0 \prec ay \preceq c \in I_v$). From Lemma 3.7(1) follows $ay \prec ay + c \preceq \max\{ay + c\} = ay$, the desired contradiction.

Finally suppose $-1 \prec 0$. Consider the inequalities $ay \prec ax \preceq ay + c$. By Lemma 3.7(2) and (3), $ay$ and $ay + c$ have the same sign, and so $ax$ has also the same sign, which is contrary to the sign of $-ay$. Particularly, we may add $-ay$ to these two inequalities and obtain $0 \preceq a(x - y) \preceq c$. By convexity of $I_v$, follows $a(y - x) \in I_v$ and since $I_v$ is a prime ideal with $a \notin I_v$, one obtains $\overline{x} = \overline{y}$. Particularly, $\overline{x} \not\preceq \overline{y}$, as desired.

The convexity of $R_v$ follows immediately from (1), just like the convexity of $I_v$.

(b) It suffices to show that (4) implies (2). So let $0 \preceq y \preceq z$ with $z \in I_v$. Assume for that $y \notin I_v$, so by convexity of $R_v$ it holds $y \in R_v - I_v = U_v$, i.e. $v(y) = 0$. Since $z \in I_v$, we get $\gamma := v(z) > 0$. We distinguish the two cases, whether $z \in q_v$ or not.

If $z \notin q_v$, there exists some $0 \preceq a \in R$ such that $v(a) = -\gamma < 0$. Axiom (QR3) yields $0 \preceq ay \preceq az$. As $0$ and $az$ lie in $R_v$, it follows by convexity of $R_v$ that $ay \in R_v$, i.e. $v(ay) \geq 0$. However, $v(ay) = v(a) + v(y) < 0$, a contradiction.

If $z \in q_v$, choose some $0 \preceq a \in R$ with $v(a) < 0$, which exists since $v$ is
a non-trivial Manis valuation. Then $0 \preceq ay \preceq az$ with $az \in R_v$. However, $ay \notin R_v$, contradicting the convexity of $R_v$.

\[\square\]

**Remark 3.13.**

1. The assumption in (b) that $v$ is non-trivial is crucial, no matter which kind of a quasi-order $\preceq$ is.

For the ordered case consider $\mathbb{Z}$ with its unique order and the trivial valuation $v$ mapping the even integers to $\infty$ and the odd integers to 0. Then $R_v = \mathbb{Z}$ is convex, while $I_v = 2\mathbb{Z}$ is not.

In the case $\preceq \subseteq \preceq_w$, take the same $v$ and let $w$ be the $p$-adic valuation on $\mathbb{Z}$ for some prime $p > 2$. Then $R_v$ is clearly convex. However, choosing $y = 2$ and $z = 1$ yields $0 = w(y) \leq w(z) = 0$ and $0 < v(y) = \infty$, but $0 = v(z)$.

2. Instead of $v$ non-trivial, one may have also demanded that $q_v = E_0$ for part (b), i.e. that the supports coincide. Then $z \in q_v$ yields $z \in E_0$, so also $y \in E_0 = q_v \subseteq I_v$ by transitivity of $\preceq$.

3. $I_v \prec I_v$ (compare Theorem 2.9) is an easy consequence of these conditions. It follows for instance immediately from the convexity of $I_v$.

4. If $\preceq$ is an order (respectively a proper quasi-order), then $\preceq'$ is also an order (respectively a proper quasi-order).

**Proof.** First suppose that $\preceq$ is an order. Comparing the definitions of ordered rings (Definition 2.3) and quasi-ordered rings (Definition 2.6), we only have to show that $\preceq'$ is compatible with $\preceq$. From $\overrightarrow{x} \preceq \overrightarrow{y}$ follows $x + c_1 \preceq y + c_2$ for some $c_1, c_2 \in I_v$. Since $\preceq$ is an order, we get $x + z + c_1 \preceq y + z + c_2$, thus, $x + z \preceq' y + z$. So $\preceq'$ is indeed an order.

Finally, suppose that $\preceq = \preceq_w$ for some valuation $w$ on $R$. We consider the map $w/v : R_v \to \Gamma_{w/v} \cup \{\infty\}$ given by

$$w/v(a + I_v) := \begin{cases} \infty & \text{if } a \in I_v \\ w(a) & \text{else} \end{cases}.$$  

(compare [3] p.45] for the field case). We prove that $w/v$ is well-defined. For $a \in I_v$ this is clear by definition. So suppose that $a \in U_v$ and $c \in I_v$.

We have to show that $w(a) = w(a + c)$. From condition (1) of the previous theorem we obtain for all $x, y \in R$ that if $w(x) \leq w(y)$, then $v(x) \leq v(y)$.

Hence, it follows from $v(a) = 0 < v(c)$ that also $w(a) < w(c)$. Lemma 2.3 yields $w(a + c) = \min\{w(a), w(c)\} = w(a)$.

It is easy to see that $w/v$ satisfies the axioms (V1) and (V2) from Definition 2.1. For (V3) note that $ab \in I_v$ if and only if $a \in I_v$ or $b \in I_v$, since $I_v$ is prime, so $w/v(ab + I_v) = \infty$ if and only if $w/v(a + I_v) + w/v(b + I_v) = \infty$.

From this observation (V3) is easily deduced. The proof of (V4) is done by a similar case distinction. Hence, $w/v$ defines a valuation on $R_v$. Its support is $\{0\}$, as $q_w \subseteq q_v \subseteq I_v$, which again follows from Theorem 5.12.1).

Moreover, for $x, y \in U_v$ (i.e. $\overrightarrow{x}, \overrightarrow{y} \neq 0$) it holds

$$\overrightarrow{x} \preceq_w \overrightarrow{y} \iff x + c_1 \preceq_w y + c_2 \text{ for some } c_1, c_2 \in I_v$$

$$\iff w(y + c_2) \leq w(x + c_1) \text{ for some } c_1, c_2 \in I_v$$

$$\iff w(y) \leq w(x)$$

$$\iff w/v(\overrightarrow{y}) \leq w/v(\overrightarrow{x}).$$
where the third equivalence follows precisely as in the proof of the well-definedness of \( w/v \), while the last equivalence is just the definition of \( w/v \).

This proves that \( \preceq_w \preceq w/v \).

\( \square \)

If \( \preceq \) is an order, then Theorem 3.12 generalizes Theorem 2.4 from ordered fields to ordered rings. Next we show that if \( \preceq \preceq w \) for some Manis valuation \( w \), then Theorem 3.12 precisely characterizes the Manis valuations \( v \) on \( R \) that are coarser than \( w \).

**Definition 3.14.** (see [5, p.415]) Let \( v, w \) be valuations on \( R \). Then \( v \) is said to be a coarsening of \( w \) (or \( w \) a refinement of \( v \)), in short, \( v \preceq w \), if there exists an order homomorphism \( \varphi : \Gamma_w \to \Gamma_v \) such that \( v = \varphi \circ w \), or equivalently, if \( R_w \subseteq R_v \) and \( I_v \subseteq I_w \).

**Lemma 3.15.** Let \( v \preceq w \) be non-trivial Manis valuations on \( R \). Then \( q_v = q_w \).

**Proof.** This is part of [12, Proposition 3.1].

Actually, Power’s proof of the previous result only requires that \( v \) is non-trivial. However, from \( v \) non-trivial and \( v \preceq w \) follows immediately that \( w \) is also non-trivial.

**Lemma 3.16.** Let \( v \) and \( w \) be non-trivial Manis valuations on \( R \). The following are equivalent:

1. \( v \) is \( \preceq_w \)-compatible (i.e. \( w(y) \leq w(z) \Rightarrow v(y) \leq v(z) \)).
2. \( v \) is a coarsening of \( w \).

**Proof.** We first show that (1) implies (2). Let \( x \in R_w \). Then \( 0 = w(1) \leq w(x) \), so also \( 0 = v(1) \leq v(x) \), thus \( x \in R_v \). Likewise, if \( x \notin I_w \), then \( w(x) \leq w(1) = 0 \), which yields that \( v(x) \leq v(1) = 0 \). Therefore \( x \notin I_v \).

Conversely, assume that (2) holds and suppose that \( w(y) \leq w(z) \). By the previous lemma we get \( q_w = q_v \), so we may assume that \( y \) is not in the support of these valuations. Moreover note that \( U_w \subseteq U_v \); indeed, if \( u \in U_w \), then \( u \in R_w \) and \( u \notin I_w \), thus \( u \in R_v \) and \( u \notin I_v \). Therefore, \( u \in U_v \). As \( w(y) \in \Gamma_w \) and \( w \) is Manis, there exists some \( a \in R \) such that \( w(a) = -w(y) \). It follows \( ay \in U_w \) and \( az \in R_w \). Therefore, \( ay \in U_v \) and \( az \in R_v \). It is easy to see that this implies \( v(y) \leq v(z) \).

