COMPLETION OF PERIOD MAPPINGS AND AMPLENESNESS OF THE
HODGE BUNDLE

MARK GREEN, PHILLIP GRIFFITHS, RADU LAZA, AND COLLEEN ROBLES

ABSTRACT. Let $M \subseteq \Gamma \setminus D$ be the image of a period map. We construct a canonical completion $\overline{M}$ of $M$ as a compact complex analytic variety. We then prove that the augmented Hodge line bundle $\hat{\Lambda}$ extends to an ample line bundle on $\overline{M}$. In particular, $\overline{M}$ is a projective algebraic variety that compactifies $M$. This is a Hodge theoretic analogue of the Satake-Baily-Borel compactification.

1. Introduction

1.1. Overview. Let $\mathcal{M}$ be the moduli space for smooth varieties $X$ of general type and with given numerical characters. In a sweeping generalization of the Deligne–Mumford compactification $\overline{M}_g$ of the moduli space of curves, Kollár, Shepherd-Barron and Alexeev (KSBA), with contributions of many others, have constructed a canonical projective completion $\overline{M}$ with geometric meaning (see [Kol13] and the references therein). Similarly to the case of stable curves, the singular varieties $X_0$ corresponding to points of the boundary $\partial \mathcal{M} = \overline{M}\setminus \mathcal{M}$ are defined by two natural requirements: $X_0$ has only semi-log-canonical singularities (the higher dimensional analogue of nodal singularities) and $K_{X_0}$ is ample. However, even in the case of surfaces of general type with small invariants, very little is known towards a

classification of the boundary varieties $X_0$, and about the global structure of $\partial M$. A natural invariant of $M$ is the period mapping $\Phi : M \rightarrow \Gamma \backslash D$ whose image $\Phi(M)$ is a quasi-projective algebraic subvariety of the complex analytic variety $\Gamma \backslash D$. Since $\Gamma \backslash D$ has a rich structure given by representation theory and arithmetic, it is natural to try to use the period map as a tool for understanding the structure of the KSBA compactification $\overline{M}$ for some moduli spaces.

The period map has been very successfully used for the study of moduli spaces of abelian varieties and $K3$ surfaces. Beyond these classical cases, to our knowledge, very little is known. (In current work in progress, we are exploring the relationship between the KSBA compactification and periods for the so called H-surfaces, surfaces of general type with $p_g = 2$, $q = 0$, $K^2 = 2$; this is one of the simplest non-classical cases.) As a first step towards using the period map to study compactified moduli, it is natural to seek a canonical completion $\Phi(M)_e$ of the image $M := \Phi(M)$ of the period map and an extension $\Phi_e : \overline{M} \rightarrow \Phi(M)_e$ of the period mapping. We note that except the classical cases (abelian varieties, and $K3$ type), $\Gamma \backslash D$ is never an algebraic variety ([GRT14]) so that both analytic and algebraic methods will be required for the study of $\Phi$ and $\Phi_e$.

Concretely, in this paper, we shall be concerned with the study of a period mapping

$$\Phi : B \rightarrow \Gamma \backslash D$$

with $B$ a smooth, quasi-projective variety having a smooth projective completion $\overline{B}$ where $Z = \overline{B} \backslash B$ is a reduced normal crossing divisor. We assume that the local monodromies $T_i$ around the irreducible branches $Z_i$ of $Z$ are unipotent. For example, this situation might arise starting with a period map $\Phi : M \rightarrow \Gamma \backslash D$ of geometric origin as above and then passing to a finite covering $B$ of a desingularization of $M$ and completing $B$ to $\overline{B}$ as described. Under these assumptions we will show that the image $M = \Phi(B)$ is a quasi-projective algebraic subvariety $M \subset \Gamma \backslash D$ of the moduli space of $\Gamma$-equivalence classes of polarized Hodge structures parametrized by the period domain $D$.[1] The main result of this paper is the construction of a (canonical) projective compactification $\overline{M}(= \Phi(M)_e)$ of $M$ (see Theorems 1.2.2 and 1.3.8 below), which to a large extent generalizes the Satake–Baily–Borel compactification in the classical case (N.B. if $M = \Gamma \backslash D$, our completion $\overline{M}$ will coincide with the SBB compactification). We will refer to $\overline{M}$ as the Hodge theoretic Satake–Baily–Borel (HT-SBB) completion of the image $M$ of the period map (1.1.1).[3]

---

[1] For some earlier results in this direction see Sommese [Som78].

[2] We will repeatedly refer to “the classical case”. This is the case when the period domain $D$ is Hermitian symmetric (or more generally, $D$ is an unconstrained Mumford-Tate domain), and $\Gamma$ is an arithmetic group. Geometrically, this corresponds to period maps for abelian varieties or $K3$ type objects (e.g. $K3$’s, hyper-Kähler manifolds, cubic 4-folds). Occasionally, when we say classical case, we implicitly assume also $M = \Gamma \backslash D$.

[3] While the construction of the Satake–Baily–Borel (SBB) compactification of a locally Hermitian symmetric $\Gamma \backslash D$ is group theoretic [BB66], it admits a robust Hodge theoretic interpretation (e.g. see [Laz16] §2 and the references therein). When $D$ is not Hermitian symmetric these two perspectives (the Hodge
The HT-SBB completion provides a canonical, projective Hodge-theoretic object that may be used to study moduli of varieties of general type. Some early examples suggest that it can give a very effective tool for this study. For instance, this HT-SBB completion can be a very effective way to organize the boundary structure of some surfaces of general type (an informal overview of some aspects of this is given in [Gri16]).

1.2. Completion of $M$ as an analytic variety. Given a period mapping (1.1.1) and completion $B \subset \overline{B}$ as described above, we set $Z_I = \bigcap_{i \in I} Z_i$ where $Z_i$ are the irreducible components of the divisor at infinity $Z = \overline{B}\setminus B$. We denote by $Z_I^* \subset Z_I$ the open strata obtained by removing from $Z_I$ the lower dimensional sub-strata. It is a consequence of [CKS86] that there is over each open stratum $Z_I^*$ a polarizable variation of mixed Hodge structure (VMHS) with weight filtration $W(N_I)$. (In the literature this VMHS is frequently referred to as the limiting mixed Hodge structures (LMHS) associated to the VHS over $B$. For the general theory of variations of mixed Hodge structures we refer to [SZ85].) Passing to the graded parts (which will be pure Hodge structures) of this variation of mixed Hodge structure gives period mappings

$$\Phi_I : Z_I^* \to \Gamma_I \setminus D_I.$$ (see §2.1.2 for details). We set

$$M_I = \Phi_I(Z_I^*)^\circ.$$

Here the exponent $^\circ$ refers to a covering space of the image $\Phi_I(Z_I^*)$ obtained by a Stein factorization of the map (1.2.1) (In particular, note $M_\emptyset$ is a finite cover of $M$). Basically, $M_I$ is obtained by taking the limiting mixed Hodge structures along the open strata $Z_I^*$, throwing out the extension data in the mixed Hodge structures, and passing to a finite covering of what is left.

With these preliminaries, we can state our first main result, which gives a completion of $M$ as a complex analytic variety.

**Theorem 1.2.2.** There exists a canonical extension $\overline{M}$ of $M$, which is a compact complex analytic variety and where there is an extension

$$\Phi_e : \overline{B} \to \overline{M}$$

of the period mapping (1.1.1). As a set, $\overline{M}$ is the quotient by a finite equivalence relation of

$$\overline{M} = M_\emptyset \amalg \left( \bigsqcup_I M_I \right).$$

The theorem is proved in Section 3.

---

Theorem 1.2.2 is a generalization of SBB, from the Hodge theoretic perspective, that compactifies the image of a period map. A group theoretic generalization of SBB that yields a “horizontal completion” $\Gamma \setminus D_h$ of the full $\Gamma \setminus D$ is forthcoming [GGLR17]. The horizontal completion is a sort of meta/universal object that captures structure universal to all $\overline{M}$ arising from period maps $\Phi : B \to \Gamma \setminus D$. 
Remark 1.2.3. The simplest instance of this result is the classical case when $D$ is Hermitian symmetric. In that situation $\Gamma\backslash D$ is a quasi-projective variety, with a projective compactification $(\Gamma\backslash D)^*$ [Sat60, BB66], and the Borel Extension Theorem [Bor72] yields an extension $\Phi_e : \overline{B} \to (\Gamma\backslash D)^*$ of the period map (1.1.1) to an algebraic map. In this situation, we can take $\overline{M}$ to be the closure of $M$. In general, such an argument would not work: the quotient $\Gamma\backslash D$ is not algebraic, and no meaningful compactification is known. Kato-Nakayama-Usui [KU09] have constructed an analogue of the toroidal compactification in the horizontal directions (though the existence of a compatible fan is still open in general). Our completion $\overline{M}$ could be obtained by taking closure in this toroidal type compactification, and “forgetting” the extension data.

In first approximation, $\overline{M}$ is obtained from $M$ by attaching the associated graded PHS’s to the limiting mixed Hodge structures arising from the period mapping (1.1.1) and describing how these fit together. The precise statement differs in that we pass to the $\Gamma$-equivalence classes of the set-theoretic mapping described above, and then we pass to a finite covering arising from a Stein factorization in the construction. See §3.1 for a detailed outline of the proof. Briefly, we first assume $\Phi$ is a local VHS over a neighborhood at infinity. Here we make use of the fact that $\Phi$ may be approximated by a nilpotent orbit. The most subtle part of the operation is showing that the $M_I$ may be glued together to give a complex analytic space. The difficulty here essentially stems from the singularities that arise as $b \to b_0 \in \overline{B}\backslash B$, and so is captured by the approximating nilpotent orbit. The relative weight filtration property plays a key role in establishing necessary “compatibility statements.” We think of this local construction as giving us “local charts” for $\overline{M}$. (They are not local coordinates in the traditional sense, but operationally serve a similar function.)

The passage to the global case requires showing that certain identifications are finite: we will see that this is a consequence of the Cattani–Deligne–Kaplan result on the algebraicity of Hodge loci.

1.3. Ampleness of the extended augmented Hodge bundle. We now turn our attention to proving that $\overline{M}$ carries a natural ample line bundle, and thus it is a projective variety. This line bundle is an extended augmented Hodge bundle, which is essentially obtained by gluing the augmented Hodge bundles on the strata $M_I$.

To start, we recall that the period domain $D$ is a homogeneous domain $D = G_\mathbb{R}/H$ that parametrizes effective, weight $n$, $Q$–polarized Hodge structure (PHS) $F^\bullet = \{F^n \subset \cdots \subset F^0\}$ (as usual viewed as filtrations) with fixed Hodge numbers.

Definition 1.3.1. The Hodge vector bundle $F \to D$ is the homogeneous vector bundle whose fibre at $F^\bullet \in D$ is $F^n$. The Hodge line bundle is

$$\Lambda = \det F.$$  

We shall frequently refer to $\Lambda$ as simply the Hodge bundle, but we will always use “vector” when discussing the Hodge vector bundle $F^n$. 
Remark 1.3.2. Other vector bundles of interest include those with fibers $\text{Gr}^p F := F^p / F^{p+1}$, but for application to moduli of varieties of general type the Hodge vector and line bundles are especially important due to the identification $F^n = H^{n,0}(X) = H^0(K_X)$, where $X$ is a smooth projective variety of dimension $n$ and $H^n(X) = \oplus_{p+q=n} H^{p,q}(X)$ is the Hodge decomposition of its $n$th cohomology group.

Definition 1.3.3. The augmented Hodge (line) bundle is
\[ \hat{\Lambda} := \bigotimes_{p=0}^{[(n-1)/2]} \det \left( F^{n-p} / F^{n-p+1} \right)^{n_p}, \quad n_p := \left( (n - p + 1)/2 \right). \]

The Hodge bundle and augmented Hodge bundle agree when $n = 1, 2$. (Weight $n = 2$ is the case in which we are primarily interested.) Very roughly, the difference between the two is that positivity of the augmented Hodge bundle corresponds to injectivity of the differential of the period map, while positivity of the Hodge bundle corresponds to injectivity of only a component of the period map; this is made precise in (1.3.4). Let
\[ \Phi_* : TB \to \bigoplus_{p=0}^{[(n-1)/2]} \text{Hom} \left( \text{Gr}^{n-p} F, \text{Gr}^{n-p-1} F \right) \]

denote the differential of the period map, and let
\[ \Phi_{*,n} : TB \to \text{Hom}(F^n, F^{n-1}/F^n) \]

denote the component taking value in the first summand. Notice that $\Phi_* = \Phi_{*,n}$ when $n = 1, 2$. The Hodge metrics on the $F^p$ induce metrics on $\Lambda$ and $\hat{\Lambda}$; let $\Omega$ and $\hat{\Omega}$ denote the corresponding curvature forms. For $\xi \in TB$ we have
\begin{align*}
\Omega(\xi) &= \|\Phi_{*,n}(\xi)\|^2 \\
\hat{\Omega}(\xi) &= \|\Phi_*(\xi)\|^2.
\end{align*}

The form $\hat{\Omega}$ descends to the image $M$, and the discussion above implies $\hat{\Omega}$ is positive on the smooth points of the image $M$ of the period mapping, while $\Omega$ is only non-negative there.

Remark 1.3.5. It is standard that the data of a period mapping (1.1.1) is equivalent to that of a (polarized) variation of Hodge structures (VHS) $(V, F^*, Q, \nabla)$ over $B$. Here $V$ is a local system with Gauss-Manin connection $\nabla : O_B(V) \to \Omega^1_B(V)$ where $O_B(V) = V \otimes O_B$, the $F^p \subset O_B(V)$ are holomorphic sub-bundles, $Q : V \otimes V \to \mathbb{Q}$ is a horizontal bilinear form and where this data induces at each point of $B$ a polarized Hodge structure. The infinitesimal period relation (IPR) is $\nabla F^p \subseteq \Omega^1_B \otimes F^{p-1}$. In this context the Hodge vector bundle $F^n$ is the pull-back of $F = F^n$ under the period map. We shall use interchangeably the data of period mappings and of variations of Hodge structure.

Under the assumption that the local monodromies around the branches $Z_i$ of $Z$ are unipotent with logarithms $N_i$, it is well known ([CKSS86] and [PS08]) that there are canonical extensions of the Hodge filtration bundles $F^p$ to vector bundles $F^p_e \to \overline{B}$ where the
infinitesimal period relation becomes $\nabla \mathcal{F}_e^p \subseteq \Omega^1_B(\log Z) \otimes \mathcal{J}_e^{p-1}$, and where $\text{Res}_Z \nabla = N_i$ (up to a factor of $2\pi \sqrt{-1}$).

**Definition 1.3.6.** We denote by $\mathcal{F}_e$ or $F_e$ the canonical extension of the Hodge vector bundle, by $\Lambda_e = \det F_e$ the canonically extended Hodge (line) bundle, and by $\hat{\Lambda}_e$ the canonically extended augmented Hodge (line) bundle.

The precise relationship between the canonical extensions of the line bundles over $B$, and the analogous line bundles over the open strata of $Z = \overline{B} \setminus B$ is given by

$$\Lambda_e |_{Z_I} = \Lambda_I \quad \text{and} \quad \hat{\Lambda}_e |_{Z_I} = \hat{\Lambda}_I.$$  

Here the left-hand sides of these two expressions are the restrictions to $Z_I^*$; and the right-hand sides are the Hodge line bundle and augmented Hodge line bundle, respectively, associated to the period mapping $\Phi_I$.

The second main result in this paper is the ampleness of the extended Hodge bundle.

**Theorem 1.3.8.** The augmented Hodge bundle extends to a holomorphic Hodge line bundle on $\hat{M}$, and there $\hat{\Lambda}_e \to \hat{M}$ is ample.

**Corollary 1.3.9.** The completion $\hat{M} = \text{Proj} R(\hat{M}, \hat{\Lambda}_e)$. (As usual, $R(\hat{M}, \hat{\Lambda}_e)$ denotes the ring of sections.)

Theorem 1.3.8 is proved in Section 6.

In the classical case $\Lambda_e = \hat{\Lambda}_e$ and this result is a consequence of the properties of the Satake-Baily-Borel construction. It is a global one in that sections of $\Lambda_e \otimes m$ that give a projective embedding of $\Gamma \setminus D$ are constructed using modular forms. As explained above, such an approach is not possible in the non-classical case. Our proof of Theorem 1.3.8 is in spirit analogous to the one used by Kodaira to show that over a compact, complex manifold a line bundle with positive Chern class in the differential-geometric sense is ample. The proof of the result here depends on some rather subtle properties of the Chern form $\hat{\Omega}$ of the augmented Hodge bundle. From (1.3.4) we see that the augmented Hodge bundle has positivity properties. It is due to [CKS86] with an important amplification in [Kol87] that $\hat{\Omega}$ defines a closed $(1, 1)$ current $\hat{\Omega}_e$ on $\overline{B}$. For the proof of Theorem 1.3.8 we need to significantly refine this in several ways.

First, since currents are differential forms with distribution coefficients, the singular support $\text{sing } \hat{\Omega}_e$ of $\hat{\Omega}_e$ is defined, and assuming (as we may) that all monodromy logarithms $N_i \neq 0$ we have

(a) **The singular support is** $\text{sing } \hat{\Omega}_e = Z$. (In general, $\text{sing } \hat{\Omega}_e \subseteq Z$.)

Next, it is well known that distributions and currents cannot in general be restricted to submanifolds. To get around this one needs a more subtle notion than just the singular support. Associated to a current $\Psi$ on a manifold $Y$ is its wave front set $\text{WF}(\Psi) \subseteq T^*Y$. If $W \subset Y$ is a submanifold whose tangent spaces are transverse to the wave front set in the
sense that $TW \subset WF(\Psi)^\perp$, then the restriction $\Psi|_W$ is a well-defined current on $W$. This suggests that one should think of a refined notion of the singularities of $\hat{\Omega}_e$ as being in $T^*\overline{B}$; in particular, one would like to assert that

(b) There exists a well-defined way of defining a restriction $\hat{\Omega}_e|_{Z^*_I}$ as a smooth $(1,1)$ form on the open strata $Z^*_I$.

That this is possible will be part of the content of Theorem 1.3.10 stated below. Morally, we may think of this result as having $WF(\hat{\Omega}_e) \subseteq \cup_I N^*_{Z^*_I/\overline{B}}$, at least so far as the restriction property (b) is concerned. Finally, given (b), the last property that we would like is

(c) $\hat{\Omega}_e|_{Z^*_I} = \hat{\Omega}_I$ is the Chern form of the Hodge bundle $\hat{\Lambda}_I \to Z^*_I$.

With this understanding we may summarize the above by the following

**Theorem 1.3.10.** The Chern form $\hat{\Omega}$ of the Hodge bundle $\hat{\Lambda} \to B$ extends to a current $\hat{\Omega}_e$ on the completion $\overline{B}$ of $B$. There it has singularities as described above. In particular, (b) and (c) hold, so that in a precise sense $\hat{\Omega}_e$ represents the Chern class of the augmented Hodge bundle $\hat{\Lambda}_e \to \overline{B}$.

**Remark 1.3.11.** Regarding the positivity of the extended Chern form $\hat{\Omega}_e$, an interpretation of the analysis behind the properties (a) and the proof of (b) above may be informally expressed as saying that the more singular the extended period mapping is, the more positive $\hat{\Omega}_e$ is. This heuristic will be further explained and used in work-in-progress where we discuss curvature properties of the extended Hodge vector bundle.

**Remark 1.3.12.** It is well known that distributions cannot in general be multiplied, and similarly for the wedge product of currents. Although not required for our purposes, the methods used to prove Theorem 1.3.10 may be used to show: The currents defined by the Chern forms of the Hodge bundle may be multiplied. More precisely, the Chern forms are given by differential forms whose coefficients are locally $L^1$ functions on $B$. Then the usual formal expressions for the wedge product of forms are used with the result being again a differential form with locally $L^1$ functions as coefficients. The resulting current is then closed and its cohomology class is given by cup product of the corresponding Chern classes.

**Remark 1.3.13.** As will be discussed in §1.4 and motivated by the Iitaka conjecture, classically interest has been focused primarily on the positivity properties of the Hodge vector and line bundles (cf. [Kol87, Vie83b] and the references therein). However for the general study of moduli it is the augmented Hodge bundle that is relevant. In this regard and interesting question is: Does either the Hodge bundle or the augmented Hodge bundle live on the KSBA completion $\overline{M}$? As will be discussed elsewhere, and using the fact that slc singularities are du Bois [KK10], one may show that the Hodge bundle lives over $\overline{M}$. The argument for this does not work for the augmented Hodge bundle when $n \geq 3$. Thus it may be that the HT-SBB completion of the image of a KSBA moduli space under the period map is especially relevant in the case of surfaces. (Recall that the Hodge and augmented Hodge line bundles agree in the surface case ($n = 2$).)
We will give two arguments for Theorem 1.3.10. The first, in Section 4, will be geometric, applies to the case that of algebraic surfaces \((n = 2)\) and essentially deals with the case of 1-parameter degenerations. An additional aspect of the argument is that it displays the estimates on the Hodge norms and the resulting connection and curvature forms giving descriptions that are more precise than the existing ones in the literature. We will show that in the geometric case the Hodge theoretically defined polarizations on the limiting mixed Hodge structure coincide, up to constants, with standard ones derived from geometry (Proposition 4.3.5).

The second proof given in Section 5 establishes the result in full generality and exhibits in detail how the very special and subtle general properties of several variable degenerations of polarized Hodge structures come into play: the argument is based on an extension of the analysis underlying the Cattani–Kaplan–Schmid estimates of the Hodge metric [CKS86, §5].

Returning to the proof of Theorem 1.3.8, using the properties of the Chern form, in Section 6, we will prove successively that the extended augmented Hodge bundle \( \hat{\Lambda}_e \to \overline{M} \) is (a) strictly nef; (b) big; and then (c) free. Here “strictly nef” means that the restriction of \( \hat{\Lambda}_e \) to any curve \( C \subset \overline{B} \) is positive (i.e. \( \hat{\Lambda}_e \cdot C > 0 \)), unless \( C \) lies in a fibre of the map \( \overline{B} \to \overline{M} \) in Theorem 1.2.2. These three properties will combine to give that \( \hat{\Lambda}_e \to \overline{M} \) is ample. Of the three the most difficult is the third. In fact, we shall show that \( \hat{\Lambda}_e \to \overline{B} \) is free, and since \( \hat{\Lambda}_e \) is trivial on the connected fibres of \( \overline{B} \to \overline{M} \) this will give that \( \hat{\Lambda}_e \) is free on \( \overline{M} \) as well.

1.4. Historical comments. We conclude this introduction with a brief historical discussion on the positivity of the curvature of the Hodge bundles up through the period (roughly the late 1980s) when the two basic properties — the sign and the nature of the singularities — were developed in the form most relevant to this paper. Since that period the positivity and singularity structure of the Hodge and related bundles has been and continues to be a very active and interesting area of research and there are excellent survey articles on this topic (cf. [Pau16] and the references cited there). As discussed above, for a variation of Hodge structure the Hodge vector bundle is almost never positive and the understanding of just how positive it actually is under geometrical assumptions on the differential of the period mapping seems to be still incomplete.

We now turn to the evolution of our understanding of the positivity of the Hodge bundles up to the period when the papers [Vie83a, Vie83b, Kol87] appeared; these works are the ones most relevant to the current work. Early computations of the curvature of homogeneous vector bundles over flag domains appeared in the 1960s and showed that their behavior in the Hermitian symmetric and non-Hermitian symmetric cases were quite

---

4For us most relevant means that the curvature of the extended Hodge line bundle exactly detects the variation of the associated graded to the limiting mixed Hodge structures along and in the normal directions to the strata of the completed period mapping. It is this geometric property that underlies Theorem 1.3.8 above.
different (cf. [GS69]). The computations of the curvature for the Hodge bundles and tangent bundles over period domains given in [Gri70a, GS69, GS75] then made the point that when restricted to integral manifolds of the infinitesimal period relation the curvatures had positivity properties analogous to those in the classical Hermitian symmetric domain setting. In particular the Hodge vector bundle was semi-positive and the Hodge line bundle had positive curvature if the differential of the period mapping had suitable injectivity properties. The paper [Fuj78] was an important development here.

The next stage was understanding the behavior of the Hodge metrics and curvature forms when a variation of Hodge structure degenerates along a normal crossing divisor. Here the works [Sch73, CKS86, Kol87] played a major role; it is worth noting that both [CKS86, Kol87] were in part motivated by algebro-geometric questions related to the Iitaka conjecture and where the singularities of the Chern form of the Hodge line bundle entered in a crucial way (cf. [Kaw81, Kaw83, Kaw85, Uen75, Uen78, Vie83a, Vie83b] and the references cited in those works).

Remark 1.4.1. As a historical note, the indication that the curvature forms had Poincaré metric singularities may have originally come from the regularity of the Gauss-Manin connection (cf. [Del70]). Briefly, the difference between periods having logarithmic singularities and having poles (essentially the difference between $\partial\overline{\partial} \log(-\log |t|)$ and $\partial\overline{\partial} \log |t|$), suggests the mild singularity behavior of the curvatures of these bundles.

Our main result (Theorem 1.3.8) may be viewed as an extension of the earlier positivity-type results, a main point being that $\text{Proj}(\Lambda_e)$ exists and may be exactly described as the general analogue of the Satake-Baily-Borel compactification in the classical cases. From an exterior differential system perspective, the maximal integral varieties $\hat{\Omega}_e = 0$ of the extended Chern form define a foliation of $\overline{\mathcal{M}}$ by complex subvarieties whose quotient by contracting the connected leaves of the foliation exactly captures identifying the limiting mixed Hodge structures that have the same associated graded. The main issue here is to make sense out of the exterior equation $\hat{\Omega}_e = 0$ when $\hat{\Omega}_e$ has singularities.

Finally we note that the curvatures of the Hodge bundles and their singularities is currently an extremely active and interesting topic; we refer to Păun [Pau16] for a recent survey paper with references to some of the current work in this area.

In the Appendix B we discuss properties of the canonically extended Hodge vector bundle $F_e$. As noted in the historical comments the positivity properties of $F_e$ have classically played an important role in the applications of Hodge theory to interesting issues in algebraic geometry. We discuss and provide a conjectural answer to the question: Just how positive is $F_e$ and the bundles natural constructed from it? We also discuss and illustrate by example the question: What information does $F_e$ have beyond that in the Hodge line bundle $\det F_e$?

Acknowledgements. We are indebted to Joseph Ostroy for telling us about Farkas’ Theorem, and to Wushi Goldring for bringing [Bru16a] to our attention.
2. Background

2.1. Asymptotics of the period map. Let $Z_i$ denote the irreducible components of the normal crossing divisor

$$Z := B \setminus B = Z_1 \cup \cdots \cup Z_\nu.$$  

Given $I \subset \{1, \ldots, \nu\}$, let $I^c$ denote the complement. The closed strata of $Z$ are the

$$Z_I := \bigcap_{i \in I} Z_i,$$
and the open strata of $Z$ are the

$$Z_I^* := Z_I - \bigcup_{j \in I^c} Z_j.$$  

We briefly review the behavior of the period map $\Phi$ in a (punctured) neighborhood of a point $b_0 \in Z$ “at infinity.” References for the definitions and properties that follow include [CKS86, Sch73].

2.1.1. Nilpotent Orbits. Recollect that $D$ parameterizes weight $n$, $Q$–polarized Hodge structures on a rational vector space $V$. We assume without loss of generality that the monodromy operator $T_i \in \text{Aut}(V, Q)$ about $Z_i^*$ is unipotent, and let $N_i := \log(T_i) \in \text{End}(V, Q)$ denote the nilpotent logarithm. Then $N_I = \sum_{i \in I} N_i$ is the nilpotent monodromy operator about $Z_I^*$.

