## Some Calabi-Yau fourfolds verifying Voisin's conjecture

## Robert Laterveer

Received: date / Accepted: date

#### Abstract

Motivated by the Bloch-Beilinson conjectures, Voisin has made a conjecture concerning zerocycles on self-products of Calabi-Yau varieties. This note contains some examples of Calabi-Yau fourfolds verifying Voisin's conjecture.

Keywords Algebraic cycles • Chow groups • motives • Voisin's conjecture
Mathematics Subject Classification (2010) 14C15, 14C25, 14C30.

## 1 Introduction

Let $X$ be a smooth projective variety over $\mathbb{C}$, and let $A^{i}(X):=C H^{i}(X)_{\mathbb{Q}}$ denote the Chow groups of $X$ (i.e. the groups of codimension $i$ algebraic cycles on $X$ with $\mathbb{Q}$-coefficients, modulo rational equivalence). As is well-known, the world of algebraic cycles is densely inhabited by open problems [6], [12], [14], [28]. One of these open problems is the following conjecture formulated by Voisin (which can be seen as a version of Bloch's conjecture for varieties of geometric genus one):

Conjecture 1 (Voisin [27]) Let $X$ be a smooth projective complex variety of dimension $n$ with $h^{j, 0}(X)=0$ for $0<j<n$ and $p_{g}(X)=1$. For any zero-cycles $a, a^{\prime} \in A^{n}(X)$ of degree 0 , we have

$$
a \times a^{\prime}=(-1)^{n} a^{\prime} \times a \text { in } A^{2 n}(X \times X) .
$$

(Here $a \times a^{\prime}$ is short-hand for the cycle class $\left(p_{1}\right)^{*}(a) \cdot\left(p_{2}\right)^{*}\left(a^{\prime}\right) \in A^{2 n}(X \times X)$, where $p_{1}$, $p_{2}$ denote projection on the first, resp. second factor.)

So far, conjecture 1 is wide open for a general $K 3$ surface (on the positive side, cf. [27], [17], [19], [18] for some cases where this conjecture is verified).

The main result of this note gives a series of examples in dimension 4 verifying Voisin's conjecture:
Theorem (=theorem 16) Let $S$ be a K3 surface obtained as (a desingularization of) a double plane branched along the union of a smooth quartic and a smooth quadric. Let $\iota: S \rightarrow S$ be the covering involution. Let $X$ be one of the following:
(i) a smooth Calabi-Yau fourfold obtained as a crepant resolution of the quotient $S^{[2]} / \iota^{[2]}$;
(ii) a smooth Calabi-Yau fourfold obtained as a crepant resolution of the quotient $(S \times S) /(\iota \times \iota)$.

Then any a, $a^{\prime} \in A^{4}(X)$ of degree 0 satisfy the equality

$$
a \times a^{\prime}=a^{\prime} \times a \text { in } A^{8}(X \times X) .
$$

[^0]It should be mentioned that theorem 16 is not empty of content: in both cases (i) and (ii), crepant resolutions of the quotient do indeed exist, thanks to work of Camere-Garbagnati-Mongardi [9] (cf. subsection 2.3 below).

As a consequence of theorem 16, a certain instance of the generalized Hodge conjecture is verified:
Corollary (=corollary 20) Let $X$ be a Calabi-Yau fourfold as in theorem 16 Then the Hodge substructure

$$
\wedge^{2} H^{4}(X) \subset H^{8}(X \times X)
$$

is supported on a divisor.
The argument proving theorem 16 is very simple, and goes as follows: thanks to the notion of multiplicative Chow-Künneth decomposition developed by Shen-Vial [23], we are reduced to proving Voisin's conjecture holds for $K 3$ surfaces $S$ as in theorem 16. This statement for $S$ was already known [17].

Conventions In this note, the word variety will refer to a reduced irreducible scheme of finite type over $\mathbb{C}$.
All Chow groups will be with rational coefficients: For any variety $X$, we will denote by $A_{j}(X)$ the Chow group of $j$-dimensional cycles on $X$ with $\mathbb{Q}$-coefficients. For $X$ smooth of dimension $n$ the notations $A_{j}(X)$ and $A^{n-j}(X)$ will be used interchangeably.