Hence, we obtain as a special case of Theorem 3.12 the following characterization of coarsenings of \( v \):

**Theorem 3.17.** Let \( v, w \) be non-trivial Manis valuations on \( R \). Then \( v \) is a coarsening of \( w \), if and only if one of the following equivalent conditions is satisfied for all \( x, y \in R \):

1. \( w(x) \leq w(y) \Rightarrow v(x) \leq v(y) \),
2. \( w(x) \leq w(y), 0 \leq v(x) \Rightarrow 0 \leq v(y) \),
3. \( w(x) \leq w(y), 0 < v(x) \Rightarrow 0 < v(y) \),
4. \( w/v : R_v \to \Gamma_w \cup \{\infty\}, x + I_v \mapsto \begin{cases} \infty & \text{if } x \in I_v \\ w(x) & \text{else} \end{cases} \) defines a valuation with support \( \{0\} \).

**Proof.** This is precisely Theorem 3.12 in the case where the quasi-order \( \preceq \) comes from a Manis valuation \( w \), and Lemma 3.10. Moreover, we simplified the convexity of \( R_v \) and \( I_v \) (in (2) and (3)) according to Lemma 3.6.

Next we show that \( I_v \prec 1 \) is not equivalent to all the other conditions of Theorem 3.12, regardless of whether \( \preceq \) is a proper quasi-order (Example 3.19) or an order (Example 3.20), even if \( v \) is non-trivial.
Theorem 3.18. Let \( R \) be a ring, \( \Gamma \subseteq \Gamma' \) ordered abelian groups, \( u : R \to \Gamma \cup \{\infty\} \) a valuation on \( R \), and \( \gamma \in \Gamma' \). For \( f = \sum_{i=0}^{n} a_i X^i \in R[X] \) define
\[
v(f) = \begin{cases} 
\infty & \text{if } f = 0 \\
\min_{0 \leq i \leq n} \{u(a_i) + i\gamma\} & \text{otherwise}.
\end{cases}
\]
Then \( v : R[X] \to \Gamma' \cup \{\infty\} \) is a valuation that extends \( u \).

Proof. As in the field case, see [3, Theorem 2.2.1].

Example 3.19. Let \( v_p : \mathbb{Q} \to \mathbb{Z} \cup \{\infty\} \) denote the \( p \)-adic valuation for some prime number \( p \in \mathbb{N} \) (see [3, p.18]), i.e. if \( 0 \neq x = \frac{a}{p^n} \in \mathbb{Q} \) (using the unique prime factorization in \( \mathbb{Z} \), then \( v_p(x) = r - s \). Apply the previous theorem with \( \gamma = 1 \) to extend \( v_p \) to a valuation \( v : \mathbb{Q}[X] \to \mathbb{Z} \cup \{\infty\} \). The valuation \( v \) is Manis, as \( v_p \) is Manis and they have the same value group. We do the same procedure with \( w \) instead of \( v \), except that this time \( \gamma = 0 \).

Note that \( v = w \) on \( \mathbb{Q} \) and \( v(f) = w(f) + i \) for some \( i \geq 0 \) if \( f \in \mathbb{Q}[X] \setminus \mathbb{Q} \). This implies \( I_v \preceq_w 1 \). Indeed, \( f \in I_v \) means \( v(f) > 0 \). But then also \( w(f) > 0 = w(1) \), and therefore \( f \preceq_w 1 \). However, \( v \) is not compatible with \( \preceq_w \). For instance we have \( w(X^2) = 0 < w(p) = 1 < w(0) = \infty \), but \( v(p) = 1 < v(X^2) = 2 \).

Example 3.20. Consider the trivial valuation \( u(x) = 0 \) for \( x \neq 0 \) on \( \mathbb{Z} \). Extend \( u \) via the previous theorem to a valuation \( v \) on \( \mathbb{Z}[X,Y] \) with \( \gamma = 1 \) (for \( X \)), respectively \( \gamma = -1 \) (for \( Y \)). Thus, for any \( 0 \neq f = \sum_{i,j} a_{ij} X^i Y^j \in \mathbb{Z}[X,Y] \), we have
\[
v(f) = \min_{i,j} \{v(a_{ij}) + i - j\}.
\]

Note that \( v \) is a Manis valuation with value group \( \mathbb{Z} \), for if \( m \) is an integer, then either \( v(X^m) = m \) (if \( m \geq 0 \)) or \( v(Y^{-m}) = m \) (else). Order \( \mathbb{Z}[X,Y] \) by declaring \( f \geq 0 :\iff f(0) \geq 0 \). Note that \( v(f) \leq 0 \) if \( a_{00} \neq 0 \). Therefore, \( I_v \subseteq \langle X, Y \rangle \subseteq E_0 \), so \( I_v < 1 \). However, \( I_v \) is not convex since \( 0 \leq Y \leq 0 \), but \( Y \notin I_v \).

Remark 3.21. In the case of ordered fields \( (K, \leq) \), the condition \( I_v < 1 \) is often times replaced with the equivalent condition \( 1 + I_v \geq 0 \) (see for instance [8, Definition 2.4] or [3, Proposition 2.2.4]). Note, however, that this is inappropriate for proper quasi-orders, as \( 1 + I_v \geq 0 \) is then trivially satisfied.

We continue this section by imposing a suitable extra condition on \( v \), such that \( I_v < 1 \) is equivalent to (1) - (3) from Theorem 3.12.

Definition 3.22. (see [5, Ch. I, Definition 5]) A valuation \( v \) on \( R \) is called local, if the pair \( (R_v, I_v) \) is local, i.e. if \( I_v \) is the unique maximal ideal of \( R_v \).

The maximal ideal of a local ring consists precisely of all non-units of the said ring. A characterization of local valuations is given in [6, Ch. I, Proposition 1.3] and [5, Proposition 5], respectively. If \( R \) is a field, then \( v \) is always a local Manis valuation.

Lemma 3.23. Let \((R, \preceq)\) be a quasi-ordered ring and \( v \) a local Manis valuation on \( R \). The following are equivalent:

1. \( v \) is compatible with \( \preceq \).
2. \( I_v \prec 1 \).

Proof. (1) implies (2) is clear, see Remark 3.20. Now suppose that (2) holds, and assume for a contradiction that there are some \( y, z \in R \) such that \( 0 \preceq y \preceq z \), but \( v(y) < v(z) \). The latter implies \( y \notin q_v \). Since \( v \) is Manis, we find some \( 0 \preceq a \preceq b \).
such that \( v(a) = -v(y) \). We obtain \( 0 = v(ay) < v(az) \), so \( ay \in U_v \) and \( az \in I_v \). As \( v \) is local and \( ay \in U_v \), \( ay \) is a unit. It follows

\[
0 < v(az) - v(ay) = v \left( \frac{az}{ay} \right),
\]

i.e. \( \frac{az}{ay} \in I_v \). Hence, (2) yields \( \frac{az}{ay} < 1 \). This implies \( az < ay \) (for if \( az \approx ay \), then \( \frac{az}{ay} \approx 1 \) by Corollary 3.10; a contradiction). On the other hand, it follows from \( y \leq z \) and \( 0 \leq a \) that \( ay \leq az \), a contradiction. □

**Corollary 3.24.** Let \( v, w \) be non-trivial Manis valuations on \( R \) such that \( v \) is local. Then \( v \) is coarser than \( w \) if and only if \( I_v \subseteq I_w \).

**Proof.** This is an immediate consequence of Lemma 3.10 and Lemma 3.23 in the case where \( \leq \leq_w \) for some non-trivial Manis valuation \( w \). □

We conclude this section by establishing a notion of rank of a quasi-ordered ring. For the sake of convenience we first consider the field case and then reduce the ring case to it.

**Definition 3.25.** (compare [6] Ch. I, Definition 2) Two valuations \( v, w \) on \( R \) are said to be **equivalent**, in short, \( v \sim w \), if \( v(x) \leq v(y) \Leftrightarrow w(x) \leq w(y) \) for all \( x, y \in R \).

Let \( v, w \) be two non-trivial Manis valuations on \( R \). From Theorem 3.12(1) and Definition 3.14 follows

\[
v \sim w \Leftrightarrow v \leq w \text{ and } w \leq v \Leftrightarrow R_v = R_w \text{ and } I_v = I_w.
\]

By abuse of language, we identify equivalent valuations (this is quite common in the literature, see for instance [6, p.11] or [12, p.256]).

**Proposition 3.26.** Let \( (K, \leq) \) be a quasi-ordered field. The set

\[
\mathcal{R} := \{ w : w \text{ is a non-trivial } \preceq \text{-compatible valuation on } K \}
\]

is totally ordered by \( \leq \) (“coarser”)

**Proof.** If \( v, w \in \mathcal{R} \), Theorem 3.12(2) yields that \( K_v \) and \( K_w \) are convex subrings of \( K \), without loss of generality \( K_w \subseteq K_v \). If equality holds, it is easy to verify that also \( I_w = I_v \), since both \( K_v \) and \( K_w \) are local. Thus, \( v = w \). If \( K_w \subseteq K_v \), it follows again by the fact that \( K_v \) and \( K_w \) are local, that \( I_v \subseteq I_w \), and therefore \( v < w \). □

**Definition 3.27.** The rank of a quasi-ordered field \( (K, \leq) \) is the order type of the totally ordered set \( \mathcal{R} \).