Let

$$\Delta := \{ \zeta \in \mathbb{C} : |\zeta| < 1 \}$$

denote the unit disc, and

$$\Delta^* := \{ \zeta \in \mathbb{C} : 0 < |\zeta| < 1 \}$$

the punctured unit disc. Fix a point $b_0 \in Z_I^*$. Let $\overline{U} \simeq \Delta^r$ be a neighborhood of $b_0$ in $\overline{B}$ so that

$$U := \overline{U} \cap B \simeq (\Delta^*)^k \times \Delta^\ell;$$

here $r = k + \ell$ and $k = |I|$. Let $\mathcal{H} \subset \mathbb{C}$ denote the upper-half plane, and let

$$\tilde{\Phi}_U : \mathcal{H}^k \times \Delta^\ell \to D$$

be a lift of $\Phi|_U$. Fix coordinates $(z, w) \in \mathcal{H}^k \times \Delta^\ell$. Then $(z, w) \mapsto (\exp(2\pi \sqrt{-1} z), w)$ defines the covering map $\mathcal{H}^k \times \Delta^\ell \to (\Delta^*)^k \times \Delta^\ell$. Here we are writing $\exp(2\pi \sqrt{-1} z)$ as short-hand for the $\Delta^*$–valued $(\exp(2\pi \sqrt{-1} z_1), \ldots, \exp(2\pi \sqrt{-1} z_k))$.

Let $\tilde{D} \supset D$ denote the compact dual of the period domain. Schmid [Sch73] showed that there exists a holomorphic map

$$F : \Delta^r = \Delta^k \times \Delta^\ell \to \tilde{D}$$

so that the lifted period map factors as

$$\tilde{\Phi}_U(z, w) = \exp \left( \sum_{i \in I} z_i N_i \right) \cdot F(\exp(2\pi \sqrt{-1} z), w).$$  

(2.1.1)
Let
\[ \ell(t_j) := \frac{\log t_j}{2\pi \sqrt{-1}}. \]
Observe that
\[ (2.1.2a) \quad \Phi_U(t, z) := \exp \left( \sum_{i \in I} \ell(t_i)N_i \right) \cdot F(t, w) \]
defines a local variation of Hodge structure
\[ (2.1.2b) \quad \Phi_U : U = (\Delta^*)^k \times \Delta^\ell \to \Gamma_U \setminus D, \]
where \( \Gamma_U \subset \Gamma \) is the local monodromy group generated by the unipotent monodromy operators \( \{ T_i \}_{i \in I} \). Notice that \( (2.1.2) \) recovers \( \Phi|_U \) after quotienting \( \Gamma_U \setminus D \to \Gamma \setminus D \) by the full monodromy group \( \Gamma \).

The (lifted) period map \( \tilde{\Phi}_U \) is approximated by the nilpotent orbit
\[ (2.1.3) \quad \tilde{\vartheta}_U(z, w) := \exp \left( \sum_{i \in I} z_i N_i \right) \cdot F(0, w) \]
as \( \text{Im } z_j \to 0 \), with \( \text{Re } z_j \) bounded. The nilpotent orbit is horizontal, and \( N_j F^p(0, w) \subset F^{p-1}(0, w) \). Setting
\[ \vartheta_U(t, w) := \exp \left( \sum_{i \in I} \ell(t_i)N_i \right) \cdot F(0, w) \]
yields a well-defined map
\[ \vartheta_U : U \to \Gamma_U \setminus D. \]
Note that the nilpotent orbit \( (2.1.3) \) is the lift of \( \vartheta_U \).

2.1.2. Limiting mixed Hodge structures. Let
\[ N_I := \sum_{i \in I} N_i \]
denote the monodromy operator about \( Z_I^* \). Let
\[ W_0(N_I) \subset W_1(N_I) \subset \cdots \subset W_{2n}(N_I) \]
denote the monodromy (shifted) weight filtration. The triple \((V, W(N_I), F(0, w))\) is a limiting mixed Hodge structure. Let
\[ \text{Gr}^W_a(N_I) := W_a(N_I)/W_{a-1}(N_I). \]
Recall that \( N_I \in \text{End}(V, Q) \) maps \( W_a(N_I) \subset V \) into \( W_{a-2}(N_I) \). Consequently there is a well-defined map \( N_I : \text{Gr}^W_a(N_I) \to \text{Gr}^W_{a-2}(N_I) \). The flag \( F(0, w) \in \tilde{D} \) induces a weight \( n + a \) Hodge structure on the the primitive spaces
\[ (2.1.4) \quad H_I^{n-a}(-a) := \ker\{ N_I^{a+1} : \text{Gr}^W_{a+n}(N_I) \to \text{Gr}^W_{n-a-2}(N_I) \}, \]

\[ ^5 \text{Typically, } "W(N)" \text{ denotes a representation-theoretic filtration with indexing that is centered at 0. In this paper, we are letting } "W(N)" \text{ denote the shifted geometric filtration } W(N)[n], \text{ with indexing that centered at } n. \text{ The reasons for this mild abuse of notation is that (i) this is the only filtration we will work with and (ii) the abuse significantly reduces notational clutter.} \]
\begin{equation}
0 \leq a \leq n, \text{ that is polarized by }
(2.1.5)
\quad Q^I_a(u, v) := Q(u, N^aI v).
\end{equation}

In this way we obtain a (local) variation of polarized Hodge structures over $\Delta^I$. Note that the latter is an open neighborhood of $b_0$ in $Z^I$. And this leads to a (global) variation of polarized Hodge structures

\begin{equation}
(2.1.6)
\Phi_I : Z_I^* \rightarrow \Gamma_I \backslash D_I.
\end{equation}

In general, $D_I$ will be a product of period domains.

\subsection*{2.1.3. Relative weight filtration property}

The relative weight filtration property (RWFP) is a compatibility statement for $W(N_I)$ and $W(N_{I'})$ when $I \subset I'$. We will be interested in applying the RWFP to the induced filtrations of $g$. Given $N \in g$ let $\text{ad} : g \rightarrow g$ denote the adjoint action. Then $\text{ad} N$ is nilpotent if and only if $N$ is; assume this is the case. Let $W(\text{ad} N)$ denote the associated weight filtration of $g$.

\begin{equation}
(2.1.7)
\ker(\text{ad} N) \subset W_0(\text{ad} N) \subset g.
\end{equation}

Since $N_{I'}$ and $N_I$ commute, we have $N_{I'} \in W_0(\text{ad} N_I)$, and an induced nilpotent action

\begin{equation}
\text{ad}^I_{a}N_{I'} : \text{Gr}^W_{a}(\text{ad} N_I) \rightarrow \text{Gr}^W_{a}(\text{ad} N_I)
\end{equation}

Let $W(\text{ad}^I_{a}N_{I'})$ be the corresponding filtration of $\text{Gr}^W_{a}(\text{ad} N_I)$. At the same time $W(\text{ad} N_{I'})$ also induces a filtration $W'_{a, b}$ of $\text{Gr}^W_{a}(\text{ad} N_I)$ by

\begin{equation}
W'_{a, b} := \frac{W_b(\text{ad} N_{I'}) \cap W_a(\text{ad} N_I)}{W_b(\text{ad} N_{I'}) \cap W_{a-1}(\text{ad} N_I)}.
\end{equation}

The \textit{relative weight filtration property} (RWFP) asserts that

\begin{equation}
(2.1.8)
W'_{a, a+b} = W_b(\text{ad}^I_{a}N_{I'}).
\end{equation}

For the arguments of \cite{Green2011} it will be convenient to describe the filtrations above in terms of a (simultaneous) eigenspace decomposition of $g_{\mathbb{R}}$. It follows from the several variable $SL(2)$–orbit theorem \cite{Cattani1986} that there exist commuting semisimple elements $Y, Y' \in g_{\mathbb{R}}$ that split the weight filtrations $W(\text{ad} N_I)$ and $W(\text{ad} N_{I'})$ in the following sense: we have a simultaneous eigenspace decomposition

\begin{equation}
\begin{split}
g_{\mathbb{R}} = \oplus g_{i,j}, \quad \text{with} \quad g_{i,j} := \{ \xi \in g_{\mathbb{R}} \mid [Y, \xi] = i \xi, \ [Y', \xi] = (i+j) \xi \},
\end{split}
\end{equation}

\footnote{Some care must be taken in passing from the local to the global case: the lift $\tilde{\Phi}_U$ is defined only up to the action of $\Gamma$. However, given a second lift $\tilde{\Phi}'_U$, there is a canonical identification of the period domain $D'_I$ with $D_I$. The global (2.1.6) is defined by fixing one $D_I$ and making this identification.}

\footnote{Any polarized, weight $n$ Hodge structure on $V$ induces a polarized, weight 0 Hodge structure on $g$. For this reason, the filtration $W(\text{ad} N)$ is centered at 0, cf. Footnote.}
that splits the weight filtrations in the sense that
\[(2.1.9) \quad W_a(\text{ad} N_I) = \bigoplus_{i \leq a} g_{i,\bullet} \quad \text{and} \quad W_b(\text{ad} N_{I'}) = \bigoplus_{i+j \leq b} g_{i,j}.\]

Moreover, if we write \(N_I = \sum N_{i,j}\) and \(N_{I'} = \sum N'_{i,j}\) with \(N_{i,j}, N'_{i,j} \in g_{i,j}\), then
\[(2.1.10) \quad N_I = N_{-2,0} \quad \text{and} \quad N_{I'} = \sum_{i \geq 0} N'_{-i,i-2};\]
the latter implies
\[(2.1.11) \quad \sum_j N'_{0,j} = N'_{0,-2}.\]

The first equation of (2.1.9) yields an identification
\[(2.1.12) \quad \text{Gr}_{W(a)}(\text{ad} N_I) \simeq g_{a,\bullet} := \bigoplus_j g_{a,j}\]
of the graded spaces with the \(Y_I\)-eigenspaces. It follows from (2.1.8) and (2.1.9) that this identification yields
\[(2.1.13) \quad W_b(\text{ad} N_{I'}) \simeq \bigoplus_{j \leq b} g_{a,j}.\]

Remark 2.1.14. We have \(N_{I'} \in W_{-1}(\text{ad} N_I)\) if and only if \(\text{ad}^I_a N_{I'} = 0\) for all \(a\). Equivalently, the filtration \(W(\text{ad}^I_a N_{I'})\) is trivial for all \(a\): \(W_{-1}(\text{ad}^I_a N_{I'}) = 0\) and \(W_0(\text{ad}^I_a N_{I'}) = \text{Gr}_{W(a)}^W(\text{ad} N_I)\). In this case (2.1.13) implies \(g_{a,b} = 0\) for all \(b \neq 0\). Then (2.1.9) implies \(W(\text{ad} N_I) = W(\text{ad} N_{I'})\); equivalently, \(W(N_I) = W(N_{I'})\).

Finally we note that the Jacobi identity implies
\[(2.1.15) \quad [g_{i,j}, g_{a,b}] \subset g_{i+a,j+b}.\]
It follows from (2.1.11), (2.1.12) and (2.1.15) that
\[(2.1.16) \quad \text{ad}^I_a N_{I'} = \text{ad} N'_{0,-2} : g_{a,\bullet} \to g_{a,\bullet}.\]

3. Completion of the image of a period mapping

3.1. Definition and properties. Recall the maps \(\Phi_I : Z^*_I \to \Gamma_I \setminus D_I\) of (2.1.6). (Note that \(B = Z^*_0, D = D_0\) and \(\Phi = \Phi_\emptyset\).) Define
\[M := \Phi(B) \quad \text{and} \quad M_I := \Phi_I(Z^*_I)\circ (\text{including the case } I = \emptyset).\]
We let
\[(3.1.1) \quad \widetilde{M} := \bigcup_I M_I,\]
and then the Hodge-theoretic Satake-Baily-Borel completion \(\overline{M}\) of \(M\) is the natural (finite) quotient of \(\widetilde{M}\). The set theoretic extension \(\Phi_e : B \to \overline{M}\) of \(\Phi\) is defined by
\[\Phi_e|_{Z^*_I} := \Phi_I.\]
We will show (Theorem 3.1.5 below) that $\overline{M}$ has a complex analytic structure and that the extended period map $\Phi_e$ is holomorphic.

First note that the $D_I$ need not be pairwise distinct: it may be the case that there is a canonical isomorphism $D_I \simeq D_{I'}$ when $I \neq I'$. When such an identification exists, $M_I$ and $M_{I'}$ will be understood as lying in the same space. The existence of such identifications is encoded in the set $K$ introduced in §3.2.5. What is important here is the following: let $I$ be the collection of all subsets $I \subset \{1, \ldots, \nu\}$. (That is, $I$ indexes the open strata $Z^*_I$.) There is a surjective map $\mathcal{I} \to \mathcal{K}$, denoted $I \mapsto K_I$, so that $K_I = K_{I'}$ implies that we have the aforementioned identification $D_I \simeq D_{I'}$. Given $K \in \mathcal{K}$, let

$$Z^*_K := \bigcup_{K_I = K} Z^*_I.$$ 

That is, $Z^*_K$ is a (disjoint) union of open strata $Z^*_I$ of the same “Hodge type”. We have $\mathcal{K} \subset \mathcal{I}$, and $K_{K_I} = K_I$. So given $K = K_I \in \mathcal{K}$, the corresponding (product of) period domain(s) $D_K := D_{K_I} \simeq D_I$ is well-defined. Consequently,

$$\Phi^*_K|_{Z^*_K} := \Phi_I$$

defines a horizontal, holomorphic map

\begin{equation}
\Phi_K^* : Z^*_K \to \Gamma_K\backslash D_K.
\end{equation}

For example, $Z_{K_0} \supset B$ is the maximal subset to which the period map $\Phi : B \to \Gamma\backslash D$ extends. The image $\Phi_K^*(Z^*_K)$ is a closed analytic subvariety of $\Gamma_K\backslash D_K$ [Gri70b, Theorem 9.6]. Let

$$Z^*_K \xrightarrow{\Phi^*_{K_0}} \tilde{M}_K \xrightarrow{\Phi^*_{K_0}} \Phi^*_K(Z^*_K) = \bigcup_{K_I = K} M_I$$

be the Stein factorization of $\Phi^*_K$. (The $\Phi^*_K$–fibres are the connected components of the $\Phi^*_K$–fibres, and the $\Phi^*_K$–fibres are finite.) Set

\begin{equation}
\tilde{M} := \bigcup_{K \in \mathcal{K}} \tilde{M}_K,
\end{equation}

and define maps

\begin{align}
\begin{array}{ccc}
B & \xrightarrow{\Phi^*_{K_0}} & \tilde{M} \\
\downarrow \Phi & & \downarrow \Phi^*_{K_0} \\
M & \xrightarrow{\Phi^*_{K_0}} & \overline{M}
\end{array}
\end{align}

by specifying

\begin{align}
\Phi^*|_{Z^*_K} := \Phi^*_K \quad \text{and} \quad \Phi^*|_{\tilde{M}_K} := \Phi^*_K,
\end{align}

$K \in \mathcal{K}$. This yields the commutative diagram

$$\begin{array}{ccc}
B & \xrightarrow{\Phi^*_{K_0}} & \tilde{M} \\
\downarrow \Phi & & \downarrow \Phi^*_{K_0} \\
M & \xrightarrow{\Phi^*_{K_0}} & \overline{M}
\end{array}$$
Theorem 3.1.5. The set $\tilde{M}$ is a complex analytic space, and $\Phi^\circ$ is a holomorphic map.

The proof proceeds in two steps:

**Step 1: the local construction.** To begin we localize at a point $b_0 \in Z^*_I$ by choosing a coordinate neighborhood $\mathbb{U} \simeq \Delta^*$ centered at $b_0$ in $\overline{B}$ so that
\[
\mathbb{U} := \mathbb{U} \cap B \simeq (\Delta^*)^k \times \Delta^\ell.
\]

Let $\Gamma_U = \{T_{i_1}^\circ, \ldots, T_{i_k}^\circ\}$ be the the local monodromy group. (Recall that $T_i = \exp(N_i)$ is the unipotent monodromy about $Z_i$. So it is implicit in the notation of (2.1.1) that, having fixed $b_0$, we index the irreducible components $Z_i$ so that $b_0 \in Z_1 \cap \cdots \cap Z_k$. This convention is in effect throughout the local construction §3.2–3.4.)

The local version of the HT-SBB completion is defined by replacing $\Phi : B \subset \overline{B} \to \Gamma \setminus D$ with the local VHS $\Phi_U : U \subset \mathbb{U} \to \Gamma_U \setminus D$ of (2.1.2) in the construction above. We run through this quickly to set notation. Let $\mathbb{I}_U \subset \mathbb{I}$ be those subsets that are contained in $\{1, \ldots, k\}$, and let $K_U = K \cap \mathbb{I}_U$. Given $I, K \in \mathbb{I}_U$, define
\[
\Delta^*_I := \{(t_1, \ldots, t_k) \in \Delta^k \mid t_i = 0 \text{ if and only if } i \in I\},
\]
so that $\mathbb{U} \cap Z^*_I = \Delta^*_I \times \Delta^\ell$. Let
\[
\Phi^*_U : \Delta^*_I \times \Delta^\ell \to \Gamma_U \setminus D_I
\]
be the VHS induced by $\Phi_U$, cf. (2.1.6). Given $K \in K_U$, and setting
\[
\Delta^*_K := \bigcup_{K_i = K} \Delta^*_I,
\]
we have the local analog of (3.1.2): a holomorphic map
\[
\Phi^*_U, K : \Delta^*_K \times \Delta^\ell \to \Gamma_U \setminus D_K.
\]

specified by
\[
\Phi^*_U, K |_{\Delta^*_I \times \Delta^\ell} = \Phi^*_U, I.
\]

The (local) **HT-SBB completion of $M_U := \Phi_U(\mathbb{U})$** is
\[
\tilde{M}_U := \bigcup_{K \in K_U} \Phi^*_U, K(\Delta^*_K \times \Delta^\ell) = \bigcup_{I \in \mathbb{I}_U} \Phi^*_U, I(\Delta^*_I \times \Delta^\ell).
\]

Let
\[
\Delta^*_K \times \Delta^\ell \xrightarrow{\Phi^*_U, K} \tilde{M}_U, K \xrightarrow{\Phi^*_U, K} \Phi^*_K(\Delta^*_K \times \Delta^\ell)
\]
be the Stein factorization of $\Phi^*_U, K$. Set
\[
\tilde{M}_U := \prod_{K \in K_U} \tilde{M}_U, K,
\]
and define maps
\[
\mathbb{U} \xrightarrow{\Phi^\circ_U} \tilde{M}_U \xrightarrow{\Phi^\circ_U} \mathbb{U}_\mathbb{U}
\]
by specifying
\[(3.1.13b) \Phi^{\circ}_{U|_{\Delta_k \times \Delta^\ell}} := \Phi^0_{U,K} \quad \text{and} \quad \Phi^\flat_{U|_{\tilde{M}_U,K}} := \Phi^\flat_{U,K},\]

\(K \in \mathcal{K}\). This yields the commutative diagram

\[
\begin{array}{ccc}
U & \xrightarrow{\Phi_U} & \tilde{U} \\
\downarrow{\Phi_U} & & \downarrow{\Phi_U} \\
M_U & \xleftarrow{\Phi_U} & \tilde{M}_U.
\end{array}
\]

The local version of Theorem 3.1.5 asserts that \(\tilde{M}_U\) is a complex analytic space and \(\Phi^\circ_U\) is a holomorphic map. The theorem is proved in two steps: first, the case that (the lift of) \(\Phi_U\) is a nilpotent orbit (Theorem 3.2.39); and second the general case (Theorem 3.4.8).

**Step 1.a: local construction for nilpotent orbits** (§3.2). Assume that \(F(t,w) = F_0\) is constant. Then \(\Phi_U\) is independent of \(w \in \Delta^\ell\). For notational convenience, we regard \(\Phi_U\) as a map \((\Delta^*)^k \to \Gamma_U \setminus D\). We will construct a monomial map

\[\mu : \Delta^k \to \mathbb{C}^m\]

with the following property: if

\[\Delta^k \xrightarrow{\mu^\circ} S_\mu \xrightarrow{\mu^\flat} \mathbb{C}^m\]

is the Stein factorization of \(\mu\), then the set of \(\mu^\circ\)-fibres is precisely the set of \(\Phi^\circ_U\)-fibres. Consequently, there is a canonical identification \(\tilde{M}_U \simeq S_\mu\) as sets. Since \(S_\mu\) has the structure of a toric variety (or more precisely an open subset in a toric variety), this gives \(\tilde{M}_U\) a natural analytic structure. Furthermore, \(\mu^\circ = \Phi^\circ_U\) under the identification \(\tilde{M}_U = S_\mu\), so that \(\Phi^\circ_U\) is holomorphic (see Theorem 3.2.39). Finally, we note that \(\overline{M}_U\) is obtained from \(\tilde{M}_U\) by a finite, set-theoretic equivalence relation (see [Kol12]). In particular, \(\overline{M}_U\) gets the structure of an analytic variety (or even algebraic space).

**Step 1.b: local construction for arbitrary VHS** (§3.4). In this case we will see that the monomial map \(\mu\) may be augmented by a vector-valued holomorphic map \(\nu\) on \(\Delta^r = \Delta^k \times \Delta^\ell\): if

\[\Delta^r \xrightarrow{\tau^\circ} S_\tau \xrightarrow{\tau^\flat} \mathbb{C}^m\]

is the Stein factorization of \(\tau = (\mu, \nu)\), then the set of \(\tau^\circ\)-fibres is precisely the set of \(\Phi^\circ_U\)-fibres. Consequently, we have a canonical identification \(\tilde{M}_U \simeq S_\tau\) as sets. This gives \(\tilde{M}_U\) the structure of a complex analytic space. Furthermore, \(\tau^\circ = \Phi^\circ_U\) under the identification \(\tilde{M}_U = S_\tau\), so that \(\Phi^\circ_U\) is holomorphic. See Theorem 3.4.8.

Perhaps surprisingly, the most technically intricate part of Step 1 is in Step 1a; essentially this is where one deals with singularities that arise as a VHS degenerates asymptotically. The *sine qua non* here is the relative weight filtration property; it ensures that the monomial maps satisfy necessary compatibility conditions.
Step 2: the global construction (§3.5). Consider a global VHS $\Phi : B \to \Gamma \backslash D$. The basic idea is to glue the local completions together and show that one obtains an analytic space $\overline{M}$ after quotienting by the full monodromy group $\Gamma$. The *sine qua non* here is the Cattani–Deligne–Kaplan result on the algebraicity of Hodge loci; it implies that the passage from the local construction to the global construction is a *finite* quotient. Consequently, the difference between working locally and globally (i.e. taking into account the monodromy action) is only a finite ambiguity, which allows us to conclude that $\overline{M}$ is an analytic space.

3.2. Step 1.a: $F(t,w) = F_0$ is constant. Here we assume that the factor $F(t,w)$ in (2.1.2) is constant. In particular, $\tilde{\Phi}_U$ is a nilpotent orbit. Then (2.1.2) implies $\Phi_U$ depends on $t \in (\Delta^*)^k$ alone; for the duration of §3.2 we will suppress $w$ and $\Delta^\ell$.

3.2.1. Fibres of $\Phi_U$. Given $t = (t_1,\ldots,t_k) \in (\Delta^*)^k$, we wish to determine which monomials $t_1^{c_1} \cdots t_k^{c_k}$ are constant on the connected fibres of

$$\Phi_U : (\Delta^*)^k \to \Gamma_U \backslash D.$$  

**Lemma 3.2.2.** The vector field $v(t) = \sum a_i t_i \partial_i$ on $(\Delta^*)^k$ is tangent to the $\Phi_U$–fibre through $t \in (\Delta^*)^k$ if and only if $\sum a_i N_i = 0$.

**Proof.** The vector field is tangent to the fibres if and only if $\Phi_U^*(v(t)) = 0$.

Recall that a nonzero nilpotent $\xi \in g_{\mathbb{R}}$ induces a vector field $X$ on $\tilde{D}$ by $X_F = \frac{\partial}{\partial z} \exp(z\xi) \cdot F |_{z=0}$, $F \in \tilde{D}$. Since $D \cong G_{\mathbb{R}} / H$, where $H$ is a compact subgroup of $G_{\mathbb{R}}$, the vector field $X$ is nonvanishing on $D$ so long as $\xi \neq 0$. It follows from this discussion that $\Phi_U^*(v(t)) = 0$ if and only if $\sum a_i N_i = 0$. \hfill $\square$

Let

$$S_{\emptyset} := \left\{ a = (a_i) \in \mathbb{R}^k : \sum a_i N_i = 0 \right\}$$

denote the set of linear relations on the $N_i$.

**Remark 3.2.4.** Lemma 3.2.2 implies that the set of connected components of the $\Phi_U$–fibres is precisely the set of maximal, connected integral manifolds of the Frobenius distribution spanned by the $\sum_i a_i t_i \partial_i$, with $(a_1,\ldots,a_k) \in S_{\emptyset}$.

Let $S_{\emptyset}^\perp$ denote the orthogonal complement of $S_{\emptyset}$ with respect to the standard inner product on $\mathbb{R}^k$. Note that both $S_{\emptyset}$ and $S_{\emptyset}^\perp$ admit bases in $\mathbb{Q}^k$; clearing denominators we may assume that the bases lie in $\mathbb{Z}^k$. Fix a basis $C_{\emptyset} := \{ c_1,\ldots,c_s \} \subset \mathbb{Z}^k$ of $S_{\emptyset}^\perp$. Define a monomial map $\mu_{\emptyset} : (\Delta^*)^k \to \mathbb{C}^s$ by $\mu_{\emptyset}(t) = (t^{c_1},\ldots,t^{c_s})$.

**Proposition 3.2.5.** The set of connected components of the $\mu_{\emptyset}$–fibres is precisely the set of connected components of the $\Phi_U$–fibres.

---

The subscript $\emptyset$ is used in order to be consistent notation introduced later in the section.
Proof. Given \( c = (c_1, \ldots, c_k) \in \mathbb{Z}^k \), note that
\[
(\sum_i a_i t_i \partial / \partial t_i) t_1^{c_1} \cdots t_k^{c_k} = (\sum_i a_i c_i) t_1^{c_1} \cdots t_k^{c_k}.
\]
Consequently, the vector field \( v_a(t) = \sum a_i t_i \partial / \partial t_i \) on \((\Delta^*)^k\) is tangent to the \( \mu_0\)-fibre through \( t \in (\Delta^*)^k \) if and only if \( a = (a_1, \ldots, a_k) \in S_0^\emptyset \). The proposition now follows from Lemma 3.2.2 and Remark 3.2.4.

A priori the monomials \( t^c \) are Laurent monomials: some of the \( c_i \) may be negative. We next show that the basis \( C^\emptyset = \{c_1, \ldots, c_s\} \) may be chosen so that the \( c_i \geq 0 \) (Lemma 3.2.7).

Let \( \mathbb{R}_+^k := \{(x_1, \ldots, x_k) \in \mathbb{R}^k : x_i > 0\} \) be the open positive “quadrant” of \( \mathbb{R}^k \), and let \( \overline{\mathbb{R}_+^k} := \{(x_1, \ldots, x_k) \in \mathbb{R}^k : x_i \geq 0\} \) denote the closure.

**Lemma 3.2.7.** The orthogonal complement \( S^\perp_0 \) admits a basis \( C_0 \subset \mathbb{R}_+^k \cap \mathbb{Z}^k \).

**3.2.2. Proof of Lemma 3.2.7.** It suffices to show that
\[
(3.2.8) \quad \text{there exists } c = (c_1, \ldots, c_k) \in \mathbb{R}_+^k \cap S^\perp_0.
\]
To see this suppose that such a \( c \) is given. Since \( S^\perp_0 \cap \mathbb{Q}^k \) is dense in \( S^\perp_0 \subset \mathbb{R}^k \), we may assume \( c \in \mathbb{Q}^k \). Again, clearing denominators we may assume that \( c \in \mathbb{Z}^k \). Without loss of generality we may suppose that the first basis element \( c_1 \in C_0 \) is \( c \). There exists \( 0 \leq n \in \mathbb{Z} \) so that \( c_j + nc \in \mathbb{R}_+^k \) for \( 2 \leq j \leq s \). This yields a basis \( \{c_1, c_2 + nc, \ldots, c_s + nc\} \) of \( S^\perp_0 \) lying in \( \mathbb{R}_+^k \cap \mathbb{Z}^k \), and establishes Lemma 3.2.7.

The assertion (3.2.8) is a consequence of the following two lemmas.