The notations $A_{h o m}^{j}(X)$ and $A_{A J}^{j}(X)$ will be used to indicate the subgroups of homologically, resp. Abel-Jacobi trivial cycles. For a morphism $f: X \rightarrow Y$, we will write $\Gamma_{f} \in A_{*}(X \times Y)$ for the graph of $f$. The contravariant category of Chow motives (i.e., pure motives with respect to rational equivalence as in [22], [21]) will be denoted $\mathcal{M}_{\mathrm{rat}}$.

We will write $H^{j}(X)$ to indicate singular cohomology $H^{j}(X, \mathbb{Q})$.

## 2 Preparatory material

### 2.1 Quotient varieties

Definition 2 A projective quotient variety is a variety $Y=X / G$, where $X$ is a smooth projective variety and $G$ is a finite group of automorphisms of $X$.

Proposition 3 (Fulton [11]) Let $Y$ be a projective quotient variety of dimension n. Let $A^{*}(Y)$ denote the operational Chow cohomology ring. The natural map

$$
A^{i}(Y) \rightarrow A_{n-i}(Y)
$$

is an isomorphism for all $i$.
Proof This is [11, Example 17.4.10].
Remark 4 It follows from proposition 3 that the formalism of correspondences goes through unchanged for projective quotient varieties (this is also noted in [11, Example 16.1.13]).

### 2.2 MCK decomposition

Definition 5 (Murre [20]) Let $X$ be a smooth projective variety of dimension $n$. We say that $X$ has a $C K$ decomposition if there exists a decomposition of the diagonal

$$
\Delta_{X}=\pi_{0}+\pi_{1}+\cdots+\pi_{2 n} \quad \text { in } A^{n}(X \times X),
$$

such that the $\pi_{i}$ are mutually orthogonal idempotents and $\left(\pi_{i}\right)_{*} H^{*}(X)=H^{i}(X)$.
(NB: "CK decomposition" is short-hand for "Chow-Künneth decomposition".)
Remark 6 The existence of a CK decomposition for any smooth projective variety is part of Murre's conjectures [20], [12].

Definition 7 (Shen-Vial [23]) Let $X$ be a smooth projective variety of dimension $n$. Let $\Delta_{X}^{s m} \in A^{2 n}(X \times$ $X \times X)$ be the class of the small diagonal

$$
\Delta_{X}^{s m}:=\{(x, x, x) \mid x \in X\} \subset X \times X \times X
$$

An MCK decomposition is a CK decomposition $\left\{\pi_{i}\right\}$ of $X$ that is multiplicative, i.e. it satisfies

$$
\pi_{k} \circ \Delta_{X}^{s m} \circ\left(\pi_{i} \times \pi_{j}\right)=0 \text { in } A^{2 n}(X \times X \times X) \text { for all } i+j \neq k
$$

(NB: "MCK decomposition" is short-hand for "multiplicative Chow-Künneth decomposition".)
Remark 8 The small diagonal (seen as a correspondence from $X \times X$ to $X$ ) induces the multiplication morphism

$$
\Delta_{X}^{s m}: h(X) \otimes h(X) \rightarrow h(X) \text { in } \mathcal{M}_{\mathrm{rat}}
$$

Suppose $X$ has a CK decomposition

$$
h(X)=\bigoplus_{i=0}^{2 n} h^{i}(X) \text { in } \mathcal{M}_{\mathrm{rat}}
$$

By definition, this decomposition is multiplicative if for any $i, j$ the composition

$$
h^{i}(X) \otimes h^{j}(X) \rightarrow h(X) \otimes h(X) \xrightarrow{\Delta_{X}^{s m}} h(X) \text { in } \mathcal{M}_{\mathrm{rat}}
$$

factors through $h^{i+j}(X)$. It follows that if $X$ has an MCK decomposition, then setting

$$
A_{(j)}^{i}(X):=\left(\pi_{2 i-j}^{X}\right)_{*} A^{i}(X),
$$

one obtains a bigraded ring structure on the Chow ring: that is, the intersection product has the property that

$$
\operatorname{Im}\left(A_{(j)}^{i}(X) \otimes A_{\left(j^{\prime}\right)}^{i^{\prime}}(X) \rightarrow A^{i+i^{\prime}}(X)\right) \subset A_{\left(j+j^{\prime}\right)}^{i+i^{\prime}}(X)
$$

It is expected that for any $X$ with an MCK decomposition, one has

$$
A_{(j)}^{i}(X) \stackrel{? ?}{=} 0 \text { for } j<0, \quad A_{(0)}^{i}(X) \cap A_{h o m}^{i}(X) \stackrel{? ?}{=} 0 ;
$$

this is related to Murre's conjectures B and D [20].
The property of having an MCK decomposition is severely restrictive, and is closely related to Beauville's "(weak) splitting property" [4]. For more ample discussion, and examples of varieties with an MCK decomposition, we refer to [23, Chapter 8], as well as [26], [24], [10].