For the following result we use that \( (R, \preceq) \) is a quasi-ordered ring if and only if \( (R/E_0, \preceq') \) is a quasi-ordered ring, where \( \overline{x} \preceq' \overline{y} \Leftrightarrow x \preceq y \) (see [11] Lemma 4.1). Moreover, we exploit that the quasi-order \( \preceq' \) uniquely extends to a quasi-order \( \preceq \) on \( K := \text{Quot}(R/E_0) \) via

\[
\overline{x} \preceq \overline{y} :\Leftrightarrow \overline{xy} \preceq' \overline{ay}
\]

(see [11] Proposition 4.3). If \( v \) is a valuation on \( R \), let \( v' \) denote the induced valuation on \( R/E_0 \), and \( \overline{v}' \) the extension of \( v' \) to \( K \). We can now prove (see [13] Lemma 4.1 for the same result in the ordered case):

**Lemma 3.28.** Let \( (R, \preceq) \) be a quasi-ordered ring and \( v \) a valuation on \( R \) with support \( q_v = E_0 \). The following are equivalent:

1. \( v \) is compatible with \( \preceq \).
2. \( v' \) is compatible with \( \preceq' \).
(3) $\overline{\psi}$ is compatible with $\preceq$.

Proof. The equivalence of (1) and (2) easily follows from the definition of $\preceq'$ and $\psi'$, respectively. We conclude by showing that (2) and (3) are equivalent. It is clear that compatibility in $K$ reduces to compatibility in $R$ as it is a universal statement. For the contrary, let $0 \preceq \frac{a}{b} \preceq \frac{c}{d}$. Then $0 \preceq x y b^2 \preceq a y b^2$. By compatibility with $v$, we obtain that $v(a y b^2) \preceq v(x y b^2)$, i.e. that $v(a y) \preceq v(x b)$. Thus, $\overline{\psi}(\frac{a}{b}) \preceq \overline{\psi}(\frac{c}{d})$. \hfill \Box

The equivalence of (1) and (3) from the previous lemma justifies to define:

**Definition 3.29.** The rank of a quasi-ordered ring $(R, \preceq)$ is the rank of the naturally associated quasi-ordered field $(\text{Quot}(R/E_0), \preceq)$.

For a further discussion on the rank of a quasi-ordered field we refer to [7, p.403].

### 4. The Baer-Krull Theorem

In the previous section we fixed a quasi-ordered ring $(R, \preceq)$ and characterized all the (local) Manis valuations on $R$, that are compatible with $\preceq$ (see Theorem 3.12 and Lemma 3.28). It is natural to ask what happens the other way round, i.e. if we fix a valued ring $(R, v)$ with $v$ Manis, can we describe all the quasi-orders on $R$ that are compatible with $v$? A positive answer is given by the Baer-Krull Theorem (see Theorem 4.10) respectively Corollary 4.11. Recall that if $\preceq$ is a $v$-compatible quasi-order on $R$, then it gives rise to a quasi-order $\preceq'$ on the residue class domain $Rv := R_v/I_v$. The said theorem establishes a connection between the $v$-compatible quasi-orders on $R$ with support sup$(v)$, and the quasi-orders on $Rv$ with support $\varnothing$. After establishing the Baer-Krull Theorem for quasi-ordered rings, we deduce a version for ordered, respectively proper quasi-ordered, rings (see Corollary 4.19) respectively Corollary 4.25. The first one yields a generalization of the classical Baer-Krull Theorem (see Theorem 4.10), while the latter gives rise to a characterization of all Manis valuations on $R$ that are finer than $v$.

When one deals with quasi-ordered rings, this theorem becomes more complicated than in the ordered field case (see Theorem 2.10). Note that the map $\eta$ there is completely determined by the signs of the elements $\pi_i$. If the quasi-order is an order, then all $\eta \in \{-1, 1\}^I$ are realizable and one gets a bijective correspondence as in Theorem 2.10. However, if the quasi-order is induced by some valuation, then all elements are non-negative, so the only $\eta$ possible is the constant map $\eta = 1$. Therefore, when we consider quasi-ordered rings $(R, \preceq)$, the best we can hope for is that $\psi$ is an injective map such that the image of $\psi$ contains all possible tuples $(\eta_{\preceq}, \preceq')$ as just described. Establishing such a result will be the aim for the rest of this paper.

**Notation 4.1.** We use the following notation for the rest of this section:

1. Let $R$ be a commutative ring with 1 and $v: R \to \Gamma_v \cup \{\infty\}$ a Manis valuation on $R$ with support $\mathfrak{q}_v$, valuation ring $R_v$, valuation ideal $I_v$, and residue class domain $Rv := R_v/I_v$, just as in Notation 3.1. Moreover, we define $\overline{R} := R_{\mathfrak{q}_v} = v^{-1}(\Gamma_v)$.

2. We fix some $\mathbb{F}_2$-basis $\{\overline{\gamma}_i : i \in I\}$ of $\Gamma_v = \Gamma_v/2\Gamma_v$, and let $\{\pi_i : i \in I\} \subseteq \overline{R}$ be such that $v(\pi_i) = \gamma_i$.

3. Given a $v$-compatible quasi-order on $R$, we denote by $\preceq'$ the induced quasi-order on $Rv$ (see Theorem 3.12(3)). By $\eta_{\preceq}$ we denote the map $I \to \{-1, 1\}$ defined by $\eta_{\preceq}(i) = 1$ if and only if $0 \preceq \pi_i$. 

Now we fix some tuple \((\eta^*, \prec^*)\) from the disjoint union 
\[
\{-1, 1\}^I \times \{\text{orders on } R^v \text{ with support } \{0\}\} \cup \{1\}^I \times \{\text{p.q.o. on } R^v \text{ with support } \{0\}\}
\]
The main part of the proof of the Baer-Krull Theorem is to construct a quasi-order on \(R\) that is mapped to \((\eta^*, \prec^*)\) under the analogue of the map \(\psi\) from Theorem 2.10. For that purpose we define a binary relation \(\preceq\) on \(R\) as a function of \(\preceq^*\) and \(\eta^*\) as follows: If \(x, y \in q_v\), declare \(x \preceq y\). Otherwise, if \(x \in R\) or \(y \in R\), consider 
\[
\gamma := \gamma_{x,y} := \max\{-v(x), -v(y)\} \in \Gamma_v.
\]
Write \(\gamma = \sum_{i \in I_{x,y}} \gamma_i\). Then \(\gamma = \sum_{i \in I_{x,y}} \gamma_i + 2v(a_{x,y})\) for some \(a_{x,y} \in \tilde{R}\), which is uniquely determined up to its value (i.e. instead of \(a_{x,y}\) one may have chosen any other element \(b_{x,y} \in R\) with \(v(b_{x,y}) = v(a_{x,y})\)). In what follows, we will just write \(\sum_i, \Pi_i\) and \(a\) instead of \(\sum_{i \in I_{x,y}}, \Pi_{i \in I_{x,y}}\) and \(a_{x,y}\), respectively, whenever \(x\) and \(y\) are clear from the context.

**Lemma 4.2.** Let \(x, y \in \tilde{R}\). With the notation above, \(x \prod_i \pi_i a^2\), \(y \prod_i \pi_i a^2 \in R_v\). Moreover, \(x \prod_i \pi_i a^2 \neq 0\) if and only if \(v(x) > v(y)\).

**Proof.** Note that 
\[
v \left( x \prod_i \pi_i a^2 \right) = v(x) + \sum_i v(\pi_i) + 2v(a) = v(x) + v(y) \geq 0,
\]
and likewise for \(y \prod_i \pi_i a^2\), so both are in \(R_v\). Moreover, 
\[
x \prod_i \pi_i a^2 = 0 \iff v(x) + \max\{-v(x), -v(y)\} > 0 \iff v(x) > v(y).
\]

\(\square\)

Particularly, we can take residues of both \(x \prod_i \pi_i a^2\) and \(y \prod_i \pi_i a^2\). The moreover part of the statement will be of great importance in the proof of Main Lemma 4.5. For the latter, we also require the following two lemmas, which extend the statements from axiom (QR3), respectively (QR5).

**Lemma 4.3.** Let \((R, \preceq)\) be a quasi-ordered ring. If \(x \preceq y\) and \(z \preceq 0\), then \(yz \preceq xz\).

**Proof.** As \(E_0\) is an ideal, we may without loss of generality assume that \(z \sim 0\). Moreover, note that if \(y \sim 0\), then \(x, z \preceq 0\), thus \(0 \preceq -x, -z\). It follows via (QR3) that \(yz \sim 0 \preceq xz\). So we may also assume that \(y \notin E_0\). From \(x \preceq y\) and \(z \preceq 0\) follows \(-xz \preceq -yz\). We claim that \(yz \sim -yz\). Once this is shown, it follows from \(-xz \preceq -y\) that \(yz \preceq -xz\). The latter implies \(y \sim x\). Indeed, either \(x \sim 0\) and therefore \(xz \sim 0\) (\(E_0\) is a prime ideal), so that we can apply (QR4); or \(x \sim 0\), i.e. \(xz \sim 0\), and therefore \(y \sim x\) \(\sim y\) \(\preceq 0 \sim xz\) (see Remark 2.11). So assume for a contradiction that \(yz \sim -yz\). Lemma 3.3 yields \(0 \preceq yz, -yz\). As \(y \notin E_0\), either \(0 \preceq y\) or \(0 \preceq -y\). So via (QR5) it follows either from \(0 \preceq yz\) (if \(0 \preceq y\)) or from \(0 \preceq -yz\) (if \(0 \preceq -y\)) that \(0 \preceq z\). Hence \(z \sim 0\), a contradiction. \(\square\)

**Lemma 4.4.** Let \((R, \preceq)\) be a quasi-ordered ring and \(x, y, z \in R\). If \(xz \preceq yz\) and \(z \preceq 0\), then \(y \preceq x\).

