Top-Down Synthesis of Multi-Agent Formation Control: 
An Eigenstructure Assignment based Approach

Takatoshi Motoyama and Kai Cai

Abstract—We propose a top-down approach for formation control of heterogeneous multi-agent systems, based on the method of eigenstructure assignment. Given the problem of achieving scalable formations on the plane, our approach globally computes a state feedback control that assigns desired closed-loop eigenvalues/eigenvectors. We characterize the relation between the eigenvalues/eigenvectors and the resulting inter-agent communication topology, and design special (sparse) topologies such that the synthesized control may be implemented locally by the individual agents. Moreover, we present a hierarchical synthesis procedure that significantly improves computational efficiency. Finally, we extend the proposed approach to achieve rigid formation and circular motion, and illustrate these results by simulation examples.

I. INTRODUCTION

Cooperative control of multi-agent systems has been an active research area in the systems control community [1], [2], [3], [4], [5]. Among many problems, formation control has received much attention [6] owing to its wide applications such as satellite formation flying, search and rescue, terrain exploration, and foraging. A main problem studied is stabilization to a rigid formation, where the goal is to steer the agents to achieve a formation with a specified size and only freedoms of translation and rotation. Several control strategies have been proposed: affine feedback laws [7], [8], nonlinear gradient-based control [9], [10], and angle-based algorithms [11]. Achieving a scalable formation with unspecified size has also been studied [12], [13]: a scalable formation may allow the group to adapt to unknown environment with obstacles or targets. In addition, [14], [15] have presented methods of controlling formations in motion.

These different methods for formation control have a common feature in design: namely bottom-up. Specifically, the inter-agent communication topology is given a priori, which defines the neighbors for each agent. Then based only on the neighborhood information, local control strategies are designed for the individual agents. The properties of the designed local strategies are finally analyzed at the systemic (i.e. global) level, and correctness is proved under certain graphical conditions on the communication topology. This bottom-up design is indeed the mainstream approach for cooperative control of multi-agent systems that places emphasis on distributed control.

In this paper, we propose a distinct, top-down approach for formation control, based on a known method called eigenstructure assignment [16], [17], [18], [19]. Different from the bottom-up approach, here there need not be any communication topology imposed a priori (in fact the agents are typically assumed independent, i.e. uncoupled), and no design will be done at the local level. Indeed, given a multi-agent formation control problem characterized by specific eigenvalues and eigenvectors (precisely defined in Section II), our approach constructs on the global level a feedback matrix (if it exists) that renders the closed-loop system to possess those desired eigenvalues/eigenvectors, thereby achieving desired formations. Moreover, the synthesized feedback matrix (its off-diagonal entries being zero or nonzero) defines the communication topology, and accordingly the computed feedback control may be implemented by individual agents. Thus our approach features “compute globally, implement locally”.

The inter-agent communication topology is a result of control synthesis, rather than given a priori. We characterize the relation between the resulting topology and the eigenstructure chosen for the synthesis. Further, we show that by appropriately choosing desired eigenvalues and the corresponding eigenvectors, special topologies (star, cyclic, line) can be designed, and the computed feedback control may be implemented locally over these (sparse) topologies.

Although our method requires centralized computation of control gain matrices, we show that a straightforward extension of the approach to a hierarchical synthesis procedure significantly reduces computation time. Empirical evidence is provided to show the efficiency of the proposed hierarchical synthesis procedure; in particular, computation of a feedback control for a group of 1000 agents needs merely a fraction of a second, which is likely to suffice for many practical purposes.

The main advantage of our top-down approach is that it is systematic, in the sense that it treats heterogeneous agent dynamics and different cooperative control specifications (characterizable by desired eigenstructure) by the same synthesis procedure. We show that scalable formation, rigid formation, and cooperative circular motion can all be addressed using the same method. Additionally, we show that this method is amenable to deal with more general cases where some agents are not self-stabilizable and the initial inter-agent connections are arbitrary.

We first proposed this eigenstructure assignment based approach in [20], where we applied it to solve the consensus problem. Then the conference precursor [21] of this paper extended the approach to solve scalable and rigid formations, and proposed a hierarchical synthesis procedure to significantly shorten the computation time. This paper differs
from [21] in the following aspects. (i) A precise relation between eigenstructure and topology is characterized (Section III). (ii) A method for imposing topological constraints on eigenstructure assignment is presented (Section III.B). (iii) More general cases where the initial inter-agent topology is arbitrary and/or there exist non-stabilizable agents are addressed (Section IV). (iv) The problem of achieving cooperative circular motion is solved. (v) All the proofs are provided.

We note that [22] also proposed an eigenstructure assignment method and applied it to the multi-agent consensus problem. Their approach is bottom-up: first a communication topology is imposed among the agents, then local control strategies are designed based on eigenstructure assignment respecting the topology, and finally the correctness of the proposed strategies is verified at the global level. By contrast, our approach is top-down: no topology is imposed \( a \ priori \), and topology is a result of control synthesis. Moreover, we characterize the relation between topology and eigenstructure, and design special topologies by selecting special eigenstructures. In addition, the problems addressed in the paper are distinct, namely scalable/rigid formation and circular motion on the plane, which involve complex eigenvalues and eigenvectors.

The rest of the paper is organized as follows. In Section II we review the basics of eigenstructure assignment and formulate the multi-agent formation control problem. In Section III we solve the problem by eigenstructure assignment, and discuss the relations between eigenvalues/eigenvectors and topologies. In Section IV we study the more general cases where the initial inter-agent topology is arbitrary and/or there exist non-stabilizable agents. In Section V we present a hierarchical synthesis procedure to reduce computation time, and in Section VI extend the method to achieve rigid formation and circular motion. Simulation examples are given in Section VII and our conclusions stated in Section VIII.

II. PRELIMINARIES AND PROBLEM FORMULATION

A. Preliminaries on Eigenstructure Assignment

First we review the basics of eigenstructure assignment [16]. Consider a linear time-invariant finite-dimensional system modeled by

\[
\dot{x} = Ax + Bu
\]

(1)

where \( x \in \mathbb{C}^n \) is the state vector, \( u \in \mathbb{C}^m \) the input vector, and \( A \in \mathbb{R}^{n \times n}, B \in \mathbb{R}^{n \times m} \).

Suppose we modify \( (1) \) by state feedback \( u = Fx \). It is well-known (e.g. [23]) that \( F \) may be chosen to assign any (self-conjugate) set of closed-loop eigenvalues for \( \dot{x} = (A + BF)x \) if and only if \((A, B)\) is controllable. Unless \( m = 1 \) (single input), however, \( F \) is not uniquely determined by a set of closed-loop eigenvalues. Indeed, with state feedback \( F \) one has additional freedom to assign certain sets of closed-loop eigenvectors. Simultaneously assigning both eigenvalues and eigenvectors is referred to as eigenstructure assignment.

Let \( \lambda \in \mathbb{C} \). It is shown in [16] that if \((A, B)\) is controllable, then there exists

\[
N(\lambda) := \begin{bmatrix} N_1(\lambda) \\ N_2(\lambda) \end{bmatrix} \in \mathbb{C}^{(n+m) \times m}
\]

(2)

with linearly independent columns such that

\[
[\lambda I - A \ B] \begin{bmatrix} N_1(\lambda) \\ N_2(\lambda) \end{bmatrix} = 0.
\]

(3)

Thus the columns of \( N(\lambda) \) form a basis of \( \text{Ker}[\lambda I - A \ B] \); \( \text{Ker} \) denotes kernel. Also we will use \( \text{Im} \) to denote image.

Lemma 1: ([16]) Consider the system \( (1) \) and suppose that \((A, B)\) is controllable and \( \text{Ker}B = 0 \). Let \( \{\lambda_1, \ldots, \lambda_n\} \) be a set of distinct complex numbers, and \( \{v_1, \ldots, v_n\} \) a set of linearly independent vectors in \( \mathbb{C}^n \). Then there is a unique \( F \) such that for every \( i \in [1, n] \), \((A + BF)v_i = \lambda_i v_i \) if and only if

\[
(v_i)_{j \in [1, n]}v_i \in \text{Im}N_1(\lambda_i)
\]

(4)

where \( N_1(\cdot) \) is in \( \mathbb{C}^n \).

Lemma II provides a necessary and sufficient condition of eigenstructure assignment. When the condition holds and thus \( F \) exists for assigning distinct complex eigenvalues \( \lambda_i \) and the corresponding eigenvectors \( v_i \) \( (i \in [1, n]) \), \( F \) may be constructed by the following procedure [16].

(i) For each \( \lambda_i \) compute a basis of \( \text{Ker}[\lambda_i I - A \ B] \). Stack the basis vectors to form \( N(\lambda_i) \) in \( \mathbb{C}^m \); partition \( N(\lambda_i) \) properly to get \( N_1(\lambda_i) \) and \( N_2(\lambda_i) \).

(ii) Find \( w_i = -N_2(\lambda_i)k_i \) where \( k_i \in \mathbb{C} \) is such that \( N_1(\lambda_i)k_i = v_i \) (the condition \( \text{Ker}B = 0 \) in Lemma I ensures that \( N_1(\lambda_i) \) has independent columns; thus \( k_i \) may be uniquely determined).

(iii) Compute \( F \) by

\[
F = [w_1 \cdots w_n][v_1 \cdots v_n]^{-1}.
\]

(5)

Note that the entries of \( F \) may include complex numbers in general. If \( \{\lambda_1, \ldots, \lambda_n\} \) is a self-conjugate set of distinct complex numbers, and \( v_i = \bar{v}_j \) whenever \( \lambda_i = \bar{\lambda}_j \) (\( \cdot \) denotes complex conjugate), then all entries of \( F \) are real numbers.

The procedure (i)-(iii) of computing \( F \) has complexity \( O(n^3) \), inasmuch as the calculations involved are solving systems of linear equations, matrix inverse and multiplication (e.g. [24]).

We note that the above eigenstructure assignment result may be extended to the case of repeated eigenvalues with generalized eigenvectors. For details refer to [17] or Appendix.