In this note, we will rely on the following result:
Theorem 9 (Shen-Vial [23|) Let $S$ be a $K 3$ surface. Then $S$ and $S^{2}$ and the Hilbert scheme $S^{[2]}$ have an MCK decomposition. Moreover, the bigraded ring structure on the Chow ring $A_{(*)}^{*}\left(S^{[2]}\right)$ coincides with the Fourier decomposition as defined in [23].

Proof For $S$, this is [23, Example 8.17]. The statement for $S^{2}$ follows because the property of having an MCK decomposition is stable under products [23, Theorem 8.6]. The statement for $S^{[2]}$ is [23, Theorem 13.4] (or alternatively [26]). Finally, the relation with the Fourier decomposition for $A^{*}\left(S^{[2]}\right)$ is [23, Theorem 15.8].

### 2.3 Calabi-Yau quotients

Definition 10 A Calabi-Yau variety is a smooth projective variety $X$ such that the canonical bundle $K_{X}$ is numerically trivial, and $h^{j, 0}(X)=0$ for all $0<j<n$.

Definition 11 (Beauville [2], [3]) A hyperkähler variety is a smooth projective simply-connected variety $X$, such that $H^{2,0}(X)$ is generated by a symplectic form.

Theorem 12 (Camere-Garbagnati-Mongardi [9]) Let $Y$ be a hyperkähler fourfold, and $\iota: Y \rightarrow Y a$ non-symplectic involution. Assume that all irreducible components of the fixed locus of $\iota$ have dimension 2. Then there exists a resolution of singularities

$$
X \rightarrow Y / \iota
$$

such that $X$ is a Calabi-Yau variety.
Proof This is the dimension 4 case of [9, Theorem 3.7].
Corollary 13 (Camere-Garbagnati-Mongardi [9]) Let $S$ be a $K 3$ surface obtained as (a desingularization of) a double plane branched along the union of a smooth quartic and a smooth quadric. Let $Y$ be the Hilbert scheme $Y:=S^{[2]}$. Let $\iota^{[2]}$ be the natural involution of $Y$ induced by the covering involution $\iota$ of $S$. Then there exists a resolution of singularities

$$
X \rightarrow Y / \iota
$$

such that $X$ is a Calabi-Yau variety.
Proof The condition in theorem 12 on the dimension of the fixed locus is verified by what is detailed in [9, Section 5.1].

Remark 14 Let $S$ and $X$ be a $K 3$ surface resp. a Calabi-Yau fourfold as in corollary 13 As explained in [9, Section 5.2], there exists a resolution

$$
X_{2} \rightarrow(S \times S) /(\iota \times \iota),
$$

such that $X_{2}$ is also a Calabi-Yau variety, and there is a rational 2:1 map $X_{2} \rightarrow X$.
Remark 15 In [9] Section 5.1 and Appendix 8], the Hodge numbers of Calabi-Yau resolutions $X$ as in corollary 13 are computed. Likewise, the Hodge numbers of the Calabi-Yau resolutions of the quotient $(S \times S) /(\iota \times \iota)$ are computed in [9, Section 5.2].

## 3 Main result

Theorem 16 Let $S$ be a $K 3$ surface obtained as (a desingularization of) a double plane branched along the union of a smooth quartic and a smooth quadric. Let $\iota: S \rightarrow S$ be the covering involution. Let $X$ be one of the following:
(i) a smooth Calabi-Yau fourfold obtained as a crepant resolution of the quotient $S^{[2]} / \iota^{[2]}$;
(ii) a smooth Calabi-Yau fourfold obtained as a crepant resolution of the quotient $(S \times S) /(\iota \times \iota)$.