**Proof.** Assume for a contradiction \(x \prec y\). The previous lemma yields \(yz \preceq xz\). Hence \(xz \sim yz\). Lemma 2.8 yields \(x \sim y\), a contradiction. \(\square\)
Main Lemma 4.5. With the notation from above, define for \( x \in \bar{R} \) or \( y \in \bar{R} \) that

\[
x \preceq y :\iff \begin{cases} &\text{Either } \prod_i \pi_i a_i^2 \preceq^* y \prod_i \pi_i a_i^2 \text{ and } \prod_i \eta^*(i) = 1 \\
&\text{or } y \prod_i \pi_i a_i^2 \preceq^* \prod_i \pi_i a_i^2 \text{ and } \prod_i \eta^*(i) = -1.\end{cases}
\]

Moreover, declare \( x \preceq y \) for \( x, y \in q_v \). Then \( \preceq \) defines a quasi-order on \( R \) with support \( E_0 = q_v \).

Proof. The proof of the Main Lemma is extensive, however, the methods are widely the same. Notably, the moreover part from Lemma 4.2 is frequently exploited. We always use the notation from above. For the sake of convenience and uniformity, we treat \( \preceq^* \) and \( \eta^* \) as an arbitrary quasi-order on \( \bar{R}_v \) with support \( \{0\} \), respectively an arbitrary map from \( I \) to \( \{-1, 1\} \), for as long as possible. In fact, the distinction whether \( \preceq^* \) is an order or induced by a valuation (in which case the map \( \eta^* \) is trivial) is only necessary at some points when we verify axiom (QR4).

First of all we show that \( \preceq \) is well-defined. Recall that \( a \in \bar{R} \) was only determined up to its value. So let \( b \in \bar{R} \) with \( v(a) = v(b) \), and suppose that

\[
\prod_i \pi_i a_i^2 \preceq^* \prod_i \pi_i a_i^2.
\]

As \( v \) is Manis, there exists some \( z \in \bar{R} \) with \( v(z) = -v(b) \), so \( v(bz) = 0 \), i.e. \( bz \neq 0 \). Particularly, \( 0 \preceq^* \bar{a}z^2 \). With axiom (QR3) follows, after rearranging, that

\[
\prod_i \pi_i b_i^2 \bar{a}z^2 \preceq^* \prod_i \pi_i b_i^2 \bar{a}z^2.
\]

We conclude by eliminating \( 0 \preceq^* \bar{a}z^2 \) via axiom (QR5).

Clearly, \( \preceq \) is reflexive and total. At next we prove transitivity. So let \( x \preceq y \) and \( y \preceq z \), without loss of generality \( x \in \bar{R} \) or \( z \in \bar{R} \). The proof is done by distinguishing four cases. First of all assume that \( v(p) = v(q) \leq v(r) \) with \( p, q, r \in \{x, y, z\} \) pairwise distinct. Then \( \gamma_{x,y} = \gamma_{y,z} = \gamma_{y,z} \in \Gamma_v \) all coincide, so \( I_{x,y} = I_{x,z} = I_{y,z} \) and \( a_{x,y} = a_{x,z} = a_{y,z} \). Hence, transitivity of \( \preceq \) follows immediately by transitivity of \( \preceq^* \). It remains to verify the cases where there is a unique smallest element among \( v(x), v(y) \) and \( v(z) \). First suppose that \( v(x) < v(y), v(z) \). Then \( \gamma_{x,y} = -v(x) = \gamma_{x,z} \), i.e. \( I_{x,y} = I_{x,z} \) and \( a_{x,y} = a_{x,z} \). We do the case \( \prod_{i \in I_{x,y}} \eta^*(i) = -1 \), the case \( \prod_{i \in I_{x,y}} \eta^*(i) = 1 \) is proven likewise. From \( x \preceq y \) and \( v(x) < v(y) \) then follows

\[
y \prod_{i \in I_{x,y}} \pi_i a_i^2 \preceq^* x \prod_{i \in I_{x,y}} \pi_i a_i^2 \]

(see Lemma 4.2). Now \( v(x) < v(z) \) and Lemma 4.2 imply that

\[
z \prod_{i \in I_{x,y}} \pi_i a_i^2 \preceq 0.
\]

Therefore, \( x \preceq z \). Next, suppose that \( v(y) < v(x), v(z) \). Then \( \gamma_{x,y} = -v(y) = \gamma_{y,z} \), i.e. \( I_{x,y} = I_{y,z} \) and \( a_{x,y} = a_{y,z} \). Again, we only do the case \( \prod_{i \in I_{x,y}} \eta^*(i) = -1 \). From \( v(y) < v(x) \) and \( x \preceq y \) follows

\[
y \prod_{i \in I_{x,y}} \pi_i a_i^2 \preceq^* x \prod_{i \in I_{x,y}} \pi_i a_i^2 \]

(see Lemma 4.2). Now \( v(x) < v(z) \) and Lemma 4.2 imply that

\[
z \prod_{i \in I_{x,y}} \pi_i a_i^2 \preceq 0.
\]
Likewise, $v(y) < v(z)$ and $y \preceq z$ implies
\[
0 \preceq y \prod_{i \in I_{x,y}} \pi_i a_{x,y}^2.
\]
Since the support of $\preceq^*$ is trivial, it follows
\[
y \prod_{i \in I_{x,y}} \pi_i a_{x,y}^2 = 0.
\]
On the other hand, $v(y) < v(x), v(z)$ yields via Lemma 4.2 that
\[
y \prod_{i \in I_{x,y}} \pi_i a_{x,y}^2 \neq 0,
\]
a contradiction. The case $v(z) < v(x), v(y)$ is proven like the case where $v(x)$ is the unique smallest value.

Next, we establish that the support of $\preceq$ is $q_v$. Assume there is some $x \in E_0$ with $x \not\in q_v$. Then $\prod I_{x,y} \pi_i a^2 \sim 0$. As the support of $\preceq^*$ is $\{0\}$, this yields $x \prod I_{x,y} \pi_i a^2 \in I_v$. However, as $v(x) < v(0) = \infty$, this contradicts Lemma 4.2. We obtain that $E_0 \subseteq q_v$.

The other implication follows immediately from the definition of $\preceq$.

It remains to verify the axioms (QR1) - (QR5) and compatibility with $v$. For the proof of (QR1) assume for a contradiction that $1 \preceq 0$. Note that $\gamma_{0,1} = 0$, so $I = 0$, and $\prod I_{x,y} \eta^*(i) = 1$. It follows from $1 \preceq 0$ that $\prod a \preceq^* 0$ for some $a \in R$ with $v(a) = 0$, i.e. $\mathfrak{p} \neq 0$. This contradicts the facts that squares are non-negative and that the support of $\preceq^*$ is trivial.

For (QR2) it is nothing to show by Remark 2.7(3). Next, we verify (QR3), i.e. we show that $x \preceq y$ and $0 \preceq z$ implies $xz \preceq yz$. By the definition of $\preceq$ and the fact that $q_v$ is an ideal, we may without loss of generality assume that $z \not\in q_v$, and that not both $x$ and $y$ are in $q_v$. Further note that
\[
\gamma_{xz,yz} = \max\{-v(xz), -v(yz)\} = \max\{-v(z), -v(0)\} + \max\{-v(x), -v(y)\} = \gamma_{0,z} + \gamma_{x,y} \in \Gamma_v.
\]
Hence, $I_{x,z}$ is the (without loss of generality) disjoint union of $I_{x,y}$ and $I_{0,z}$, which implies
\[
\prod_{i \in I_{x,z}} \eta^*(i) = \prod_{i \in I_{x,y}} \eta^*(i) \cdot \prod_{i \in I_{0,z}} \eta^*(i).
\]
Moreover, $a_{x,y} = a_{x,y} a_{0,z}$.

First consider the case $\prod_{i \in I_{0,z}} \eta^*(i) = 1$. This yields $0 \preceq^* z \prod_{i \in I_{0,z}} \pi_i a_{0,z}^2$. Now let $\prod_{i \in I_{x,y}} \eta^*(i) = -1 = \prod_{i \in I_{x,z}, y} \eta^*(i)$. Then
\[
0 \preceq^* y \prod_{i \in I_{x,y}} \pi_i a_{x,y}^2 \preceq^* x \prod_{i \in I_{x,y}} \pi_i a_{x,y}^2.
\]
Applying (QR3) yields
\[
yz \prod_{i \in I_{x,y}} \pi_i a_{x,y}^2 a_{0,z}^2 \preceq^* xz \prod_{i \in I_{x,y}} \pi_i a_{x,y}^2 a_{0,z}^2.
\]
Hence, $xz \preceq yz$. The case $\prod_{i \in I_{x,z}} \eta^*(i) = 1 = \prod_{i \in I_{x,z}} \eta^*(i)$ is proven analogously. The proof for $\prod_{i \in I_{0,z}} \eta^*(i) = -1$ is also almost the same; we just apply Lemma 4.2 instead of axiom (QR3).