B. Problem Formulation

Consider a heterogeneous multi-agent system where each agent is modeled by a first-order ODE:

\[
\dot{x}_i = a_i x_i + b_i u_i, \quad i = 1, \ldots, n.
\]

(6)
Here $x_i \in \mathbb{C}$ is the state variable, $u_i \in \mathbb{C}$ the control variable, $a_i \in \mathbb{R}$ and $b_i(\neq 0) \in \mathbb{R}$ are constant parameters. Thus each agent is a point mass moving on the complex plane, with possibly stable ($a_i < 0$), semistable ($a_i = 0$) or unstable ($a_i > 0$) dynamics. The requirement $b_i \neq 0$ is to ensure stabilizability/controllability of $(a_i, b_i)$; thus each agent is stabilizable/controllable. Note that represented by (9), the agents are independent (i.e. uncoupled) and no inter-agent topology is imposed at this stage.

In vector-matrix form, the system of $n$ independent agents is

$$\dot{x} = Ax + Bu$$

(7)

where $x := [x_1 \cdots x_n]^\top \in \mathbb{C}^n$, $u := [u_1 \cdots u_n]^\top \in \mathbb{C}^n$, $A := \text{diag}(a_1, \ldots, a_n)$ and $B := \text{diag}(b_1, \ldots, b_n)$; here diag$(\cdot)$ denotes a diagonal matrix with the specified diagonal entries. Consider modifying (7) by a state feedback $u = Fx$ and thus the closed-loop system is

$$\dot{x} = (A + BF)x.$$  

(8)

Straightforward calculation shows that the diagonal entries of $A + BF$ are $a_i + b_i F_{ii}$, and the off-diagonal entries $b_i F_{ij}$. Since $b_i \neq 0$, the off-diagonal entries $(A + BF)_{ij} \neq 0$ if and only if $F_{ij} \neq 0$ $(i \neq j)$.

In view of the structure of $A + BF$, we can define a corresponding directed graph $\mathcal{G} = (\mathcal{V}, \mathcal{E})$ as follows: the node set $\mathcal{V} := \{1, \ldots, n\}$ with node $i \in \mathcal{V}$ standing for agent $i$ (or state $x_i$); the edge set $\mathcal{E} \subseteq \mathcal{V} \times \mathcal{V}$ with edge $(j, i) \in \mathcal{V}$ if and only if $F$’s off-diagonal entry $F_{ij} \neq 0$. Since $F_{ij} \neq 0$ implies that $x_i$ uses $x_j$ in its state update, we say for this case that agent $j$ communicates its state $x_j$ to agent $i$, or $j$ is a neighbor of $i$. The graph $\mathcal{G}$ is therefore called a communication network among agents, whose topology is decided by the off-diagonal entries of $F$. Thus the communication topology is not imposed a priori, but emerges as the result of applying the state feedback control $u = Fx$.

Now we define the formation control problem of the multi-agent system (7).

**Problem 1:** Consider the multi-agent system (7) and specify a vector $f \in \mathbb{C}^n$ $(f \neq 0)$. Design a state feedback control $u = Fx$ such that for every initial condition $x(0)$, $\lim_{t \to \infty} x(t) = cf$ for some constant $c \in \mathbb{C}$.

In Problem 1 the specified vector $f$ represents a desired formation configuration in the plane. By formation configuration we mean that the geometric information of the formation remains when scaling and rotational effects are discarded. Indeed, by writing the constant $c \in \mathbb{C}$ in the polar coordinate form (i.e. $c = |c|e^{j\theta}$, $j = \sqrt{-1}$), the final formation $cf$ is the configuration $f$ scaled by $|c|$ and rotated by $\theta$. The constant $c$ is unknown a priori and in general depends on the initial condition $x(0)$. Note also that Problem 1 includes the consensus problem as a special case when $f = 1 := [1 \cdots 1]^\top$.

To solve Problem 1 we note the following fact.

**Proposition 1:** Consider the multi-agent system (7) and state feedback $u = Fx$. If $A + BF$ has a simple eigenvalue 0, with the corresponding eigenvector $f$, and other eigenvalues have negative real parts, then for every initial condition $x(0)$, $\lim_{t \to \infty} x(t) = cf$ for some $c \in \mathbb{C}$.

**Proof:** The solution of the closed-loop system (8) is $x(t) = e^{(A + BF)t}x(0)$. Since $A + BF$ has a simple eigenvalue 0, with the corresponding eigenvector $f$, and other eigenvalues have negative real parts, it follows from the standard linear systems analysis that $x(t) \to (w^\top x(0))f$ as $t \to \infty$. Here $w \in \mathbb{C}^n$ is the left-eigenvector of $A + BF$ with respect to the eigenvalue 0. Therefore $\lim_{t \to \infty} x(t) = cf$, where $c := w^\top x(0)$.

In view of Proposition 1 if the specified eigenvalues and the corresponding eigenvectors may be assigned by state feedback $u = Fx$, then Problem 1 is solved. To this end, we resort to eigenstructure assignment.

**III. MAIN RESULTS**

In this section, we solve Problem 1, the formation control problem of multi-agent systems, by the method of eigenstructure assignment. The following is our first main result.

**Theorem 1:** Consider the multi-agent system (7) and let $f$ be a desired formation configuration. Then there always exists a state feedback control $u = Fx$ that solves Problem 1, i.e.

$$(\forall x(0) \in \mathbb{C}^n)(\exists c \in \mathbb{C}) \lim_{t \to \infty} x(t) = cf.$$}

(9)

**Proof:** By Proposition 1 the multi-agent system (7) with $u = Fx$ achieves a formation configuration $f \in \mathbb{C}^n$ if the closed-loop matrix $A + BF$ has the following eigenstructure: (i) its eigenvalues $\{\lambda_1, \lambda_2, \ldots, \lambda_n\}$ satisfy $0 = \lambda_1 < |\lambda_2| \leq \cdots \leq |\lambda_n|$, and $(\forall i \in [2, n])\text{Re}(\lambda_i) < 0$ (9) (ii) the corresponding eigenvectors

$$\{v_1, v_2, \ldots, v_n\} \text{ are linearly independent, and } v_1 = f.$$  

(10)

So we must verify that the above eigenstructure is assignable by state feedback $u = Fx$ for the multi-agent system (7). Note that except for $(\lambda_1, v_1)$ which is fixed, we have freedom to choose $(\lambda_i, v_i)$, $i \in [2, n]$. For simplicity we let $\lambda_i$ be all distinct, and thus Lemma 1 can be applied.

In (7), we have $A = \text{diag}(a_1, \ldots, a_n)$, $B = \text{diag}(b_1, \ldots, b_n)$, and $b_i \neq 0$ for all $i \in [1, n]$. Thus it is easily checked that the pair $(A, B)$ is controllable and Ker$B = 0$. To show that there exists $F$ such that $(A + BF)v_1 = \lambda_1 v_1$, for each $i \in [1, n]$ (with $\lambda_i$, $v_i$ specified above), it suffices to verify the condition (4) of Lemma 1.

First, for $\lambda_1 = 0$, we find a basis for

$$\text{Ker}[\lambda_1 I - A] B = \text{Ker}[-A] B$$

and derive $N_1(\lambda_1) = B$ and $N_2(\lambda_1) = A(N_1(\cdot), N_2(\cdot))$ in (2). Thus Im$N_1(\lambda_1) = \mathbb{C}^n$, and hence $v_1 \in \text{Im}N_1(\lambda_1)$, i.e. the condition (4) of Lemma 1 holds.

Next, let $i \in [2, n]$; we find a basis for Ker$[\lambda_i I - A] B$ and derive $N_1(\lambda_i) = B$ and $N_2(\lambda_i) = A - \lambda_i I$. So again Im$N_1(\lambda_i) = \mathbb{C}^n$, and $v_i \in \text{Im}N_1(\lambda_i)$, i.e. the condition (4) of
Lemma 1 holds. Therefore, we conclude that there always exists a state feedback $u = Fx$ such that the multi-agent system (7) achieves the formation configuration $f$. □

In the proof we considered distinct eigenvalues $\lambda_i$, $i \in [1, n]$; hence the control gain matrix $F$ may be computed by (5). The computed $F$ in turn gives rise to the agents’ communication graph $G$. The following is an illustrative example.

**Example 1:** Consider the multi-agent system (7) of 4 single integrators (that is, $a_i = 0$ and $b_i = 1$, $i = 1, ..., 4$).

(i) **Square formation** with $f = [1 \ j \ -1 \ -j]^\top$ ($j = \sqrt{-1}$). Let the desired closed-loop eigenvalues be $\lambda_1 = 0$, $\lambda_2 = -1$, $\lambda_3 = -2$, $\lambda_4 = -3$ and the corresponding eigenvectors be $v_1 = f$, $v_2 = [1 \ 1 \ 0 \ 0]^\top$, $v_3 = [0 \ 1 \ 1 \ 0]^\top$, $v_4 = [0 \ 0 \ 1 \ 1]^\top$. By (5) one computes the control gain matrix $F_1$, which determines the corresponding communication graph $G_1$ (see Fig. 1).

Observe that $F_1$ contains complex entries, which may be viewed as control gains for the real and imaginary axes, respectively, or scaling and rotating gains on the complex plane. Also note that $G_1$ has a spanning tree with node 4 the root, and the computed feedback control $u = Fx$ can be implemented by the four agents individually.

(ii) **Consensus** with $f = [1 \ 1 \ 1 \ 1]^\top$. Let the desired eigenvalues be $\lambda_1 = 0$, $\lambda_2 = -1$, $\lambda_3 = -3$, $\lambda_4 = -4$ and the corresponding eigenvectors be $v_1 = f$, $v_2 = [1 \ 1 \ 0 \ 1]^\top$, $v_3 = [1 \ 0 \ 0 \ 1]^\top$, $v_4 = [0 \ 0 \ 1 \ -1]^\top$. Again by (5) one computes the control gain matrix $F_2$ and the corresponding graph $G_2$ (see Fig. 1).

Note that in this case $F_2$ is real and $G_2$ strongly connected. But unlike the usual consensus algorithm (e.g. [2]), $-F_2$ is not a graph Laplacian matrix for the entries (2, 1) and (3, 1) are positive. Thus our eigenstructure assignment based approach may generate a larger class of consensus algorithms with negative entries.