**Lemma 3.2.9.** Fix a linear subspace \( S \subset \mathbb{R}^k \) and let \( S^\perp \) be the orthogonal complement with respect to the standard inner product on \( \mathbb{R}^k \). There is a unique subset \( K \) of \( \{1, \ldots, k\} \) for which there exist
\[
v = (v_1, \ldots, v_k) \in \overline{\mathbb{R}_+^k} \cap S \quad \text{with} \quad v_i > 0 \quad \text{if and only if} \quad i \in K,
\]
\[
\tilde{v} = (\tilde{v}_1, \ldots, \tilde{v}_k) \in \overline{\mathbb{R}_+^k} \cap S^\perp \quad \text{with} \quad \tilde{v}_i > 0 \quad \text{if and only if} \quad i \in K^c.
\]

**Lemma 3.2.10.** The intersection \( \overline{\mathbb{R}_+^k} \cap S_0^\emptyset \) is trivial.

**Proof.** Given \( I \subset \{1, \ldots, k\} \), let
\[
\sigma_I := \{ \sum_{i \in I} a_i N_i \mid 0 < a_i \}
\]
denote the associated cone. The independence of the weight filtration \( W(N) \) on the choice of \( N \in \sigma_I \) yields the lemma.

The proof of Lemma 3.2.9 is a consequence of the following result from classical linear programming.
Farkas Alternative Lemma 3.2.11. Given a real \( r \times k \) matrix \( A \) and \( b \in \mathbb{R}^r \), of the following two problems exactly one has a solution:

(i) there exists \( x \in \mathbb{R}^k_+ \) such that \( Ax = b \); or
(ii) there exists \( y \in \mathbb{R}^r \) such that \( A^t y \in \mathbb{R}^k_+ \) and \( y^t b < 0 \).

Proof of Lemma 3.2.9. Fix an orthonormal basis \( \{ e_1, \ldots, e_k \} \) of \( \mathbb{R}^k \), and let \( \{ \mu_1, \ldots, \mu_s \} \subset \mathbb{R}^k_+ \) be any basis of \( S^\perp \). Regard the \( \mu_a \) as row vectors of length \( k \); fix \( 1 \leq i \leq k \) and define an \((s + 1) \times k\) matrix

\[
A_i := \begin{bmatrix}
\mu_1 \\
\vdots \\
\mu_s \\
e_i
\end{bmatrix}.
\]

Set \( b = (0, \ldots, 0, 1) \in \mathbb{R}^{s+1} \). According to Lemma 3.2.11 either

(a) there exists \( x_i = (x_{i,1}, \ldots, x_{i,k}) \in \mathbb{R}^k_+ \cap S \) so that \( x_{i,i} = 1 \),

or

(b) there exists \( y = (y_1, \ldots, y_s+1) \in \mathbb{R}^{s+1} \) so that \( \bar{x}_i = (\bar{x}_{i,1}, \ldots, \bar{x}_{i,k}) := \sum_{a=1}^{s} y_a \mu_a \in \mathbb{R}^k_+ \cap S^\perp \) and \( \bar{x}_{i,i} > 0 \).

Define \( K := \{ i \mid (a) \text{ holds} \} \). Then the complement \( K^c = \{ i \mid (b) \text{ holds} \} \). Define

\[
v := \sum_{i \in K} x_i \in S \cap \mathbb{R}^k_+ ,
\]

\[
\bar{v} := \sum_{i \in K^c} \bar{x}_i \in S^\perp \cap \mathbb{R}^k_+ .
\]

Then \( 0 = \langle v, \bar{v} \rangle \) implies that \( v_i > 0 \) if and only if \( i \in K \), and \( \bar{v}_i > 0 \) if and only if \( i \in K^c \).

It remains to establish uniqueness. If \( K \) and \( K' \) both satisfy the conditions in the lemma, then we have quartets \( \{ v, \bar{v}; K, K^c \} \) and \( \{ v', \bar{v}'; K', (K')^c \} \). If \( K \cap (K')^c \neq \emptyset \), then \( \langle v, \bar{v}' \rangle > 0 \) contradicting \( v \in S, \bar{v}' \in S^\perp \). Therefore \( K \cap (K')^c = \emptyset \). Likewise, \( K^c \cap K' = \emptyset \). Whence uniqueness. \hfill \Box

3.2.3. Induced nilpotent orbits on strata. For each index set \( I \subset \{1, \ldots, k\} \) recall the stratum (3.1.6) in the natural stratification of \( \Delta^k \). For example, \( \Delta^*_\emptyset = (\Delta^*)^k \), and \( \Delta^*_\{1, \ldots, k\} = 0 \in \Delta^k \).

More generally, \( I \subset I' \) implies

\[
\Delta^*_I \subset \Delta_I := \{ t \in \Delta^k \mid t_i = 0, \ \forall \ i \in I \} .
\]

Let

\[
(3.2.12) \quad \Phi_{\emptyset, I} : \Delta^*_I \to \Gamma_{\emptyset, I} \setminus D_I .
\]

be the analog of (2.1.6) for the degeneration of \( \Phi_{\emptyset}(t) \) as \( t_I \to 0 \). To be explicit, let \( t_I \) be the restriction of the coordinates \( t \) on \( \Delta^k \) to \( \Delta^*_I \) (so that \( t_I = 0 \) if and only if \( i \in I \)). The
flag $\sum_{j \notin I} \exp(\ell(t_j)N_j)F_0$ determines a Hodge structure

\begin{equation}
\tilde{\Phi}_{U, I, a}(t_I) = \exp \left( \sum_{j \notin I} \ell(t_j)N_{a,j}^I \right) \cdot F_a
\end{equation}

on $\text{Gr}_a^{W(N_I)}$ that is polarized by (2.1.5). Here $N_{a,j}^I : \text{Gr}_a^{W(N_I)} \to \text{Gr}_a^{W(N_I)}$ is the endomorphism induced by $N_j$; and, if $D_{I,a}$ is the period domain that $\tilde{\Phi}_{I,a}$ takes value in, then $F_a \in \tilde{D}_{I,a}$. In particular, $\tilde{\Phi}_{I,a}$ is a nilpotent orbit on $D_{I,a}$. Finally, $D_I = \prod_a D_{I,a}$ and $\tilde{\Phi}_{U, I} = (\tilde{\Phi}_{U,I,a})_a$ is a lift of (3.2.12). Write

\begin{equation}
\tilde{\Phi}_{U, I}(t_I) = \exp \left( \sum_{j \notin I} \ell(t_j)N_j^I \right) \cdot F_I
\end{equation}

Note that $\Phi_U = \Phi_{\emptyset}$.

3.2.4. Fibres of $\Phi_{U, I}$. We develop a characterization of the connected components of the $\Phi_{U, I}$–fibres by monomial maps: this section generalizes the results of §§3.2.1–3.2.2, and this material will be used to construct the monomial map in §3.2.6.

We leave it to the reader to verify the following analogue of Lemma 3.2.2 for the map (3.2.12).

**Lemma 3.2.15.** The vector $v(t) = \sum_{j \in I} c_j t_j \partial / \partial t_j$ on $\Delta_I^*$ is tangent to the $\Phi_{U, I}$–fibre through $t_I = (t_j)_{j \in I} \in \Delta_I^*$ if and only if $\sum_{j \in I} c_j N_j \in W_{-1}(\text{ad} N_I)$.

We note that both sums in Lemma 3.2.15 may be taken over all $j \in \{1, \ldots, k\}$: in the first sum we have $t_i = 0$ on $\Delta_I^*$ for $i \in I$; and in the second sum $N_i \in W_{-2}(\text{ad} N_I) \subset W_{-1}(\text{ad} N_I)$.

Define

$$S_I := \left\{ a = (a_i) \in \mathbb{R}^k : \sum a_i N_i \in W_{-1}(\text{ad} N_I) \right\}.$$

**Remark 3.2.16.** The analog of Remark 3.2.4 holds: the set of connected components of the $\Phi_{U, I}$–fibres are the maximal, connected integral manifolds of the Frobenius distribution spanned by the $\sum a_i t_i \partial / \partial t_i$, with $(a_i) \in S_I$.

Since the $N_i$ commute, (2.1.1) yields $\sigma_I \subset W_{-2}(N_I) \subset W_{-1}(N_I)$. So

$$\left\{ (a_i) \in \mathbb{R}^k \mid a_i > 0, \forall i \in I; a_j = 0, \forall j \notin I \right\} \subset S_I;$$

therefore

$$\left\{ (a_i) \in \mathbb{R}^k \mid a_j = 0, \forall j \notin I \right\} \subset S_I.$$

Let

$$S_I^\perp \subset \left\{ (c_i) \in \mathbb{R}^k \mid c_i = 0, \forall i \in I \right\}$$

denote the orthogonal complement of $S_I$ with respect to the standard inner product on $\mathbb{R}^k$. 
Example. The containment $N_i \in W_{-2}(\sigma_{\{1,\ldots,k\}}) \subset W_{-1}(\sigma_{\{1,\ldots,k\}})$, for all $i$, implies

$$S_{\{1,\ldots,k\}} = \mathbb{R}^k \text{ and } S_{\{1,\ldots,k\}}^\perp = 0.$$  

Let $K_I \subset \{1,\ldots,k\}$ be the subset associated to $S_I$ by Lemma 3.2.9. The containment (3.2.17) implies

(3.2.18) $I \subset K_I$.

Example. From Lemma 3.2.10 we see that $K_{\emptyset} = \emptyset$.

Define $\mathbb{R}^k_{+,I} := \{(x_1,\ldots,x_k) \in \mathbb{R}^k \mid x_i = 0, \forall i \in I; \; x_i > 0, \forall i \notin K_I\}$, so that

(3.2.19) $\overline{\mathbb{R}^k_{+,I}} := \{(x_1,\ldots,x_k) \in \mathbb{R}^k \mid x_i = 0, \forall i \in I; \; x_i \geq 0, \forall i \notin K_I\}$.

The following lemma is an analog of Lemma 3.2.7.

**Lemma 3.2.20.** The vector space $S_I^\perp$ admits a basis $C_I \subset \mathbb{Z}^k \cap \mathbb{R}^k_{+,I}$.

The proof (which is a straightforward generalization of that establishing Lemma 3.2.7) is left to the reader.

**Remark 3.2.21.** Note that, $\mathbb{R}^k_{+,I} \subset \mathbb{R}^k_+$ if and only if $I = K_I$. In particular, Lemma 3.2.20 alone does not suffice to ensure that we can choose a basis $C_I$ so that the monomials $\{t^c \mid c \in C_I\}$ have nonnegative exponents. That such choice is possible will follow from Corollary 3.2.31 cf. (3.2.32).

Define a monomial map

(3.2.22) $\mu_I : \Delta_I^+ \rightarrow \mathbb{C}^{|C_I|}$ by $\mu_I(t) := (t^c)_{c \in C_I}$.

We have the following analog of Proposition 3.2.5.

**Proposition 3.2.23.** The set of connected components of $\mu_I$–fibres is precisely the set of connected components of $\Phi_{U,I}$–fibres.

The proof (which is a straightforward generalization of that establishing Proposition 3.2.5) is left to the reader.

3.2.5. Compatibility.

**Lemma 3.2.24.** If $I \subset I'$, then $S_I \subseteq S_{I'}$. In particular, $S_{I'}^\perp \subset S_I^\perp$.

**Remark 3.2.25.** It is a consequence of this lemma and Proposition 3.2.23 that the monomials $\{t^c \mid c \in S_{I'}^\perp\}$ are locally constant on the $\Phi_{U,I}$–fibres.
Proof. We follow the notation of Section 2.1.3. Suppose \((a_1, \ldots, a_k) \in S_I\). Set \(\tilde{N} = \sum a_i N_i \in W_{-1}(\text{ad } N_I)\). Because the \(N_i\)'s commute, it is immediate that

\[
(3.2.26) \quad \tilde{N} \in W_0(\text{ad } N_I) \cap W_0(\text{ad } N_{I'}) \quad (2.1.9) \quad \bigoplus_{i \leq 0, i + j \leq 0} g_{i,j}.
\]

Write \(\tilde{N} = \sum_{i,j} \tilde{N}_{i,j}\) with \(\tilde{N}_{i,j} \in g_{i,j}\). The hypothesis \(\tilde{N} \in W_{-1}(\text{ad } N_I)\) implies

\[
(3.2.27) \quad \tilde{N}_{0,j} = 0 \quad \text{for all } j.
\]

We want to prove \(\tilde{N} \in W_{-1}(\text{ad } N_{I'})\); equivalently, \(\tilde{N}_{i,j} = 0\) for all \(i + j = 0\). Given (3.2.26), this is equivalent to showing that

\[
(3.2.28) \quad \tilde{N}_{i,-i} = 0 \quad \text{for all } i \leq 0.
\]

We will argue by induction on \(i\). As noted in (3.2.27), (3.2.28) holds for \(i = 0\). Fix \(i_o < 0\) and suppose (3.2.28) holds for \(i_o < i \leq 0\); we will show (3.2.28) holds for \(i = i_o\). This will complete the induction and the proof of the lemma.

Since the \(N_j\) all commute, we have \(\text{ad } N_{I'}(\tilde{N}) = [N_{I'}, \tilde{N}] = 0\). The inductive hypothesis, the Jacobi identity (2.1.15), and the identifications (2.1.12) and (2.1.16) imply \(\tilde{N}_{i_o,-i_o}\) lies in the kernel of \(\text{ad } N_{I'}\). Since this kernel lies in \(W_0(\text{ad } N_{I'})\), it follows from (2.1.13) that \(\tilde{N}_{i_o,-i_o} = 0\); that is, (3.2.28) holds for \(i = i_o\). \(\square\)

Conversely, suppose that \(c = (c_1, \ldots, c_k) \in S^+_I\). If \(I \subset I'\) but \(I \subsetneq I' \cap K_I\), then (as noted in Remark 3.2.21) a priori we may have \(j \in I'\) with \(c_j < 0\). In this case, the monomial \(t^c\) will not restrict to \(\Delta^*_I\). In particular the monomial map \(\mu_I\) of (3.2.22) may not extend to all of \(\Delta^k\). The following lemma is the key to showing that this situation can be avoided, cf. (3.2.32).

**Lemma 3.2.29.** If \(I \subset I' \subset K_I\), then \(S_I = S_{I'}\).

**Proof.** By the defining property of \(K_I\) there exist \(a_i > 0, i \in K_I\), so that

\[
(3.2.30a) \quad \sum_{i \in K_I} a_i N_i \in W_{-1}(\text{ad } N_I)\.
\]

Then Remark 2.1.14 yields

\[
(3.2.30b) \quad W(N_I) = W(N_{K_I}).
\]

So \(S_I = S_{K_I}\). Lemma 3.2.24 completes the proof. \(\square\)

**Corollary 3.2.31.** (a) If \(I \subset I' \subset K_I\), then \(K_I = K_{I'}\).

(b) \(S_I = S_{K_I}\) and \(K_{K_I} = K_I\).

There are a number of significant implications of the corollary: First, it enables us to choose the bases \(C_I\) in Lemma 3.2.20 so that

\[
(3.2.32) \quad C_I = C_{K_I} \subset \mathbb{Z}^k \cap \mathbb{R}^k_{+,K_I} \subset \mathbb{Z}^k \cap \overline{\mathbb{R}}^k_+.
\]
As a consequence, the monomial map \( \mu_I \) of (3.2.22) extends to \( \Delta^k \).

Second, and recalling (3.2.30), the corollary implies that \( D_I \simeq D_{K_I} \), and we may regard (3.2.12) as a map

\[
\Phi_{U,I} : \Delta^*_I \rightarrow \Gamma_{U,K_I} \backslash D_{K_I}.
\]

Let \( K_U := \{ K_I \mid I \subset \{1, \ldots, k\} \} \) be the collection of all subsets \( K \subset \{1, \ldots, k\} \) of the form \( K = K_I \) for some \( I \subset \{1, \ldots, k\} \). Given \( K \in \mathcal{K}_U \), recall the definitions (3.1.8) and (3.1.9). We have the following analog of Proposition 3.2.23.

**Proposition 3.2.35.** Given \( K \in \mathcal{K}_U \), the set of connected components of \( \Phi_{U,K}^* \)-fibres is precisely the set of connected components of the fibres of the monomial map

\[
\mu_K : \Delta^*_K \rightarrow \mathbb{C}^{C_K} \quad \text{sending} \quad t \mapsto (t^c)_{c \in C_K}.
\]

**Proof.** This follows from Proposition 3.2.23, (3.2.32), (3.2.30) (which implies that \( N_j \in W_{-2}(N_I) \subset W_{-1}(N_i) \), for all \( j \in K = K_I \), so that \( N^j_{a,j} = 0 \) for all \( a \)) and (3.2.3). Details are left to the reader.

3.2.6. Definition of the monomial map. We are now ready to define the monomial map \( \mu : \Delta^k \rightarrow \mathbb{C}^m \). Define

\[
C = \bigcup_{K \in \mathcal{K}_U} C_K.
\]

Set \( m = |C| \) and write \( C = \{ c_1, \ldots, c_m \} \). Define the monomial map

\[
(3.2.36a) \quad \mu = (\mu_K)_{K \in \mathcal{K}_U} : \Delta^k \rightarrow \mathbb{C}^m
\]

of (??) by

\[
(3.2.36b) \quad \mu(t) = (t^{c_1}, \ldots, t^{c_m}) \in \mathbb{C}^m.
\]

**Remark 3.2.37.** The basic idea behind the monomial maps is that in the case of nilpotent orbits the period map is determined by a morphism of groups, in particular algebraic morphisms. Thus, viewing the punctured disks \( \Delta^*_K \) as open subsets in the tori \( (\mathbb{C}^*)^{K^c} \), the period map will be given by a monomial map (again in the nilpotent orbit case), and the images will be included in the image tori. The relative weight filtration property allows us to glue these image tori in a consistent way. Thus, in this situation, (locally) the compactified period map is nothing but a map of toric varieties.

Proposition 3.2.35 asserts that the monomial map \( \mu \) distinguishes the (connected components) of the fibres of \( \Phi_{U,K}^* \). The monomial map also distinguishes the distinct \( \Delta^*_K \), in the following sense.

**Lemma 3.2.38.** If \( K \neq K' \in \mathcal{K}_U \), then \( \mu(\Delta^*_K) \cap \mu(\Delta^*_K') = \emptyset \).
Proof. The monomials \( t^c \) of \( \mu_K \) will vanish on \( \Delta^*_J \) if and only if \( J \not\subset K \) (equivalently, \( K^c \cap J \neq \emptyset \)). And if \( J \subset K \), then \( t^c \) is nonconstant (unless \( K = \{1, \ldots, k\} \)) and nowhere vanishing on \( \Delta^*_J \). So to prove the lemma, it suffices to show that if \( K_I = K \) and \( K_J = K' \), then either \( J \not\subset K_I \) or \( I \not\subset K_J \). Suppose the converse holds: both \( J \subset K_I \) and \( I \subset K_J \). Then Lemma 3.2.24 and Corollary 3.2.31(b) imply \( S_J \subset S_K = S_I \) and \( S_I \subset S_{K'} = S_J \); that is, \( S_J = S_I \), forcing \( K_I = K_J \), a contradiction. \( \square \)

3.2.7. Completion of \( \Phi_U \). Given \( K \in K_U \), recall (3.1.11), (3.1.12), and (3.1.13). Let \( \Delta^k \xrightarrow{\mu^c} S_\mu \xrightarrow{\mu^b} \mathbb{C}^m \) be the Stein factorization of the monomial map \( \mu \). Then Proposition 3.2.35 and Lemma 3.2.38 imply the set of \( \Phi_U^0 \)-fibres is precisely the set of \( \mu^0 \)-fibres. This establishes

**Theorem 3.2.39** (Local completion of nilpotent orbit). There is a canonical identification \( \tilde{M}_U \simeq S_\mu \) as sets, under which \( \Phi_U^0 = \tau^0 \). This gives \( \tilde{M}_U \) the structure of a toric variety, and \( \Phi_U^0 \) is holomorphic with respect to this structure.

3.3. Example. We will illustrate, with our “favorite example”, how one might anticipate Theorem 3.2.39. Let \( \overline{M}_g \) denote the Deligne-Mumford compactification of the moduli of genus \( g \) curves. The maximal degeneration in \( \overline{M}_2 \) of a genus 2 curve is the nodal curve consisting of two components meeting in 3 points (aka as the $ curve)

Fix a neighborhood \( \overline{U} \simeq \Delta^3 \) of this curve in \( \overline{M}_2 \). We will (i) describe the corresponding nilpotent orbit, and (ii) illustrate how the above proof works in this case. The picture is

![Diagram](image)

The maximally degenerate curve corresponding to the origin is the $ curve above, the curves on the axes outside the origin will be
those on the 2-planes outside the axes will be

and those in the interior will be smooth. We will see, by inspection of this example and without reference to the theory developed in § 3.2, that the monomial mapping characterizing the (connected components) of the fibres of the VHS $\Phi_{U,I}$ is

$$\Delta^3 \xrightarrow{\mu} \mathbb{C}^4$$

$$(t_1, t_2, t_3) \mapsto (t_1 t_2, t_1 t_3, t_2 t_3, t_1 t_2 t_3).$$

We note that

1. The axes all map to a point.

The curves on the axes have moduli; their normalizations are ($\mathbb{P}^1$, 4 points) and the cross ratio of the 4 points gives the modulus. But this parameter is in the extension data of the limiting mixed Hodge structure and it disappears when we pass to the associated graded.

2. The level sets on the faces are parabolas $t_1 t_2 = c$, etc.

The curves on the faces have two moduli; their normalizations are ($E$, 2 points) where $E$ is an elliptic curve. The 2 points are in the extension data of the limiting mixed Hodge structure; the associated graded is the Hodge structure of $E$. Note that as $c \to 0$ the level sets tend to the two axes; this is the compatibility result (§ 3.2.5) in this case.

For the computation, we may choose a symplectic basis for $V = \mathbb{Z}^4$ with the standard alternating form so that

$$N_i = \begin{pmatrix} 0 & S_i \\ 0 & 0 \end{pmatrix}$$

where

$$S_1 = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \quad S_2 = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}, \quad S_3 = \begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}.$$  

9 The alert reader will notice that, while it carries the same information, this monomial map is not the same as that constructed in § 3.2. Specifically, that section yields the following:

- Since the $N_i$ are linearly independent, we have $S_\emptyset = 0$, so that $S_\emptyset^+ = \mathbb{R}^3$. This would contribute three monomials of the form (say) $t_1 t_2 t_3, t_1^2 t_2 t_3, t_1 t_2^2 t_3$.
- For $I = \{1\}$, we have $N_1, N_2 - N_3 \in W_{-1}(\text{ad } N_1)$ and $S_I = \text{span}\{(1, 0, 0), (0, 1, -1)\}$, so that $S_I^+ = \text{span}\{(0, 1, 1)\}$. This contributes the monomial $t_2 t_3$.
- For $I = \{1, 2\}$, we have $N_1, N_2, N_3 \in W_{-1}(\text{ad } N_I)$, so that $S_I = \mathbb{R}^3$ and $S_I^+ = 0$. This contributes no monomials.

So that $\mu(t) = (t_1 t_2, t_2 t_3, t_3 t_1, t_1 t_2 t_3, t_1^2 t_2 t_3, t_1 t_2 t_3 t_2^2) \in \mathbb{C}^6$. 
For example we may take for the vanishing cycles $\delta_1, \delta_2, \delta_3$ giving rise to the Picard-Lefschetz transformations corresponding to the $N_i$ to be those in the picture

Here the standard basis for $\mathbb{Z}^4$ is $e_1, e_2, f_1, f_2$, where $e_i$ corresponds to $\delta_i$ for $i = 1, 2$ and $f_i$ is the dual 1-cycle to $\delta_i$. The period matrix for the nilpotent orbit is

\[
\begin{pmatrix}
1 & 0 \\
0 & 1 \\
\ell(t_1 t_3) & \ell(t_3) \\
\ell(t_3) & \ell(t_2 t_3)
\end{pmatrix}.
\]

The $N_i$ are linearly independent so that the period mapping has no positive dimensional fibres in $(\Delta^*)^3$. On the face corresponding to $t_1 = 0$ which corresponds to the monodromy logarithm $N_1$, we have $e_1 \in W_1(N_1)$, $f_1 \in W_{-1}(N_1)$ and $e_2, f_2 \in W_0(N_1)$. Thus $W_{-1}(\text{ad} N_1)$ takes $e_1 \to \mathbb{Z} f_2$ and $e_2 \to \mathbb{Z} f_1$. And so it is the set of endomorphisms $\left( \begin{smallmatrix} 0 & 0 \\ 0 & 1 \end{smallmatrix} \right) \in \text{End}(V)$ where $S = \left( \begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix} \right)$. This gives $N_3 - N_2 - N_1 \in W_{-1}(\text{ad} N_1)$ and the monomial constant on the fibres is $t_2 t_3$.

As a final comment we note that

(3) The image of the monomial mapping $\Delta^3 \to \mathbb{C}^4$ lies in the toroidal algebraic variety

\[ z_2^2 = z_1 z_2 z_3. \]

As one sees from the construction of (3.2.36), this is a general feature of monomial mappings associated to nilpotent orbits.

3.4. Step 1.b: local construction for arbitrary VHS. We now consider the general case, dropping our assumption that the function $F(t, w)$ in (2.1.2) is constant.

3.4.1. Fibres of $\Phi_U$. Shrinking the neighborhood $\overline{U} \simeq \Delta^r$ if necessary, there exists a canonical choice of holomorphic map $X : \Delta^r \to g_\mathbb{C}$ so that

(3.4.1) $F(t, w) = \exp(X(t, w)) \cdot F(0).$

The map $X$ is determined as follows. (See [Cat14] for further discussion.) The pair $(W(N), F(0))$, where $N := N_1 + \cdots + N_k$ is the sum of the logarithms of the local unipotent monodromies about $b_0$, is a MHS. Let $g_\mathbb{C} = \oplus g^{p,q}$ be the Deligne splitting, and define

\[
g^{p,*} := \bigoplus_q g^{p,q}, \quad n := g^{<0,*} = \bigoplus_{p<0} g^{p,*} \quad \text{and} \quad p := g^{\geq0,*} = \bigoplus_{p \geq 0} g^{p,*}.
\]
then $g_C = p \oplus n$, $p$ is the Lie algebra of the stabilizer of $F(0)$ in $G_C$, and $n$ is a nilpotent Lie algebra. Consequently, there exists a unique holomorphic map

$$X : \Delta^r \to n$$

such that $X(0) = 0$ and (3.4.1) holds. Define holomorphic

$$X^{-p} : \Delta^r \to g^{-p} \cdot$$

by $X(t, w) = X^{-1}(t, w) + X^{-2}(t, w) + \cdots$. Horizontality of (3.4.1) implies that:

(i) The subspace $E(t, w) \subset g_{-1}$ spanned by $\{N_i + 2\pi \sqrt{-1} t_i \partial_i X^{-1}(t, w) \mid 1 \leq i \leq k\} \cup \{\partial_{w_j} X^{-1}(t, w) \mid 1 \leq j \leq \ell\}$ is abelian. In particular, $X(t, w)$, with $t_I \in \Delta_I^*$, commutes with $\{N_i \mid i \in I\}$.

(ii) The functions $X^{-p}(t, w)$, with $p \geq 2$, are functions of $\sum_{i=1}^k \ell(t_i) N_i + X^{-1}(t, w)$. In particular, $X^{-p}(t, w)$ is constant for all $p \geq 2$ if and only if $\sum_{i=1}^k \ell(t_i) N_i + X^{-1}(t, w)$ is constant.

The second implies that the vector field

$$v(t, w) := \sum_{i=1}^k a_i t_i \partial_{t_i} + \sum_{j=1}^\ell b_j \partial_{w_j},$$

on $U \simeq (\Delta^*)^k \times \Delta^\ell$ is tangent to the $\Phi_U$-fibre through $(t, w)$ if and only if

$$0 = d \left( \sum_{i=1}^k \ell(t_i) N_i + X^{-1}(t, w) \right) (v(t, w))$$

(3.4.2)

$$= \frac{1}{2\pi \sqrt{-1}} \sum_{i=1}^k a_i N_i + v(t, w) X^{-1}(t, w).$$

A change of variable will allow us to decouple this equation into two, one involving the $N_i$, and the second terms independent of the $N_i$; cf. (3.4.4).