Then any $a, a^{\prime} \in A_{\text {hom }}^{4}(X)$ satisfy the equality

$$
a \times a^{\prime}-a^{\prime} \times a=0 \quad \text { in } A^{8}(X \times X) .
$$

Proof It will suffice to treat case (ii). Indeed, let $X_{1}$ be a smooth fourfold as in case (i). As we have seen (remark 14), $X_{1}$ is rationally dominated by a fourfold $X_{2}$ which is as in case (ii). The rational map $\phi: X_{2} \longrightarrow X_{1}$ gives rise to a commutative diagram

$$
\begin{array}{cc}
A_{\text {hom }}^{4}\left(X_{2}\right) \otimes A_{\text {hom }}^{4}\left(X_{2}\right) & \rightarrow A^{8}\left(X_{2} \times X_{2}\right) \\
\uparrow\left(\phi^{*}, \phi^{*}\right) & \uparrow(\phi \times \phi)^{*} \\
A_{\text {hom }}^{4}\left(X_{1}\right) \otimes A_{\text {hom }}^{4}\left(X_{1}\right) & \rightarrow A^{8}\left(X_{1} \times X_{1}\right)
\end{array}
$$

(Here the horizontal arrows are defined as $\left(a, a^{\prime}\right) \mapsto a \times a^{\prime}-a^{\prime} \times a$.) Since the vertical arrows are injective, we are reduced to proving the statement for $X_{2}$.

Let us now treat case (ii), i.e. let us suppose $X=X_{2}$ is obtained as a crepant resolution of

$$
Z:=(S \times S) /(\iota \times \iota)
$$

where $S$ is a double plane as in the theorem.
Lemma 17 The morphism $f: X \rightarrow Z$ induces isomorphisms

$$
\begin{aligned}
f^{*}: \quad A_{0}(Z) & \xlongequal{\cong} A^{4}(X), \\
(f \times f)^{*}: \quad A_{0}(Z \times Z) & \cong
\end{aligned} A^{8}(X \times X),
$$

Proof As $Z$ is a projective quotient variety, proposition 3 applies, i.e. the natural map $A^{4}(Z) \rightarrow A_{0}(Z)$ (from operational Chow cohomology to the Chow group) is an isomorphism. Let $T \subset Z$ denote the singular locus, and $E:=f^{-1}(T) \subset X$ the exceptional divisor. Thanks to [13], there exist exact sequences

$$
0 \rightarrow A^{i}(Z) \rightarrow A^{i}(X) \oplus A^{i}(T) \rightarrow A^{i}(E)
$$

for all $i$. Taking $i=4$, and noting that $A^{4}(T)=A^{4}(E)=0$ for dimension reasons, we obtain an isomorphism

$$
f^{*}: \quad A_{0}(Z)=A^{4}(Z) \xrightarrow{\cong} A^{4}(X) .
$$

The argument for $Z \times Z$ is only notationally different.
The resolution morphism $f: X \rightarrow Z$ induces a commutative diagram

$$
\begin{array}{r}
A_{\text {hom }}^{4}(X) \otimes A_{h o m}^{4}(X) \rightarrow A^{8}(X \times X) \\
\uparrow\left(f^{*}, f^{*}\right) \\
\\
A_{\text {hom }}^{4}(Z) \otimes(f \times f)^{*} \\
A_{h o m}^{4}(Z) \rightarrow A^{8}(Z \times Z)
\end{array}
$$

Since vertical arrows are isomorphisms (lemma 17 ), we are reduced to proving the statement for $Z$, i.e. we need to prove that for all $a, a^{\prime} \in A_{\text {hom }}^{4}(Z)$, one has equality

$$
\begin{equation*}
a \times a^{\prime}-a^{\prime} \times a=0 \quad \text { in } A^{8}(Z \times Z) . \tag{1}
\end{equation*}
$$

Next, we reduce to $S \times S$ using the following lemma:
Lemma 18 Let $q: S \times S \rightarrow Z$ denote the quotient morphism. Then

$$
\operatorname{Im}\left(A_{h o m}^{4}(Z) \xrightarrow{q^{*}} A^{4}(S \times S)\right)=A_{(4)}^{4}(S \times S) .
$$

Proof First, we observe that

$$
\operatorname{Im}\left(A_{h o m}^{4}(Z) \xrightarrow{q^{*}} A^{4}(S \times S)\right) \subset A_{h o m}^{4}(S \times S)=\bigoplus_{j \in\{2,4\}} A_{(j)}^{4}(S \times S)
$$

Next, we observe that

$$
\operatorname{Im}\left(A^{4}(Z) \xrightarrow{q^{*}} A^{4}(S \times S)\right)=A^{4}(S \times S)^{(\iota \times \iota)}
$$