We remark that in our approach, the convergence speed to the desired formation configuration is assignable. This is because the convergence speed is dominated by the eigenvalue $\lambda_2$, with the second largest real part, of the closed-loop system $\dot{x} = (A + BF)x$; and in our approach $\lambda_2$ is freely assignable. The smaller the Re($\lambda_2$) is, the faster the convergence to formation occurs (at the cost of higher control gain). As an example, for (ii) in Example 1 assign the second largest eigenvalue $\lambda_2 = -2$ (originally $-1$), and change $v_4 = [0 \ 0 \ 1 \ 1]$. This results in a new feedback matrix $F'_2 = [-4 \ 1 \ 2 \ 1]$

which has zero entries at the same locations as $F_2$. Thus with the same topology, $F'_2$ achieves faster convergence speed.

As we have seen in Example 1, the feedback matrix $F$’s off-diagonal entries, which determine the topology of $G$, are dependent on the choice of eigenvalues as well as eigenvectors. Namely different sets of eigenvalues and eigenvectors result in different inter-agent communication topologies. Our next result characterizes a precise relation between the eigenvalues/eigenvectors and the topologies.

**Theorem 2:** Consider the multi-agent system (7) and $f$ a desired formation configuration. Let the eigenstructure $\lambda_i$ and $v_i$ ($i = 1, \ldots, n$) be as in (9) and (10), and denote the rows of $[v_1 \cdots v_n]^{-1}$ by $v_i^*$. Then the communication graph $G = (V, E)$ of the (closed-loop) multi-agent system is such that

$$(i_1, j_1), \ldots, (i_K, j_K) \notin E \quad (K \geq 1)$$

if and only if the vector $[\lambda_2 \cdots \lambda_n]^\top$ is orthogonal to the subspace spanned by the $K$ vectors:

$$[v_{i_2}^* v_{i_3}^* \cdots v_{i_K}^*] \top, \ldots, [v_{i_2} v_{i_3}^* \cdots v_{i_K}^*] \top.$$

**Proof:** For each $\lambda_i$, $i \in [1, n]$, we derive from (3) that

$$(\lambda_i I - A)N_1(\lambda_i) + BN_2(\lambda_i) = 0$$

Choose $N_1(\lambda_i) = B$ and $N_2(\lambda_i) = -(\lambda_i I - A)$ to satisfy the above equation. Then $K_i = N_i^{-1}(\lambda_i) v_i = B^{-1} v_i$, and $w_i = -N_2(\lambda_i) v_i = (\lambda_i I - A) B^{-1} v_i$. By (5) we have

$$F = [v_1 \cdots v_n][v_1 \cdots v_n]^{-1}$$

$$= [(\lambda_1 I - A) B^{-1} v_1 \cdots (\lambda_n I - A) B^{-1} v_n][v_1 \cdots v_n]^{-1}$$

$$= B^{-1}(-A[v_1 \cdots v_n] + [\lambda_1 v_1 \cdots \lambda_n v_n])[v_1 \cdots v_n]^{-1}$$

$$= -B^{-1} A + B^{-1} [v_1 \cdots v_n][\lambda_1 \cdots \lambda_n][v_1^* \cdots v_n^*]^\top.$$
only if the vector $[\lambda_2 \cdots \lambda_n]^\top$ is orthogonal to each of the following $K$ vectors:

$$[v_{2i_1} v_{2j_1} \cdots v_{ni_1} v_{nj_1}]^\top, \ldots, [v_{2iK} v_{2jK} \cdots v_{nKiK} v_{nKjK}]^\top.$$  

Namely $[\lambda_2 \cdots \lambda_n]^\top$ is orthogonal to the subspace spanned by these $K$ vectors.

Once the desired eigenvalues and eigenvectors are chosen, Theorem 2 provides a necessary and sufficient condition to check the interconnection topology among the agents, without actually computing the feedback matrix $F$. On the other hand, the problem of choosing an appropriate eigenstructure to match a given topology is more difficult, inasmuch as there are many free variables to be determined in the eigenvalues and eigenvectors. While we shall investigate inasmuch as there are many free variables to be determined in the eigenvalues and eigenvectors. While we shall investigate the general problem of eigenstructure design for imposing particular topologies in our future work, in the next subsection, nevertheless, we show that choosing certain appropriate eigenstructures results in certain special (sparse) topologies. With these topologies the synthesized control $u = Fx$ may be implemented in a distributed fashion.

A. Special Topologies

We show how to derive the following three types of special topologies by choosing appropriate eigenstructures.

1) Star Topology: A directed graph $G = (V, E)$ is a star topology if there is a single root node, say node 1, and $E = \{(1,i) | i \in [2, n]\}$. Thus all the other nodes receive information from, and only from, the root node 1. In terms of the total number of edges, a star topology is one of the sparsest topologies, with the least number $(n - 1)$ of edges, that contain a spanning tree. Now consider the following eigenstructure.

    - eigenvalues: $\lambda_1 = 0, \lambda_2, \ldots, \lambda_n$ distinct
    - and $\text{Re}(\lambda_2), \ldots, \text{Re}(\lambda_n) < 0$

    eigenvectors: $[v_1 \ v_2 \cdots \ v_n] = \begin{bmatrix} f_1 & 0 & \cdots & 0 \\
    f_2 & 1 & \cdots & 0 \\
    \vdots & \vdots & \ddots & \vdots \\
    f_n & 0 & \cdots & 1 \end{bmatrix}$ \hspace{1cm} \text{(independent)} \hspace{1cm} (12)

**Proposition 2:** Consider the multi-agent system (7). If the eigenstructure (12) is used in the synthesis of feedback control $u = Fx$, then Problem 1 is solved and the resulting graph $\mathcal{G}$ is a star topology.

**Proof:** First, it follows from the proof of Theorem 1 that the eigenstructure (12) can be assigned to the closed-loop matrix $A + BF$. Then by Proposition 1 Problem 1 is solved.

Now proceed analogously to the proof of Theorem 2 and derive $A + BF$ as in (11). Substituting into (11) the eigenvalues and eigenvectors in (12), as well as we derive

$$A + BF = \begin{bmatrix} 0 & 0 & \cdots & 0 \\
    -\lambda_2 f_1 & \lambda_2 & 0 & \cdots \\
    \vdots & \vdots & \ddots & \vdots \\
    -\lambda_n f_1 & 0 & \cdots & \lambda_n \end{bmatrix}.$$  

Therefore the corresponding graph $\mathcal{G}$ is a star topology with node 1 the root.

2) Cyclic Topology: A directed graph $G = (V, E)$ is a cyclic topology if $E = \{(1, 2), (2, 3), \ldots, (n - 1, n), (n, 1)\}$. Consider the following eigenstructure.

    - eigenvalues: $\{\lambda_1, \lambda_2, \ldots, \lambda_n\} = \{0, \omega^{-1}, \ldots, \omega^{n-1} - 1\}$
    - eigenvectors: $[v_1 \ v_2 \cdots \ v_n] = \begin{bmatrix} f_1 & f_1 & \cdots & f_1 \\
    f_2 & f_2 & \cdots & f_2 \\
    \vdots & \vdots & \ddots & \vdots \\
    f_n & f_n & \cdots & f_n \end{bmatrix}$

    \hspace{1cm} \text{(independent)} \hspace{1cm} (13)

where $\omega := e^{2\pi j/n}$ ($j = \sqrt{-1}$).

**Proposition 3:** Consider the multi-agent system (7). If the eigenstructure (13) is used in the synthesis of feedback control $u = Fx$, then Problem 1 is solved and the resulting graph $\mathcal{G}$ is a cyclic topology.

**Proof:** Following the same lines as the proof of Proposition 2 and using the eigenstructure in (13) and

$$[v_1 \ v_2 \cdots \ v_n]^{-1} = \frac{1}{n} \begin{bmatrix} 1 & 1 & \cdots & 1 \\
    f_1 & f_1 & \cdots & f_1 \\
    f_2 & f_2 & \cdots & f_2 \\
    \vdots & \vdots & \ddots & \vdots \\
    f_n & f_n & \cdots & f_n \end{bmatrix}$$

we derive

$$A + BF = \begin{bmatrix} -1 & f_1 & 0 & \cdots & 0 \\
    0 & -1 & f_2 & \cdots & 0 \\
    \vdots & \vdots & \ddots & \vdots & \vdots \\
    0 & 0 & \cdots & f_{n-1} & 0 \\
    f_n & f_n & \cdots & f_n & -1 \end{bmatrix}.$$  

By inspection, we conclude that the corresponding graph $\mathcal{G}$ is a cyclic topology.

3) Line Topology: A directed graph $G = (V, E)$ is a (directed) line topology if there is a single root node, say node 1, and $E = \{(1, 2), (2, 3), \ldots, (n - 1, n)\}$. A line topology is also one of the sparsest topologies containing a spanning tree. Now consider the following eigenstructure.

    - eigenvalues: $\lambda_1 = 0, \lambda_2 = \cdots = \lambda_n = -1$
    - eigenvectors: $[v_1 \ v_2 \cdots \ v_n] = \begin{bmatrix} f_1 & 0 & \cdots & 0 \\
    f_2 & 0 & \cdots & -f_2 \\
    \vdots & \vdots & \ddots & \vdots \\
    f_{n-1} & 0 & \cdots & -f_{n-1} \\
    f_n & -f_n & \cdots & -f_n \end{bmatrix}$

    \hspace{1cm} \text{(independent)} \hspace{1cm} (14)
**Proposition 4:** Consider the multi-agent system (7). If the eigenstructure (14) is used in the synthesis of feedback control $u = Fx$, then Problem 1 is solved and the resulting $G$ is a line topology. 

Note that in (14) we have repeated eigenvalues ($\lambda_2$) and the corresponding generalized eigenvectors. As a result, Lemma 1 and 5 for computing the control gain matrix $F$ cannot be applied to this case. Instead, we resort to the generalized method of [17], and provide a proof of Proposition 4 in Appendix.

**B. Topology Constrained Eigenstructure Assignment**

We end this section by presenting an alternative approach to imposing topological constraints on eigenstructure assignment.