3.4.2. Change of coordinates. Let $s = \dim \sigma_I \leq k$, and write $I = \{i_1, \ldots, i_k\}$ so that $\{N_{i_1}, \ldots, N_{i_s}\}$ is a maximal set of linearly independent vectors in $\{N_i \mid i \in I\}$. It will simplify notation, and cause no loss of generality, to assume $i_j = j$, for all $1 \leq j \leq k$. Fix a basis $\{N_1, \ldots, N_s, \xi_1, \ldots, \xi_t\}$ of $g^{-1} \cdot$, and define holomorphic functions $f_\alpha(t, w)$ and $g_\beta(t, w)$ by

$$X^{-1}(t, w) = \sum_{\alpha=1}^s f_\alpha(t, w) N_\alpha + \sum_{\beta=1}^t g_\beta(t, w) \xi_\beta.$$

Now consider the coordinates $(\tau, w)$ on $\Delta^k \times \Delta^\ell$ given by

$$\tau_i := \exp(2\pi \sqrt{-1} f_i(t, w)) t_i, \quad \forall 1 \leq i \leq s,$$

$$\tau_i := t_i, \quad \forall s + 1 \leq i \leq k.$$
Then
\[ \ell(\tau_i) := f_i(t, w) + \ell(t_i), \quad \forall \ 1 \leq i \leq s, \]
\[ \ell(\tau_i) := \ell(t_i), \quad \forall \ s + 1 \leq i \leq k, \]
so that
\[ (3.4.3) \quad \sum_{i=1}^{k} \ell(t_i)N_i + X^{-1}(t, w) = \sum_{i=1}^{k} \ell(\tau_i)N_i + \tilde{X}^{-1}(\tau, w), \quad \text{where} \]
\[ \tilde{X}^{-1}(\tau, w) := \sum_{\beta=1}^{t} g_{\beta}(\tau, w) \xi_{\beta}, \quad \text{with} \quad g_{\beta}(\tau, w) = g_{\beta}(t(\tau), w). \]
Notice that \( \tilde{X}^{-1}(\tau, w) \) is linearly independent of span\( \{ N_1, \ldots, N_k \} \) whenever \( \tilde{X}^{-1}(\tau, w) \neq 0. \)

The new coordinates have the properties:
(i) The sets \( \Delta^*_I = \{ t_i = 0, \ i \in I ; \ t_j \neq 0, \ j \notin I \} \) and \( \tilde{\Delta}^*_I := \{ \tau_i = 0, \ i \in I; \ \tau_j \neq 0, \ j \notin I \} \) agree.
(ii) There exists a holomorphic map \( \tilde{X} : \Delta^r \to \mathfrak{n}, \) with \( \tilde{X}(0,0) = 0 \) and \( g^{-1} \cdot \)–valued component equal to \( \tilde{X}^{-1}(\tau, w), \) so that the expression for (2.1.2) in the coordinates \( (\tau, w) \) is
\[ \Phi_U(\ell(\tau), w) = \exp \left( \sum_{i=1}^{k} \ell(\tau_i)N_i \right) \cdot \tilde{F}(\tau, w), \]
with \( \tilde{F}(\tau, w) = \exp(\tilde{X}(\tau, w)) \cdot F_0. \)

Therefore, there is no loss of generality in assuming that the \( (\tau, w) \) were our initial choice of coordinates \( (t, w) \). That is, we may suppose that the coordinates \( (t, w) \) where chosen so that \( f_{\alpha}(t, w) = 0. \) Then (3.4.2) holds if and only if
\[ (3.4.4) \quad 0 = \sum_{i=1}^{k} a_i N_i \quad \text{and} \quad 0 = v(t, w) X^{-1}(t, w). \]
Recall the monomial map \( \mu_0(\tau) = (t^c)_{c \in S_\theta} \) of (3.2.1) and regard \( (\mu_0, X) \) as a map \( (\Delta^*)^k \times \Delta^\ell \to \mathbb{C}^{[C]} \oplus \text{span}_{\mathbb{C}}(\xi_1, \ldots, \xi_t) \subset \mathbb{C}^{[C]} \oplus \mathfrak{g}_{-1}. \) The discussion above yields

**Proposition 3.4.5.** The set of connected components of the \( \Phi_U \)–fibres is precisely the set of connected components of the \( (\mu_0, X^{-1}) \)–fibres.

3.4.3. *Induced nilpotent orbits on strata.* Now suppose that \( I \subset \{1, \ldots, k\}. \) Let \( t_I = (t_1, \ldots, t_k) \in \Delta^*_I \) (that is, \( t_i = 0 \) if and only if \( i \in I \)). Recalling (2.1.2), the induced VHS (2.1.6)
\[ (3.4.6a) \quad \Phi_{U,I} : \Delta^*_I \times \Delta^\ell \subset \Delta^k \times \Delta^\ell \to \Gamma_{U,I} \setminus D_I \]
is given by
\[(3.4.6b) \Phi_{U,I}(t_I, w) = \exp \left( \sum_{j \not\in I} \ell(t_j) N^I_j \right) \cdot F_I(t_I, w), \]

where (as discussed in §2.1.1–2.1.2) the flag $F_I(t_I, w) \in \hat{D}_I$ is induced by $F(t_I, w) = \exp(X(t_I, w)) \cdot F(0) \in \hat{D}$, and $N^I_j : \text{Gr}_a W^{(N_I)} \to \text{Gr}_a W^{(N_I)}$ is the endomorphism induced by $N_j \in W_0(\text{ad} N_I), j \not\in I$. As in §3.4.1, we have $F_I(t_I, w) = \exp(X_I(t_I, w)) \cdot F_I(0)$, where

the holomorphic, Lie algebra valued $X_I(t_I, w)$ is a “quotient” of $X(t_I, w)$ that is defined as follows. From (2.1.7) and §3.4.1(i) we see that $X(t_I, w) \in W_0(\text{ad} N_I)$. Consequently, $X(t_I, w)$ induces $X_{I,a}(t_I, w) : \text{Gr}_a W^{(N_I)} \to \text{Gr}_a W^{(N_I)}$. Write $X_I(t_I, w) = (X_{I,a}(t_I, w))$. Moreover, the fact that $X(t_I, w)$ commutes with the $N_i, i \in I$, implies that $X_I(t_I, w)$ preserves the primitive subspaces (2.1.4), and is an infinitesimal isometry of the polarization (2.1.5).

Consequently, $\exp(X_I(t_I, w))$ is an automorphism of the (product of) period domain(s) $D_I$.

Let $X_I^{-1}(t_I, w) : \text{Gr}_a W^{(N_I)} \to \text{Gr}_a W^{(N_I)}$ be the endomorphism induced by $X^{-1}(t_I, w)$. Given $K \in \mathcal{K}_U$ define
\[\nu_K(t_I, w) := (X_I^{-1}(t_I, w))_{K=K_I}.\]

We leave it an exercise for the reader to show that the argument of §3.4.1 may be adapted (in a straightforward manner) to prove:

**Proposition 3.4.7.** Given $K \in \mathcal{K}_U$, the set of connected components of the $\Phi^*_{U,K}$-fibres is precisely the set of connected components of the $(\mu_K, \nu_K)$-fibres.

**3.4.4. Completion of $\Phi_U$.** Given $K \in \mathcal{K}_U$, recall (3.1.11), (3.1.12), and (3.1.13). Define
\[\nu := (\nu_K)_{K \in \mathcal{K}_U},\]

and set
\[\tau := (\mu, \nu).\]

Let
\[\Delta^r \xrightarrow{\tau^0} S_\tau \xrightarrow{\tau^0} \tau(\Delta^r)\]

be the Stein factorization of $\tau$. Then Proposition 3.4.7 and Lemma 3.2.38 imply the set of $\Phi_U^0$-fibres is precisely the set of $\tau^0$-fibres. This establishes

**Theorem 3.4.8** (Local completion of VHS). There is a canonical identification $\tilde{M}_U \simeq S_\mu$ as sets, under which $\Phi^0_U = \tau^0$. This gives $\tilde{M}_U$ (and then $\tilde{M}_U^0$) the structure of a complex analytic variety, and $\Phi^0_U$ is holomorphic with respect to this structure.
3.5. **Step 2: global construction.** Recall the notations/definitions of §3.1. We have a commutative diagram

\[
\begin{array}{ccc}
\widetilde{U} & \xrightarrow{\Phi_\emptyset^\circ} & \widetilde{M_\emptyset} & \xrightarrow{\Phi_\emptyset^\circ} & M_\emptyset \\
\downarrow & & \downarrow \rho_\emptyset & & \\
\overline{B} & \xrightarrow{\Phi^\circ} & \overline{M} & \xrightarrow{\Phi^\circ} & M.
\end{array}
\]

(3.5.1)

The surjection \( \rho : \overline{M_\emptyset} \to \overline{M} \) is given by passing from the quotient by the local monodromy to the quotient by the full monodromy. Specifically, when restricted to strata \( \overline{U} \cap Z^*_K = \Delta^*_K \times \Delta^\ell \), the diagram (3.5.1) becomes

\[
\begin{array}{ccc}
\overline{U} \cap Z^*_K & \xrightarrow{\Phi^\circ_{\emptyset, K}} & \widetilde{M^*_{\emptyset, K}} & \xrightarrow{\Phi^\circ_{\emptyset, K}} & M^*_\emptyset \\
\downarrow & & \downarrow & & \\
Z^*_K & \xrightarrow{\Phi^\circ_K} & \widetilde{M_K} & \xrightarrow{\Phi^\circ_K} & M_K.
\end{array}
\]

with \( \rho_K : \Gamma^*_{\emptyset, K} \setminus D_K \to \Gamma_K \setminus D_K \) the obvious projection. We have seen that \( \widetilde{M^*_\emptyset} \) has the the structure of a complex analytic variety (Theorem 3.4.8). We claim that \( \widetilde{M^*_\emptyset} \) is a local coordinate chart for \( \Phi_\emptyset(\overline{U}) \subset \overline{M} \) in the sense that the fibres of \( \rho \circ \Phi_\emptyset^\circ \) are finite. Equivalently, it suffices to show that the fibres of \( \rho_K \circ \Phi^*_{\emptyset, K} \) are finite. We will prove this for \( K = \emptyset \); the argument will obviously apply to all strata. For \( K = \emptyset \) the diagram is

\[
\begin{array}{ccc}
\overline{U} & \xrightarrow{\Phi^\circ_{\emptyset, \emptyset}} & \widetilde{M^*_{\emptyset, \emptyset}} & \xrightarrow{\Phi^\circ_{\emptyset, \emptyset}} & M^*_{\emptyset} \\
\downarrow & & \downarrow \rho_{\emptyset} & & \\
\overline{B} & \xrightarrow{\Phi^\circ_{\emptyset}} & \overline{M_{\emptyset}} & \xrightarrow{\Phi^\circ_{\emptyset}} & M \subset \Gamma \setminus D.
\end{array}
\]

**Proposition 3.5.2.** The fibres of \( \rho_{\emptyset} \circ \Phi^*_{\emptyset, \emptyset} : \widetilde{M^*_{\emptyset, \emptyset}} \to M \) are finite.

We shall derive this proposition in §3.5.1 as a consequence of Cattani–Deligne–Kaplan’s result on the algebraicity of Hodge loci.

3.5.1. **Cattani–Deligne–Kaplan.** We consider the global VHS given by the product

\[
\Phi \times \Phi : B \times B \to (\Gamma \setminus D) \times (\Gamma \setminus D).
\]

(3.5.3)
In terms of local systems (Remark 3.5.1), we think of $\Phi$ as given by a local system $\mathcal{V}_Z \to B$ with $\mathcal{V} = \mathcal{V}_Z \otimes \mathbb{Q}$ satisfying the usual conditions, and using the bilinear form $Q$ we identify the fibre $\mathcal{V}_{b_1} \otimes \mathcal{V}_{b_2}$ over $(b_1, b_2) \in B \times B$ with $\text{Hom}(\mathcal{V}_{b_1}, \mathcal{V}_{b_2})$. The condition to have a morphism of Hodge structures

$$\zeta : \mathcal{V}_{b_1} \to \mathcal{V}_{b_2}$$

preserving the integral structure is then equivalent to having an integral Hodge class $\zeta \in \text{Hom}(\mathcal{V}_{Z,b_1}, \mathcal{V}_{Z,b_2})$. The condition that under parallel transport $\zeta$ remain a Hodge class in a neighborhood of $(b_1, b_2)$ in $B \times B$ defines a local analytic subvariety in the neighborhood. Cattani, Deligne and Kaplan’s result on the algebraicity of Hodge loci [CDK95, Theorem 1.1] has the following immediate consequence:

**Theorem 3.5.4** (Cattani–Deligne–Kaplan). The locus $\mathcal{H}_c := \{ (b_1, b_2) \in B \times B \mid \exists \text{ an integral Hodge class } \zeta \in \text{Hom}(\mathcal{V}_{Z,b_1}, \mathcal{V}_{Z,b_2}) \text{ with Hodge length } \| \zeta \| \leq c \}$ is a global algebraic subvariety in $B \times B$.

By a *determination* $\mathcal{V} \simeq \mathcal{V}_Z$ we mean an identification of $\mathcal{V}$ with $\mathcal{V}_Z$ up to the action of the global monodromy group $\Gamma \subset \text{Aut}(\mathcal{V}_Z, \mathcal{Q})$.\(^{11}\)

**Corollary 3.5.5.** The locus $\mathcal{J} := \{ (b_1, b_2) \in B \times B \mid \exists \xi \in \text{Hom}(\mathcal{V}_{Z,b_1}, \mathcal{V}_{Z,b_2}) \text{ such that } \exists \text{ determinations } \mathcal{V}_{Z,b_1} \simeq \mathcal{V}_Z, \mathcal{V}_{Z,b_2} \simeq \mathcal{V}_Z \text{ with respect to which } \xi \text{ is the identity} \}$ is a global algebraic subvariety in $B \times B$.

**Proof of Corollary 3.5.5.** Let $\|\text{id}\|$ denote the Hodge length of the identity $\text{id} : \mathcal{V}_Z \to \mathcal{V}_Z$. Then $\mathcal{J}$ is a subvariety of $\mathcal{H}_{\|\text{id}\|}$ and the corollary follows from Theorem 3.5.4.\(\square\)

**Proof of Proposition 3.5.2.** Let $\mathcal{U}_i \simeq (\Delta^*)^{k_i} \times \Delta^{\ell_i}, i = 1, 2$, be two neighborhoods at infinity in $B$, and let $\Phi_{\mathcal{U}_i} : \mathcal{U}_i \to \Gamma_{\mathcal{U}_i}/\Delta$ be the local variations of Hodge structure (2.1.2). Then the restriction of (3.5.3) to $\mathcal{U}_1 \times \mathcal{U}_2$ factors

$$
\begin{array}{c}
\mathcal{U}_1 \times \mathcal{U}_2 \\
\Phi_{\mathcal{U}_1} \times \Phi_{\mathcal{U}_2} \to (\Gamma_{\mathcal{U}_1}/\Delta) \times (\Gamma_{\mathcal{U}_2}/\Delta) \\
\rho_0 \times \rho_0 \to (\Gamma/\Delta) \times (\Gamma/\Delta).
\end{array}
$$

Recall the Stein factorization $\Phi_{\mathcal{U}_i} = \Phi_{\mathcal{U}_i,0} \circ \Phi_{\mathcal{U}_i,0}$. This gives us a factorization

$$(\Phi \times \Phi)_{|\mathcal{U}_1 \times \mathcal{U}_2} = (\rho_0 \times \rho_0) \circ (\Phi_{\mathcal{U}_1,0} \times \Phi_{\mathcal{U}_2,0}) \circ (\Phi_{\mathcal{U}_1,0} \times \Phi_{\mathcal{U}_2,0}).$$

The fibres of $\Phi_{\mathcal{U}_1,0} \times \Phi_{\mathcal{U}_2,0}$ are connected, while the fibres of $(\rho_0 \times \rho_0) \circ (\Phi_{\mathcal{U}_1,0} \times \Phi_{\mathcal{U}_2,0})$ are discrete. We wish to see that these discrete fibres are finite over the diagonal $\Gamma/\Delta \hookrightarrow \Gamma/\Delta \times \Gamma/\Delta$. If we define

$$\mathcal{R} := \{ (b_1, b_2) \in B \times B \mid \Phi(b_1) = \Phi(b_2) \},$$

\(^{10}\)See also [CK14] for a clear summary and discussion.

\(^{11}\)The issue of whether or not $\Gamma$ is an arithmetic group does not enter (so that e.g. $\Gamma$ could be a thin matrix group).
then this is equivalent to showing that $\mathcal{R} \cap (\mathcal{U}_1 \times \mathcal{U}_2)$ consists of only finitely many components.

(i) If $\Gamma = \text{Aut}(V_Z, Q)$, then $\mathcal{R} = \mathcal{I}$ and the desired result follows from Corollary 3.5.5. However, if $\Gamma \not\subseteq \text{Aut}(V_Z, Q)$, then we have only $\mathcal{R} \subset \mathcal{I}$. Recall that $M = \Phi(B)$ has finite volume [Gri70b, Theorem 9.6]. This implies that

(ii) the fibres of the projection of $M = \Phi(B) \subset \Gamma \backslash D$ to $\text{Aut}(V_Z, Q) \backslash D$ are finite.

The proposition now follows from (i) and (ii). $\square$

**Remark 3.5.6.** It is instructive to review the essential (for us) implication of Theorem 3.5.4 in the case that $\dim B = 1$. For this we localize around a point $p \in \overline{B} \backslash B$ where we have the picture

Here we identify the slit disc with the strip $|\text{Re } z| < 1/2$ in the upper-half-plane and think of $t_n, t'_n$ as being points $(\tilde{t}_n, \tilde{t}'_n)$ in this strip with $\text{Im } \tilde{t}_n, \text{Im } \tilde{t}'_n \to \infty$. Then $\Phi(t_n) = \Phi(t'_n)$ in $\Gamma \backslash D$ is equivalent to $\gamma_n \tilde{\Phi}(\tilde{t}_n) = \tilde{\Phi}(\tilde{t}'_n)$. By restricting to the strip $|\text{Re } z| < 1/2$ we have eliminated the local monodromy around the puncture. Therefore, if $t_n, t'_n$ are infinite sequences of points tending to the origin in $\Delta^*$ and that are identified by $\Phi$ in $\Gamma \backslash D$, then we conclude that $\Phi$ is constant. What this means is that the image of $\Delta^*$ in $\Gamma \backslash D$ cannot look like

(The idea in the picture is that the $\bigcirc$'s should be approaching the origin.) A similar argument shows that we cannot localize around two different points $p, p'$ in $\overline{B} \backslash B$ to have a picture

where $\Phi(t_n) = \Phi(t'_n)$ in $\Gamma \backslash D$.

4. **Curvature properties of the extended Hodge bundle: the surface case**

Theorem 1.3.10 is a central ingredient in the proof of Theorem 1.3.8. We give two proofs of Theorem 1.3.10. The first, given in this section, will be inductive on the singular strata of the boundary divisor. Moreover, it will be restricted to the geometric case arising from a family of varieties, one of the points being that in this situation the singularities of
the Hodge norms are localizable and visible analytically in a way that is suggestive of the general case. The second argument is given in §5; it provides a proof of the general result. (Finally, Theorem 1.3.8 is proved in §6.)

Throughout this section we assume that \( n = 2 \); in particular, the Hodge bundle and the augmented Hodge bundle coincide (\( \Lambda = \hat{\Lambda} \)).

4.1. **Currents.** We begin by discussing two general properties of currents that will arise. On an \( n \)-dimensional complex manifold \( Y \), we denote by \( A^{p,q}_c(Y) \) the compactly supported smooth \((p,q)\) forms. A current \( T \) of type \((p,q)\) gives a linear function

\[
T_\psi(\alpha) = \int_Y \psi \wedge \alpha.
\]

The currents we shall encounter will be differential \((p,q)\) forms \( \psi \) with coefficients in the space of locally \( L^1 \) functions, and the corresponding current \( T_\psi \) is given by

\[
T_\psi(\alpha) = \int_Y \psi \wedge \alpha.
\]

The differential \( \partial T_\psi(\alpha) \) is defined as usual by

\[
\partial T_\psi(\beta) = \pm \int_Y \psi \wedge \partial \beta,
\]
where the sign is determined by the condition that \( \partial T_\psi = T_{\partial \psi} \) when \( \psi \) is smooth. Similarly we may define \( \partial T_\psi \) and \( \partial \partial T_\psi \).

For the \( \psi \)'s we shall use, we will also be able to define \( \partial \psi \) by applying the formal rules of calculus to the coefficient functions of \( \psi \). The equality

\[
(4.1.1) \quad \partial T_\psi = T_{\partial \psi}
\]

shall mean: first the coefficients \( \partial \psi \) computed formally are locally \( L^1 \) functions; and secondly that the currents satisfy (4.1.1). Similar notions hold for \( \overline{\partial} T_\psi \) and \( \overline{\partial} \partial T_\psi \).

**Definition** 4.1.2. We shall say that the current represented by a locally \( L^1 \) differential form \( \psi \) has the property NR if \( \partial \psi, \overline{\partial} \psi, \overline{\partial} \partial \psi \) computed formally have \( L^1 \) coefficients, and if (4.1.1) holds for \( \partial \psi, \overline{\partial} \psi \) and \( \overline{\partial} \partial \psi \). The term “NR” is meant to suggest “no residues.”

**Remark** 4.1.3. The property NR implies that the currents defined by \( \psi, \partial \psi, \partial \partial \psi \) have vanishing Lelong numbers (cf. [Dem12]).

**Example** 4.1.4. In \( \mathbb{C} \), we have \( \partial \overline{\partial} \log |z| = 0 \) formally, while up to a constant the equation of currents

\[
\partial \overline{\partial} T_{\log |z|} = \delta_0 dz \wedge d\bar{z}
\]

holds. On the other hand, again up to a constant,

\[
\partial \overline{\partial} \log (- \log |z|) = \frac{dz \wedge d\bar{z}}{|z|^2 (\log |z|)^2}
\]

\[\text{Cf. [Dem12] for a general account and references to the literature.}\]
holds both formally and in the sense of currents, so $\log (\log |z|)$ has the property NR while $\log |z|$ does not.

In both these examples the coefficients of the derivatives computed formally are in $L^1$; the difference is that for $\log |z|$ we pick up a residue term in $\partial \overline{\partial} T_{\log |z|}$, while no such term arises in $\partial \overline{\partial} T_{\log (-\log |z|)}$.

For the second property we first recall that a current $T$ on $Y$ has a singular support $\text{sing} T \subset Y$, defined to be the smallest closed subset such that on the complement $Y \setminus \text{sing} T$, the current $T$ is represented by a smooth differential form.

**Remark 4.1.5.** In this work we will want to restrict singular differential forms to submanifolds. Our approach here is motivated by the notion the wave front set $\text{WF}(T) \subset T^*Y$. If $W \subset Y$ is a submanifold, then in general the restriction to $W$ of a distribution or current $T$ given on $Y$ is not defined. However if $W \subset Y$ is a submanifold whose tangent spaces are transverse to the wave front set in the sense that

$$TW \subset \text{WF}(T)^\perp$$

then the restriction $T|_W$ is valid. The singular differential forms that we work with will satisfy an analogous (and essential) restriction property.

**Example 4.1.7.** As an illustration of what will occur, we note as above that the currents we shall be interested in will be constructed from locally $L^1$-functions. It may or may not be possible to simply restrict such a function in the usual sense and obtain a well-defined function. As a simple example of what will be done below, on $\Delta \times \Delta$ with coordinates $(t,w)$, the current given by $1/\log |t| + f(w)$ where $f(w)$ is smooth may be restricted to $\{0\} \times \Delta$ to give $f(w)$.

### 4.2. Singularity structure.

**Definition 4.2.1.** A positive function $h$ defined in $U \cong \Delta^* \times \Delta^\ell$ is said to have logarithmic singularities if it is of the form

$$h = P (\log |t_1|^{-1}, \ldots, \log |t_k|^{-1}) + R (\log |t_1|^{-1}, \ldots, \log |t_k|^{-1})$$

Here $P(x_1, \ldots, x_k)$ a homogeneous polynomial whose coefficients are real, take value in $C^\infty(\overline{U})$, and are positive in the sense that

$$P(x_1, \ldots, x_k) > 0 \text{ if all } x_i > 0.$$

The polynomial $R$ is real, has $C^\infty(\overline{U})$ coefficients, and is of lower order than $P$ in the sense to be explained below. Finally $h$ satisfies the following conditions:

(i) $\log h$ has the property NR;

Note that “$\partial \log |z|$ computed formally in in $L^1$” means that $\partial \log |z| \wedge \alpha$ is in $L^1$ for any $C^\infty$ form $\alpha$.

A good discussion of this with illustrative examples and references may be found on Wikipedia.

To be precise, the notation $\log |t|^a$ indicates $\log(|t|^a)$; we drop the parentheses to streamline notation.
(ii) the current $\Omega_h := (i/2)\partial\bar{\partial} \log h$ is positive and has the property that the restriction to $\Delta_1^* \times \Delta_\ell^*$ is well-defined. (Note that the last is the analog of (4.1.6) that we require.) Because of (i) the current $\Omega_h$ is defined on $\Delta^k \times \Delta^\ell$ so that (ii) makes sense.

(4.2.2)

For the remainder of this section, and for all of §4.3, we will restrict to the case $k = 1$, so that $\mathcal{U} \cong \Delta^* \times \Delta^\ell$.

Remark 4.2.3. This is essentially the case of 1-parameter degenerations with dependence on holomorphic parameters. In fact, for notational simplicity, we shall also assume that $\ell = 1$, so that we are working in $\Delta^* \times \Delta$ with coordinates $(t, w)$.

The functions $h$ we shall consider will be of the form

$$ h = A(t, w) \left( \log |t|^{-1} \right)^m \left( 1 + \frac{B_1(t, w)}{\log |t|^{-1}} + \cdots + \frac{B_m(t, w)}{(\log |t|^{-1})^m} \right) $$

where $A(t, w)$ and the $B_i(t, w)$ are $C^\infty$ functions on $\Delta \times \Delta$ and $A(0, w) > 0$. We note that the expression (4.2.4) is invariant under holomorphic coordinate changes

$$ \begin{cases} 
  t' = tf(t, w) & f(t, w) \neq 0 \\
  w' = g(t, w) & g_w(0, u) \neq 0.
\end{cases} $$

As will be seen below, the motivation for considering functions of this form arises from the periods of holomorphic differentials in a degenerating family of algebraic varieties.

Proposition 4.2.6. The function (4.2.4) has logarithmic singularities.

Proof. Denoting by $C$ the term in parentheses, since $\log h = \log A + \log(m \log |t|^{-1}) + \log C$ the only issue concerns the log $C$ term. In

$$ \partial\bar{\partial} \log C = \frac{\partial C}{C} \wedge \frac{\overline{\partial} C}{C} - \frac{\partial\overline{\partial} C}{C^2} $$

we shall separately examine the singularities in each term. For the first the most singular terms arise from:

- $\partial \left[ \frac{1}{(\log |t|^{-1})^a} \right] \wedge \overline{\partial} \left[ \frac{1}{(\log |t|^{-1})^b} \right]$, with $a, b > 0$. This is of the order $\frac{dt \wedge d\overline{t}}{|t|^2 (\log |t|^{-1})^c}$, with $c \geq 4$, and hence is $o(\text{PM})$, where

$$ \text{PM} := \frac{dt \wedge d\overline{t}}{|t|^2 (\log |t|^{-1})^2} $$

is the Poincaré metric.

- $\partial \left[ \frac{1}{(\log |t|^{-1})^a} \right] \wedge \alpha$, with $a > 0$ and $\alpha$ smooth ($C^\infty$). This is of the order $\frac{dt}{|t| (\log |t|^{-1})^c} \wedge \beta$, with $c \geq 2$ and $\beta$ smooth, and is again $o(\text{PM})$. 