The proof of axiom (QR4) is divided into five subcases. First suppose that $v(x) < v(z), v(y) < v(z)$. Either way, $\gamma_{x,y} = \gamma_{x+z,y+z}$. Moreover, in both cases $z \prod_{i \in I_{0,z}} \pi_i a_{0,z}^2 = 0$. From this observation, the claim follows immediately. Further
note that if $\preceq^*$ is an order and $x \prec y$, we obtain $x + z \prec y + z$, because orders preserve strict inequalities under addition. We will exploit this fact below.

If $v(z) < v(x), v(y)$, then $\gamma_{y,z} = \gamma_{x+z,y+z}$. Note that

$$x \prod_{i \in I_{x,y}} \pi_i a_{x,y}^2 = 0 = y \prod_{i \in I_{y,z}} \pi_i a_{y,z}^2$$

by Lemma 4.2. It is easy to see that then $x + z \preceq y + z$. Suppose now that $v(x) = v(z) < v(y)$. Then $\gamma_{x,y} = \gamma_{y,z} = \gamma_{x+z,y+z}$. From $v(x) < v(y)$ follows that $y \prod_{i \in I_{x,y}} \pi_i a_{x,y}^2 = 0$. We distinguish two subcases. If $\prod_{i \in I_{x,y}} \eta^*(i) = 1$, then $x \preceq y$ yields

$$x \prod_{i \in I_{x,y}} \pi_i a_{x,y}^2 \preceq^* y \prod_{i \in I_{x,y}} \pi_i a_{x,y}^2 = 0.$$ 

As $z \sim y$, one may add $z \prod_{i \in I_{x,y}} \pi_i a_{x,y}^2$ on both sides. This concludes the present subcase. On the other hand, if $\prod_{i \in I_{x,y}} \eta^*(i) = -1$, then $\eta^* \neq 1$, so $\preceq^*$ is an order. Thus, one may add $z \prod_{i \in I_{x,y}} \pi_i a_{x,y}^2$ on both sides as well. Next, suppose that $v(y) = v(z) < v(x)$. Then $\gamma_{x,y} = \gamma_{x+z,y+z}$. It holds $x \prod_{i \in I_{x,y}} \pi_i a_{x,y}^2 = 0$. If $\prod_{i \in I_{x,y}} \eta^*(i) = 1$, then $x \preceq y$ yields $0 \preceq^* y \prod_{i \in I_{x,y}} \pi_i a_{x,y}^2$ and one may conclude by adding $z \prod_{i \in I_{x,y}} \pi_i a_{x,y}^2$ on both sides. Analogously, if $\prod_{i \in I_{x,y}} \eta^*(i) = -1$, one may also add $z \prod_{i \in I_{x,y}} \pi_i a_{x,y}^2$ on both sides, as the support of $\preceq^*$ is zero. Finally, suppose that $v(x) = v(y) = v(z)$. If they are all in $c$, then also $x + z, y + z \in c$, and therefore $x + z \preceq y + z$. So suppose that $v(x) = v(y) = v(z) \in \Gamma(Z)$. It holds

$$\gamma_{x+z,y+z} = \max\{-v(x+z), -v(y+z)\} \preceq -v(z).$$

First suppose that equality holds. Then $\max\{-v(x+z), -v(y+z)\} = -v(z)$, i.e. all $\gamma$’s coincide. If $\prod_{i \in I_{x,y}} \eta^*(i) = 1$, the claim follows immediately from (QR4) and the fact that $y \sim z$ by simply adding $z \prod_{i \in I_{x,y}} \pi_i a_{x,y}^2$ to both sides of the inequality $x \prod_{i \in I_{x,y}} \pi_i a_{x,y}^2 \preceq^* y \prod_{i \in I_{x,y}} \pi_i a_{x,y}^2$. If $\prod_{i \in I_{x,y}} \eta^*(i) = -1$, then $\preceq^*$ must be an order and we may simply add $z \prod_{i \in I_{x,y}} \pi_i a_{x,y}^2$ on both sides anyway.

Last but not least assume that $< \text{ holds, i.e. } \max\{-v(x+z), -v(y+z)\} < -v(z)$. Then $v(z) < (x+z), v(y+z)$. By Lemma 4.2, $p \prod_{i \in I_{x,y}} \pi_i a_{x,y}^2 \neq 0$ for $p \in \{x, y, z\}$, whereas

$$(x + z) \prod_{i \in I_{x,y}} \pi_i a_{x,y}^2 = 0 = (y + z) \prod_{i \in I_{x,y}} \pi_i a_{x,y}^2.$$ 

Therefore,

$$(x + z) \prod_{i \in I_{x,y}} \pi_i a_{x,y}^2 = (y + z) \prod_{i \in I_{x,y}} \pi_i a_{x,y}^2 = -z \prod_{i \in I_{x,y}} \pi_i a_{x,y}^2.$$ 

Particularly, we may assume that $\preceq^*$ is an order, since in the proper quasi-ordered case

$$y \prod_{i \in I_{x,y}} \pi_i a_{x,y}^2 \sim -y \prod_{i \in I_{x,y}} \pi_i a_{x,y}^2 = z \prod_{i \in I_{x,y}} \pi_i a_{x,y}^2,$$ 

contradicting the assumption $y \sim z$. We claim that $x + z \sim 0 \sim y + c$, which clearly implies $x + z \preceq y + z$. Assume for a contradiction that $x + z \sim 0$. If $x + z \prec 0$, it follows from the case “$v(x) < v(z)$” (where $x + z$ plays the role of $x$, 0 the one of $y$ and $-z$ the one of $z$; recall that $v(x+z) < v(z)$) above and the fact that $\preceq^*$ is an order, that $x \sim -z$, contradicting $x \sim -z$. Likewise, if $0 < x + z$, it follows from the case “$v(y) < v(z)$” that $-z < x$, again a contradiction. Therefore $x + z \sim 0$. The same reasoning shows that $y + z \sim 0$ as well.
Finally, we prove axiom (QR5). Suppose that \( xz \preceq yz \) and \( 0 \prec z \). Clearly \( z \in \bar{R} \), as \( 0 \sim z \). Moreover, let without loss of generality \( x \in \bar{R} \) or \( y \in \bar{R} \). Note that \( \gamma_{xz,yz} = \gamma_{x,y} + \gamma_{z,0} \), and \( \prod_{i \in I_{xz,yz}} \eta^*(i) = \prod_{i \in I_{x,y}} \eta^*(i) \prod_{i \in I_{z,0}} \eta^*(i) \), and \( a_{xz,yz} = a_{0,z}a_{x,y} \), as in the proof of (QR3) above.

First let \( \prod_{i \in I_{xz,yz}} \eta^*(i) = 1 \). Then \( 0 \prec y \prod_{i \in I_{xz,yz}} \pi_{i}a_{0,z}^2 \). If \( \prod_{i \in I_{x,y}} \eta^*(i) = 1 \), also \( \prod_{i \in I_{z,0}} \eta^*(i) = 1 \). We obtain

\[
\frac{yz}{\prod_{i \in I_{x,y}} \pi_{i}a_{x,y}^2} \geq \frac{xz}{\prod_{i \in I_{x,y}} \pi_{i}a_{x,y}^2}.
\]

Eliminating \( \prod_{i \in I_{x,y}} \pi_{i}a_{0,z}^2 \) via (QR5) yields

\[
y \prod_{i \in I_{x,y}} \pi_{i}a_{x,y}^2 \geq x \prod_{i \in I_{x,y}} \pi_{i}a_{x,y}^2,
\]

and therefore \( x \preceq y \). If \( \prod_{i \in I_{x,y}} \eta^*(i) = 1 \), then \( \prod_{i \in I_{x,y}} \eta^*(i) = 1 \), and the proof is likewise.

Now let \( \prod_{i \in I_{x,y}} \eta^*(i) = 1 \). Then \( \prod_{i \in I_{x,y}} \pi_{i}a_{x,y}^2 \prec 0 \). If \( \prod_{i \in I_{x,y}} \eta^*(i) = 1 \), then \( \prod_{i \in I_{x,y}} \eta^*(i) = 1 \). It follows

\[
\frac{yz}{\prod_{i \in I_{x,y}} \pi_{i}a_{x,y}^2} \geq \frac{xz}{\prod_{i \in I_{x,y}} \pi_{i}a_{x,y}^2}.
\]

Applying Lemma 4.8 yields \( x \prod_{i \in I_{x,y}} \pi_{i}a_{x,y}^2 \geq y \prod_{i \in I_{x,y}} \pi_{i}a_{0,z}^2 \). Therefore, \( x \preceq y \).

The case \( \prod_{i \in I_{x,y}} \eta^*(i) = 1 \) is analogue.

We conclude by showing that \( \preceq \) is \( v \)-compatible. Suppose \( 0 \preceq x \preceq y \) but \( v(x) < v(y) \) for some \( x, y \in R \). Note that \( \gamma_{0,x} = -v(x) = \gamma_{x,y} \). If \( \prod_{i} \eta^*(i) = -1 \), then \( 0 \preceq x \) yields

\[
x = \prod_{i \in I_{0,x}} \pi_{i}a_{0,x}^2 \preceq 0 = y \prod_{i \in I_{0,z}} \pi_{i}a_{0,z}^2,
\]

i.e. \( y \prec x \), a contradiction. The same argument works for \( \prod_{i \in I_{0,z}} \eta^*(i) = 1 \). \( \square \)

**Remark 4.6.** The quasi-order \( \preceq \) from the Main Lemma becomes very simple in the case where \( x \in U_e \) and \( y \in R_0 \) (or vice versa). Note that then \( \gamma_{x,y} = 0 \). This implies \( I = \emptyset \). Hence, \( \prod_{i} \eta^*(i) = 1 \). Moreover, the element \( a \) satisfies \( v(a) = 0 \), so by well-definedness of \( \preceq \) we may simply choose \( a = 1 \). Therefore \( x \preceq y \Leftrightarrow x \preceq y \).