Suppose that we have computed by (5) a feedback matrix $F$ to achieve a desired formation, i.e. the closed-loop matrix $(A + BF)$’s eigenvalues $\lambda_1, ..., \lambda_n$ and eigenvectors $v_1, ..., v_n$ satisfy (9) and (10). Note now that a topological constraint is imposed such that agent $i$ cannot receive information from agent $j$ (for reasons such as cost or physical impossibility). Unfortunately, in the computed $F$ the $(i,j)$-entry $F_{ij} \neq 0$. Thus our goal is to derive a new feedback matrix $\hat{F}$, by suitably modifying $F$, such that $\hat{F}_{ij} = 0$. In doing so, the new closed-loop matrix $A + BF$ will generally have different eigenvalues $\hat{\lambda}_1, ..., \hat{\lambda}_n$ and eigenvectors $\hat{v}_1, ..., \hat{v}_n$. Hence we must check if these new eigenvalues and eigenvectors still satisfy (9) and (10).

Our approach proceeds as follows, which is inspired by the “constrained feedback” method in [18]. Writing $V := [v_1 \cdots v_n]$ and $J := \text{diag}(\lambda_1, ..., \lambda_n)$, we have from (11):

$$(A + BF)V = VJ$$

$$\Rightarrow BFV = VJ - AV$$

$$\Rightarrow FV = B^{-1}(VJ - AV).$$

Let $\psi := B^{-1}(VJ - AV)$ and denote by $\psi_i$ the $i$th row of $\psi$, also $F_i$ the $i$th row of $F$. Then the above equation is rewritten in terms of Kronecker product and row stacking as follows:

$$\begin{bmatrix} V^T & 0 & \cdots & 0 \\ 0 & V^T & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & V^T \end{bmatrix} \begin{bmatrix} F_1^T \\ \vdots \\ F_n^T \end{bmatrix} = \begin{bmatrix} \psi_1^T \\ \vdots \\ \psi_n^T \end{bmatrix}. $$

To constrain the $(i,j)$-entry of $F$ to be zero, we focus on the equation $V^TF_i = \psi_i$. Deleting $F_{ij}$ from $F_i$ as well as the $j$th column of $V^T$, we obtain the reduced equation:

$$\hat{V}^T\hat{F}_i = \psi_i^T$$

(15)

where $\hat{V}^T \in \mathbb{C}^{n \times (n-1)}$ is the matrix $V^T$ with $j$th column deleted and $\hat{F}_i^T \in \mathbb{C}^{n-1}$ the vector $F_i^T$ with $j$th element deleted. Now view the entries of $\hat{F}_i$ as the unknowns (i.e. (15) contains $n$ equations with $n-1$ unknowns $\hat{F}_{i1}, ..., \hat{F}_{i(j-1)} \hat{F}_{i(j+1)}, ..., \hat{F}_{in}$). Using the pseudoinverse of $\hat{V}^T$, denoted by $(\hat{V}^T)^+$, we derive

$$\hat{F}_i = (\hat{V}^T)^+\psi_i.$$

(16)

By (16) we set the new feedback matrix

$$\hat{F} := \begin{bmatrix} \hat{F}_{i1} & \cdots & \hat{F}_{i(j-1)} & 0 & \hat{F}_{i(j+1)} & \cdots & \hat{F}_{in} \\ \vdots & \ddots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & \cdots & \hat{F}_{in} \end{bmatrix}$$

(17)

namely $\hat{F}$ is the same as the originally computed $F$ except for the $i$th row replaced by $\hat{F}_i$ computed in (16) and $\hat{F}_{ij} = 0$.

While the new feedback matrix $\hat{F}$ satisfies the imposed topological constraint, the eigenstructure of $A + BF$ is generally different from that of $A + BF$. Therefore, we must verify if the new eigenvalues/eigenvectors still satisfy (9) and (10), i.e. achieve formation control. This verification need not always be successful, but in case it does turn out successful, we are guaranteed to achieve the desired formation with a feedback matrix satisfying the imposed topological constraint. We illustrate the above method by the following example.

**Example 2:** Consider the multi-agent system (7) of 5 single integrators (that is, $a_i = 0$ and $b_i = 1$, $i = 1, ..., 5$), and the desired formation is simply consensus ($f = [1 1 1 1 1]^T$). Choose the following eigenvalues and eigenvectors

$$\text{eigenvalues: } \{\lambda_1, \lambda_2, \lambda_3, \lambda_4, \lambda_5\} = \{0, -1, -2, -3, -4\}$$

$$\text{eigenvectors: } [v_1 v_2 v_3 v_4 v_5] = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ 1 & 1 & 0 & 0 & 0 \\ 1 & 0 & 1 & 1 & -1 \\ 1 & 0 & 0 & 1 & 0 \\ 1 & 0 & 1 & 0 & 1 \end{bmatrix}$$

and compute by (5) the feedback matrix $F$ to achieve consensus:

$$F = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 \\ 2.5 & -1 & 1.5 & -1.5 & -1.5 \\ 2 & 0 & -3 & 0 & 1 \\ 3 & 0 & 0 & -3 & 0 \\ 3 & 0 & 1 & -1 & -3 \end{bmatrix}.$$ 

Suppose that the topological constraint is that agent 2 cannot receive information from agent 4, i.e. the (2, 4)-entry of $F$ ($F_{24} = -1.5$) must be set to be zero. For this we first derive equation $V^T F_i^T = \psi_i^T$ as follows:

$$\begin{bmatrix} 1 & 1 & 1 & 1 & | F_{21} \\ 0 & 1 & 0 & 0 & | F_{22} \\ 0 & 1 & 0 & 1 & | F_{23} \\ 0 & 0 & 1 & 1 & | F_{24} \\ 0 & 1 & -1 & 0 & | F_{25} \end{bmatrix} = \begin{bmatrix} 0 \\ -1 \\ 0 \\ 0 \\ -4 \end{bmatrix}.$$ 

The above derivation may be readily extended to deal with more than one topological constraint.
Deleting $F_{24}$ from $F_2^T$ and the 4th column of $V^T$, we obtain the reduced equation (15):

$$
\begin{bmatrix}
1 & 1 & 1 & 1
0 & 1 & 0 & 0
0 & 0 & 1 & 1
0 & 0 & 1 & 0
0 & 1 & -1 & 1
\end{bmatrix}
\begin{bmatrix}
\hat{F}_{21}
\hat{F}_{22}
\hat{F}_{23}
\hat{F}_{25}
\end{bmatrix}
= \begin{bmatrix}
0
-1
0
0
-4
\end{bmatrix}.
$$

Solve this equation for the unknowns $\hat{F}_{21}, \hat{F}_{22}, \hat{F}_{23}, \hat{F}_{25}$, we compute by (16):

$$
\hat{F}_2^T = \begin{bmatrix}
\hat{F}_{21}
\hat{F}_{22}
\hat{F}_{23}
\hat{F}_{25}
\end{bmatrix}
= \begin{bmatrix}
1.8571 \\
-1.4286 \\
0.8571 \\
-1.2857
\end{bmatrix}.
$$

Finally set as (17) the new feedback matrix

$$
\hat{F} = \begin{bmatrix}
0 & 0 & 0 & 0 & 0 \\
1.8571 & -1.4286 & 0.8571 & 0 & -1.2857 \\
2 & 0 & -3 & 0 & 1 \\
3 & 0 & 0 & -3 & 0 \\
3 & 0 & 1 & -1 & -3
\end{bmatrix}.
$$

Observe that (only) the second row of $\hat{F}$ has entries all different from that of the original $F$, and the (2,4)-entry $\hat{F}_{24} = 0$. Moreover the eigenstructure of the new closed-loop matrix $A + B\hat{F} (= \hat{F})$ is

eigenvalues: $\{\hat{\lambda}_1, \hat{\lambda}_2, \hat{\lambda}_3, \hat{\lambda}_4, \hat{\lambda}_5\} = \{0, -1.4286, -2, -3, -4\}$
eigenvectors: $[\hat{v}_1 \; \hat{v}_2 \; \hat{v}_3 \; \hat{v}_4 \; \hat{v}_5] = \begin{bmatrix}1 & 0 & 0 & 0 & 0 \\
1 & 2.2361 & -1.0477 & -0.8047 & -1.1352 \\
1 & 0 & -1.3969 & 1.4753 & 1.3623 \\
1 & 0 & 0 & 1.4753 & 1.3623 \\
1 & 0 & -1.3969 & 0 & -1.3623\end{bmatrix}$.

Hence these new eigenvalues/eigenvectors still satisfy (9) and (10), and therefore consensus is achieved despite of the imposed topological constraint. (In fact, since $\hat{\lambda}_2 < \lambda_2$, we have faster convergence with the new $\hat{F}$.)

### IV. General Multi-Agent Systems

So far we have considered the multi-agent system in (7), where the agents are uncoupled and each is (self-) stabilizable (the matrices $A, B$ are diagonal and $B$’s diagonal entries nonzero). For (7) we have shown in Theorem 1 that a state feedback control, based on eigenstructure assignment, always exists to drive the agents to a desired formation.

More generally, however, the agents may be initially interconnected (owing to physical coupling or existence of communication channels), and/or some agents might not be capable of stabilizing themselves (though they can receive information from others). It is thus of interest to inquire, based on the eigenstructure assignment approach, what conclusions we can draw for formation control in these more general cases.

#### A. Arbitrary Inter-Agent Connections

First we consider the case where the agents have arbitrary initial interconnection, while keeping the assumption that they are individually stabilizable. That is, we consider the following multi-agent system

$$\dot{x} = Ax + Bu \tag{18}$$

where $x \in \mathbb{C}^n, u \in \mathbb{C}^n, A \in \mathbb{R}^{n \times n}$ and $B = \text{diag}(b_1, \ldots, b_n)$ ($b_i \neq 0$). The matrix $A$ is now an arbitrary real matrix, modeling an arbitrary (initial) communication topology among the agents.

It turns out, despite the general $A$ matrix, that the same conclusion as Theorem 1 holds.