The terms $\partial \log C$ and $\partial \log C$ may be estimated by those above. For $\partial \partial C/C^2$, the most singular terms are of the order $\partial \partial [\frac{1}{(\log |t|^{-1})^a}] \sim \frac{dt \wedge d\bar{t}}{|t|^2 (\log |t|^{-1})^{a+2}}$, with $a \geq 1$, which is again $o(\text{PM})$.

Note that the estimates in this argument have no room to spare. □

4.3. Proof of Theorem 1.3.10 in the weight $n = 2$ case. We denote by

$$\Omega_h = \frac{\sqrt{-1}}{2} \partial \partial \log h$$

the curvature form associated to the function $h$ in (4.2.4). Then

$$(4.3.1) \Omega_h = m \frac{\sqrt{-1}}{2} A(v, w) \frac{dt \wedge d\bar{t}}{|t|^2 (\log |t|)^2} + o(\text{PM})$$

and, assuming that $m > 0$, it is positive with

$$\text{sing} \Omega_h = \{0\} \times \Delta.$$

It defines a closed, positive $(1,1)$ current on $\Delta \times \Delta$ (cf. [CKS86] and [Kol87]). As for $\text{WF}(\Omega_h)$, the terms in $\Omega_h$ not containing a $dt$ or $d\bar{t}$ are of the form $\gamma (\log |t|)^{-a}$, where $\gamma$ is a smooth $(1,1)$ form and $a > 0$. Thus although it is not the case that $\text{WF}(\Omega_h) = N^*_{\{0\} \times \Delta/\Pi}$ is the co-normal bundle of $\{0\} \times \Delta$ in $\Delta \times \Delta$ in the usual sense, the restriction $\Omega_h|_{\{0\} \times \Delta}$ is a well-defined smooth $(1,1)$ form. Indeed, the above calculation shows that to define restriction we may use the prescription:

- In the formula for $\partial \partial \log h$ first set $dt = d\bar{t} = 0$.
- Then the limit as $t \to 0$ of the remaining terms exists (i.e., set $1/\log |t|^{-1} = 0$).

The calculation in the proof of Proposition 4.2.6 gives

$$(4.3.2) \Omega_e|_{\{0\} \times \Delta} = \frac{\sqrt{-1}}{2} \partial \partial \log A(0, w).$$

The point in (ii) is that in what remains after (i), the term $\log |t|^{-1}$ only appears in the denominator and with positive powers. We note that the above prescription is invariant under the coordinate changes (4.2.5).

We now apply the above to a weight $n = 2$ variation of Hodge structure over $\Delta^* \times \Delta$. Denote the canonically extended Hodge bundle by $F_e \to \Delta \times \Delta$ and let $\sigma(t, w)$ be a nowhere vanishing holomorphic section of this bundle. We assume that $m$ is maximal with $\sigma \in W_{n+m}(N) \cap F_e$, and denote by $\sigma_m(w)$ the projection of $\sigma(0, w)$ in $\text{Gr}^W_{n+m}(N) F_e$. Then $\sigma_m(w)$ is a non-zero section of $\text{Gr}^W_{n+m}(N) \cap F_e$ over $\{0\} \times \Delta$.

**Proposition 4.3.3.** The Hodge norm $\|\sigma(t, w)\|^2$ is of the form (4.2.4), and

$$\partial \partial \log \|\sigma(t, w)\|^2|_{\{0\} \times \Delta} = \partial \partial \log \|\sigma_m(w)\|^2.$$

A consequence of the proposition is the following special case of Theorem 1.3.10.
Corollary 4.3.4. If $\Omega_e$ is the Chern form of the extended Hodge line bundle $\Lambda_e \rightarrow \Delta \times \Delta$, and if $\Omega_{\{0\} \times \Delta}$ is the Chern form of the gradeds to the associated variation of mixed Hodge structure along $\{0\} \times \Delta$, then the restriction $\Omega_e|_{\{0\} \times \Delta}$ is defined agrees with $\Omega_{\{0\} \times \Delta}$.

Proof of Proposition 4.3.3. We shall prove the proposition in the weight $n = 2$ geometric case of a family $X^* \rightarrow \Delta^* \times \Delta$ of smooth surfaces where $\sigma(t, w)$ is a section of $\pi_* \omega_{X/\Delta^* \times \Delta}$ given by a family

$$
\psi(t, w) \in H^0(\Omega^2_{X(t, w)})
$$

of holomorphic 2-forms along the smooth fibres $X_{(t, w)} = \pi^{-1}(t, w)$. By base change and semi-stable reduction we may assume that we have a smooth completion $X \rightarrow \Delta \times \Delta$ of the family where the singular fibres $X_{(0, w)}$ have normal crossings. The local models are

(a) $X_{(0, w)}$ is smooth and the mapping $\pi$ is locally given by $(x_1, x_2, x_3, w) \rightarrow (x_1, w)$; i.e., $t = x_1$;

(b) $X_{(0, w)}$ has a smooth double curve and the mapping $\pi$ is given by $(x_1, x_2, x_3, w) \rightarrow (x_1 x_2, w)$; i.e., $t = x_1 x_2$;

(c) $X_{(0, w)}$ has a double curve with triple points and the mapping $\pi$ is locally given by $(x_1, x_2, x_3, w) \rightarrow (x_1 x_2 x_3, w)$; i.e., $t = x_1 x_2 x_3$.

By a standard property of the canonical extension, the 2-forms giving sections of $\pi_* \omega_{X/\Delta^* \times \Delta}$ are locally Poincaré residues

$$
\psi(t, w) = \text{Res} \left[ \frac{g(x_1, x_2, x_3, w) dx_1 \wedge dx_2 \wedge dx_3}{f(x_1, x_2, x_3, w)} \right]
$$

where $g$ is holomorphic and $f$ is given by

(a) $f = x_1 - t$,

(b) $f = x_1 x_2 - t$,

(c) $f = x_1 x_2 x_3 - t$

in the three cases listed above. The properties of the extension $\psi(0, w)$ to a section of $F_0 \rightarrow \{0\} \times \Delta$ relative to the weight fibration are, for each of the cases above:

(a) The double and single residues of $\psi(0, w)$ are zero. Then $\psi(0, w)$ induces a non-zero section of $\text{Gr}_2^{W(N)}$ and $\psi(0, w)$ is a holomorphic 2-form on the desingularization $\tilde{X}_{(0, w)}$ of $X_{(0, w)}$.

(b) The double residues of $\Psi(0, w)$ are zero. Then $\psi(0, w) \in W_3(N)$ and $\psi(0, w)$ induces a non-zero section in $\text{Gr}_3^{W(N)}$ if the single residues of $\psi(0, w)$ along the double curve are non-zero; i.e., if $g(0, 0, 0, w) = 0$ but $g(x_1, 0, x_3, w) \neq 0$.

(c) The form $\psi(0, w)$ induces a non-zero section in $\text{Gr}_4^{W(N)}$ if, and only if, the double residues of $\psi(0, w)$ at the triple points are not all zero; i.e., if $g(0, 0, 0, w) \neq 0$.

The Hodge norm is, up to a constant, the $L^2$-norm

$$
\|\psi(t, w)\|^2 = \int_{X_{(t, w)}} \psi(t, w) \wedge \overline{\psi(t, w)}
$$
of the holomorphic 2-forms $\psi(t, w)$. Then $\|\psi(t, w)\|^2$ has an expansion in terms of powers of $\log |t|^{-1}$, and the local contributions to the expansion in each of the above cases are respectively

(a) $\|\psi(t, w)\|^2 = \int |g(0, x_2, x_3, w)|^2 dx_2 \wedge d\bar{x}_2 \wedge dx_3 \wedge d\bar{x}_3$, 

(b) $\|\psi(t, w)\|^2 = \left( \int |g(x_1, 0, 0, w)|^2 dx_1 \wedge d\bar{x}_1 \right) \log |t|^{-1} + C(t, w)$, 

(c) $\|\psi(t, w)\|^2 = |g(0, 0, 0, w)|^2 (\log |t|^{-1})^2 + B_1(t, w) \log |t|^{-1} + B_2(t, w)$,

where $B_1, B_2, C$ are smooth functions. This establishes the first part of the proposition: namely, that the Hodge norms are of the form (4.2.4).

For the second part we will discuss the above three cases. In case (a) the 2-form $\psi(0, w)$ is holomorphic on the desingularization $\tilde{X}_{(0, w)}$ and the polarizing form is just the usual one given by $\int_{\tilde{X}_{(0, w)}} \psi(0, w) \wedge \psi(0, w)$.

In case (b) $\sigma_3(w)$ is a section of $Gr^{W(N)}_3 (LMHS)$, which is a Tate twist of a variation of Hodge structure of weight one. Geometrically, the double residues of $\psi(0, w)$ are zero and the single residues induce holomorphic 1-forms $Res \psi(0, w)$ on the normalization $\tilde{D}_w$ of the double curve of $X_{(0, w)}$. In this case there are two potential polarizing forms

(i) $Q(Nu, v)$ on $Gr^{W(N)}_3 (LMHS)$ (Hodge-theoretic one); 

(ii) $\int_{\tilde{D}_w} Res \psi(0, w) \wedge \overline{Res \psi(0, w)}$ (algebro-geometric one).

Up to a constant these polarizations agree; in §4.4 we will prove

**Proposition 4.3.5.** On $Gr^{W(N)}_3 (LMHS)$ the polarizing form arising from the limiting mixed Hodge structure coincides with the natural polarizing form on sub-Hodge structures of $H^{1,0}(\tilde{D}_w)$. (This result holds in full generality for $\pi_* \omega_X/(\Delta^\epsilon)^k \times \Delta^\epsilon$.)

In case (c), $\sigma_4(w)$ is a section of $Gr^{W(N)}_4 (LMHS)$, which is a family of polarized Hodge-Tate structures along $\{0\} \times \Delta$. The period domain is 0-dimensional and its curvature form $\sqrt{1/2} \partial \bar{\partial} \log A(0, w)$, where $A(0, w) = |h(w)|^2$ with $h(w)$ holomorphic, is zero. However, it is of interest to observe that the polarizing form on $Gr^{W(N)}_4 (LMHS)$ is by definition $Q(N^2 u, \bar{v})$. On the other hand

$$h(w) = \sum \text{double residues of } \psi(0, w),$$

where the sum is over a subset of the double residues at the triple points of $X_{(0, w)}$. The identifications of the polarizing form on $Gr^{W(N)}_4 (LMHS)$ with $|h(w)|^2$ will be discussed in §4.4.

---

16 More precisely, one has a family of Hodge metrics on a single Hodge structure (this one being Hodge-Tate). This defines a Hermitian line bundle on the parameter space, and the associated curvature form is zero.
Proof of Corollary 4.3.4. We take a section
\[ \sigma(t, w) = \psi_1(t, w) \wedge \cdots \wedge \psi_p(t, w) \]
of \( \det F_e \) where the \( \psi_i(t, w) \) give a framing of the canonically extended Hodge vector bundle \( F_e \rightarrow \Delta \times \Delta \) that is adapted to the weight filtration \( W(N) \cap F_e \). As previously noted, that means that we filter the sections of \( F_e \rightarrow \Delta \times \Delta \) by their logarithmic growth along \( \{0\} \times \Delta \). Setting \( h^0 = \dim I^{0,0} \) and \( h^{1,0} = \dim I^{1,0} \), where we recall the \( I^{p,q} \) are the Hodge decomposition of \( \text{Gr}(\text{LMHS}) \) along \( \{0\} \times \Delta \), the calculation in the proof of the proposition gives that up to a constant
\[ \Omega_e = (2h^0 + h^{1,0})\text{PM} + \text{LOT} \]
where \( \text{LOT} \) are lower order terms in the sense that that the ratio \( \text{LOT}/\text{PM} \) tends to zero as \( t \to 0 \). Moreover the restriction \( \Omega_e|_{\{0\} \times \Delta} \) of the current \( \Omega_e \) is defined and there it coincides with the Chern form of the Hodge line bundle for the VHS over \( \{0\} \times \Delta \) given by the associated graded to the LMHS defined there. □

Remark 4.3.6. As noted in Remark 4.2.3, the assumption \( \ell = 1 \) was made only for notational convenience. It is straightforward to see that both Proposition 4.3.3 and Corollary 4.3.4 hold for the general case \( w \in \Delta^\ell \).

At this point we may complete the argument for Theorem 1.3.10 in the introduction in the special case where we consider only the weight \( n = 2 \) case, and we restrict to the geometric situation where the period mapping (1.1.1) arises from a projective family \( X^* \rightarrow \Delta^k \times \Delta^\ell \) of smooth algebraic surfaces.

Proof of Theorem 1.3.10 in the weight \( n = 2 \) case. Given Remark 4.2.3 Corollary 4.3.4 establishes the result for \( k = 1 \). To complete the argument we now consider the case of a period mapping (1.1.1) for arbitrary \( k \) and \( \ell \). It suffices to prove

Claim 4.3.7. The general case may be reduced to the case \( k = 1 \) by a succession of 1-parameter degenerations.

The claim is a consequence of the several-variable SL(2) orbit theorem [CKSS6]. We will prove the claim in the case that \( k = 2 \), the argument extends in a straightforward fashion.

Recall (2.1.2) that the nilpotent orbit approximating the degeneration \( \lim_{t_1 \to 0} \Phi(t_1, t_2; w) \) induces a variation of polarized Hodge structure (VPHS) \( \Phi_1(t_2, w) \) over \( \Delta^* \times \Delta^\ell \). Likewise the degeneration \( \lim_{t_2 \to 0} \Phi_1(t_2, w) \) induces a VPHS \( \Phi_{12}(w) \) over \( \Delta^\ell \). Similarly, the degeneration \( \lim_{t_2 \to 0} \Phi_{12}(w) \) induces a VPHS \( \Phi(w) \) over \( \Delta^\ell \). It is a consequence of the SL(2) orbit theorem that \( \Phi(w) = \Phi_{12}(w) \), and this establishes the claim. □
4.4. **Proof of Proposition 4.3.5.** We will describe the limiting mixed Hodge structure and its polarization for a family of surfaces $X \xrightarrow{\pi} \Delta$ with central fibre $X = \bigcup_{i \in I} X_i$, with $I$ and ordered index set, a reduced normal crossing divisor in a smooth 3-fold $X$. The usual notations

$$X^{[1]} = \coprod_i X_i, \quad X^{[2]} = \bigcap_{i<j} X_i \cap X_j, \quad X^{[3]} = \bigcap_{i<j<k} X_i \cap X_j \cap X_k$$

will be used for the desingularized strata of $X$.

4.4.1. **The limiting mixed Hodge structure.** The groups that appear in the complex whose cohomology gives the associated graded to the LMHS are $H_a(X^{[b]})(-c), 0 \leq c \leq b-1$. The $I_{\ell} = \text{Gr}_{\ell} W(N) = \bigoplus_{p+q=\ell} I_{p,q}, \quad 0 \leq \ell \leq 4.$

are the $E_2$-terms of a spectral sequence, where the $E_1$-terms and differential $d_1: E_1 \to E_1$ will now be described in dual pairs.

Letting $G$ and $R$ denote the Gysin and restriction maps, respectively, for $\text{Gr}_4 W(N)$ and $\text{Gr}_0 W(N)$ we have the dual complexes

$$(4.4.1a) \quad H^0(X^{[2]})(-2) \xrightarrow{G} H^2(X^{[1]})(-1) \xrightarrow{G} H^4(X^{[1]})$$

$$(4.4.1b) \quad H^0(X^{[1]}) \xrightarrow{R} H^0(X^{[2]}) \xrightarrow{R} H^0(X^{[1]}).$$

The initial and terminal cohomology groups are

$$(4.4.2a) \quad I_4 = \{I^{2,2} = \ker \{G : H^0(X^{[2]})(-2) \to H^2(X^{[1]})(-1)\}\}$$

$$(4.4.2b) \quad I_0 = \{I^{0,0} = \text{coker} \{R : H^0(X^{[2]}) \to H^0(X^{[1]})\}\}.$$ 

Here $N^2 : I^{2,2} \to I^{0,0}$ is the “identity” under the composition

$$\ker G \to H^0(X^{[3]})(-2) \to H^0(X^{[3]}),$$

where “identity” means the usual identity mapping that ignores Tate twists.

Next $\text{Gr}_2 W(N)$ is the cohomology in the middle of the complex

$$\begin{array}{ccc}
H^2(X^{[1]}) & \xrightarrow{G'} & H^0(X^{[2]})(-1) \\
\downarrow & & \downarrow R' \\
H^0(X^{[2]})(-1) & \xrightarrow{R} & H^2(X^{[2]}) \\
\downarrow G & & \downarrow \\
H^0(X^{[3]})(-1)
\end{array}$$

18A general reference for this discussion is Chapter 11 in [PS08]. Here we will use the setting and notations developed in [GG16].
As noted in [GG16], it is a consequence of the Friedman condition for smoothability [Fri83] that the above is actually a complex; i.e., that the composition \((R' \oplus G) \circ (G' \oplus R) = 0\). We will explain this in more detail \(\S 4.4.3\).

The monodromy maps are induced by

\[
\begin{align*}
\ker G & \subset H^0(X^{[3]})(-2) \quad \text{cf. (4.4.1a)} \\
\text{id} & \downarrow N \quad \downarrow \text{id} \\
\text{id} & \downarrow N \\
\ker G & \subset H^0(X^{[3]})(-1) \quad \text{cf. (4.4.3)} \\
\text{id} & \downarrow N \\
\text{id} & \downarrow N \\
coker R & \subset H^0(X^{[3]}) \quad \text{cf. (4.4.1b)},
\end{align*}
\]

and the iteration \(N^2\) is (4.4.2).

For the odd weights for \(\text{Gr}^W(N)(\text{LMHS})\) the analogue of (4.4.1) is the pair of dual complexes

\[
\begin{align*}
(4.4.4a) & \quad H^1(X^{[2]})(-1) \xrightarrow{G} H^3(X^{[1]}) \\
(4.4.4b) & \quad H^1(X^{[2]}) \xrightarrow{R} H^1(X^{[2]}),
\end{align*}
\]

and we have

\[
I_3 = \ker (4.4.4a) \quad \text{and} \quad I_1 = \coker (4.4.4b).
\]

Monodromy is given by

\[
\ker G \subset H^1(X^{[2]})(-1) \xrightarrow{\text{“identity”}} H^1(X^{[2]}) \rightarrow \coker R.
\]

Replacing \(X\) by \(X_w\) we then have the descriptions

- \(F_a^2 \cap \text{Gr}_4^W(N) = I^{2,2} \subset H^1(X^{[2]})(-1)\) is represented by the double residues of forms \(\psi(0, w)\);
- \(F_a^2 \cap \text{Gr}_3^W(N) = I^{2,1} \subset H^0(\Omega^1_{X^{[2]}})(-1)\) is represented by single residues of forms \(\psi(0, w)\) whose double residues are zero;
- \(F_a^2 \cap \text{Gr}_2^W(N) = I^{2,0} \subset H^0(\Omega^2_{X^{[1]}})\) is represented by the holomorphic 2-forms \(\psi(0, w)\) both whose double and single residues vanish.

4.4.2. Polarizations. We now turn to the issue of polarizations. There are two polarizing forms on the groups

\[
I^{2,k} = F_a^2 \cap \text{Gr}_{2+k}^W(N)(\text{LMHS}), \quad k = 2, 1.
\]

One is the Hodge-theoretic one arising from

\[
\tilde{Q}(u, \tilde{v}) = Q(N^k u, \tilde{v}).
\]

The other is the geometric one obtained by:

- First taking limits, we realize the elements in \(I^{2,k}\) as singular differential forms on \(X_{(0,w)}\).
Then by taking sequential residues of these forms we obtain holomorphic differentials on the desingularized strata $X^{[1+k]}_X$ of $X_{(0,w)}$.

Finally we take the usual polarizing forms $\int \alpha \wedge \bar{\beta}$ of holomorphic forms on smooth varieties. Proposition 4.3.5 asserts: The Hodge-theoretic and geometric polarizing forms coincide.

Proof of Proposition 4.3.5. We shall give the argument for this in the critical case $k = 1$. The situation is this:

- We have a family $X_t$ of smooth surfaces specializing to a singular surface $X_0$ that has a double curve $D_0 \subset X_0$.
- The $\psi_t$ are holomorphic 2-forms in $H^0(\Omega^2_{X_t})$ that specialize to $\psi_0 \in H^0(\Omega^2_{\tilde{X}_0}(\tilde{D}_0))$, which is a 2-form on the normalization $\tilde{X}_0$ of $X_0$ having a log pole on the inverse image $\tilde{D}_0$ of the double curve on $X_0$.

As we have seen (§4.3), there is an expansion $\int_{X_t} \psi_t \wedge \bar{\psi}_t = C \log \frac{1}{|t|} + \text{LOT}$. On the other hand we have the 1-form $\text{Res}(\tilde{\psi}_0) =: \psi_0 \in H^0\left(\Omega^1_{\tilde{D}_0}\right)$, and the assertion is that up to a universal constant

$$C = \int_{\tilde{D}_0} \text{Res} \psi_0 \wedge \text{Res} \psi_0.$$ 

By localizing along $\tilde{D}_0$ and iterating the integral, this essentially amounts to the following 1-variable result: In $\mathbb{C}^2$ we consider the analytic curve $C_t$ given by $xy = t$. On $C_t$ we take the Poincaré residue

$$\varphi_t = \text{Res} \left[ \frac{g(x,y)dx \wedge dy}{xy - t} \right].$$

Then locally

$$\int_{C_t} \varphi_t \wedge \bar{\varphi}_t = |g(0,0)|^2 \log |t|^{-1} + \text{LOT}. \quad \square$$

4.4.3. Friedman condition for smoothability. We conclude this section with a brief discussion of some of how parts of [Fri83] apply to complexes constructed from an abstract normal crossing divisor $X = \bigcup X_i$ to give conditions on complexes constructed from the cohomology group $H^a(X^{[b]})(\ominus c)$ to be the $E_1$-term of a spectral sequence whose abutment is a limiting mixed Hodge structure. If $D = \bigcup_{i<j} D_{ij}$ is the double locus of $X$, then as in [Fri83] in terms of $X$ above there is defined the infinitesimal normal bundle $\mathcal{O}_D(X)$, and a necessary condition for the smoothability of $X$ is

$$(4.4.5) \quad \mathcal{O}_D(X) \cong \mathcal{O}_D.$$ 

If $X$ is smoothable to be the central fibre in $X \rightarrow \Delta$, then $\mathcal{O}_D(X) = \mathcal{O}_D \otimes \mathcal{O}_X(X)$. The cohomological implications of (4.4.5) then give conditions that diagrams such as (4.4.3)

---

19 For 0-dimensional varieties this is just the usual product of complex numbers.
actually be complexes whose cohomology is then the associated graded to a limiting mixed
Hodge structure. In other words, the condition (4.4.5) is sufficient to construct as in
[PS08] the spectral sequence that would arise from \( X \to \Delta \). To keep the notation as simple
as possible we shall do the case where \( X = X_1 \cup X_2 \cup X_3 \) where \( X_i \) is locally given by
\( x_i = 0 \) in \( \mathbb{C}^3 \). If \( X \) is smoothable so that along the double locus the smoothing is given by
\( x_1x_2 = t \), then the relation \( dt = x_2dx_1 + x_1dx_2 \) translates away from the triple points into

\[
\mathcal{O}_{D_{12}}(X_1) \otimes \mathcal{O}_{D_{12}}(X_2) \cong \mathcal{O}_{D_{12}}.
\]

For a smoothable triple point \( p \) given by \( x_1x_2x_3 = t \) we have \( dt = x_2x_3dx_1 + x_1x_3dx_2 +
\]
\( x_1x_2dx_3 \), which at \( x_1x_2 = 0, x_3 = 0 \) gives

\[
\mathcal{O}_{D_{12}}(X_2) \otimes \mathcal{O}_{D_{12}}(X_2) \otimes \mathcal{O}_{D_{12}}(p) \cong \mathcal{O}_{D_{12}}.
\]

From this we obtain the \textit{triple point formula}

\[
(4.4.6) \quad D_{12}^2|_{X_1} + D_{12}^2|_{X_2} + 1 = 0,
\]

where \( D_{12}^2|_{X_i} \) is the self intersection of \( D_{12} \) in \( X_i \).

We now explain how (4.4.6) enters into (4.4.3). In

\[
\begin{array}{ccc}
H^2(X[1]) & \xrightarrow{G^*} & H^0(X[2])(-1) \\
& \xrightarrow{R} & H^0(X[3])(-1)
\end{array}
\]

the map is

\[
[D_{12}]|_{X_1} - [D_{12}]|_{X_2}
\]

\[
1_{D_{12}} \xrightarrow{1_p}
\]

\[\text{This discussion may be extended to the case when } X \text{ is locally a product of normal crossing divisors (such as arise from stable nodal curves), and also to the several parameter case where } X \text{ is locally a product of normal crossing divisors such as arise in the semi-stable reduction constructed in [AK00]. The details and applications of this will appear elsewhere.}\]
where \([D_{12}]|_{X_1}\) is the class of \(D_{12}\) in \(H^2(X_1)\). For

\[
\begin{align*}
H^2(X^{[1]}) & \xrightarrow{R'} \ H^2(X^{[2]}) = H^2(X_{12}) \oplus H^2(X_{13}) \oplus H^2(X_{23}) \\
& \xrightarrow{G} H^0(X^{[3]})(-1)
\end{align*}
\]

the maps are induced by

\[ (4.4.7) \quad [D_{12}]|_{X_1} - [D_{12}]|_{X_2} \to (D^2_{12}|_{X_2} + D^2_{21}|_{X_1}) [X_{12}] \oplus (-[X_{13}]) \oplus (-[X_{23}]) \]

where as above \(D^2_{21}|_{X_1}\) is the self-intersection of \(D_{12}\) in \(X_2\) and similarly for \(D^2_{21}|_{X_1}\), and where \([X_{ij}]\) is the fundamental class of \(X_{ij}\). The points here are:

(a) If \(C\) is a smooth, irreducible curve on a surface \(Y\), then the restriction \(H^2(Y) \to H^2(C)\) maps the class \([C] \in H^2(Y)\) of \(C\) to the self-intersection number \(C^2\) times the generator of \(H^2(C)\); this accounts for the first term in \((4.4.7)\).

(b) If \(C, C'\) are smooth, irreducible curves in \(Y\) meeting a point, then \(H^2(Y) \to H^2(C')\) maps \([C]\) to a generator of \(H^2(C')\); this accounts for the last two terms in \((4.4.7)\).

Using the above to compute the maps \(G', R', G, R\) in \((4.4.3)\) we may draw the conclusion

The triple point formula for each pair of components of \(X\) implies that \((4.4.3)\) is a complex.

Appendix to \S 4. Extension of the geometric argument to the general case. In this section we discuss some of the issues that arise in trying to extend the above geometric argument to the case of an arbitrary VPHS.