For the proof of the Baer-Krull Theorem we require two more lemmas. They will be used to compare the “size” of two quasi-orders on \( R \).

**Lemma 4.7.** Let \( (R, \preceq) \) be a quasi-ordered ring and \( x \in R \). Then \( E_0 + \{x\} \subseteq E_x \).

**Proof.** For \( x \in E_0 \) there is nothing to show. So let \( y \in R \setminus E_0 \) such that \( y = c + x \) for some \( c \in E_0 \). Remark 2.4 yields \( c + x \sim x \), so \( y \in E_x \). \( \square \)

**Lemma 4.8.** Let \( (R, \preceq) \) be a quasi-ordered ring and \( x \in R \). If \( E_0 + \{x\} \subseteq E_x \), then \( E_x = -\bar{E}_x \).

**Proof.** Let \( z \in E_x \) be arbitrary and \( y \in E_x \setminus (E_0 + \{x\}) \). We will show that \( -y \in E_x \). From \( z \sim x \sim y \) and Corollary 3.10, then follows \( -z \sim -y \sim x \), i.e. also \( -z \in E_x \), what proves that \( E_x = -\bar{E}_x \).

The proof that \( -y \in E_x \) is like in [H p.208]. Assume for a contradiction that \( -y \not\in E_x \). Then \( y \preceq x \prec y \), thus \( 0 \preceq x - y \). Likewise, it follows from \( x \preceq y \prec -y \) that \( x - y \preceq 0 \). Therefore, \( x - y \in E_0 \), i.e. \( y \in E_0 + \{x\} \), a contradiction. Hence, \( -y \in E_x \), i.e. \( E_x = -\bar{E}_x \). \( \square \)
Notation 4.9. For a prime ideal \( p \) of \( R \) denote by \( \mathcal{X}_p(R) \) the set of all quasi-orders on \( R \) with support \( p \). Analogously, denote by \( \mathcal{X}_{o,p}(R) \) (respectively \( \mathcal{X}_{p,p}(R) \)) the set of all orders (respectively proper quasi-orders) on \( R \) with support \( p \). If \( R \) is a field, we omit the index \( p \) for obvious reasons.

In the Baer-Krull Theorem we demand that the support of the quasi-orders coincides with the support of our valuation. Note that it actually suffices to demand \( \text{supp}(v) \subseteq \text{supp}(\leq) \), the other implication being implied as follows: If \( x \in \text{supp}(\leq) \), then \( 0 \leq x \leq 0 \), so compatibility yields \( v(x) = \infty \in q_o \).

**Theorem 4.10.**  (Baer-Krull Theorem for quasi-ordered rings I)  

Let \( R \) be a commutative ring with 1 and \( v \) a Manis valuation on \( R \). Then

\[
\psi: \{ \leq \in \mathcal{X}_o(R): \leq \text{ is } v\text{-compatible} \} \to \{-1, 1\}^I \times \mathcal{X}_{(0)}(Rv),
\]

\[
\leq \mapsto (\eta_{\leq}, \leq^v)
\]

is a well-defined map such that \( \psi \restriction \psi^{-1}(A) : \psi^{-1}(A) \to A \) is a bijection, where \( A := \{-1, 1\}^I \times \mathcal{X}_{(0)}(Rv) \cup \{1\}^I \times \mathcal{X}_{p, (0)}(Rv) \).

**Proof.** By Theorem 3.12(3) the map \( \phi \) is well-defined. Next, let \((\eta^v, \leq^v) \in A \) be arbitrary. We prove that \( \psi \) maps the quasi-order \( \leq \) constructed in the Main Lemma to the tuple \((\eta^v, \leq^v)\). First we verify that \( \eta_{\leq} = \eta^v \). To compare \( \pi_i \) and 0 w.r.t. \( \leq \), let \( \gamma := \max\{-v(\pi_i), -v(0)\} = -\gamma_i \), i.e. \( \gamma = v(\pi_i a^2) \) for some \( a \in R \). Hence, we have to consider 0 and \( \pi_i a^2 = (\pi_i a)^2 \), and to distinguish whether \( \eta^v(i) \) equals 1 or \(-1 \). Note that \( 0 \prec \pi_i a^2 \), as it is a square and \( \leq^v \) has trivial support. From this observation we obtain

\[
\eta_{\leq}(i) = 1 \iff 0 \leq \pi_i \iff \eta^v(i) = 1,
\]

and therefore \( \eta_{\leq} = \eta^v \).

Next, we prove that \( \leq^v = \leq^v \). Assume without loss of generality that not both \( x, y \in I_o \). Then also \( x + c \) and \( y + d \) are not both in \( I_o \), for all \( c, d \in I_o \). It follows from Remark 4.10 that \( x + c \leq y + d \iff y + d = y + d \).

Thus,

\[
\mathcal{P} \leq^v \mathcal{Q} \iff \exists c_1, c_2 \in I_o: x + c_1 \leq y + c_2
\]

\[
\iff \exists c_1, c_2 \in I_o: x + c_1 \leq^v y + c_2
\]

\[
\iff \mathcal{P} \leq^v \mathcal{Q}.
\]

where the first equivalence just uses the definition of \( \leq^v \).

We conclude by showing that \( \psi \restriction \psi^{-1}(A) \) is injective. Let \( \leq_1 \in \psi^{-1}(A) \) be arbitrary, and denote by \( \leq_2 \) the quasi-order on \( R \) defined by \( \eta_{\leq_2} \), and \( \leq_1^v \) (see Main Lemma).

We prove that \( \leq_1 = \leq_2 \). First of all we claim that \( \leq_1 \leq_2 \). So let \( x, y \in R \). Since \( \leq_1 \) and \( \leq_2 \) have both support \( q_o \), we may without loss of generality assume that \( x \notin q_o \) or \( y \notin q_o \). Let \( I, \pi_i \) and \( a \) be as in the definition of the quasi-order \( \leq_2 \). First suppose that \( \prod_{i} \eta_{\leq_1}(i) = -1 \), i.e. \( \prod_{i} \pi_i a^2 \prec_1 0 \). With Lemma 4.3 and Lemma 1.4 we obtain

\[
x \leq_1 y \iff y \prod_i \pi_i a^2 \leq_1 x \prod_i \pi_i a^2
\]

\[
\iff y \prod_i \pi_i a^2 \leq_1 \prod_i \pi_i a^2
\]

\[
\iff x \leq_2 y.
\]

Likewise, if \( \prod_{i} \eta_{\leq_2}(i) = 1 \), we just apply (QR3) instead of Lemma 4.3 and (QR5) instead of Lemma 4.4 to get the same result. Thus, \( \leq_1 \leq_2 \). For the rest of the proof we distinguish the cases \(-1 \sim_2 1 \) and \(-1 \sim_2 1 \).
If $-1 \sim_{\leq_1} 1$, then Lemma 2.8 yields $-x \sim_{\leq_2} x$ for all $x \in \tilde{R}$, so $E_{x, \leq_2} \neq E_{y, \leq_2}$ for all such $x$. From Lemma 4.7 and Lemma 4.8 follows $E_{x, \leq_2} = q_0 + \{x\}$ for all $x \in R$. So Lemma 4.7 yields that $\leq_2$ is the smallest quasi-order with support $q_0$ possible. Therefore, $\leq_1 \leq_2 \leq_2$ implies equality, as desired. So suppose for the rest of this proof that $-1 \sim_{\leq_2} 1$. We distinguish the subcases $v(x) \neq v(y)$ and $v(x) = v(y)$.

If $v(x) \neq v(y)$, then Lemma 4.2 states $x \prod \pi_i a^2 \neq 0$ and $y \prod \pi_i a^2 = 0$, or vice versa. We show $\leq_1 = \leq_2$ by proving that the only $\Rightarrow$ above is also an equivalence. First suppose that $y \prod \pi_i a^2 = 0$. Assume for a contradiction that

$$0 = y \prod \pi_i a^2 \sim_1 x \prod \pi_i a^2$$

but $x \prod \pi_i a^2 \sim_1 y \prod \pi_i a^2$. Then we find some $c_1, c_2 \in I_v$ such that $c_1 \sim_1 x \prod \pi_i a^2 + c_2$. With Lemma 3.7(1) follows $c_1 - c_2 \sim_1 x \prod \pi_i a^2 \sim_1 y \prod \pi_i a^2$, thus convexity of $I_v$ yields $x \prod \pi_i a^2 \in I_v$, contradicting $x \prod \pi_i a^2 \neq 0$. Now suppose that $x \prod \pi_i a^2 = 0$. Then we obtain that

$$y \prod \pi_i a^2 + c \sim_1 x \prod \pi_i a^2 \sim_1 y \prod \pi_i a^2,$$

and taking residues yields that $y \prod \pi_i a^2 = 0$, since the support of $\sim_1$ is trivial, a contradiction.