**Theorem 3:** Consider the multi-agent system (18) and let $f$ be a desired formation configuration. Then there always exists a state feedback control $u = Fx$ that achieves formation control, i.e.

$$(\forall x(0) \in \mathbb{C}^n)(\exists e \in \mathbb{C})\ lim_{t \to \infty} x(t) = ef.$$

**Proof:** The proof proceeds similarly to that of Theorem 1. First, for the diagonal matrix $B$ in (18), we have (regardless of $A$) that the pair $(A, B)$ is controllable and $	ext{Ker}B = 0$.

It is left to verify if the (distinct) eigenvalues $\lambda_1, \ldots, \lambda_n$ and eigenvectors $v_1, \ldots, v_n$ as in (9) and (10) satisfy the condition (4) of Lemma 1. Let $i \in [1, n]$. Since

$$[\lambda_i I - A \; B] \begin{bmatrix} B \\ B^{-1}(A - \lambda_i I)B \end{bmatrix} = 0$$

we find a basis for $	ext{Ker}[\lambda_i I - A \; B]$ and derive

$$N_1(\lambda_i) = B \quad N_2(\lambda_i) = B^{-1}(A - \lambda_i I)B.$$

Thus $\text{Im}N_1(\lambda_i) = \mathbb{C}^n$, and $v_i \in \text{Im}N_1(\lambda_i)$, i.e. the condition (4) of Lemma 1 holds. Therefore, there always exists a state feedback $u = Fx$ such that the multi-agent system (18) achieves the formation configuration $f$.

In the proof of Theorem 1, we derived $N_1(\lambda_i) = B$ and $N_2(\lambda_i) = A - \lambda_i I$. Since $A$ was diagonal and diagonal matrices commute, there held

$$[\lambda_i I - A \; B] \begin{bmatrix} B \\ A - \lambda_i I \end{bmatrix} = 0.$$ 

For a general $A$ as in Theorem 3, we have found instead

$$N_1(\lambda_i) = B \quad N_2(\lambda_i) = B^{-1}(A - \lambda_i I)B$$

that deal with arbitrary $A$ without depending on the commutativity of matrices.

**Theorem 3** asserts that, as long as the agents are individually stabilizable, formation control is achievable by eigenstructure assignment regardless of how the agents are initially interconnected. The final topology, on the other hand, is in general determined by the initial connections ‘plus’ additional ones resulted from the chosen eigenvalues/eigenvectors (as has been discussed in Section III). It may also be possible, however, that the initial connections are
‘decoupled’ by the corresponding entries of the synthesized feedback matrix. This is illustrated by the following example.

Consider again Example 1(i), but change \( A \) from the zero matrix to the following

\[
A = \begin{bmatrix}
0 & 0.5 & 0 & 0 \\
0 & 0 & 0 & 0 \\
-0.5 & 0 & 0 & 0 \\
0 & 0 & 2 & 0
\end{bmatrix};
\]

that is, agents 1 and 2, 3 and 1, 4 and 3 are initially inter-connected. Assigning the same eigenstructure as in Example 1(i), we obtain the feedback matrix

\[
F = \begin{bmatrix}
-1 & -0.5 & 0 & j \\
1 & -2 & 0 & -2 - j \\
-0.5 & 1 & -3 & 1 - 2j \\
0 & 0 & -2 & 0
\end{bmatrix}.
\]

Then the closed-loop matrix \( A + BF \) (where \( B \) is the identity matrix) is

\[
A + BF = \begin{bmatrix}
-1 & 0 & 0 & j \\
1 & -2 & 0 & -2 - j \\
-1 & 1 & -3 & 1 - 2j \\
0 & 0 & 0 & 0
\end{bmatrix}
\]

which is the same as the feedback matrix \( F_1 \) (as well as the closed-loop matrix) in Example 1(i). Thus despite the initial coupling, the final topology turns out to be the same as that of Example 1(i). In particular, in the final topology agents 1 and 2, 4 and 3 are ‘canceled’ by the corresponding entries of the feedback matrix \( F \).

B. Existence of Non-Stabilizable Agents

Continuing to consider arbitrary initial topology (i.e. general \( A \)), we further assume that some agents cannot stabilize themselves (i.e. the corresponding diagonal entries of \( B \) in (18) are zero). Equivalently, the non-stabilizable agents have no control inputs. In this case, achieving a desired formation is possible only if those non-stabilizable agents may take advantage of information received from others (via connections specified by \( A \)). This is a problem of global formation stabilization with locally unstabilizable agents, which has rarely been studied in the literature. We aim to provide an answer using our top-down eigenstructure assignment based approach.

Without loss of generality, assume that only the first \( m \) (< \( n \)) agents are stabilizable. Thus the multi-agent system we consider in this subsection is

\[
\dot{x} = Ax + Bu
\]

where \( x \in \mathbb{C}^n, u \in \mathbb{C}^m, A \in \mathbb{R}^{n \times n} \) and

\[
B = \begin{bmatrix}
b_1 \\
\vdots \\
b_m
\end{bmatrix} \in \mathbb{R}^{n \times m} (m < n)
\]

\( b_i \neq 0, \ i \in [1, m] \).

Theorem 4: Consider the multi-agent system (19) and let \( f \) be a desired formation configuration. Also let \( \lambda_1, \ldots, \lambda_n \) and \( v_1, \ldots, v_n \) be the desired eigenvalues and eigenvectors satisfying (9) and (10). If

(i) the pair \( (A, B) \) is controllable, and
(ii) \( \text{Im}B \subseteq \text{Im}(A - \lambda_i I) \) for all \( i \in [1, n] \), and
(iii) \( v_i \in \text{Im}N_1(\lambda_i) \) for all \( i \in [1, n] \), where \( N_1(\lambda_i) \) satisfies \( (A - \lambda_i I)N_1(\lambda_i) = B \),

then there exists a state feedback control \( u = Fx \) that achieves formation control, i.e.

\((\forall x(0) \in \mathbb{C}^n)(\exists c \in \mathbb{C}) \lim_{t \to \infty} x(t) = cf.\)

Proof: First observe from (19) that \( \text{Ker}B = 0 \), since \( B \)'s columns are linearly independent. Now let \( i \in [1, n] \). Since \( (A, B) \) is controllable (condition (i)), there exist \( N_1(\lambda_i) \) and \( N_2(\lambda_i) \) such that (2) holds. Setting \( N_2(\lambda_i) = I \), we derive from (3) the following matrix equation

\[
(A - \lambda_i I) N_1(\lambda_i) = B. \tag{20}
\]

Since \( \text{Im}B \subseteq \text{Im}(A - \lambda_i I) \) (condition (ii)), this equation has a solution \( N_1(\lambda_i) \) (which is determined by \( A, B, \lambda_i \)). Finally, since \( v_i \in \text{Im}N_1(\lambda_i) \) (condition (iii)), the condition (4) of Lemma 1 is satisfied. Therefore the desired eigenvalues and eigenvectors satisfying (9) and (10) may be assigned by a state feedback control \( u = Fx \), i.e. formation control is achieved.

Theorem 4 provides sufficient conditions to ensure solvability of the formation control problem for multi-agent systems with non-stabilizable agents. In the following we illustrate this result by working out a concrete example, where \( A \) represents a directed line topology and there is only one agent that is stabilizable (i.e. \( B \) is simply a vector).

Example 3: Consider the multi-agent system \( \dot{x} = Ax + Bu \) with

\[
A = \begin{bmatrix}
a_1 & 0 & 0 & \ldots & 0 \\
a_2 & a_2 & 0 & \ldots & 0 \\
\vdots & \vdots & \ddots & \ddots & \vdots \\
0 & \tilde{a}_m & a_m & \ldots & 0
\end{bmatrix}, \quad B = \begin{bmatrix}
b_1 \\
\vdots \\
b_m
\end{bmatrix}
\]

where \( a_1, \ldots, a_n, \tilde{a}_2, \ldots, \tilde{a}_m, b_1 \) are nonzero. Namely \( A \) represents a directed line topology with agent 1 the root, and \( B \) means that only agent 1 is stabilizable. Thus this is a single-input multi-agent system – by controlling only the root of a directed line.

First, it is verified that \( (A, B) \) is controllable, i.e. condition (i) of Theorem 4 is satisfied. To ensure condition (ii),
ImB ⊆ Im(A − λ,lI), it suffices to choose each desired eigenvector λi (i ∈ [1, n]) such that λi ≠ aj for j ∈ [1, n] (i.e. every eigenvalue is distinct from the nonzero diagonal entries of A). At the same time, these eigenvalues must satisfy (9).

Having condition (ii) hold, equation (20) has a solution N1(λi). Let us solve (20)

\[
\begin{bmatrix}
a_1 - \lambda_i & 0 & 0 \\
\frac{b_1}{a_2} & a_2 - \lambda_i & \vdots \\
0 & \ddots & \ddots \\
0 & & a_n - \lambda_i
\end{bmatrix}
N_1(\lambda_i) =
\begin{bmatrix}
b_1 \\
0 \\
\vdots \\
0
\end{bmatrix}
\]

and obtain an explicit solution

\[
N_1(\lambda_i) = \left[ \frac{b_1}{(a_1 - \lambda_i)(a_2 - \lambda_i)} \right].
\]

Hence to ensure condition (iii) of Theorem 4 we must choose each desired eigenvector v_i (i ∈ [1, n]) such that v_i ∈ ImN1(λi) and (10) is satisfied. In particular, for i = 1 we have λ_1 = 0 and v_1 = f; thus v_1 ∈ ImN1(λ1) means that the formation vector f must be such that

\[
f = c \left[ \frac{b_1}{a_1} - \frac{b_1 b_2}{a_1 a_2} \cdots \frac{(-1)^{n-1} b_1 b_2 \cdots b_n}{a_1 a_2 \cdots a_n} \right] \tau
\]

where c ∈ C (c ≠ 0). This characterizes the set of all achievable formation configurations for the single-input multi-agent system under consideration.

We conclude that, by controlling only one agent, indeed the root agent of a directed line topology, it is not possible to achieve arbitrary formation configurations but those determined by the nonzeros entries of the matrices A and B in the specific manner as given in (21).