The setting is a projective family \(X^* \xrightarrow{\pi} \Delta^k \times \Delta^\ell\) of smooth varieties \(X_{(t,w)} = \pi^{-1}(t,w)\) where \((t, w) = (t_1, \ldots, t_k; w_1, \ldots, w_\ell)\) are coordinates in \(\Delta^k \times \Delta^\ell\). According to Abramovich–Karu [AK00], after successive modifications and base changes the above family may be completed to \(X \xrightarrow{\pi} \Delta^k \times \Delta^\ell\), where \(X\) is smooth and the singular fibres \(X_w = \pi^{-1}(0, w)\) are locally a product of reduced normal crossing varieties. For the purposes of illustration we take the case \(k = 2, \ell = 1\) of a degenerating family of surfaces. The strata of \(X_w\) together with local coordinates on \(X\) and the mapping \(\pi\) are

\[
\begin{align*}
X^{[1]}_w(x_1, x_2, x_3, x_4) & \to (t_1 = x_3, t_2 = x_4), \\
X^{[2]}_w(x_1, x_2, x_3, x_4) & \to (t_1 = x_1x_2, t_2 = x_4), \\
X^{[3]}_w(x_1, x_2, x_3, x_4) & \to (t_1 = x_1x_2x_3, t_2 = x_4), \\
X^{[2]}_w(x_1, x_2, x_3, x_4) & \to (t_1 = x_1x_2, t_2 = x_3x_4),
\end{align*}
\]

and similarly for \(X^{[1,2]}_w\) and \(X^{[1,3]}_w\). The sections \(\psi(t, w)\) of the direct image of the relative dualizing sheaf are locally double Poincaré residues of 4-forms where the two functions in
the denominator are the defining equations of the graph of \( \pi \). For example, for \( X^{[2,2]}_w \)

\[
\psi(t, w) = \text{Res} \text{Res} \left[ \frac{f(x_1, x_2, x_3, x_4)dx_1 \wedge dx_2 \wedge dx_3 \wedge dx_4}{(x_1x_2 - t_1)(x_3x_4 - t_2)} \right].
\]

The highest order terms in the expansion of the Hodge norm

\[
\| \psi(t, w) \|^2 = \int_{X(t, w)} \psi(t, w) \wedge \overline{\psi(t, w)}
\]

are of the form

\[
A_1(w)(\log |t_1|^{-1})^2 + B(w) \log |t_1|^{-1} \log |t_2|^{-1} + A_2(w)(\log |t_2|^{-1})^2.
\]

The lower order terms are of the form

\[
C_1(w) \log |t_1|^{-1} + C_2(w) \log |t_2|^{-1} + D(w).
\]

When we compute \( \partial \overline{\partial} \log \| \psi(t, w) \|^2 \) and set \( dt_1 = d\overline{t}_1 = dt_2 = d\overline{t}_2 = 0 \) it is possible that we could be left with a term like \( \frac{\log |t_1|^{-1} + \log |t_2|^{-1}}{\log |t_1|^{-1} \log |t_2|^{-1}} \), which does not have a limit as \( t_1, t_2 \to 0 \). Consequently we need some control of what can appear in \( \partial \overline{\partial} \log \| \psi(t, w) \|^2 \). As we will see in [5] the several-variable SL(2) orbit theorem gives us this control.

5. Curvature properties of the extended augmented Hodge bundle

In this section we will give a proof of Theorem 1.3.10 for an arbitrary variation of Hodge structure.

5.1. Preliminaries. Recall the notations of \( \square 1.3 \). Given \( b_0 \in \overline{\mathcal{B}} \setminus \mathcal{B} \), we will show that \( \lim_{b \to b_0} \hat{\Omega}_b = \hat{\Omega}_{I,b_0} \), in a suitably interpreted sense (Theorem 5.1.1). This is essentially a local statement about \( b_0 \). So we may assume that \( \Phi \) is a local VHS (2.1.2) over \( \mathcal{U} \simeq (\Delta^\ast)^k \times \Delta^\ell \), where \( \mathcal{U} = \overline{\mathcal{U}} \cap \mathcal{B} \) with \( \overline{\mathcal{U}} \simeq \Delta^r \) \( \times \Delta^\ell \) \( \approx (t, w) \) a local coordinate chart on \( \overline{\mathcal{B}} \) centered at \( b_0 \). Suppose that \( b_0 \in Z^*_I \), and let \( \Phi_I \) denote the induced (local) VHS (3.4.6) over \( \overline{\mathcal{U}} \cap Z^*_I \simeq \Delta^\ell \). We may assume, without loss of generality, that \( I = \{1, \ldots, k\} \). Recall (3.13) our notations \( F_e \to \overline{\mathcal{U}} \) for the canonically extended Hodge vector bundle, and \( \hat{\Lambda}_e \to \Delta^r \) for the augmented Hodge (line) bundle. Likewise, over \( (\Delta^\ast)^k \times \Delta^\ell \) we have the augmented Hodge (line) bundle \( \hat{\Lambda}_I \). The bundles \( \hat{\Lambda}_e, \hat{\Lambda}_I \) have metrics induced by the polarizing forms (2.1.5) \( \square 22 \) and we denote by \( \hat{\Omega}_e, \hat{\Omega}_I \) the corresponding Chern forms.

Theorem 1.3.10 may be reformulated as

**Theorem 5.1.1.** The curvature forms satisfy

\[
\lim_{b \to b_0} \hat{\Omega}_b \equiv \hat{\Omega}_{I,b_0} \text{ modulo } \{dt_i, d\overline{t}_i \mid 1 \leq i \leq k\}.
\]

Implicit in the statement of the theorem is the assertion that the limit exists. Theorem 5.1.1 is a consequence of

\[ \square 21 \]The term \( \log |t_1|^{-1} \) corresponds to \( N_1 \), the term \( \log |t_2|^{-1} \) to \( N_2 \), and \( \log |t_1|^{-1} + \log |t_2|^{-1} \) to \( N_1 + N_2 \).

\[ \square 22 \]These metrics are nondegenerate but will generally be indefinite. (The metric on \( F^n \) is definite.)
Theorem 5.1.2. Let $\Omega_p$ and $\Omega_{p,I}$ be the Chern forms of the line bundles $\det F^p$ and $\det F^p_I$. Then

$$\lim_{b \to b_0} \Omega_{p,b} \equiv \Omega_{p,I,b_0} \mod \{dt_i, d\bar{t}_i \mid 1 \leq i \leq k\}.$$ 

We will prove Theorem 5.1.2 in the case that $p = n$. The general argument for Theorem 5.1.2 is the same, with a change in the notations. And our main application will be to the moduli of surfaces of general type, in which case $\Lambda = \hat{\Lambda}$ (and it suffices to consider $p = n$).

Proof of Theorem 5.1.1. This follows directly from Theorem 5.1.2 and the fact that $\hat{\Lambda}$ is expressed as a tensor product of the powers of the $\det F^p$'s (Definition 1.3.3). □

When specialized to the case that $p = n$, Theorem 5.1.2 becomes

Theorem 5.1.3. Let $\Omega := \Omega_n$ and $\Omega_{I} := \Omega_{n,I}$ be the Chern forms of the line bundles $\Lambda = \det F^n$ and $\Lambda_{I} = \det F^n_I$. Then

$$\lim_{b \to b_0} \Omega_b \equiv \Omega_{I,b_0} \mod \{dt_i, d\bar{t}_i \mid 1 \leq i \leq k\}.$$ 

The remainder of §5 is devoted to the proof of Theorem 5.1.3. In outline, the argument proceeds as follows:

◦ After giving a coordinate reformulation of the theorem (§5.1.4), we review some properties and results that will be invoked in the proof (§5.1.5–5.1.7).

◦ The behavior of $\log |t_i| / \log |t_j|$ as $t \to 0$ determines a set of commuting horizontal SL(2)’s that is well-suited to studying $\Omega$ as $t \to \infty$ (§5.2). Such SL(2)’s were first utilized by Cattani–Kaplan–Schmid in their estimates of the Hodge metric [CKS86, §5]. (The CKS analysis assumed that $\ell = 0$ (so that $w \in \Delta^\ell$ plays no role). Those results extend to the setting that we are interested in a straight-forward manner, as we will sketch.) Those SL(2)’s determine a semisimple endomorphism $\varepsilon(s, u; w)$. The property (5.2.11) of the $\varepsilon(s, u; w)$, and the several-variable nilpotent orbit theorem yield Lemma 5.2.17, which is the key to showing that $\lim_{t \to 0} \Omega$ exists.

◦ The material in §5.2 (specifically, Lemma 5.2.17) is applied in §5.3 to prove Theorem 5.1.3.

5.1.1. Deligne’s $\mathbb{R}$–split PMHS. Set

$$N := N_1 + \cdots + N_k \text{ and } W := W(N).$$

Recall the notation (2.1.2) for the local variation of Hodge structure $\Phi(t, w) = \exp \left( \sum_{i \in I} \ell(t_i) N_i \right) \cdot F(t, w)$. In general, the LMHS $(W, F(0, w))$ will not be $\mathbb{R}$–split. It will be convenient to work with Deligne’s associated $\mathbb{R}$–split MHS $(W(N), \tilde{F}_w)$, cf. [CKSS6, (2.20)]; here $\tilde{F}_w = \exp(-\sqrt{-1} \delta_w) \cdot F(0, w)$. The element $\delta_w \in \mathfrak{g}_{\mathbb{R}}$ commutes with the $N_i$, and $w \mapsto \delta_w$ is a real analytic map $\Delta^\ell \to \mathfrak{g}_{\mathbb{R}}$. Let

$$(5.1.4) \quad V_{\mathbb{C}} = \bigoplus \tilde{F}_{w}^{p,q} \text{ and } \mathfrak{g}_{\mathbb{C}} = \bigoplus \tilde{g}_{w}^{p,q}$$
be the associated Deligne splittings. Set
\[ \tilde{n}_w := \bigoplus_{p < 0 \atop q} \tilde{g}_w^{p,q} = \tilde{g}_w^{-*}. \]

Note that
\[ \mathfrak{g}_C = \tilde{n}_w \oplus \tilde{p}_w, \]
where \( \tilde{p}_w \) is the Lie algebra of \( \text{Stab}_{G_C}(\tilde{F}_w) \). There exists a unique holomorphic map
\[ X : \tilde{U} \to \tilde{n}_0 \]
so that \( X(0, 0) = 0 \) and
\[ \Phi(t, w) = \exp \left( \sqrt{-1} \delta_0 + \sum_{i=1}^{k} \ell(t_i)N_i \right) \zeta(t, w) \cdot \tilde{F}_0, \]
where
\[ \zeta(t, w) := \exp X(t, w). \]
See [CKS86, §5] for details. Set
\[ \nu_0 := \exp \left( \sqrt{-1} \delta_0 + \sum_{i=1}^{k} \ell(t_i)N_i \right). \]

5.1.2. The metric \( h_{\Lambda}(t, w) \) on \( \Lambda \). Given \( u, v \in \tilde{F}_0^n \), \( u(t, w) = \nu_0(t)\zeta(t, w) \cdot u \) and \( v(t, w) = \nu_0(t)\zeta(t, w) \cdot v \) are local sections of \( F^n \to (\Delta^*)^k \times \Delta^\ell \), and the Hermitian metric on the Hodge bundle \( F^n \to U \) is given by
\[ h_{\Lambda}(u(t, w), v(t, w)) = (\sqrt{-1})^{n}Q \left( \nu_0(t)\zeta(t, w) \cdot u, \nu_0(t)\zeta(t, w) \cdot v \right). \]
If we fix a basis \( \{\nu_a\} \) of \( \tilde{F}_0^n \), then \( \{\nu_a(t, w)\} \) is a framing of \( F^n \to \tilde{U} \), and the metric on \( \Lambda = \det F^n \) is
\[ h_{\Lambda}(t, w) = \det (h_{\nu_a}(\nu_a(t, w), \nu_b(t, w))). \]

5.1.3. The metric \( h_{\Lambda_I}(t, w) \) on \( \Lambda_I \). Let \( X_0^{p,q} \) denote the component of \( X \) taking value in \( \tilde{g}_0^{p,q} \). Define \( X_I(w) = \bigoplus X_0^{-p,p}(0, w) \), and set
\[ \zeta_I(w) := \exp X_I(w). \]
Refine the basis \( \{\nu_a\} \) so that \( \nu_a \in \tilde{I}_0^{n,q} \) for some \( q = q(a) \). Define
\[ \nu_{I,a}(w) := \zeta_I(w) \nu_a. \]
Then \( \{\nu_{I,a}(w)\} \) may be canonically identified with a framing of \( F_I^n \to \Delta^\ell \). The Hermitian metric on \( F_I^n \) is given by
\[ h_{F_I^n}(w)_{ab} := h_{F_I^n}(\nu_{I,a}(w), \nu_{I,b}(w)) \]
\[ = \begin{cases} (\sqrt{-1})^{n-q} Q \left( \nu_{I,a}(w), N^q \nu_{I,b}(w) \right), & \text{if } q = q(a) = q(b), \\ 0 & \text{otherwise.} \end{cases} \]
And the metric on \( \Lambda_I = \det F^n_I \) is
\[
(5.1.11) \quad h_{\Lambda_I}(w) = \det (h_{F^n_I}(\nu_I, a(w), \nu_I, b(w))).
\]

We will further assume that the basis \( \{ \nu_a \} \) has been chosen so that
\[
\sqrt{\tau^a q} Q(Nq \nu_a, \nu_b) = \delta_{ab},
\]
for \( q = q(a) = q(b) \). Then \( h_{F^n_I}(w) \) is a block-diagonal matrix, with diagonal blocks \( h_{F^n_I}(w) = (h_{F^n_I}(w)_{ab})_{q(a) = q(b) = q} \), and
\[
h_{\Lambda_I}(w) = \prod_{q=0}^n h_{\Lambda_I}^q(w),
\]
where \( h_{\Lambda_I}^q(w) := \det h_{F^n_I}(w) \).

5.1.4. **Local coordinate reformulation of Theorem 5.1.3**. Comparing (5.1.8) and (5.1.11), we see that the local coordinate formulation of Theorem 5.1.3 is equivalently, given a sequence \( m t = (m t_1, \ldots, m t_k) \in (\Delta^*)^k \) converging to 0, we wish to show that
\[
(5.1.12b) \quad \lim_{m \to \infty} \partial_{w_i} \partial_{\overline{w}_j} \log h_{\Lambda}(m t, w) = \partial_{w_i} \partial_{\overline{w}_j} \log h_{\Lambda}(w).
\]

Writing \( \ell(t_j) = z_j = x_j + \sqrt{-1} y_j \), we have \( y_j = -\frac{1}{n} \log |t_j| \). Restricting to a subsequence if necessary (and dropping the subscript \( m \)), we may assume without loss of generality that either \( y_i/y_j \to 0 \), \( y_i/y_j \to \infty \), or \( y_i/y_j \) is bounded (away from both 0 and \( \infty \)). Reordering indices if necessary, we may assume that there exists \( K = \{ k_1, \ldots, k_\rho \} \subset \{ 1, \ldots, k \} = I \) so that \( 1 \leq k_1 < \cdots < k_\rho = k \) so that \( y_{k_\alpha}/y_{k_{\alpha+1}} \to \infty \) and \( y_j/y_{k_\alpha} \) is bounded for all \( k_{\alpha-1} < j < k_\alpha \). In [5.2.1] we will employ a collection of commuting SL(2)'s that is well-suited to studying the asymptotic behavior of \( \partial_{w_i} \partial_{\overline{w}_j} \log h_{\Lambda}(t, w) \) under such a sequence.

5.1.5. **A simplifying property**. If \( A(t) \) and \( B(t, w) \) are two real-analytic, functions, then
\[
(5.1.13) \quad \partial_{w_i} \partial_{\overline{w}_j} \log (A(t) B(t, w)) = \partial_{w_i} \partial_{\overline{w}_j} \log B(t, w).
\]

We will apply this in the case that \( A(t) \) and \( B(t, w) \) are the determinants of two matrix-valued functions. For example, for the purposes of computing the right-hand side of (5.1.12), we may replace \( h_{\Lambda_I}(w) \) with
\[
(5.1.14a) \quad h_{\Lambda_I}^q(w) := \det (h_{F^n_I}^q(w)_{ab}),
\]
where
\[
(5.1.14b) \quad h_{F^n_I}^q(w)_{ab} := \begin{cases} Q \left( Nq \zeta_I(w) \nu_a, \zeta_I(w) \nu_b \right), & \text{if } q = q(a) = q(b), \\ 0 & \text{otherwise}. \end{cases}
\]
That is, (5.1.13) implies
\[
(5.1.15) \quad \partial_{w_i} \partial_{\overline{w}_j} \log h_{\Lambda_I}(w) = \partial_{w_i} \partial_{\overline{w}_j} \log h_{\Lambda_I}^q(w).
\]
5.1.6. Horizontality. Horizontality implies that $X(0, w)$ also commutes with the $N_i$ (cf. §3.4.1(i)). That is, $X(0, w)$ lies in the Lie algebra

$$(5.1.16) \quad \mathfrak{z}_C := \{ Z \in \mathfrak{g}_C \mid [Z, N_j] = 0, \forall j \} = \bigcap_{j=1}^k \ker \text{ad} N_j$$

of the centralizer

$${\mathcal Z}_C := \{ g \in G_\mathbb{C} \mid \text{Ad}_g N_i = N_i, \forall i \}.$$ 

Notice that $\mathcal{Z}_C$ is defined over $\mathbb{Q}$, preserves the weight filtration $W(N)$, and that the Lie algebra inherits the Deligne splitting $\mathfrak{z}_C = \bigoplus_{p+q \leq 0} \mathfrak{z}^{p,q}_C$, with $\mathfrak{z}^{p,q}_C := \mathfrak{z}_C \cap \mathfrak{g}^{p,q}_\mathbb{C}$. The function $X_I(w)$ of §5.1.3 is the component of $X(0, w)$ taking value in $\tilde{\mathfrak{g}}_0, 0 := \bigoplus_{p+q=0} \tilde{\mathfrak{g}}^{p,q}_0$. In particular, $\zeta_I(w)$ commutes with the $\{N_j\}_{j=1}^k$.

5.1.7. Relationship between the $\mathbb{R}$–split $\tilde{F}_w$. The Hodge filtrations $\tilde{F}_w$ are all congruent to $\tilde{F}_0$ under the action of $\mathbb{Z}_R$ [KP16]. In particular, we may choose a real analytic function $\psi : \Delta^\ell \to \exp(\mathfrak{z}_R) \subset \mathbb{Z}_R$ so that $\psi(0)$ is the identity and

$$(5.1.17) \quad \psi(w) \cdot \tilde{F}_w = \tilde{F}_0$$

23This choice of $\psi(w)$ is not unique. There is a unique choice of $\psi_C : \Delta^\ell \to \exp(\mathfrak{z}_C \cap \mathfrak{h}) \subset \mathbb{Z}_C$ so that $\psi_C(0)$ is the identity and $\psi_C(w) \cdot \tilde{F}_w = \tilde{F}_0$. Nonetheless it is better to work with the $\mathbb{Z}_R$–value $\psi(w)$, because the Hermitian metric $h_{F^n}$ is $G_\mathbb{R}$–invariant, but not $G_\mathbb{C}$–invariant. And ultimately the argument and result are independent of our choice.

24The arguments of [CKS86 §5] assume that $\ell = 0$, so that the holomorphic parameter $w$ does not play a role. However, the proofs there (up to and including that of [CKS86 (5.14)]) all apply, in a straightforward manner, in our more general setting to yield the assertions below.
Let
\[
\mathcal{A} := \text{(real) analytic functions of } (u, w) \in \mathbb{R}^k_+ \times \Delta^k,
\]
\[
\mathcal{L} := \text{Laurent polys. in } \{s_α^{1/2}\} \text{ with coef. in } \mathcal{A},
\]
\[
\mathcal{O} := \text{pullback to } \mathcal{H}^k \times \Delta^k \text{ of the ring of holo. germs at } 0 \in \Delta^r = \Delta^k \times \Delta^k
\]
via \(\mathcal{H}^k \to (\Delta^*)^k \to \Delta^k\),
\[
\mathcal{L}^\beta := \text{polys. in } s_α^{-1/2} \text{ with coef. in } \mathcal{A},
\]
\[
(\mathcal{O} \otimes \mathcal{L})^\beta := \text{subring of } \mathcal{O} \otimes \mathcal{L} \text{ gen. by } \mathcal{O}, \mathcal{L}^\beta, \text{ and all monomials of the form}
\]
\[
t_j s_1^{m_1/2} \cdots s_ρ^{m_ρ/2} \text{ with } m_α \in \mathbb{Z} \text{ and } m_α \neq 0 \text{ only if } j \leq i_α.
\]
We identify \(\mathbb{R}_+^k\) with \(\mathbb{R}_+^k \times \mathbb{R}_+^k\) by \(y \mapsto (s, u)\). Recall that \(\mathcal{H} \subset \mathbb{C}\) denotes the upper-half plane. Given \(c > 0\) define
\[
(\mathbb{R}_+^k)_c^K := \left\{ y \in \mathbb{R}_+^k \mid s_α > c, \ 1/c < u_j^α < c \right\}
\]
\[
(\mathcal{H}_c^k)_c^K := \left\{ z \in \mathcal{H}_c^k \mid z = x + \sqrt{-1}y, \ y \in (\mathbb{R}_+^k)_c^K \right\}
\]
\[
(\Delta^k)_c^K := \left\{ t \in (\Delta^*)^k \mid \ell(t_j) \in (\mathcal{H}_c^k)_c^K \right\}.
\]

**Lemma 5.2.1** ([CKSS6 (5.7)]). (a) For any \(c > 1\), the regions \((\Delta^k)_c^K\) corresponding to the various permutations of the variables and choices of \(K \subset \{1, \ldots, k\}\) cover the intersection of \((\Delta^*)^k\) with a neighborhood of \(0 \in \Delta^k\). (b) The set \((\mathcal{O} \otimes \mathcal{L})^\beta\) consists of precisely those elements in \(\mathcal{O} \otimes \mathcal{L}\) that are bounded on \((\Delta^k)_c^K\) for some (any) \(c\).

**Remark 5.2.2.** The coordinates \(y = (s, u)\) are well-adapted to study the asymptotic behavior of the Hodge metric and Chern form for the sequence \(m_t\) of §5.1.4. Throughout the remainder of §5 the notation
\[
f(x, s, u; w) \sim g(x, u; w) \quad \text{(or } f(t, w) \sim g(x, u; w))
\]
will indicate that \(f(x, s, u; w)\) converges to \(g(x, u; w)\) as \(s_1, \ldots, s_ρ \to \infty\), and that this convergence is uniform on compact subsets of \(x \in \mathbb{R}^k \times \{u_α \in \mathbb{R}_+^k\} \times \{w \in \Delta^k\}\).

5.2.2. **Commuting \(\text{SL}(2)'s.** Define
\[
N_α(u) := N_κ_α + \sum_{k_α-1 < j < k_α} w_j^α N_j = \frac{1}{y_κ_α} \sum_{k_α-1 < j \leq k_α} y_j N_j.
\]
Note that
\[
\sum_{j=1}^k y_j N_j = \sum_{α=1}^ρ (s_α s_α+1 \cdots s_ρ) N_α(u).
\]
Since each \(\exp(\sum z_j N_j) \cdot \tilde{F}_w\) is a nilpotent orbit, it follows that \(\exp(\sum z_κ N_κ(u)) \cdot \tilde{F}_w\) is also a nilpotent orbit. The several-variable \(\text{SL}(2)\)–orbit theorem ([CKSS6 (4.20)]) associates to this nilpotent orbit a collection \(\{ν_α : \text{SL}(2, \mathbb{C}) \to G_\mathbb{C}\}_α\) of commuting horizontal \(\text{SL}(2)'s.\)
Let \( \{ \hat{N}_\alpha(u,w), \hat{Y}_\alpha(u,w), \hat{N}_\alpha^+(u,w) \}_{\alpha=1}^{\rho} \) denote the \( \nu_\alpha \)-images of the standard generators of \( \mathfrak{sl}(2,\mathbb{R}) \). Each of \( \hat{N}_\alpha, \hat{Y}_\alpha \) and \( \hat{N}_\alpha^+ \) are \( \mathfrak{g}_R \)-valued members of \( \mathcal{A} \). Furthermore,

\[
(5.2.3) \quad \left\{ \hat{N}_\alpha(u,w), \hat{Y}_\alpha(u,w), \hat{N}_\alpha^+(u,w) \right\}_{\alpha=1}^{\rho} = \text{Ad}_{\psi(w)}^{-1} \left\{ \hat{N}_\alpha(u,0), \hat{Y}_\alpha(u,0), \hat{N}_\alpha^+(u,0) \right\},
\]

for all \( 1 \leq \alpha \leq \rho \).

**Proof of (5.2.3).** This is a consequence of (5.1.17) and [CKS86, (4.75)]: note that the functions \( T = T(W,F) \) and \( \Phi = \Phi(Y,F) \) of [CKS86, p. 506] are \( G_\mathbb{R} \)-equivariant. □

Define

\[
(5.2.4) \quad Y^\alpha(u,w) := \sum_{\beta=1}^{\alpha} \hat{Y}_\beta(u,w) \text{ for all } \alpha \leq \rho.
\]

It follows directly from the CKS–construction that

\[
(5.2.5) \quad Y^\rho(u,w) \text{ is the element of } \mathfrak{g}_R \text{ acting on } \tilde{g}_w, \ell \text{ by } \ell \in \mathbb{Z};
\]

in particular, \( Y^\rho_w := Y^\rho(u,w) \) is independent of \( u \).

5.2.3. Eigenspace decompositions. Set

\[
\varepsilon(y, w) = \varepsilon(s, u; w) := \exp \left( \frac{1}{2} \sum_{\alpha} \log s_\alpha Y^\alpha(u,w) \right) = \text{Ad}_{\psi(w)}^{-1} \varepsilon(s, u; 0).
\]

Recall that the eigenvalues of \( Y^\alpha(u,w) \) are integers. Both the eigenvalues and their multiplicities are independent of \( (u,w) \), while the eigenspaces depend real-analytically on \( (u,w) \).

If \( Y^\alpha(u,w) \) acts by the eigenvalue \( e_\alpha \in \mathbb{Z} \), then \( \varepsilon(s, u; w) \) acts by the eigenvalue \( \prod_\alpha s_\alpha^{e_\alpha/2} \).

So \( \varepsilon(s, u; w) \) is a \( G_\mathbb{R} \)-valued function in \( L \). Additionally \( Y^\alpha(u,w) \in \mathfrak{g}^{0,0}_w, \mathfrak{g}_R^+, \mathfrak{g}_R \), so that \( Y^\alpha(u,w) \) preserves the Deligne splittings (5.1.4). Since the \{\( Y^\alpha(u,w) \)\}_{\alpha=1}^{\rho} are commuting semisimple endomorphisms, it follows that each

\[
(5.2.6) \quad \tilde{I}^{\rho,q}_w \text{ decomposes into a direct sum of simultaneous eigenspaces for the } Y^\alpha(u,w), 1 \leq \alpha \leq \rho.
\]

Therefore

\[
(5.2.7) \quad \tilde{I}^{\rho,q}_w \text{ decomposes into a direct sum of } \varepsilon(s,u;w)-\text{eigenspaces}.
\]

Consequently, both \( \varepsilon \) and \( \varepsilon^{-1} \) preserve the Deligne splittings; in particular,

\[
(5.2.8) \quad \varepsilon(s,u;w) \cdot \tilde{I}_w = \tilde{I}_w.
\]

Since the \{\( Y_\alpha(u,w) \)\}_{\alpha=1}^{\rho} are commuting semisimple endomorphisms, the Lie algebra admits a simultaneous eigenspace decomposition

\[
\mathfrak{g}_R = \bigoplus_{e_1,\ldots,e_\rho} \mathfrak{g}_{e_1,\ldots,e_\rho}(u,w),
\]
with \( \text{ad} Y^\alpha \) acting on \( g_{e_1,\ldots,e_\rho} \) by the scalar \( e_\alpha \in \mathbb{Z} \). In particular,

\[
(5.2.9) \quad \text{Ad}_{\varepsilon(s,u,w)} \text{ acts on } g_{e_1,\ldots,e_\rho}(u,w) \text{ by the scalar } \prod_{\alpha} s_\alpha^{e_\alpha/2}.
\]

The eigenspaces \( g_{e_1,\ldots,e_\rho}(u,w) \) depend real-analytically on \((u,w)\), and \(5.2.4\) implies

\[
g_{e_1,\ldots,e_\rho}(u,w) = \text{Ad}^{-1}_{\psi(w)} g_{e_1,\ldots,e_\rho}(u,0).
\]

Recollect that the common intersection of the weight filtrations

\[
(5.2.10) \quad \mathfrak{w} := \bigcap_{\alpha=1}^\rho W_0(\text{ad}(N_1 + \cdots + N_\alpha)) = \bigoplus_{e_1,\ldots,e_\rho \geq 0} g_{-e_1,\ldots,-e_\rho}(u,w)
\]

is the direct sum of the eigenspaces for the nonpositive eigenvalues. Suppose that \( U(u,w) \in \mathfrak{w} \) depends real-analytically on \((u,w)\). Let \( U'(u,w) \) denote the component of \( U(u,w) \) taking value in

\[
g_{0,\ldots,0}(u,w) = \{ X \in g \mid [Y^\alpha(u,w),X] = 0, \forall \alpha \},
\]

with respect to the decomposition \(5.2.10\). Then \(5.2.9\) yields

\[
(5.2.11) \quad \varepsilon(s,u;w) \exp(U(u,w)) \varepsilon(s,u;w)^{-1} \rightarrow \exp(U'(u,w)),
\]

cf. Remark \(5.2.2\).