(where $A^{*}()^{(\iota \times \iota)}$ denotes cycles invariant under $(\iota \times \iota)$ ).
The following claim concludes the proof of lemma 18 .
Claim We have

$$
(\iota \times \iota)^{*}= \begin{cases}\text { id }: & A_{(4)}^{4}(S \times S) \rightarrow A^{4}(S \times S) \\ - \text { id }: & A_{(2)}^{4}(S \times S) \rightarrow A^{4}(S \times S)\end{cases}
$$

To prove the claim, we note that

$$
\iota^{*}= \begin{cases}-\mathrm{id}: & A_{(2)}^{2}(S) \rightarrow A^{2}(S)  \tag{2}\\ \mathrm{id}: & A_{(0)}^{2}(S) \rightarrow A^{2}(S)\end{cases}
$$

Indeed, let $p: S \rightarrow V:=S / \iota$ denote the quotient morphism. Then we have

$$
p^{*} p_{*}=\mathrm{id}+\iota^{*}: \quad A^{i}(S) \rightarrow A^{i}(S) \quad \forall i .
$$

On the other hand,

$$
p^{*} p_{*}=0: \quad A_{h o m}^{2}(S) \rightarrow A_{h o m}^{2}(S)
$$

because $V$ is birational to $\mathbb{P}^{2}$ and so $A_{h o m}^{2}(V)=0$. This proves the first line of (2). For the second line of (2), we note that $A_{(0)}^{2}(S)$ is one-dimensional and spanned by the class of the intersection $D \cdot D^{\prime}$, where $D, D^{\prime}$ are any non-zero effective divisors [5]. Letting $B \subset S$ denote the inverse image of the ramification locus, and setting $D=D^{\prime}=B$ establishes the second line of (2).

The equalities (2) suffice to prove the claim, since

$$
A_{(j)}^{4}(S \times S)=\bigoplus_{j_{1}+j_{2}=j} A_{\left(j_{1}\right)}^{2}(S) \otimes A_{\left(j_{2}\right)}^{2}(S)
$$

(because of the bigraded ring structure), and

$$
A^{2}(S)=A_{(0)}^{2}(S) \oplus A_{(2)}^{2}(S)
$$

(because $\pi_{1}^{S}=0$ ). This proves the claim, and hence lemma 18
Lemma 18 implies there is a commutative diagram

$$
\begin{array}{ccc}
A_{(4)}^{4}(S \times S) \otimes A_{(4)}^{4}(S \times S) & \rightarrow & A_{(8)}^{8}\left(S^{4}\right) \\
\uparrow\left(q^{*}, q^{*}\right) & & \uparrow(q \times q)^{*} \\
A_{\text {hom }}^{4}(Z) \otimes A_{\text {hom }}^{4}(Z) & \rightarrow A^{8}(Z \times Z)
\end{array}
$$

We observe that the right vertical arrow is obviously injective (indeed, $\left.(q \times q)_{*}(q \times q)^{*}=4 \mathrm{id}\right)$. Hence, to prove equality (1), it suffices to prove the following statement: for any $a, a^{\prime} \in A_{(4)}^{4}(S \times S)$, there is equality

$$
\begin{equation*}
a \times a^{\prime}-a^{\prime} \times a=0 \quad \text { in } A^{8}\left(S^{4}\right) \tag{3}
\end{equation*}
$$

Since

$$
A_{(4)}^{4}(S \times S)=A_{(2)}^{2}(S) \otimes A_{(2)}^{2}(S)=A_{\text {hom }}^{2}(S) \otimes A_{\text {hom }}^{2}(S),
$$

we can further reduce (3) to a statement for $S$. This statement for $S$ is known to hold:
Proposition 19 Let $S$ be a $K 3$ surface obtained as (a desingularization of) a double plane branched along the union of a smooth quartic and a smooth quadric. For any $a, a^{\prime} \in A_{\text {hom }}^{2}(S)$, one has

$$
a \times a^{\prime}-a^{\prime} \times a=0 \quad \text { in } A^{4}(S \times S) .
$$

Proof This is [17, Proposition 14].
This concludes the proof of theorem 16
As a corollary, a particular case of the generalized Hodge conjecture is verified:
Corollary 20 Let X be a Calabi-Yau fourfold as in theorem 16. Then the Hodge substructure

$$
\wedge^{2} H^{4}(X) \subset H^{8}(X \times X)
$$

is supported on a divisor.