V. HIERARCHICAL EIGENSTRUCTURE ASSIGNMENT

In the previous sections, we have shown that a control gain matrix F can always be computed (as long as every agent is stabilizable) such that the multi-agent formation Problem 1 is solved. Computing such F by (5) (see the eigenstructure assignment procedure in Section II) has complexity O(n3), where n is the number of agents. Consequently the computation cost becomes expensive as the number of agents increases.

To address this issue of centralized computation, we propose in this section a hierarchical synthesis procedure. We shall show that the control gain matrix F computed by this hierarchical procedure again solves Problem 1, which moreover significantly improves computational efficiency (empirical evidence provided in Section VII).

For clarity of presentation, let us return to consider the multi-agent system (7), and Problem 1 with the desired formation configuration f ∈ C^n (f ≠ 0). Partition the agents into l (≥ 1) pairwise disjoint groups. Let group k (∈ [1, l]) have n_k (≥ 1) agents; n_k may be different and Σ_k=1^n_k = n.

Now for the configuration f and x, u, A, B in (7), write in accordance with the partition (possibly with reordering)

\[
f = \begin{bmatrix} g_1 \\ \vdots \\ g_l \end{bmatrix}, \quad x = \begin{bmatrix} y_1 \\ \vdots \\ y_l \end{bmatrix}, \quad u = \begin{bmatrix} w_1 \\ \vdots \\ w_l \end{bmatrix},
A = \begin{bmatrix} A_1 & & \\ & \ddots & \\ & & A_l \end{bmatrix}, \quad B = \begin{bmatrix} B_1 & & \\ & \ddots & \\ & & B_l \end{bmatrix}
\]

where g_k, y_k, w_k ∈ C^n_k and A_k, B_k ∈ C^n_k × n_k, k ∈ [1, l]. Thus for each group k, the dynamics is

\[
\dot{y}_k = A_k y_k + B_k w_k.
\]

For later use, also write \(g_{k1}, y_{k1}, w_{k1}\) (resp. \(A_{k1}, B_{k1}\)) for the first component of \(g_k, y_k, w_k\) (resp. (1,1)-entry of \(A_k, B_k\)), and \(y_0 := [y_{11} \cdots y_{1l}]^T, g_0 := [g_{11} \cdots g_{1l}]^T, w_0 := [w_{11} \cdots w_{1l}]^T, A_0 := \text{diag}(A_{11}, \ldots, A_{1l}), B_0 := \text{diag}(B_{11}, \ldots, B_{1l})\).

The vector \(y_k\) (k ∈ [1, l]) is the local formation configuration for group k, while \(y_0\) is the formation configuration for the set of the first component agent from each group. We assume that these configurations are all nonzero, i.e. \(g_k \neq 0\) for \(k \in [1, l]\) and \(y_0 \neq 0\). Now we present the hierarchical synthesis procedure.

(i) For each group k ∈ [1, l] and its dynamics (22), compute \(F_k\) by (5) such that \(A_k + B_k F_k\) has a simple eigenvalue 0 with the corresponding eigenvector \(g_k\), and other eigenvalues have negative real parts; moreover the topology defined by \(F_k\) has a unique root node \(y_{k1}\) (e.g. star or line by the method given in Section III.A).

(ii) Treat \(\{y_{k1}| k \in [1, l]\}\) (the group leaders) as a higher-level group, with the dynamics

\[
\dot{y}_0 = A_0 y_0 + B_0 w_0.
\]

Compute \(F_0 ∈ C^{l \times l}\) by (5) such that \(A_0 + B_0 F_0\) has a simple eigenvalue 0 with the corresponding eigenvector \(y_0\), and other eigenvalues have negative real parts.

(iii) Set the control gain matrix \(F := F_{\text{low}} + F_{\text{high}}\), where

\[
F_{\text{low}} := \begin{bmatrix} F_1 & & \\ & \ddots & \\ & & F_l \end{bmatrix}
\]

and \(F_{\text{high}}\) is partitioned according to \(F_{\text{low}}\), with each block row (i, j), i, j ∈ [1, l]

\[
(F_{\text{high}})_{ij} = (F_0)_{ij} \begin{bmatrix} 1 & 0 & \cdots & 0 \\ 0 & 0 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & 0 \end{bmatrix}
\begin{bmatrix} 0 & \cdots & 0 \\ 0 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & 0 \end{bmatrix}.
\]
The computational complexity of Step (i) is $O(n^3)$, where $\hat{n} := \max\{n_1, \ldots, n_l\}$; and Step (ii) is $O(l^3)$. Let $\hat{n} := \max\{\hat{n}, l\}$. Then the complexity of the entire hierarchical synthesis procedure is $O(\hat{n}^3)$. With proper group partition, this hierarchical procedure can significantly reduce computation time, as demonstrated by an empirical study in Section VII.

Note that in Step (i) of the above procedure, requiring the topology defined by each $F_k$ to have a unique root, i.e. a single leader, is for simplicity of presentation. It can be extended to the case of multiple leaders, and then in Step (ii) treat all the leaders at the higher-level. On the other hand, the number of leaders should be kept small such that the high-level control synthesis in Step (ii) can be done efficiently.

The correctness of the hierarchical synthesis procedure is asserted in the following.

**Theorem 5:** Consider the multi-agent system (7) and let $f$ be a desired formation configuration. Then the state feedback control $u = Fx$ synthesized by the hierarchical synthesis procedure solves Problem 1, i.e.

$$\forall x(0) \in \mathbb{C}^n \exists \in \mathbb{C} \lim_{t \to \infty} x(t) = cf.$$ 

**Proof:** For each $k \in [1, l]$ let $y_k := [y_{k1} \ldots y_{kn}]^\top$ and $y_k := [g_{k1} \ldots g_{kn}]^\top \in \mathbb{C}^{n_k-1}$. Thus $y_k$ and $g_k$ are $y_k, g_k$ with the first element removed. By Step (i) of the hierarchical synthesis procedure, since $y_k$ is the unique root node, we can write $\hat{y}_k = (A_k + B_k F_k)y_k$ as follows:

$$\begin{bmatrix}
\hat{y}_k \\
\dot{y}_k
\end{bmatrix} = \begin{bmatrix}
H_k & G_k
\end{bmatrix} \begin{bmatrix}
y_k \\
\dot{y}_k
\end{bmatrix}.$$ 

Then by the eigenstructure of $A_k + B_k F_k$, all the eigenvalues of $G_k$ have negative real parts and

$$\begin{bmatrix}
H_k & G_k
\end{bmatrix} \begin{bmatrix}
y_k \\
\dot{y}_k
\end{bmatrix} = 0. \quad (24)$$

Reorder $x = [y_1^\top \ldots y_l^\top]^\top$ to get $\hat{x} := [\hat{y}_1 \hat{y}_1^\top \ldots \hat{y}_l \hat{y}_l^\top]^\top$. Then there is a permutation matrix that similarly transforms the control gain matrix $F$ in Step (iii) to $\hat{F}$, and $\hat{x} = \hat{F}\hat{x}$ is

$$\begin{bmatrix}
y_k \\
\dot{y}_k
\end{bmatrix} = \begin{bmatrix}
A_0 + B_0 F_0 & 0 \\
H_1 & G_1 \\
\ldots & \ldots & \ldots & \ldots & \ldots \\
H_l & G_l \\
y_k \\
\dot{y}_k
\end{bmatrix} \begin{bmatrix}
y_k \\
\dot{y}_k
\end{bmatrix}.$$ 

It then follows from the eigenstructure of $A_0 + B_0 F_0$ assigned in Step (ii) and (24) above that the matrix $\hat{F}$ has a simple eigenvalue 0 with the corresponding eigenvector $\hat{f} := [\hat{y}_1 \hat{g}_1 \ldots \hat{y}_l \hat{g}_l]^\top$, and other eigenvalues have negative real parts. Hence (cf. Proposition 1).

$$\forall \hat{x}(0) \in \mathbb{C}^n \exists \hat{c} \in \mathbb{C} \lim_{t \to \infty} \hat{x}(t) = \hat{c}\hat{f}.$$ 

Since $\hat{x}$ (resp. $\hat{f}$) is just a reordering of $x$ (resp. $f$), the conclusion follows and the proof is complete.

VI. RIGID FORMATION AND CIRCULAR MOTION

In this section we show that our method of eigenstructure assignment may be easily extended to address problems of rigid formation and circular motion.

A. Rigid Formation

First, we extend our method to study the problem of achieving a rigid formation, one that has translational and rotational freedom but fixed size.

**Problem 2:** Consider the multi-agent system (7) and specify $f \in \mathbb{C}^n (f \neq 0)$ and $d > 0$. Design a control $u$ such that for every initial condition $x(0), \lim_{t \to \infty} x(t) = c1 + df e^{\iota \theta}$ for some $c \in \mathbb{C}$ and $\theta \in [0, 2\pi]$.

In Problem 2, the goal of the multi-agent system (7) is to achieve a rigid formation $df$, with translational freedom in $c$, rotational freedom in $\theta$, and fixed size $d$.

We now present the rigid-formation synthesis procedure.

(i) Compute $F$ by (5) such that $A + BF$ has two eigenvalues 0 with the corresponding (non-generalized) eigenvectors $1$ and $f$, and other eigenvalues have negative real parts.

Moreover the topology defined by $F$ is 2-rooted with exactly 2 roots (say nodes 1 and 2). This topology may be achieved by assigning appropriate eigenstructures, e.g.

eigenvalues: $\lambda_1 = \lambda_2 = 0, \lambda_3, \ldots, \lambda_n$ distinct

and $\text{Re}(\lambda_3), \ldots, \text{Re}(\lambda_n) < 0$

eigenvectors: $[v_1 v_2 v_3 \cdots v_n] = \begin{bmatrix} 1 & f_1 & 0 & \cdots & 0 \\ 1 & f_2 & 0 & \cdots & 0 \\ 1 & f_3 & 1 & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & f_n & 0 & \cdots & 1 \end{bmatrix}$

(25)

(ii) Let $f_1, f_2$ be the first two components of $f$, and set

$$\begin{cases}
\dot{x}_1 = \left([x_2 - x_1]|x_2 - x_1|^2 - d^2[f_2 - f_1]^2\right) := r(x_1, x_2) \\
\dot{x}_2 = \left([x_1 - x_2]|x_1 - x_2|^2 - d^2[f_1 - f_2]^2\right)
\end{cases}.$$ 

(iii) Set the control

$$u := Fx + B^{-1} \begin{bmatrix} r(x_1, x_2) \\ 0 \end{bmatrix}.$$ 

(26)

The idea of the above synthesis procedure is to first use eigenstructure assignment to achieve a desired formation configuration with two leaders, and then control the size of the formation by stabilizing the distance between the two leaders to the prescribed $d$. The latter is inspired by [13]. Our result is the following.