### 5.2.4. Asymptotic behavior.

We will find it useful to rewrite \(5.1.6\) as

\[
(5.2.12a) \quad \Phi(t,w) = \psi(w) \exp(\sum x_j N_j) \nu_w(y) \xi(t,w) \cdot \tilde{F}_w,
\]

where

\[
(5.2.12b) \quad \nu_w(y) := \exp \sqrt{-1} \left( \text{Ad}^{-1}_{\psi(w)} \delta_0 + \sum_{i=1}^k y_i N_i \right)
\]

\[
(5.2.13) \quad \xi(t,w) := \psi(w)^{-1} \zeta(t,w) \psi(w) = \exp \text{Ad}^{-1}_{\psi(w)} X(t,w).
\]

Define

\[
\mu(s,u;w) := \varepsilon(s,u;w) \xi(0,w) \varepsilon(s,u;w)^{-1}.
\]

Recall that \( X(0,w) = \log \zeta(0,w) \) takes value in the centralizer \( z = \bigcap_j \ker(\text{ad} N_j) \) of the \( \{ N_j \}_{j=1}^k \) (\(5.1.6\)). Notice that

\[
(5.2.13) \quad \mathfrak{z} \subset \bigcap_{\alpha=1}^\rho \ker(\text{ad}(N_1 + \cdots + N_\alpha)) \subset \bigcap_{\alpha=1}^\rho W_0(\text{ad}(N_1 + \cdots + N_\alpha)) = \mathfrak{w}.
\]

Let \( X_u(w) \) denote the component of \( X(0,w) \) taking value in \( g_{0,\ldots,0}(u,0) \) with respect to the decomposition \( g_{0,\ldots,0} = \bigoplus g_{e_1,\ldots,e_\rho}(u,0) \), and set \( \zeta_u(w) := \exp(X_u(w)) \). Then \(5.2.4\) implies

\[
U'(u,w) = \text{Ad}^{-1}_{\psi(w)} X_u(w).
\]

**Lemma 5.2.14.** Both \( \mu \) and \( \mu^{-1} \) belong to \( \mathcal{L}^b \), and

\[
\mu(s,u;w) \rightarrow \exp \text{Ad}^{-1}_{\psi(w)} X_u(w) = \psi(w)^{-1} \zeta_u(w) \psi(w).
\]
Proof. Write \( \xi(0, w) = \exp(U(w)) \) with \( U(w) = \text{Ad}^{-1}_{\psi(w)} X(0, w) \). The lemma follows from (5.2.11).

Define \( \lambda = \lambda_1 \cdot \lambda_2 \) by
\[
\begin{align*}
\lambda_1(t, w) &:= \epsilon(s, u; w) \nu_w(y) \epsilon(s, u; w)^{-1} \\
\lambda_2(t, w) &:= \epsilon(s, u; w) \xi(t, w) \epsilon(s, u; w)^{-1},
\end{align*}
\]
so that
(5.2.15) \( \Phi(t, w) = \psi(w) \exp \left( \sum x_j N_j \right) \epsilon(t, w)^{-1} \lambda(t, w) \epsilon(t, w) \cdot \tilde{F}_w. \)

Set
(5.2.16) \( N(u, w) := \sum_{\alpha} \hat{\mathcal{N}}_{\alpha}(u, w) \text{ Ad}^{-1}_{\psi(w)} N(u, 0). \)

Lemma 5.2.17 ([CKS86, §5]). Both \( \lambda \) and \( \lambda^{-1} \) belong to \( (\mathcal{O} \otimes \mathcal{L})^b \), and
\[ \lambda(t, w) \rightarrow \psi(w)^{-1} \exp(\sqrt{-1} N(u, 0)) \zeta_u(w) \psi(w). \]

When \( \ell = 0 \), the lemma is proved by Cattani–Kaplan–Schmid in [CKS86, pp. 511–512]. Their argument extends to the general case with only minor modification; we sketch the proof here for completeness.

Proof. The proof of [CKS86 (5.12)] applies here to yield
\[
\begin{align*}
\text{Ad}_{\epsilon(s, u; w)} \text{Ad}^{-1}_{\psi(w)} \delta_0 &\rightarrow 0, \\
\text{Ad}_{\epsilon(s, u; w)} \sum_{i=1}^{k} y_i N_i &\rightarrow N(u, w),
\end{align*}
\]
so that
(5.2.19) \( \lambda_1(t, w) \rightarrow \exp(\sqrt{-1} N(u, 0)). \)

From (5.1.6) and (5.2.12) we see that the nilpotent orbit asymptotically approximating \( \Phi(t, w) \) is
\[
\theta(t, w) = \left( \sqrt{-1} \delta_0 + \sum_{i=1}^{k} \ell(t_i) N_i \right) \zeta(0, w) \cdot \tilde{F}_0
= \psi(w) \exp \left( \sum x_j N_j \right) \nu_w(y) \zeta(0, w) \cdot \tilde{F}_w
= \psi(w) \exp \left( \sum x_j N_j \right) \epsilon(s, u; w)^{-1} \lambda_1(s, u; w) \epsilon(s, u; w) \zeta(0, w) \cdot \tilde{F}_w.
\]

Fix a \( G_\mathbb{R} \)-invariant distance \( d \) on \( D \). Keeping (5.2.8) and (5.2.15) in mind, the nilpotent orbit theorem [CKS86 (1.15.iii)] implies
\[ d \left( \Phi(t, w), \theta(t, w) \right) = d \left( \lambda(t, w) \cdot \tilde{F}_w, \lambda_1(t, w) \mu(s, u; w) \cdot \tilde{F}_w \right) \rightarrow 0. \]

It then follows from Lemma 5.2.14 and (5.2.19) that
\[ \lambda(t, w) \cdot \tilde{F}_w \rightarrow \exp(\sqrt{-1} N(u, w)) \cdot \psi(w)^{-1} \zeta_u(w) \psi(w) \cdot \tilde{F}_w. \]

Therefore
\[ \lambda_2(t, w) \cdot \tilde{F}_w \rightarrow \psi(w)^{-1} \zeta_u(w) \psi(w) \cdot \tilde{F}_w. \]
Since both $\lambda_2(t, w)$ and $\psi(w)^{-1} \zeta_u(w)\psi(w)$ take value in $\exp(\hat{n}_u)$, it follows from (5.1.5) that (5.2.20)
\[
\lambda_2(t, w) \rightarrow \psi(w)^{-1} \zeta_u(w)\psi(w).
\]
The lemma now follows from (5.2.16), (5.2.19) and (5.2.20). \hfill \square

5.3. **Computing the limit.** First we show that the limit on the left-hand side of (5.1.12) exists, and then we show that equality holds.

Define
\[
h^1_{ab} = h^1_{ab}(u, w) := Q \left( \exp(2\sqrt{-1}N(u, 0))\zeta_u(w) v_a, \overline{\zeta_u(w)} v_b \right),
\]
and $h^1(u, w) := \det(h^1_{ab}(u, w))$.

**Lemma 5.3.2.** Suppose that $t \in (\Delta^s)^K$. Then
\[
\partial_{w_i} \partial_{\overline{w_j}} \log h_A(t, w) \rightarrow \partial_{w_i} \partial_{\overline{w_j}} \log h^1(u, w).
\]

**Proof.** Setting
\[
\tilde{v}_a(w) := \psi(w)^{-1} v_a,
\]
we have
\[
v_a(t, w) = \psi(w) \exp\left(\sum x_j N_j \varepsilon(s, u; w)^{-1} \lambda(t, w) \varepsilon(s, u; w) \cdot \tilde{v}_a(w)\right).
\]
Since $\tilde{v}_a(w) \in \hat{I}^n_{w, q}$, for some $q = q(a)$, it follows from (5.2.6) that we may choose real analytic functions $A^c_a(u, w)$ so that $A^c_a(u, w)\tilde{v}_c(w)$ is an eigenvector of $Y^\alpha(u, w)$ with eigenvalue $e_{\alpha a} \in \mathbb{Z}$, $1 \leq \alpha \leq \rho$, and that $I^c_{w, q}$ is spanned by these eigenvectors. Furthermore, it follows from (5.2.3) and (5.3.3) that we may assume that $A^c_a(u, w) = A^c_a(u)$ is independent of $w$. The matrix $A(u) = (A^c_a(u))$ is nonsingular; let $A^{-1}(u) = (B^b_c(u))$ denote the inverse. Then
\[
\varepsilon(s, u; w) \cdot \tilde{v}_a(w) = \sum_{b, c} B^c_a(u) \left( \prod_{\alpha} s_{\alpha c}^{e_{\alpha a}/2} \right) A^b_c(u) \tilde{v}_b(w).
\]
So, setting
\[
C^b_c(s, u) := \sum_{c} B^c_a(u) \left( \prod_{\alpha} s_{\alpha c}^{e_{\alpha a}/2} \right) A^b_c(u),
\]
we have
\[
h_{ab}(t, w) := h_{F^n}(v_a(t, w), v_b(t, w))
= (\sqrt{-1})^n Q \left( \lambda(t, w) \varepsilon(s, u; w) \cdot \tilde{v}_a(w), \overline{\lambda(t, w) \varepsilon(s, u; w) \cdot \tilde{v}_b(w)} \right)
= (\sqrt{-1})^n \sum_{c, d} Q \left( \lambda(t, w) \cdot \tilde{v}_c(w), \lambda(t, w) \cdot \tilde{v}_d(w) \right) C^c_a(s, u) C^d_b(s, u).
\]
This yields
\[
h_A(t, w) = \det(h_{ab}(t, w))
= \det(C) \det \left[ (\sqrt{-1})^n Q \left( \lambda(t, w) \cdot \tilde{v}_a(w), \overline{\lambda(t, w) \cdot \tilde{v}_b(w)} \right) \right] \det(C).
\]
Notice that
\[ \det C = \prod_{\alpha, c} s_{\alpha c}^{e_{ac}/2}. \]

So (5.1.13) yields
\[ (5.3.4) \quad \partial_{w_i} \partial_{w_j} \log h_A(t, w) = \partial_{w_i} \partial_{w_j} \log \det \left[ Q \left( \lambda(t, w) \cdot \nu_a(w), \lambda(t, w) \cdot \nu_b(w) \right) \right]. \]

By Lemma 5.2.17 and (5.3.3) we have
\[ (5.3.5) \quad \partial_{w_i} \partial_{w_j} \log h(\lambda(t, w)) = \partial_{w_i} \partial_{w_j} \log h_A(t, w). \]

The lemma now follows from (5.3.4), (5.3.5) and (5.3.6). \( \square \)

From the lemma we see that in order to prove (5.1.12), and establish Theorem 5.1.3, it remains to show that
\[ (5.3.7) \quad \partial_{w_i} \partial_{w_j} \log h^1(u, w) = \partial_{w_i} \partial_{w_j} \log h_A(t, w). \]

**Proof of (5.3.7).** First recall that \( \sum y_j N_j \) commutes with \( \xi(0, w) \). Consequently, \( \text{Ad}_{\xi(s, u; w)} \sum y_j N_j \) commutes with \( \mu(s, u; w) \). It follows from Lemma 5.2.14 and (5.2.18) that \( N(u, w) \) and \( \psi(w)^{-1} \zeta(u) \psi(w) \) commute. Then (5.2.16) implies \( N(u, 0) \) and \( \zeta(u) \psi(w) \) commute. Finally, we note that (5.2.5) implies that \( \zeta(u) \) preserves the \( \tilde{I}_{0, \ell} = \oplus_{p+q=\ell \tilde{P}_q^0} \), for all \( \ell \). These observations, along with the fact that \( N(u, 0) \) polarizes the MHS \( (W, \tilde{F}_0) \), implies
\[ h_{ab}^1(u, w) := \begin{cases} (2\sqrt{-1})^q Q \left( \zeta(u)N(u, 0)^q \nu_a, \zeta(u) \nu_b \right), & q = q(a) = q(b); \\ 0, & \text{otherwise}. \end{cases} \]

The observation (5.1.13) implies
\[ (5.3.8) \quad \partial_{w_i} \partial_{w_j} \log h^1(u, w) = \partial_{w_i} \partial_{w_j} \log h^2(u, w), \]

where \( h^2(u, w) = \det(h_{ab}^2(u, w)) \) is given by
\[ h_{ab}^2(u, w) := \begin{cases} Q \left( \zeta(u)N(u, 0)^q \nu_a, \zeta(u) \nu_b \right), & q = q(a) = q(b); \\ 0, & \text{otherwise}. \end{cases} \]

Each of the cones
\[ \sigma := \text{span}_{R>0} \{ N_1, \ldots, N_k \} \quad \text{and} \quad \hat{\sigma}_u := \text{span}_{R>0} \{ \hat{N}_1(u, 0), \ldots, \hat{N}_p(u, 0) \} \]
is contained in an \( \text{Ad}(G_{0,0}^{0,0}) \)-orbit, where
\[
G_{0,0}^{0,0} := \left\{ g \in G_{\mathbb{R}} \mid \text{Ad}_g \tilde{h}_{0}^{p,q} = \tilde{h}_{0}^{p,q}, \ \forall \ p, q \right\},
\]
is the real group preserving the Deligne splitting, cf. [Rob16 Corollary 4.9]. Additionally, [CKS86 (4.20.vi)] implies they lie in the same orbit. In particular, there exists \( g(u) \in G_{0,0}^{0,0} \) so that \( N(u, 0) = \text{Ad}_{g(u)}N \). Therefore \( N(u, 0)^a v_a = g(u)N^q g(u)^{-1}v_a \). Since \( g(u) \) preserves both \( \tilde{I}^{n,q} \) and \( N^q(\tilde{I}^{n,q}) = \tilde{I}^{n,q,0} \), there exist functions \( g(u)^a_q, q = q(a) = q(b) \), so that
\[
(5.3.9) \quad N(u, 0)^a v_a = g(u)N^q g(u)^{-1}v_a = g(u)_a b N^q v_b.
\]
So we have
\[
h_{ab}^2(u, w) := \begin{cases} g(u)^a g(u)^b \prod_{\gamma} h_{cd}^2(u, w), & q = q(a) = q(b); \\ 0, & \text{otherwise.} \end{cases}
\]
where
\[
h_{cd}^3(u, w) := \begin{cases} Q \left( \zeta(u)N^q v_c, \zeta(u) v_d \right), & q = q(a) = q(b); \\ 0, & \text{otherwise.} \end{cases}
\]
Setting \( h^3(u, w) = \det(h_{ab}^2(u, w)) \), (5.1.13) and (5.3.8) yield
\[
(5.3.11) \quad \partial_{\epsilon_i} \partial_{\epsilon_j} \log h^3(u, w) = \partial_{\epsilon_i} \partial_{\epsilon_j} \log h^3(u, w).
\]
From (5.1.15) and (5.3.11) we see that in order to complete the proof of (5.3.7) it remains to show that
\[
(5.3.12) \quad \partial_{\epsilon_i} \partial_{\epsilon_j} \log h^3(u, w) = \partial_{\epsilon_i} \partial_{\epsilon_j} \log h^3(u, w).
\]
Recall that \( \zeta_{I}(w) = \exp(X_{I}(w)) \), with \( X_{I}(w) \) taking value in
\[
\mathfrak{z} \subset \mathfrak{w} = \bigoplus_{\epsilon_1, \ldots, \epsilon_p \geq 0} \mathfrak{g}_{-\epsilon_1, \ldots, -\epsilon_p}(u, 0).
\]
(cf. (5.1.6) (5.1.9), (5.2.10) and (5.2.13)). In fact, (5.2.5) implies that \( X_{I}(w) \) is the component of \( X(0, w) \in \mathfrak{z} \) taking value in
\[
\mathfrak{z} \cap \ker Y_0 = \mathfrak{z} \cap \bigoplus_{\epsilon_1, \ldots, \epsilon_{p-1} \geq 0} \mathfrak{g}_{-\epsilon_1, \ldots, -\epsilon_{p-1}, 0}(u, 0),
\]
and that this intersection is independent of \( u \). Consequently, \( \zeta_{u}(w) = \exp X_{u}(w) \), with \( X_{u}(w) \) the component of \( X_{I}(w) \) (or \( X(0, w) \)) taking value in \( \mathfrak{g}_{0,\ldots,0}(u, 0) \). It follows from (5.2.11) that
\[
(5.3.13) \quad \varepsilon(s, u; 0) \zeta_I(w) \varepsilon(s, u; 0)^{-1} = \exp \text{Ad}_{\varepsilon(s, u; 0)} X_I(w) \overset{\rightarrow}{\longrightarrow} \exp X_u(w) = \zeta_u(w).
\]
Since \( Q \) is \( G \)-invariant, and \( \varepsilon(s, u; 0) \) is \( G_{\mathbb{R}} \)-valued, we have
\[
(5.3.14) \quad Q \left( \varepsilon(s, u; 0) \zeta_I(w) \varepsilon(s, u; 0)^{-1} N^q v_a, \varepsilon(s, u; 0) \zeta_I(w) \varepsilon(s, u; 0)^{-1} v_b \right) = Q \left( \zeta_I(w) \varepsilon(s, u; 0)^{-1} N^q v_a, \zeta_I(w) \varepsilon(s, u; 0)^{-1} v_b \right).
\]
Setting
\[ h''_{ab}(s, u; w) := \begin{cases} Q \left( \zeta_I(w)\varepsilon(s, u; 0)^{-1}N^q \nu_a, \zeta_I(w)\varepsilon(s, u; 0)^{-1}\nu_b \right), & q = q(a) = q(b), \\ 0 & q(a) \neq q(b), \end{cases} \]
and recalling the definition (5.3.10), (5.3.13) and (5.3.14) yield
\[ h''(s, u; w) := \det (h''_{ab}(s, u; w)) \rightarrow h^3(u, w) \]
and
\[ \partial_{w_i} \partial_{w_j} h''(s, u; w) \rightarrow \partial_{w_i} \partial_{w_j} h^3(u, w). \]

On the other hand, as noted after (5.2.7), \( \varepsilon(s, u; 0) \) preserves both \( \tilde{I}_{0}^{n,q} = \text{span}\{\nu_a\}_{q=q(a)} \) and \( \tilde{I}_{0}^{n-q,0} = \text{span}\{N^q\nu_a\}_{q=q(a)} \). In particular, there exist invertible matrices \( A(s, u)^{c}_{a} \) and \( B(s, u)^{d}_{b} \) so that \( \varepsilon(s, u; 0)^{-1}N^q \nu_c = A(s, u)^{c}_{a} N^q \nu_a \) and \( \varepsilon(s, u; 0)^{-1} \nu_b = B(s, u)^{d}_{b} \nu_d \). Consequently,
\[ h''_{ab}(s, u; w) = \sum_{q=q(c)=q(d)} A(s, u)^{c}_{a} Q \left( \zeta_I(w)N^q \nu_c, \zeta_I(w)\nu_d \right) B(s, u)^{d}_{b} \]
\[ = \sum_{q=q(c)=q(d)} A(s, u)^{c}_{a} h'_{F'}(w)^{c}_{d} B(s, u)^{d}_{b}, \]
where the last equality is due to (5.1.14b). Then (5.1.13), (5.1.14) and (5.3.16) yield
\[ \partial_{w_i} \partial_{w_j} \log h''(s, u; w) = \partial_{w_i} \partial_{w_j} \log h'_{A'}(w). \]
The desired (5.3.12) now follows from (5.3.15) and (5.3.17). \( \square \)

6. Proof that the extended augmented Hodge bundle is ample

In this section we will prove Theorem 1.3.8: the extended augmented Hodge bundle \( \hat{A}_e \rightarrow \hat{M} \) is ample. The proof will be given in two steps, the first of which is a general result – not related to Hodge theory – and is an extension to singular varieties of the classical Kodaira theorem. The second step will extend the proof of the first to the case where the metric and curvature have singularities of the type described in Sections 4 and 5.

6.1. Extension of Kodaira’s theorem. In this step it will be convenient to change our notation to better reflect the general nature of the result being proved. Thus we assume
- \( X \) is a compact, complex analytic variety;
- \( L \rightarrow X \) is a holomorphic line bundle having a Hermitian metric whose Chern form \( \Omega \) is positive in the Zariski tangent spaces to \( X \).
We further assume that \( X \) is covered by open neighborhoods \( U \) which are realized as analytic subvarieties in \( \mathbb{C}^N \), and that the restrictions \( L|_U \cong O_U \) are trivialized and the metric in \( L|_U \) is the restriction to \( U \) of a positive smooth function defined on an open set in \( \mathbb{C}^N \).
- \( \tilde{X} \rightarrow X \) is a desingularization of \( X \) with connected fibres; we set \( \tilde{L} = \pi^*L \).
Although it is probably not necessary, we also assume that \( \tilde{X} \) is a smooth projective variety, as this will be the case for our application to Hodge theory.
Definition 6.1.1. The line bundle $L$ is:

- **ample** if for any coherent analytic sheaf $\mathcal{F} \to X$, we have $h^q(\mathcal{F} \otimes L^m) = 0$ for $q > 0$ and $m \geq m_0(\mathcal{F})$;
- **strictly nef** if for any analytic curve $C \subset X$ we have $L \cdot C = \deg(L|_{C_{\text{red}}}) > 0$.

Theorem 6.1.2. The line bundle $L \to X$ is ample.

Finally we shall relax the first assumption above in that we allow $X$ to be a complex analytic scheme; i.e., we do not assume that the analytic space $(X, \mathcal{O}_X)$ is reduced. This is necessary as the proof will be given by induction on $\dim X$, and even if $X$ itself is reduced we shall see that in the intermediate steps of the argument the analytic varieties that arise may not be reduced. The second assumption above should then be that $L_{\text{red}} \to X_{\text{red}}$ has a Hermitian metric with a positive Chern form as described there.

The argument establishing Theorem 6.1.2 is an adaptation of the standard one in algebraic geometry; e.g. [KM98, pages 31ff]. The building blocks are the following three lemmas. (It is really the Lemmas 6.1.3 and 6.1.4 that are needed for the argument.)

Lemma 6.1.3. The line bundle $L \to X$ is strictly nef.

Proof. For any $k$-dimensional analytic subvariety $Z \subset X$ we have $$L^k \cdot Z := c_1(L)^k[Z_{\text{red}}] > 0.$$ The reason for this is that for $\tilde{C} = \pi^{-1}(C) \subset \tilde{X}$ we first have $$c_1(L)[C_{\text{red}}] = c_1(\tilde{L})[\tilde{C}_{\text{red}}].$$ Then $\tilde{\Omega} = \pi^*(\Omega)$ is non-negative $(1,1)$ form on $\tilde{X}$ with the property that for $\xi \in T\tilde{X}$, $$\tilde{\Omega}(\xi) = 0 \iff \pi_*(\xi) = 0.$$ It follows that $$c_1(\tilde{L})[\tilde{C}_{\text{red}}] = \int_{\tilde{C}_{\text{red}}} \tilde{\Omega} > 0.$$

Lemma 6.1.4. The line bundle $L \to X$ is big.

Proof. This is a direct consequence of results of Demailly [Dem12], specifically his holomorphic Morse inequalities. It also follows from the work of Siu [Si] on the Grauert-Riemenschneider conjecture. If $\dim X = d$, then since $\tilde{\Omega} \geq 0$ and $\tilde{\Omega}^d > 0$ on a Zariski open set in $\tilde{X}$, it follows from the Riemann-Roch theorem that the Euler characteristic $$\chi[L^m] = cm^d + \cdots, \quad c > 0.$$ By Demailly (loc. cit.) $$h^q(\tilde{L}^m) = o(m^d), \quad q > 0$$ which gives that $\tilde{L} \to \tilde{X}$ is big.
We next have
\[ 0 \to \mathcal{O}_X \to \pi_* \mathcal{O}_{\tilde{X}} \to \mathcal{F} \to 0, \]
where \( \mathcal{F} \) is supported on a proper subvariety of \( X \). Since \( \tilde{L} \) is trivial on the connected fibres of \( \tilde{X} \), we have
\[ 0 \to L^m \to \pi_* \tilde{L}^m \to \mathcal{F} \otimes L^m \to 0. \]
The lemma now follows from
\[ H^0(\tilde{X}, \tilde{L}^m) \cong H^0(X, \pi_* \tilde{L}^m) \]
and the big-ness of \( \tilde{L} \to \tilde{X} \).

The key step in the proof of Theorem 6.1.2 is

**Lemma 6.1.5.** The line bundle \( L \to X \) is free.

**Proof.** We allow the case that \( X \) is not reduced, and follow the classical argument. Replacing \( L \) by a high power, we use (6.1.3) to give that there exists a possibly non-reduced effective divisor \( Y \in |L| \). By the induction assumption, \( L_Y = \mathcal{O}_Y(L) \) is ample. From the cohomology sequence of
\[ 0 \to L^m_X - 1 \to L^m_X \to L^m_Y \to 0 \]
and \( h^1(L_Y^m) = 0, \) for \( m \gg 0, \) we obtain
\[ H^1(L_Y^m - 1) \to H^1(L_Y^m) \to 0, \quad m \geq m_0. \]
Thus the \( h^1(L^m) \) are non-increasing for \( m \geq m_0 \), and for \( m \geq m_1 \) we will have
\[ H^1(L_Y^m - 1) \sim H^1(L_Y^m). \]
This gives
\[ H^0(L_X^m) \to H^0(L_Y^m) \to 0. \]
Then since \( L_Y \to Y \) is free the same will be true for \( L_X \to X \).

**Proof of Theorem 6.1.2**. In the case that \( X \) is reduced the linear systems \( |mL| \) for \( m \gg 0 \) give holomorphic — not just meromorphic — maps
\[ \varphi_m : X \to \mathbb{P}^{N_m} \]
with
\[ \varphi_m^* \mathcal{O}_{\mathbb{P}^{N_m}}(1) = L^m. \]
By Lemma 6.1.3 no positive-dimensional subvariety of \( X \) is contracted by \( \varphi_m \), so that \( \varphi_m \) is a finite map and this gives the result in this case.

To give the argument when \( X \) may not be reduced we proceed by induction on \( \dim X \). If \( \dim X = 1 \) the result follows from
\[ \deg \left( L|_{X, \text{red}} \right) > 0 \]
where $X_\alpha$ are the irreducible components of $X$. If $\dim X$ is arbitrary, assuming as we may that $X$ is irreducible, in the exact sequence
\begin{equation}
0 \to \mathcal{F} \to \mathcal{O}_X \to \mathcal{O}_{X_{\text{red}}} \to 0
\end{equation}
the sheaf $\mathcal{F}$ has a filtration whose associated graded sheaves $\operatorname{Gr}^i \mathcal{F}$ are $\mathcal{O}_{X_{\text{red}}}$-modules. Tensoring (6.1.6) with $L^m$ and using the result $h^1(\mathcal{O}_{X_{\text{red}}}, \operatorname{Gr}^i \mathcal{F} \otimes L^m) = 0$ for $m \gg 0$ in the reduced case leads, by the usual spectral sequence argument, to $h^1(X, \mathcal{F} \otimes L^m) = 0$ for $m \gg 0$.

6.2. **Proof of Theorem 1.3.8.** The proof of Theorem 1.3.8 now may be completed by combining the argument just given with Theorem 1.3.10 as stated in the introduction. We first note that for any irreducible curve $C \subset M$ we have
\begin{equation}
\deg \left( \hat{\Lambda}_e \mid_C \right) = \int_C \hat{\Omega}_e > 0.
\end{equation}
Indeed, for some index set $I$ the intersection $C^* =: C \cap Z^*_I$ will be a Zariski open set in $C$. From the analysis of the singularities of $\hat{\Omega}_e$ given in Section 4 (cf. Proposition 4.3.3), it follows that the integral in (6.2.1) is defined. By the construction of $\mathcal{M}$, the image $\Phi_I(C^*) \subset \Gamma_I \setminus D_I$ is a (possibly non-complete) curve, and consequently the integral is positive.