So finally suppose that $v(x) = v(y)$, and assume for a contradiction that $x \sim_{\leq_2} y$, but $x \sim_1 y$. Choose $a \in \tilde{R}$ such that $0 \sim_1 a$ (and hence $0 \sim_2 a$) and $v(a) = v(x) = v(y)$. Note that $ax \sim_1 ay$ if and only if $x \sim_1 y$ (by (QR5) and (QR3)), and also $ax \sim_{\leq_2} ay$ if and only if $x \sim_{\leq_2} y$ (Lemma 2.8 and Corollary 3.10). So we may replace $x$ and $y$ with $ax$ and $ay$. In other words, we may without loss of generality assume that $v(x) = v(y) = 0$. It holds $y \sim_2 x$. So by definition of $\leq_2$ and the fact that $v(x) = v(y) = 0$, we get that $\mathfrak{F} \sim_1 \mathfrak{F}$ (see Remark 4.6). Thus, exist some $c_1, c_2 \in I_v$ such that $y + c_1 \sim_1 x + c_2$, respectively, $y \sim_1 x + c$ for $c : = c_2 - c_1$ (see Lemma 3.7(1)). Recall that $-1 \sim_{\leq_2} 1$. But then also $-1 \sim_1 1$. Otherwise $-1 \sim_1 0$, but $-1 \neq 2$, contradicting the fact that $\leq_1 \leq_2$. Therefore, Corollary 3.10 and Lemma 3.8 yield that all elements in $R$ are non-negative with respect to $\sim_1$. Particularly, $0 \sim_1 -1$. So Lemma 3.11 implies $y \sim_1 x + c \sim_1 \max\{x, c\} \sim_1 y$, a contradiction (note that $y \sim c$ would contradict the convexity of $I_v$, as $0 \sim_1 y$). This finishes the proof of the Baer-Krull Theorem.

Note that for the sake of uniformity, we avoided the dichotomy from 11, Theorem 3.8], stating that every quasi-ordered ring is either an ordered or else a valued ring, throughout the entire paper. Taking this theorem into consideration, the Baer-Krull Theorem simplifies as follows:

**Corollary 4.11.** (Baer-Krull Theorem for quasi-ordered rings II)

Let $R$ be a commutative ring with 1 and $v$ a Manis valuation on $R$. Then the map

$$\psi: \{z \in \mathcal{X}_q(R): z \text{ is } v\text{-compatible}\} \to \mathcal{A},$$

$$z \mapsto (\eta_{\sim z}, \sim')$$

is a bijection, where $\mathcal{A}$ is defined as in Theorem 4.10.

**Proof.** [11, Theorem 3.8] and Remark 3.13(4) yield that $\psi^{-1}(\mathcal{A})$ coincides with the domain of $\psi$. The statement follows now immediately from the previous theorem.

We continue our discussion of the Baer-Krull Theorem by weakening the assumption that $v$ is Manis. So let $(R, v)$ be an arbitrary valued ring with support $\mathfrak{p}$ and value group $\Gamma := \Gamma_v$. Note that the Manis property is not necessary to choose an $\mathbb{F}_2$-basis of $\Gamma = \Gamma/2\Gamma$ with preimages in $R$, as for any $\gamma \in \Gamma$ either $\gamma \in v(\tilde{R})$, or
−γ ∈ v(\bar{R}), or both. Let the π_i, γ_i etc. be as above. Furthermore, let ν denote the unique extension from v to \( K := \text{Quot}(R/p) \). Then Corollary 4.11 yields a bijective correspondence

\[
\psi: \{ \preceq \in \mathcal{X}(K) : \preceq \text{ is } \nu\text{-compatible} \} \to \mathcal{A},
\]

\[
\preceq \mapsto (\eta_{\preceq}, \preceq'),
\]

where \( \mathcal{A} := \{-1, 1\}^I \times \mathcal{X}(K\nu) \cup \{1\}^I \times \mathcal{X}(K\nu) \).

From [11, Proposition 2.7] we know that any quasi-order \( \preceq \) on \( R \) with support \( p \) uniquely extends to a quasi-order \( \preceq \) on \( K := \text{Quot}(R/p) \). Moreover, from Lemma 3.28 follows that \( \preceq \) is \( v \)-compatible if and only if \( \preceq \) is \( \nu \)-compatible. Hence, there is a bijective correspondence

\[
\lambda: \{ \preceq \in \mathcal{X}_p(R) : \preceq \text{ is } v\text{-compatible} \} \to \{ \preceq \in \mathcal{X}(K) : \preceq \text{ is } \nu\text{-compatible} \},
\]

\[
\preceq \mapsto \preceq.
\]

Considering the composition \( \psi \circ \lambda \) yields:

**Theorem 4.12.** (Baer-Krull Theorem for quasi-ordered rings III)
Let \( R \) be a commutative ring with 1 and \( v \) a valuation on \( R \). Then the map

\[
\psi \circ \lambda: \{ \preceq \in \mathcal{X}_p(R) : \preceq \text{ is } v\text{-compatible} \} \to \mathcal{A},
\]

\[
\preceq \mapsto (\eta_{\preceq}, \preceq')
\]

is a bijection, where \( \mathcal{A} := \{-1, 1\}^I \times \mathcal{X}(K\nu) \cup \{1\}^I \times \mathcal{X}(K\nu) \).

In the last step we want the co-domain to go back from \( K\nu \) to \( R\nu \) again. Note that if \( v \) is a valuation on \( R \) with support \( p \), then \( R\nu \) is a domain. So we can consider \( L := \text{Quot}(R\nu) \). We can also take the extension \( \nu \) from \( v \) to \( K := \text{Quot}(R/p) \), and then consider the residue class field \( K\nu = K\nu/I\nu \).

**Lemma 4.13.** Let \( v \) be a valuation on \( R \) with support \( p \), and let \( \nu \) denote the unique extension from \( v \) to \( K := \text{Quot}(R/p) \). Then \( L := \text{Quot}(R\nu) \) is (isomorphic to) a subfield of \( K\nu \).

**Proof.** We consider the canonical map

\[
\varphi: R\nu \to K\nu, x \mapsto \frac{x+p}{1+p} + I\nu.
\]

Note that

\[
x \in \ker(\varphi) \iff \frac{x+p}{1+p} \in I\nu \iff x+p \in I\nu \iff x \in I\nu,
\]

where \( v' \) denotes the valuation on \( R/q_v \) defined by \( v'(\bar{x}) = v(x) \) (see [11, Lemma 2.5]). So the homomorphism theorem yields that \( K\nu \) is a field containing the domain \( R\nu/I\nu = R\nu \). Hence, it also contains its quotient field \( L \).

**Definition 4.14.** ([13, p. 975]) Let \( R \) be a commutative ring with 1 and \( v \) a valuation on \( R \). Then \( v \) is said to be special*, if \( \text{Quot}(R\nu) = K\nu \).

Note that we write special*, because in [6] “special valuations” refer to a different class of valuations. Let us give a few examples for special*-valuations.

**Lemma 4.15.** Any Manis valuation is special*.

**Proof.** By Lemma 4.13 it suffices to show that \( K\nu \) is a subfield of \( \text{Quot}(R\nu) \). We argue again via the homomorphism theorem. This time, we consider the map

\[
\varphi: K\nu \to \text{Quot}(R\nu), \frac{x+p}{y+p} \mapsto \frac{x+I\nu}{y+I\nu}.
\]
Example 4.16.

(1) For any prime number $p \in \mathbb{N}$, the $p$-adic valuation $v$ on $R = \mathbb{Z}$ is special*. We have

$$\text{Quot}(Rv) = \mathbb{F}_p = K_{v}.$$ 

(2) Let $S$ be a ring and $R = S[\mathcal{X}]$. The degree valuation $v : R \to \mathbb{Z} \cup \{\infty\}$, $f \mapsto -\deg(f)$ is special*. We have

$$\text{Quot}(Rv) = \mathbb{Q} = K_{v}.$$ 

Note that for special* valuations there is a bijective correspondence between the orderings on $Rv$ and $K_{v} = \text{Quot}(Rv)$. This allows us to reformulate the Baer-Krull Theorem for this class. Let $\mu$ denote the map sending $(\eta_\leq, \leq')$ to $(\eta_\leq, \leq')$, i.e. $\mu$ restricts the quasi-order $\leq'$ on $K_{v}$ to the subring $Rv$, while it is the identity in the first component, as, by the choice of the $\pi_i$, the equality $\eta_\leq = \eta_\leq$ holds.

**Theorem 4.17.** (Baer-Krull Theorem for quasi-ordered rings IV) Let $R$ be a commutative ring with 1 and $v$ a special* valuation on $R$. Then the map

$$\mu \circ \psi \circ \lambda : \{\preceq \in X_p(R) : \preceq \text{ is } v\text{-compatible}\} \to A,$$

$$\preceq \mapsto (\eta_\leq, \leq')$$

is a bijection, where $A := \{-1, 1\}^I \times X_o(Rv) \sqcup \{1\}^I \times X_o(\text{Quot}(Rv))$.