**Proposition 5:** Consider the multi-agent system (7) and let $f \in \mathbb{C}^n, d > 0$. Then the control $u$ in (26) synthesized by the rigid-formation synthesis procedure solves Problem 2 for all initial conditions $x(0)$ with $x_1(0) \neq x_2(0)$.

For repeated eigenvalues with non-generalized eigenvectors, the eigenstructure assignment result Lemma [1] and the computation of control gain matrix $F$ in (5) remain the same as for the case of distinct eigenvalues.

2 For repeated eigenvalues with non-generalized eigenvectors, the eigenstructure assignment result Lemma [1] and the computation of control gain matrix $F$ in (5) remain the same as for the case of distinct eigenvalues.

3 A 2-rooted topology is one where there exist 2 nodes from which every other node $v$ can be reached by a directed path after removing an arbitrary node other than $v$ [13].
Proof: First, by a similar argument to that in the proof of Theorem 1 we can show that the desired eigenvalues/eigenvectors (two eigenvalues at 0 with eigenvectors 1 and \( f \); all other eigenvalues with negative real parts) may always be assigned for the multi-agent system (1). As a result (cf. Proposition 1),

\[
(\forall x(0) \in C^n)(\exists \alpha, \alpha' \in C) \lim_{t \to \infty} x(t) = \alpha 1 + \alpha' f.
\]

Moreover, choosing the eigenstructure in (25) and following similarly to the proof of Proposition 2 we can show that the resulting topology defined by \( F \) is 2-rooted with nodes 1 and 2 the only two roots.

With the 2-rooted topology and the design in Step (ii), it follows from [13, Theorem 4.4] that for all \( x(0) \) with \( x_1(0) \neq x_2(0) \), we have \( c' = df e^{j\theta} \) for some \( \theta \in [0, 2\pi] \).

An illustrative example of achieving rigid formations is provided in Section VII below.

B. Circular Motion

We apply the eigenstructure assignment approach to solve a cooperative circular motion problem, in which the agents all circle around the same center while keeping a desired formation configuration. This cooperative task may find useful applications in target tracking and encircling (e.g. [25], [26]).

Problem 3: Consider the multi-agent system (7) and specify \( f \in C^n \) (\( f \neq 0 \)) and \( b \in R \) (\( f \neq 0 \)). Design a state feedback control \( u = Fx \) such that for every initial condition \( x(0) \), \( \lim_{t \to \infty} x(t) = c1 + c'e^{j\theta} \) for some \( c, c' \in C \) and \( j = \sqrt{-1} \).

In Problem 3, the goal is that the agents of (7) all circle around the same center \( c \) at rate \( b \), while keeping the formation configuration \( f \) scaled by \( |c'| \).

Our result is the following.

Proposition 6: Consider the multi-agent system (7) and let \( f \in C^n \), \( b \in R \). Then there always exists a state feedback control \( u = Fx \) that solves Problem 3.

Proof: By a similar argument to that in the proof of Theorem 1 we can show that for (7) there always exists \( F \) such that \( (A+BF) \) has the following eigenstructure:

- eigenvalues: \( \lambda_1 = 0, \lambda_2 = bj, \lambda_3, \ldots, \lambda_n \) distinct
- and \( \text{Re}(\lambda_3), \ldots, \text{Re}(\lambda_n) < 0 \)
- eigenvectors: \( v_1 = 1, v_2 = f, \{v_1, v_2, \ldots, v_n\} \) independent

Then (cf. Proposition 1),

\[
(\forall x(0) \in C^n)(\exists c, c' \in C) \lim_{t \to \infty} x(t) = \alpha 1 + \alpha' f e^{j\theta}.
\]

That is, Problem 3 is solved.

The key point to achieving circular motion is to assign one, and only one, pure imaginary eigenvalue \( bj \), associated with the formation vector \( f \). The circular motion is counter-clockwise if \( b > 0 \), and clockwise if \( b < 0 \). One may easily speed up or slow down the circular motion by specifying the value \(|b|\).

Also note that, by a similar synthesis procedure to that for rigid formation in the previous subsection, the multi-agent system (7) can be made to achieve circular motion while keeping a rigid formation with some specified size \( d > 0 \).

Circular motion may be applied to the task of target encircling, which is illustrated by an example in the next section.

VII. SIMULATIONS

We illustrate the eigenstructure assignment based approach by several simulation examples. For all the examples, we consider the multi-agent system (7) with 5 heterogeneous agents, where

\[
A = \text{diag}(1.6, 4.7, 3.0, -0.7, -4.2),
B = \text{diag}(0.2, 1.5, -0.5, -3.3, -3.7).
\]

Thus the first 3 agents are unstable while the latter 2 are stable; all agents are stabilizable.

First, to achieve a scalable (regular) pentagon formation, assign the following eigenstructure:

- eigenvalues: \( \{\lambda_1, \ldots, \lambda_5\} = \{0, -1, -2, -3, -4\} \)
- eigenvectors: \( v_1 \cdots v_5 = \begin{bmatrix} e^{2\pi i x_1} & -1 & 0 & 0 & 0 \\ e^{2\pi i x_2} & 1 & 0 & 0 & 0 \\ e^{2\pi i x_3} & 0 & 0 & 0 & 0 \\ e^{2\pi i x_4} & -2 & -1 & 1 & 0 \\ e^{2\pi i x_5} & -2 & 0 & -1 & 1 \end{bmatrix} \)

By (5) compute the control gain matrix

\[
F = \begin{bmatrix} -10.5 \pm 1.8164j & 2.5 \pm 1.8164j & 0 & 0 & 0 \\ 0.3333 + 0.2422j & -3.4667 + 0.2422j & 0 & 0 & 0 \\ -0.4721 \pm 2.3511j & -0.4721 \pm 2.3511j & 10 & -2 & 0 \\ -0.0442 \pm 0.4403j & 1.1679 \pm 0.4403j & 0 & 0 & 0 \\ -0.3979 + 0.4391j & 0.1427 + 0.4391j & 0 & -0.5405 + 0.0541j & 0 \end{bmatrix}
\]

Simulating the closed-loop system with initial condition \( x(0) = [1 + j, 1 - 0.5j, 1j, -1 + j]^\top \), the result is displayed in Fig. 2. Observe that a regular pentagon is formed, and the topology determined by \( F \) contains a spanning tree.

Next, to achieve a rigid pentagon formation, we follow the method presented in Section VI.A: first assign the following
A part of the multi-agent system; hence the augmented circle around that there is a static target, say by circular motion introduced in Section VI.B. Suppose specified sizes are formed.

Fig. 3. Rigid regular pentagon formation, with size \( d = 5, 10, 15 \) (x: initial positions, \( \circ \): steady-state positions)

Moreover, choose the following eigenstructure:

- eigenvectors: \( \{v_1 \cdots v_5\} = \begin{bmatrix} 1 \ e^{\frac{2\pi j x_1}{5}} \ 1 \ e^{\frac{2\pi j x_2}{5}} \ 1 \ e^{\frac{2\pi j x_3}{5}} \ 1 \ e^{\frac{2\pi j x_4}{5}} \ 1 \ e^{\frac{2\pi j x_5}{5}} \end{bmatrix} \)

Thus the desired formation is (again) a regular pentagon and the target \( x_0 \) is at the center of this pentagon. Moreover, by the eigenvectors the resulting topology will contain a spanning tree with \( x_0 \) (the target) being the root. Corresponding to the formation vector is the eigenvalue \( j \); hence the agents will perform circular motion at rate 1. Since the center will not move (\( x_0 \) at the center is the root), this makes the first 5 agents encircle the target \( x_0 \).

By (5) we compute the control gain matrix

\[
F = \begin{bmatrix} -8 & 0 & 0 & 0 & 0 \\ 0 & -3.1333 & 0 & 0 & 0 \\ 0.618 + 1.9021j & -2.618 - 1.9021j & 8 & 0 & 0 \\ -0.303 + 0.9326j & -0.303 - 0.9326j & 0 & 0.3939 & 0 \\ -1.0614 + 0.7711j & 0.2506 - 0.7711j & 0 & 0 & -0.3243 \end{bmatrix}
\]

Thus the topology determined by \( F \) is 2-rooted with nodes 1 and 2 the only two roots. Then for different sizes \( (d = 5, 10, 15) \), we obtain by (26) the control \( u \). Simulating the closed-loop system with the same initial condition \( x(0) \) as above, the result is displayed in Fig. 3 where pentagons with specified sizes are formed.

Further, we consider the task of target encircling and solve it by circular motion introduced in Section VI.B. Suppose that there is a static target, say \( x_6 \) with \( \dot{x}_6 = u_6 \) (\( u_6 \) is constantly zero), and the goal is make the same 5 agents as above circle around \( x_6 \). For this we treat the target \( x_6 \) as part of the multi-agent system; hence the augmented \( A' \) and \( B' \) are

\[
A' = \text{diag}(1.6, 4.7, 3.0, -0.7, -4.2, 0) \\
B' = \text{diag}(0.2, 1.5, -0.5, -3.3, -3.7, 1)
\]

and by (5) compute the control gain matrix

\[
F = \begin{bmatrix} -8 + 5j & 0 & 0 & 0 & 0 \\ -10.428 + 0.84j & -2.38 & 0 & 0 & 0 \\ 4.4116 - 0.7331j & 0 & 10 & 0 & 0 \\ 0.5571 + 0.7795j & 0 & 0.697 & -1.4664 - 0.7975j \\ -0.5911 + 0.9447j & 0 & 0 & 0 & -0.0040 - 0.9447j \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix}
\]

to assign the above eigenstructure. Indeed, the corresponding topology has a spanning tree whose root is \( x_6 \) and \( \dot{x}_6 = 0 \). Simulating the closed-loop system with the initial condition \( x(0) = [1 - 0.5j - 2 + 2j - 2 + j - 1 + j - j 1 + j] \), the result is displayed in Fig. 4. Observe that the target stays put at its initial position \( 1 + j \), while other agents circle around it.