Proof As noted by Voisin [27], this follows from the truth of conjecture 1 The argument is as follows. First, we note that $X$ satisfies the standard conjecture of Lefschetz type $B(X)$ (because $S \times S$ does, and the two-dimensional centers which are blown-up in the resolution process do). This implies the Künneth components $\pi_{i}^{X}$ are algebraic [15], [16].

Because $h^{2,0}(X)=0$, the Künneth components $\pi_{2}^{X}$ and $\pi_{6}^{X}$ may be represented by cycles supported on $D \times D$ where $D \subset X$ is a divisor. Also, since $H^{3}(X)$ injects into $H^{3}(E)$ (where $E \subset X$ denotes the exceptional divisor for the resolution morphism $X \rightarrow Z$ where $Z$ is a projective quotient variety), and $H^{3}(E)=N^{1} H^{3}(E)$ (because quotient singularities are rational), we find that $H^{3}(X)=N^{1} H^{3}(X)$ (here $N^{*}$ denotes the coniveau filtration [7]). This implies that $\pi_{3}^{X}$ is supported on $V \times D$ and $\pi_{5}^{X}$ is supported on $D \times V$, where $D \subset X$ is a divisor and $V \subset X$ is of dimension 2 .

Define $\pi_{4}^{X}$ as

$$
\pi_{4}^{X}:=\Delta_{X}-\pi_{0}^{X}-\pi_{2}^{X}-\pi_{3}^{X}-\pi_{5}^{X}-\pi_{6}^{X}-\pi_{8}^{X} \quad \in A^{4}(X \times X)
$$

where $\pi_{0}^{X}, \pi_{8}^{X}$ are canonically defined (as in [22]), and $\pi_{2}^{X}, \pi_{3}^{X}, \pi_{5}^{X}, \pi_{6}^{X}$ are as above. (Note that $\pi_{1}^{X}$ and $\pi_{7}^{X}$ are 0 , because $X$ is Calabi-Yau.) For dimension reasons, none of the $\pi_{j}^{X}, j \neq 4$ act on $A_{\text {hom }}^{4}(X)$ and so

$$
\begin{equation*}
A_{\text {hom }}^{4}(X)=\left(\pi_{4}^{X}\right)_{*} A^{4}(X) \tag{4}
\end{equation*}
$$

Let us now define a correspondence

$$
\Gamma:=\frac{1}{2}\left(\Delta_{X \times X}-\Gamma_{\tau}\right) \circ\left(\pi_{4}^{X} \times \pi_{4}^{X}\right) \quad \in A^{8}\left(X^{4}\right)
$$

where $\tau: X \times X \rightarrow X \times X$ denotes the involution $(x, y) \mapsto(y, x)$. In view of equality (4), theorem 16 can be translated as saying that

$$
\begin{equation*}
\Gamma_{*} A^{8}(X \times X)=0 \tag{5}
\end{equation*}
$$

An argument à la Bloch-Srinivas [8] implies that a correspondence $\Gamma$ with the property (5) has a decomposition

$$
\Gamma=\Gamma_{1}+\Gamma_{2} \quad \in A^{8}\left(X^{4}\right)
$$

where $\Gamma_{1}$ and $\Gamma_{2}$ are supported on $D \times X \times X$ resp. on $X \times X \times D$, for some divisor $D \subset X \times X$.
By construction, $\Gamma$ acts on cohomology as a projector on $\wedge^{2} H^{4}(X) \subset H^{8}(X \times X)$. To prove the corollary, it only remains to show that

$$
\begin{equation*}
\left(\Gamma_{j}\right)_{*} H^{8}(X \times X) \subset N^{1} H^{8}(X \times X), \quad j=1,2 . \tag{6}
\end{equation*}
$$

For $\Gamma_{2}$ this is obvious. For $\Gamma_{1}$, this is true because the action of $\Gamma_{1}$ on $H^{8}(X \times X)$ factors over $H^{8}(\widetilde{D})$ (where $\widetilde{D}$ denotes a resolution of singularities), and $H^{8}(\widetilde{D})=N^{1} H^{8}(\widetilde{D})$ (hard Lefschetz for the sevenfold $\widetilde{D}$ ). This proves the inclusion (6) for $j=1$, since it is known that the coniveau filtration is preserved by correspondences ([25, Proposition 1.2] or [1]).