**Remark 4.18.** In any of our four versions, the Baer-Krull Theorem simplifies much further, if the value group $\Gamma_v$ is 2-divisible, because then $\overline{\Gamma_v} = \Gamma_v/2\Gamma_v$ is trivial, and therefore $I = \emptyset$.

So for instance in Theorem 4.17 if $v$ is special* and $\Gamma_v$ is 2-divisible, then there is a bijective correspondence

$$\mu \circ \psi \circ \lambda : \{\preceq \in X_p(R) : \preceq \text{ is } v\text{-compatible}\} \to X_o(Rv) \sqcup X_o(\text{Quot}(Rv)), $$

$$\preceq \mapsto (\eta_\leq, \leq').$$

We conclude this paper by deducing Baer-Krull Theorems for ordered, respectively proper quasi-ordered, rings, from Theorem 4.17 and Corollary 4.11. The former statement immediately implies:
Corollary 4.19. (Baer-Krull Theorem for ordered rings)

Let \( R \) be a commutative ring with \( 1 \) and \( v \) a special* valuation on \( R \). Then the map
\[
\psi : \{ \leq \in X_{\geq q_v} (R) : \text{is } v\text{-compatible} \} \to \{-1, 1\}^I \times X_{\geq q_v} (R_v), \\
\leq \mapsto (\eta \leq, \leq')
\]
is a bijection.

If \( R \) is a field, then this result coincides with Theorem 2.10. Further note that if \( \Gamma_v \) is 2-divisible, then Corollary 4.19 simplifies in the same manner as explained in Remark 4.18. Moreover, the statement becomes evidently much easier if the domain \( R_v \) is uniquely ordered.

Lemma 4.20. For a domain \( R \), the following are equivalent:

1. \( R \) is uniquely ordered.
2. 0 is not a sum of non-zero squares and for each \( a \in R \), there exists some non-zero \( b \) such that either \( ab^2 \) or \( -ab^2 \) is a sum of squares.

Proof. In the proof we exploit the fact that \( R \) is uniquely ordered if and only if \( K := \text{Quot}(R) \) is uniquely ordered. Note that the latter is equivalent to the fact that for any \( a \in K^* \), either \( a \) or \( -a \) (and not both) is a sum of squares.

We first show that (2) implies (1). So let \( \frac{x}{y} \in K^* \) with \( x, y \in R \). Then \( xy \in R \). So there exists some \( 0 \neq b \) such that (wlog) \( xyb^2 \) is a sum of squares in \( R \), say \( xyb^2 = \sum p_i^2 \), with \( p_i \in R \). Then
\[
\frac{x}{y} = \sum_i \left( \frac{p_i}{y b} \right)^2
\]
is a sum of squares in \( K \). Moreover, \( -\frac{x}{y} \) is not a sum of squares in \( K \), since otherwise 0 would be a sum of non-zero squares in \( R \).

We conclude by showing that (1) implies (2). So suppose that \( R \) is uniquely ordered, i.e. also \( K \) is uniquely ordered. Hence, 0 is not a sum of non-zero squares in \( K \), but then this is also the case in \( R \). Now let \( a \in R \subseteq K \). Then \( a \) or \( -a \) is a sum of squares, say
\[
\pm a = \sum_i \left( \frac{x_i}{y_i} \right)^2 \quad (x_i, y_i \in R).
\]
This yields
\[
\pm a \prod_i y_i^2 = \sum_i \left( x_i \prod_{j \neq i} y_j \right)^2.
\]
Hence, \( b := (\prod_i y_i)^2 \) satisfies (2).

Our version of the Baer-Krull Theorem allows us to transfer [3, Corollary 2.2.6] to the ring case. In analogy to the field case, we call an ordered ring \((R, \leq)\) Archimedean, if for any \( x \in R \) there exists some \( n \in \mathbb{N} \) such that \( x < n \), and otherwise non-Archimedean.

Corollary 4.21.

1. If \( R \) carries a non-trivial Manis valuation whose residue class domain is real, then \( R \) admits a non-Archimedean ordering.

2. Conversely, if \( R \) carries a non-Archimedean ordering, then \( R \) admits a non-trivial valuation with real residue class domain.

Proof.

(1) The non-Archimedean ordering is derived exactly as in the field case. So let \( v \) be a non-trivial Manis valuation on \( R \), and let \( \leq \) denote an ordering on \( R_v \). Choosing \( n = 1 \) and applying the Baer-Krull Theorem for ordered rings yields an ordering \( \leq \) on \( R \) such that \( v \) and \( \leq \) are compatible. Particularly,
If 

Proof. Let 

Moreover, 

since 

is a non-trivial Manis valuation. Now let 

be a valuation on 

be a valued ring for some Manis valuation 

be a commutative ring with 

This yields that 

is a non-Archimedean ordering on 

(2) For the converse we first consider the case where 

is a domain. Let 

denote a non-Archimedean ordering on 

Then 

extends uniquely to a non-Archimedean ordering on 

From 

Corollary 2.2.6] follows that 

carries a non-trivial valuation 

with real residue class field 

Note that the restriction 

of 

is a non-trivial valuation 

and 

Moreover, the map 

is a ring homomorphism with kernel 

so 

is real as a subring of the real ring 

For the general case, note that if 

is a non-Archimedean ordering then 

defines a non-Archimedean ordering on the domain 

with support 

and the value groups of 

coincide, i.e. 

is non-trivial as well. By definition of 

it is easy to see that 

inherits the order from 

Remark 4.22. In the first statement of the previous corollary, the assumption that the valuation is Manis is crucial in order to obtain that 

for instance any 

-valuation on 

For the converse, we can not derive surjectivity of 

because the restriction of a field valuation to a subring is in general not Manis. For instance any field valuation restricted to the integers is either trivial or not Manis. since 

admits no non-trivial Manis valuation. The latter is due to the fact that the triangle inequality yields 

The Baer-Krull Theorem for quasi-ordered rings also gives rise to a characterization of all Manis valuations 

on 

that are finer than 

if we additionally assume that 

is non-trivial.

Corollary 4.23. (Baer-Krull Theorem for proper quasi-ordered rings I)

Let 

be a commutative ring with 1 and 

a special* valuation on 

Then the map 

is a bijection.

Now recall from Theorem 3.12 and Remark 4.13(4) that if 

is 

-compatible, then 

(see Remark 4.13(4) for the proof and a definition of 

Further note that the Manis property is not required for deducing (4) from (1) in Theorem 3.12. This allows us to reformulate the previous corollary more precisely (see Corollary 4.24).

Lemma 4.24. Let 

be a valued ring for some Manis valuation 

on 

and let 

be a valuation on 

such that 

is 

-compatible and 

Then 

is Manis if and only if 

is Manis.

Proof. If 

is some arbitrary valuation of 

then 

is additively closed by axiom (V3) of Definition 2.1. So in order to show that 

is Manis, it suffices to prove that 

is closed under additive inverses.
Suppose that \(w\) is Manis. Let \(\gamma := w/v(\pi) \in \Gamma_{w/v}\) be arbitrary, \(a \in U_v\). Then \(w/v(\pi) = w(a)\). Since \(w\) is Manis, there exists some \(b \in R\) such that \(w(b) = -w(a)\). Thus, \(w(ab) = 0 = w(1)\). By \(v\)-compatibility of \(\preceq_w\), we obtain that also \(v(ab) = 0\). Since \(a \in U_v\), also \(b \in U_v\). Therefore, it holds \(w/v(\pi) = w(b) = -\gamma \in \Gamma_{w/v}\).

Now assume that \(w/v\) is Manis, and let \(a \in R\) such that \(w(a) := \gamma \in \Gamma_w\). We show that there exists some \(b \in R\) with \(w(b) = -\gamma\). Note that \(a \notin q_v\), since \(q_v = q_w\).

Since \(v\) is Manis, we find some \(y \in R\) such that \(ay \in U_v\). So \(w/v(\pi)y = w(ay) =: \gamma_1\). By surjectivity of \(w/v\), there exists some \(z \in R\) such that \(w/v(\pi)z = w(z) = -\gamma_1\). Therefore, \(w(z) = -w(a) - w(y)\). This yields \(w(yz) = -w(a) = -\gamma\), i.e. \(b = yz\).

**Corollary 4.25.** *(Baer-Krull Theorem for proper quasi-ordered rings II)*

Let \(R\) be a commutative ring with 1 and \(v\) a Manis valuation on \(R\). Then the map
\[
\psi: \{ w: w \text{ Manis, } \preceq_w \text{ v-comp.}, q_w = q_v \} \to \{ u: u \text{ Manis val. on } R_v, q_u = \{0\} \},
\[
\psi \mapsto w/v
\]
is a bijection.

**Proof.** We deduce this corollary from Corollary 4.23. As mentioned above, if \(\preceq = \preceq_w\) is a proper quasi-order compatible with \(v\), then \(\preceq = \preceq_{w/v}\). Moreover we have shown in the previous lemma that \(w\) is Manis if and only if \(w/v\) is Manis. So we may restrict both the domain and co-domain of \(\psi\) to proper quasi-orders that come from a Manis valuation.

Since \(v\) and \(w\) are both Manis and \(\preceq_w\) is compatible with \(v\), it follows via Lemma 3.16 that the previous corollary characterizes precisely all Manis refinements \(w\) of \(v\), if the valuation \(v\) (and then also \(w\)) is non-trivial.