Finally, we present an empirical study on the computation time of synthesizing feedback matrix \( F \). In particular, we compare the centralized synthesis by (5) and the hierarchical synthesis in Section V; the result is listed in Table I for different numbers of agents. Here for the hierarchical synthesis, we partition the agents in such a way that the number of agents encircling the target is 5.

\[\text{Computation is done by Matlab R2014b on a laptop with Intel(R) Core(TM) i7-4510U CPU@2.00GHz 2.60GHz and 8.00GB memory.}\]
groups and the number of agents in each group is ‘balanced’ (to make \( n \) small); e.g. 100 agents are partitioned into 10 groups of 10 agents each; 500 agents are partitioned into 23 groups of 23 agents each plus 6 groups of 22 each. Observe that the hierarchical synthesis is significantly more efficient than the centralized one, and the efficiency increases as the number of agents increases. In particular, for 1000 agents only 0.525 seconds needed, the hierarchical approach might well be sufficient for many practical purposes.

### VIII. Concluding Remarks

We have proposed a top-down, eigenstructure assignment based approach to synthesize state feedback control for solving multi-agent formation problems. The relationship between the eigenstructures used in control synthesis and the resulting topologies among agents has been characterized, and special topologies have been designed by choosing appropriate eigenstructures. More general cases where the initial inter-agent coupling is arbitrary and/or there exist non-stabilizable agents have been studied, and a hierarchical synthesis procedure has been presented that improves computational efficiency. Further, the approach has been extended to achieve rigid formation and circular motion.

In our view, the proposed top-down approach to multi-agent formation control is complementary to the existing (mainstream) bottom-up approach (rather than opposed to). Indeed, the bottom-up approach, if successful, can produce scalable control strategies effective for possibly time-varying topologies, nonlinear agent dynamics, and robustness issues like communication failures, which are the cases very difficult to be dealt with by the top-down approach. On the other hand, bottom-up design is generally challenging, requiring significant insight into the problem at hand and possibly many trial-and-errors in the design process; by contrast, top-down design is straightforward and can be automated by algorithms. Hence we suggest the following. When a control researcher or engineer faces a distributed control design problem for achieving some new cooperative tasks, one can start with a linear time-invariant version of the problem and try the top-down approach to derive a solution. With the ideas and insights gained from such a solution, one may then try the bottom-up design possibly for time-varying and nonlinear cases.

In future work, we aim to apply the top-down, eigenstructure assignment based approach to solve more complex cooperative control problems of multi-agent systems. In particular, our immediate goals are to achieve formations in three dimensions with obstacle avoidance abilities, as well as to deal with agents with higher-order (heterogeneous, possibly non-stabilizable) dynamics.

### IX. Appendix

We provide the proof of Proposition \( \ref{prop:eg_assignment} \). For this we first briefly review the eigenstructure assignment method in [17] for dealing with repeated eigenvalues and generalized eigenvectors.

**Lemma 2:** (\[17\]) Consider the system (1) and suppose that \((A, B)\) is controllable and \(\ker B = 0\). Let \(\{d_1, \ldots, d_k\} (k \leq n)\) be a set of positive integers satisfying \(\sum_{i=1}^{k} d_i = n\), \(\{\lambda_1, \lambda_2, \ldots, \lambda_k\}\) be a set of complex numbers, and \(\{v_{11}, \ldots, v_{1d_1}, \ldots, v_{k1}, \ldots, v_{k\lambda k}\}\) a set of linearly independent vectors in \(\mathbb{C}^n\). Then there is a feedback matrix \(F\) such that for every \(i \in [1, k]\),

\[
\begin{align*}
(\lambda_i I - A - BF)v_{jj} &= 0 \quad &j = 1, \ldots, d_i
\end{align*}
\]

if and only if

\[
(\exists w_{ij} \in \mathbb{C}^m, v_{ij}) \left[ \begin{array}{c} v_{i1}(\lambda_i) \\ w_{i1}(\lambda_i) \end{array} \right] = 0
\]

\[
\left[ \begin{array}{c} v_{i2}(\lambda_i) \\ w_{i2}(\lambda_i) \end{array} \right] = v_{i(j-1)}, \quad j = 2, \ldots, d_i.
\]

\begin{equation}
(27)
\end{equation}

**Lemma 2** provides a necessary and sufficient condition for assigning repeated eigenvalues \(\lambda_i (i \in [1, k])\) with eigenvector \(v_{i1}\) and generalized eigenvectors \(v_{i2}, \ldots, v_{id_i}\) (corresponding to a Jordan block of the closed-loop matrix \(A + BF\)). When the condition holds and thus \(F\) exists, \(F\) may be constructed by the following procedure \(\ref{prop:eg_assignment}\).

(i) Compute the following (maximal-rank) matrices

\[
N_i = \begin{bmatrix} N_{11} & N_{12} \\ N_{21} & N_{22} \end{bmatrix}, \quad S_i = \begin{bmatrix} S_{11} & \vdots \\ \vdots & S_{22} \end{bmatrix}
\]

satisfying

\[
\left[ \begin{array}{c} \lambda_i I - A - B \\ \lambda_i I - A \end{array} \right] \begin{bmatrix} N_{11} & N_{12} \\ N_{21} & N_{22} \end{bmatrix} = 0, \quad \left[ \begin{array}{c} \lambda_i I - A - B \\ \lambda_i I - A \end{array} \right] \begin{bmatrix} S_{11} & \vdots \\ \vdots & S_{22} \end{bmatrix} = -I.
\]

\((S_i)\) needs to be computed only when \(d_i > 1\).

(ii) From the following vector chain

\[
\begin{align*}
v_{i1} &= N_{11}p_{i1} \\
v_{i2} &= N_{11}p_{i2} - S_{11}v_{i1} \\
&\vdots \\\nv_{id_i} &= N_{11}p_{id_i} - S_{11}v_{i(d_i-1)}
\end{align*}
\]

find the vectors \(p_{i1}, \ldots, p_{id_i}\). Then generate a new vector chain as follows:

\[
\begin{align*}
w_{i1} &= -N_{21}p_{i1} \\
w_{i2} &= -N_{21}p_{i2} + S_{21}v_{i1} \\
&\vdots \\\nw_{id_i} &= -N_{21}p_{id_i} + S_{21}v_{i(d_i-1)}
\end{align*}
\]
We have $p_{11} = B^{-1}v_{11}$. Hence

$$w_{11} = -N_{21}p_{11} = -AB^{-1}v_{11} = [-a_1f_1/b_1 \cdots -a_nf_n/b_n]^\top.$$

It is verified that $w_{11}$, together with $v_{11}, \lambda_1$, satisfies the first equation of (27).

Second, for $\lambda_2 = -1$ (with $d_2 = n - 1$), in Step (i) we derive $N_{12} = B, N_{22} = (A + I), S_{12} = B, S_{22} = (A + I) - B^{-1}$. Then in Step (ii), from the chain

$$v_{21} = N_{12}p_{21},$$
$$v_{22} = N_{12}p_{22} - S_{12}v_{21},$$
$$\vdots$$
$$v_{2(n-1)} = N_{12}p_{2(n-1)} - S_{12}v_{2(n-2)}$$

we find

$$p_{21} = [0 \cdots 0 -f_{n}\top/b_n],$$
$$p_{22} = [0 \cdots 0 -f_{n-1}\top/b_{n-1} - f_n/b_n - f_n],$$
$$\vdots$$
$$p_{2(n-1)} = [0 -f_{2}\top/b_2 - f_3\top/b_3 - \cdots - f_n/b_n - f_n\top/b_n].$$

Hence we obtain

$$w_{21} = N_{12}p_{21} = [0 \cdots 0 (a_n + 1)f_{n}\top/b_n]^\top,$$
$$w_{22} = N_{12}p_{22} - S_{12}v_{21} = [0 \cdots 0 (a_{n-1} + 1)f_{n-1}\top/b_{n-1} - a_nf_n/b_n]^\top,$$
$$\vdots$$
$$w_{2(n-1)} = N_{12}p_{2(n-1)} - S_{12}v_{2(n-2)} = [0 (a_2 + 1)f_2/b_2, a_3f_3/b_3 \cdots a_nf_n/b_n]^\top.$$

The chain $\{w_{11}, w_{21}, \ldots, w_{2(n-1)}\}$, together with $\{v_{21}, v_{22}, \ldots, v_{2(n-1)}\}$, and $\lambda_2(= -1)$, is verified to satisfy (27). Hence it follows from Lemma 2 that the above eigenstructure can be assigned to the closed-loop matrix $A + BF$. Then by Proposition 1, Problem $\alpha$ is solved.

Finally we compute the feedback matrix $F$. Let $W = \begin{bmatrix} w_{11} & w_{21} & \cdots & w_{2(n-1)} \end{bmatrix}$. Since

$$V^{-1} = \begin{bmatrix} f_1 & f_2 & \cdots & f_n \\ 0 & f_2 & \cdots & f_n \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & f_n \end{bmatrix},$$

we obtain by $F = WV^{-1}$ that

$$F = \begin{bmatrix} -\frac{a_1}{b_1} & \frac{f_2}{b_2} & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ \frac{-f_{n-1}}{b_{n-1}} & \frac{-f_n}{b_n} & \cdots & \frac{-a_n}{b_n} \end{bmatrix}.$$

Therefore the closed-loop matrix is

$$A + BF = \begin{bmatrix} 0 & 0 & \cdots & 0 \\ \frac{f_2}{b_2} & \frac{-1}{b_2} \& \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ \frac{-f_{n-1}}{b_{n-1}} & \frac{-f_n}{b_n} & \cdots & \frac{-1}{b_n} \end{bmatrix}$$

and the corresponding graph $G$ is a line topology.