We next show that if $\dim M = d$, then the integral
\begin{equation}
\int_{\mathcal{M}} \hat{\Omega}_e^d > 0
\end{equation}
is defined and is positive. This result is proved in [CKS86] with important amplifications in [Kol87]. It also follows from the calculation in Sections 4 and 5. In a neighborhood of a point in a codimension one stratum $Z^*_I$ the calculations in Section 4 easily give the result. In general one needs to consider possible cross-terms of the form
\[
dt_i \wedge \alpha \left( \frac{\log |t_i|}{|t_i|} \right)^a \quad \frac{\dt_j \wedge \alpha}{|t_j| \left( \log \frac{1}{|t_j|} \right)^b}
\]
where $\alpha$ is either $C^\infty$ or has a $\dt_j / |t_j| \left( \log \frac{1}{|t_j|} \right)^b$ term. The first case is easy, since $\dt_j$ must appear elsewhere in $\hat{\Omega}_e^d$. In the second case, since both $a, b$ are positive any such term will not cause the integral to diverge.

Once we have (6.2.1) and (6.2.2) we need to adapt the argument used in §6.1 to complete the proof. Let $Y \subset \mathcal{M}$ be the divisor of a nonzero section of $\hat{\Lambda}_e \otimes m \to \mathcal{M}$. If the restriction of $\hat{\Lambda}_e$ to each irreducible component of $Y$ is ample, then $\hat{\Lambda}_e \to Y$ is ample; so we may assume without loss of generality that $Y$ is irreducible. If the intersection $Y \cap M$ is Zariski open in $Y$, then after a standard modification to $\overline{B}_Y := \pi^{-1}(Y) \subset \overline{B}$ we may suppose that $\overline{B}_Y$ is smooth and the complement of $B_Y := \pi^{-1}(Y \cap M)$ in $\overline{B}_Y$ is a normal crossing divisor. In general, there will be a stratum $Z^*_I$ of $Z$ with the property that $Z^*_I \cap B_Y$ is Zariski open in $\overline{B}_Y$. Then we may use the period mapping $\Phi_I: Z^*_I \to \Gamma_I \setminus D_I$ to obtain the desired result.
The approach above may be summarized as follows. If the restriction $\hat{\Omega}_e|_{Y_{\text{red}}}^{0}$ is defined, then we just use the argument that was given for $L \to X$ in §6.1. In general there will be a Zariski open $Y_{\text{red}}^0 \subset Y$ with the property that $\hat{\Omega}_e|_{Y_{\text{red}}}^{0}$ is defined. The argument then proceeds as above.

Appendix A. The Siegel property

A.1. The one–variable case: Schmid’s work. Schmid [Sch73, (5.29)] proved the following:

**Theorem A.1.1** (Schmid). Let $\hat{\Phi} : \mathcal{H} \to D$ be a lift of a one-variable period map $\Phi : \Delta^* \to \Gamma \backslash D$. Given $c_1, c_2 > 0$, there exists a Siegel domain $\mathcal{D} \subset D$ so that $\hat{\Phi}(z) \in \mathcal{D}$ when $|\text{Re } z| < c_1$ and $\text{Im } z > c_2$.

This result is a consequence of the Nilpotent Orbit Theorem and Schmid’s [Sch73, (5.25)]. The latter basically asserts

**Proposition A.1.2** (Schmid). Given a one-variable nilpotent orbit $\theta(z) := \theta(zN) \cdot F$, the point $\theta(\sqrt{-1}y)$ lies in a Siegel domain when $y \gg 0$.

So to generalize Theorem A.1.1 to the several-variable case, it appears that it would suffice to generalize this result of nilpotent orbits to the several-variable case. Unfortunately it does not.

A.2. Feasibility of generalizing Schmid. The definition (§A.3) of a Siegel domain $\mathcal{D}^{P,K}$ depends on a choice of parabolic subgroup $P \subset G$ and maximal compact subgroup $K \subset G$. Schmid’s statements in [Sch73, §5] are for the case that $P$ is a minimal (rational) parabolic subgroup $P_0$. These do not generalize:

There exist several–variable nilpotent orbits $\theta(z_1, \ldots, z_s)$ on the period domain $D$ for Hodge numbers $h = (2, 2)$ for which there exist no $(P_0, K)$–Siegel domain so that $\theta(\sqrt{-1}y_1, \ldots, \sqrt{-1}y_s) \in \mathcal{D}^{P_0,K}$ when $y_j \gg 0$ (Claim A.5.8).

This is the sense in which Schmid’s Proposition A.1.2 does not generalize. However, there is another parabolic that, unlike the minimal parabolic, is canonically associated with the nilpotent orbit: if $P$ is the (in general, non-minimal) parabolic stabilizing the weight filtration of $\theta$, then one might imagine that the answer to the following question is “yes”.

*Given any several–variable nilpotent orbit $\theta(z_1, \ldots, z_s)$ on the period domain $D$ for Hodge numbers $h = (2, 2)$, are the points $\theta(z_1, \ldots, z_s)$ contained in a $(P, K)$–Siegel domain when $|\text{Re } z_j|$ is bounded and $\text{Im } z_j \gg 0$?*

An affirmative answer to this questions seems to us to be the most natural and plausible generalization of Schmid’s one-variable result. If it fails, then it seems extremely unlikely that any generalization of Schmid’s one-variable result will hold (i.e., that it might hold for another choice of parabolic). Unfortunately, we will see that the answer is indeed “no” (Claims A.5.8 and A.5.9).
A.3. Siegel domains. Let $D$ be any period domain with automorphism group $G$. The definition of a Siegel domain depends on a choice of parabolic subgroup $P \subset G$ and maximal compact subgroup $K$. Briefly: Let $P = UAM \simeq U \times A \times M$ be the Langlands decomposition of $P$; here

- $U$ is the unipotent radical of $P$,
- $A = \exp(\mathfrak{a})$, with $\mathfrak{a} \subset \mathfrak{p}$ a diagonalizable (abelian) subalgebra,
- $Z(A) = A \times M$ is a Levi subgroup,
- both $A$ and $M$ are invariant under the Cartan involution $\theta_K$ determined by $K$.

Together $G = PK$ and the Langlands decomposition yield the horospherical decomposition

$$D = U \times A \times (MZ)$$

where $Z = K \cdot \varphi$, with $\varphi \in D$ satisfying $\text{Stab}_G(\varphi) \subset K$.

Let $\Sigma(\mathfrak{u}, \mathfrak{a}) \subset \mathfrak{a}^*$ be a choice of simple roots for the action of $\mathfrak{a}$ on $\mathfrak{u}$. We may identify $\Sigma(\mathfrak{u}, \mathfrak{a})$ with characters $\Sigma(U, A)$ on $A$ as follows: given $a = \exp(\xi) \in A$, define $a^\alpha = e^{\alpha(\xi)}$. Given $t > 0$, define

$$A_t := \{ a \in A \mid a^\alpha > t, \ \forall \alpha \in \Sigma \}.$$

A Siegel domain is any set of the form

$$\mathcal{D}^{P,K}_{\omega,t,\mu} := \omega A_t \mu \cdot Z \subset D,$$

where $\omega \subset U$ and $\mu \subset M$ are open pre-compact sets. Note that $\omega A_t \mu \subset UAM = P$ is open, so that $\mathcal{D}^{P,K}_{\omega,t,\mu}$ is open in $D$.

A.4. Nilpotent orbits. Fix a several variable nilpotent orbit

$$\theta(z) = \exp(\sum z_j N_j) \cdot F;$$

here $z = (z_1, \ldots, z_s) \in \mathbb{C}^s$. Let $(W, F)$ be the associated MHS. Let $(W, \tilde{F} = e^{\sqrt{-1}t}F)$ be Deligne’s associated $\mathbb{R}$-split MHS, with Deligne splittings

$$V_C = \oplus I^{p,q} \text{ and } g_C = \oplus g^{p,q},$$

and $\mathbb{R}$-split nilpotent orbit

$$\tilde{\theta}(z) := \exp(\sum z_j N_j) \cdot \tilde{F}.$$

Set

$$N := \sum N_j,$$

and

$$\varphi := \exp(\sqrt{-1}N) \cdot \tilde{F} \in D.$$

Let $K \subset G$ be the maximal compact subgroup containing the stabilizer of $\varphi$. Let $P \subset G$ be the parabolic subgroup stabilizing the filtration $W$. If the $N_a \in \mathfrak{g}_Q$, then $W$ and $P$ are defined over $\mathbb{Q}$. Assume this is the case.

Set

$$G^{0,0} = \{ g \in G \mid g(I^{p,q}) = I^{p,q}, \ \forall \ p, q \}.$$
Let
\[ N := \text{Ad}(G^{0,0}) \cdot N \subset \mathfrak{g}_{-1,-1} \]
be the \( G^{0,0} \)-orbit of \( N \). Then

**Lemma A.4.1 (BPR16).** The nilpotent cone \( \sigma \) is contained in the orbit \( N \). Conversely, any nilpotent cone \( \tau = \text{span}_{\mathbb{R}^>0}\{M_1,\ldots,M_r\} \subset N \) generated by commuting nilpotents \( M_j \) underlies a nilpotent orbit through \( \bar{F} \).

**A.5. The counter-example: \( h = (2,2) \).** There are two types of MHS on the period domain \( D \) for \( h = (2,2) \); that is, there are two types of Hodge diamonds. One is Hodge–Tate. For the other, the polarizing nilpotent cones are necessarily one dimensional, so that the associated nilpotent orbits are one-variable. Here Schmid’s Proposition A.1.2 applies: “eventually” the nilpotent orbit lies in a Siegel domain. We will show that the several-variable nilpotent orbits of Hodge–Tate type fail to “eventually” lie in Siegel domains (Claims A.5.8 and A.5.9).

**A.5.1. Set-up.** Suppose
\[ V = \mathbb{Q}^4 = \text{span}_{\mathbb{Q}}\{e_1,\ldots,e_4\}. \]
Define a skew–symmetric bilinear form \( Q \) on \( V \) by \( Q(u,v) = u^t q v \), where
\[ q := \begin{pmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \\ 0 & -1 & 0 & 0 \\ -1 & 0 & 0 & 0 \end{pmatrix}. \]
Let \( D \) be the period domain parameterizing \( Q \)-polarized Hodge structures on \( D \) with Hodge numbers \( h = (2,2) \). Fix point \( \varphi \in D \) by
\[ H^{1,0}_{\varphi} := \text{span}_{\mathbb{C}}\{\zeta_1 = e_1 + \sqrt{-1}e_4, \zeta_2 = e_2 + \sqrt{-1}e_3\}. \]
Note that the maximal compact subgroup of \( G \) containing the stabilizer of \( \varphi \) is the group \( K \) of \( \{A.5.1\} \) Then
\[ G = \text{Aut}(\mathbb{R}^4,Q) = \text{Sp}(4,\mathbb{R}) \quad \text{and} \quad K = \text{Stab}_G\varphi = \text{U}(2). \]
The Lie algebras are
\[ \mathfrak{g} = \left\{ \begin{pmatrix} a & b & s & t \\ c & d & u & s \\ x & y & -d & -b \\ z & x & -c & -a \end{pmatrix} \middle| a,b,c,\ldots,z \in \mathbb{R} \right\}. \]
and

\[ \mathfrak{k} = \mathfrak{g} \cap \mathfrak{so}(4) = \{ X \in \mathfrak{g} \mid X + X^t = 0 \} = \left\{ \begin{pmatrix} 0 & b & s & t \\ -b & 0 & u & s \\ -s & -u & 0 & -b \\ -t & -s & b & 0 \end{pmatrix} \right\} \mid b, s, t, u \in \mathbb{R} \}.

A.5.2. A minimal parabolic. Let \( \mathfrak{p}_0 \subset \mathfrak{g} \) be the minimal parabolic subalgebra of upper-triangular matrices. Then \( \mathfrak{p}_0 = \mathfrak{a}_0 \oplus \mathfrak{u}_0 \), where

\[ \mathfrak{a}_0 = \left\{ \text{diag}(a, d, -d, -a) := \begin{pmatrix} a & 0 & 0 & 0 \\ 0 & d & 0 & 0 \\ 0 & 0 & -d & 0 \\ 0 & 0 & 0 & -a \end{pmatrix} \mid a, d \in \mathbb{R} \right\}
\]
is the maximal abelian subalgebra of diagonal matrices, and

\[ \mathfrak{u}_0 = \left\{ \begin{pmatrix} 0 & b & s & t \\ 0 & 0 & u & s \\ 0 & 0 & 0 & -b \\ 0 & 0 & 0 & 0 \end{pmatrix} \right\} \mid b, s, t, u \in \mathbb{R} \}
\]
are the strictly upper-triangular matrices. Note that the real rank of \( \mathfrak{g} \) is \( 2 = \dim \mathfrak{a}_0 \).

Remark A.5.1 (Siegel domains). In this example \( M_0 \) is the set of diagonal matrices of the form \( \text{diag}(\epsilon_1, \epsilon_2, -\epsilon_2, -\epsilon_1) \), with \( \epsilon_j = \pm 1 \). These matrices all act trivially on \( \varphi \). So \( U_0 A_0 M_0 \cdot \varphi = U_0 A_0 \cdot \varphi \). Therefore, the \((P_0, K)\)-Siegel domains in \( D \) are of the form

\[ \mathcal{D}_{\omega, t}^{P_0, K} = \omega A_{0, t} \cdot \varphi, \]

with \( \omega \subset \exp(\mathfrak{u}_0) = U_0 \) an open pre-compact set, and

(A.5.2) \[ A_{0, t} := \{ \text{diag}(e^a, e^d, e^{-d}, e^{-a}) \mid a, d \in \mathbb{R}, a - d, 2d > \ln t \} \]
\[ \subset A_0 := \exp(\mathfrak{a}_0), \]

with \( t > 0 \). Here we are using the simple roots \( \{ \epsilon_1 - \epsilon_2, 2\epsilon_2 \} = \Sigma(\mathfrak{a}_0, \mathfrak{u}_0) \) where \( \{ \epsilon_1, \epsilon_2 \} \) is the basis of \( \mathfrak{a}_0^* \) dual to \( \{ e_1^1 - e_2^1, e_2^2 - e_3^2 \} \subset \mathfrak{a}_0 \).

A.5.3. A maximal parabolic. Let \( \mathfrak{p} \subset \mathfrak{g} \) be the maximal parabolic subalgebra stabilizing \( \text{span}_\mathbb{R}\{\epsilon_1, \epsilon_2\} \). Then \( \mathfrak{p} = \mathfrak{u} \oplus \mathfrak{a} \oplus \mathfrak{m} \), where

\[ \mathfrak{a} = \text{span}_\mathbb{R}\{Y = \text{diag}(-1, -1, 1, 1)\}, \]
\[
\mathfrak{m} = \left\{ \begin{pmatrix} a & b & 0 & 0 \\ c & -a & 0 & 0 \\ 0 & 0 & a & -b \\ 0 & 0 & -c & -a \end{pmatrix} \right\} \quad | \quad a, b, c \in \mathbb{R} \quad \simeq \mathfrak{sl}(2, \mathbb{R}).
\]

and
\[
\mathfrak{u} = \left\{ \begin{pmatrix} 0 & 0 & s & t \\ 0 & 0 & u & s \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix} \right\} \quad | \quad s, t, u \in \mathbb{R} \right\}.
\]

**Remark A.5.3 (Siegel domains).** In this example \( M = \text{SL}(2, \mathbb{R}) \). We have \( \Sigma(a,u) = \{ \varepsilon_1 + \varepsilon_2 = 2\varepsilon_2 \} \), so that
\[
A_t = \{ \text{diag}(e^a, e^a, e^{-a}, e^{-a}) | 2a > \ln t \}.
\]

**A.5.4. Commuting SL(2)'s.** Let \( \{ e^1, \ldots, e^4 \} \) denote the dual basis of \( V^* \), and set
\[
e_i^j := e_i \otimes e^j.
\]

The following two commuting standard triples \( \{ \hat{N}^+_j, Y_j, \hat{N}_j \} \subset \mathfrak{g} \)
\[
\hat{N}_1 = -e_4^1, \quad Y_1 = e_4^1 - e_1^1, \quad \hat{N}_1^+ = e_4^1,
\]
\[
\hat{N}_2 = -e_3^2, \quad Y_2 = e_3^2 - e_2^2, \quad \hat{N}_2^+ = e_3^2.
\]
determine horizontal SL(2)'s at the point \( \varphi \in D \) given by
\[
H_{\varphi}^{2,0} = \text{span}_\mathbb{C}\{e_3 - \sqrt{-1}e_2, e_4 - \sqrt{-1}e_1\}.
\]

The filtration
\[
\hat{W} := W(\hat{N})[-1]
\]
is independent of our choice of \( \hat{N} \) in the cone
\[
\hat{\sigma} := \text{span}_{\mathbb{R}_>0}\{\hat{N}_1, \hat{N}_2\}.
\]
To be explicit
\[
\hat{W}_0 = \hat{W}_1 = \text{span}_{\mathbb{R}}\{e_1, e_2\} \quad \text{and} \quad \hat{W}_2 = V_{\mathbb{R}}.
\]
Set
\[
\hat{F} := \text{span}_{\mathbb{C}}\{e_3, e_4\} \in \hat{D}.
\]
Then \( (\hat{W}, \hat{F}) \) is a MHS polarized by \( \hat{\sigma} \). Modulo the action of \( G \) we may assume that
\[
(W, F) = (\hat{W}, \hat{F}),
\]

\[25\text{If we define } F_j \in \hat{D} \subset \text{Gr}(2, \mathbb{C}^4) \text{ by}
\]
\[
F_1 = \text{span}_{\mathbb{C}}\{e_4, e_2 + \sqrt{-1}e_3\},
\]
\[
F_2 = \text{span}_{\mathbb{C}}\{e_3, e_1 + \sqrt{-1}e_4\},
\]
then the \( (W(N_j)[-1], F_j) \) are \( \mathbb{R} \)-split PMHS.
and \( \hat{\sigma} \subset \mathcal{N} \). We make this assumption.

A.5.5. Details for \( G^{0,0} \) and \( \mathcal{N} \). Any element \( g \in G^{0,0} \) is of the form

\[
(A.5.4a) \quad g = \begin{pmatrix} B & 0 \\ 0 & B' \end{pmatrix},
\]

with

\[
(A.5.4b) \quad B = \begin{pmatrix} b_1 & b_2 \\ b_3 & b_4 \end{pmatrix} \quad \text{and} \quad B' = \frac{1}{\det P} \begin{pmatrix} b_1 & -b_2 \\ -b_3 & b_4 \end{pmatrix}
\]

invertible 2 \times 2 matrices. We have

\[
\text{Ad}_g(\lambda_1 \hat{N}_1 + \lambda_2 \hat{N}_2) = \begin{pmatrix} 0 & \eta \\ 0 & 0 \end{pmatrix},
\]

with

\[
\eta = B \begin{pmatrix} 0 & -\lambda^1 \\ -\lambda^2 & 0 \end{pmatrix} (B')^{-1} = -\lambda^1 \begin{pmatrix} b_1 b_3 & b_1 b_1 \\ b_3 b_3 & b_3 b_1 \end{pmatrix} - \lambda^2 \begin{pmatrix} b_2 b_4 & b_2 b_2 \\ b_4 b_4 & b_4 b_2 \end{pmatrix}.
\]

Remark A.5.5. We have

\[
\mathfrak{g}_{\mathbb{R}}^{-1,-1} = \text{span}_{\mathbb{R}} \{ e_1^4, e_2^3, e_1^3 + e_2^4 \}.
\]

The boundary of \( \mathcal{N} \) is the \( G^{0,0} \) orbit of \( \hat{N}_1 = -e_1^4 \). Moreover, the orbit is convex. So our given nilpotent cone \( \sigma \subset \mathcal{N} \), is contained in a nilpotent cone

\[
\sigma' = \text{span}_{\mathbb{R}^{>0}} \{ N'_1, \ldots, N'_s \} \subset \mathcal{N}
\]

with \( N'_j \in \partial \mathcal{N} \). Without loss of generality, we will assume that \( \sigma = \sigma' \) and \( N_j = N'_j \). In particular,

\[
N_j = -r_j(e_1^3 + e_2^4) - p_je_2^3 - q_je_1^4,
\]

with

\[
(A.5.6a) \quad p_j, q_j \geq 0 \quad \text{and} \quad r_j^2 = p_j q_j.
\]

Moreover, we may assume that \( \hat{N}_1 + \hat{N}_2 = -e_1^4 - e_2^3 \in \sigma \). In fact, we assume that

\[
\hat{N}_1 + \hat{N}_2 = \sum N_j;
\]

equivalently,

\[
(A.5.6b) \quad \sum r_j = 0 \quad \text{and} \quad \sum p_j = 1 = \sum q_j.
\]
A.5.6. Nilpotent orbits and Siegel sets. It will be convenient to introduce the following notation. Define
\[ \|y\|^2 := \sum y_j^2 \quad \text{and} \quad \lambda_j := \frac{y_j}{\|y\|}, \]
so that
\[ y_j = \|y\| \lambda_j. \] (A.5.7)
Set
\[ \lambda = (\lambda_1, \ldots, \lambda_s), \]
and
\[ N_\lambda := \sum \lambda_j N_j, \]
so that \( \tilde{\theta}(\sqrt{-1} y_1, \ldots, \sqrt{-1} y_s) = \exp(\sqrt{-1} \|y\| N_\lambda) \cdot \tilde{F} \). For fixed \( \lambda \), Schmid’s Proposition A.1.2 asserts that \( \exp(\sqrt{-1} \|y\| N_\lambda) \) lies in a \((P_0, K)\)-Siegel domain if \( \|y\| \gg 0 \). (From here it is straightforward to show that \( \exp(\zeta N_\lambda) \) lies in a \((P_0, K)\)-Siegel domain if \( \text{Re}\zeta \) is bounded and \( \text{Im}\zeta \gg 0 \).) Claim A.5.8 asserts that this fails (when \( s > 1 \)) if we allow \( \lambda \) to vary. Likewise, Claim A.5.9 asserts that \( \tilde{\theta}(z_1, \ldots, z_s) \) fails to lie in a \((P, K)\)-Siegel domain when the \( \text{Re} z_j \) are bounded and \( \text{Im} z_j \gg 0 \) (Claim A.5.9).

Claim A.5.8. If \( s > 1 \), then there exist no bounds \( c_1, c_2 > 0 \) so that \( \tilde{\theta}(z_1, \ldots, z_s) \) is contained in a \((P_0, K)\)-Siegel domain when \( \text{Re} z_j \) bounded and \( \text{Im} z_j \gg 0 \).

Claim A.5.9. If \( s > 1 \), then there exist no bounds \( c_1, c_2 > 0 \) so that \( \tilde{\theta}(z_1, \ldots, z_s) \) is contained in a \((P, K)\)-Siegel domain when \( \text{Re} z_j \) bounded and \( \text{Im} z_j \gg 0 \).

Proof of Claim A.5.8. We will show that, for all \( T > 0 \), there exists no \((P_0, K)\)-Siegel domain containing \( \tilde{\theta}(\sqrt{-1} y_1, \ldots, \sqrt{-1} y_s) \) for all \( y_j > T \). On the one hand we have
\[ \tilde{\theta}(\sqrt{-1} y_1, \ldots, \sqrt{-1} y_s) = \exp(\sqrt{-1} (y_1 N_1 + \cdots + y_s N_s)) \cdot \tilde{F} \] (A.5.10)
\[ = \text{span}_\mathbb{C} \{ e_3 - \sqrt{-1}(\sum r_j y_j)e_1 - \sqrt{-1}(\sum p_j y_j)e_2, \quad e_4 - \sqrt{-1}(\sum q_j y_j)e_1 - \sqrt{-1}(\sum q_j y_j)e_2 \}. \]
Set
\[ r(y) := \sum r_j y_j, \quad p(y) := \sum p_j y_j \quad \text{and} \quad q(y) := \sum q_j y_j. \]
On the other hand, elements of \( U_0 = \exp(u_0) \) are of the form
\[ \nu = \begin{pmatrix} 1 & \beta & u_1 & u_3 \\ 0 & 1 & u_0 & u_2 \\ 0 & 0 & 1 & -\beta \\ 0 & 0 & 0 & 1 \end{pmatrix}. \]
with \( u_1 - u_2 = \beta u_0 \). Elements of \( A_0 \) are of the form \( \gamma = \text{diag}(e^a, e^d, e^{-d}, e^{-a}) \) with \( a, d \in \mathbb{R} \). So elements of \( U_0 A_0 \cdot \varphi \) are of the form

\[
\nu \gamma \cdot H^{1.0}_\varphi = \nu \cdot \text{span}_\mathbb{C}\{e_3 - \sqrt{-1}e^{2d}e_2, e_4 - \sqrt{-1}e^{2a}e_1\}
\]

(A.5.11)

Comparing (A.5.10) and (A.5.11), we see that we see that

\[
\tilde{\theta}(A.5.11)
\]

To see the problem with the third equation, consider the case that \( \sigma \) is a problem. Substituting with (A.5.7), the equations above become

\[
\begin{align*}
\text{(Note some)} & \quad \nu \delta \cdot H^{1.0}_\varphi = \text{span}_\mathbb{C}\left\{e_3 - \sqrt{-1}\beta e^{2d}e_1 - \sqrt{-1}e^{2a}e_1, e_4 - \sqrt{-1}(e^{2a} + \beta^2 e^{2d})e_1 - \sqrt{-1}(\beta e^{2d})e_2\right\}.
\end{align*}
\]

(A.5.12)

Comparing (A.5.10) and (A.5.12), we see that

\[
\begin{align*}
\text{(A.5.13)} & \quad r(y) = \beta e^{2d}, \quad p(y) = e^{2d} \quad \text{and} \quad q(y) = e^{2a} + \beta^2 e^{2d},
\end{align*}
\]

and \( \tilde{\theta}(\sqrt{-1}y_1, \ldots, \sqrt{-1}y_s) \) will lie in a \((P_0, K)\)-Siegel domain when \( y_j \gg 0 \) if and only if \( \beta \) is bounded and there exists \( t > 0 \) so that \( e^{2a}/e^{2d}, e^{2d} > t \) for \( y_j \gg 0 \). Solving (A.5.13) yields

\[
\begin{align*}
\quad e^{2d} & = p(y) \to \infty \text{ as } y_j \to \infty \text{ (assuming some } p_i \neq 0 \text{)},
\quad \beta & = \frac{r(y)}{p(y)} \text{ is bounded},
\quad e^{2a}/e^{2d} & = \frac{q(y)}{p(y)} - \left(\frac{r(y)}{p(y)}\right)^2.
\end{align*}
\]

(Note some \( p_i \) is necessarily nonzero, else \( \sigma = \text{span}_{\mathbb{R}}{\hat{N}_1} \subset \partial \mathcal{N} \).) The third expression is a problem. Substituting with (A.5.7), the equations above become

\[
\begin{align*}
\quad e^{2d} & = ||y|| p(\lambda) \to \infty \text{ as } y_j \to \infty \text{ (some } p_i \neq 0 \text{)},
\quad \beta & = \frac{r(\lambda)}{p(\lambda)} \text{ is bounded},
\quad e^{2a}/e^{2d} & = \frac{q(\lambda)}{p(\lambda)} - \left(\frac{r(\lambda)}{p(\lambda)}\right)^2.
\end{align*}
\]

To see the problem with the third equation, consider the case that \( \sigma = \hat{\sigma} \); that is, \( s = 2 \) and \( p_1 = 1, p_2 = 0, q_1 = 0, q_2 = 1, \) so that \( r_1 = 0 \). We have \( r(\lambda) = 0 \) and \( q(\lambda)/p(\lambda) = \lambda_2/\lambda_1 = y_2/y_1 \), which may be arbitrarily close to zero regardless of the size of \( y_j \). \( \square \)
Proof of Claim A.5.9. In this case elements of $U = \exp(u)$ are of the form
\[
\nu = \begin{pmatrix}
1 & 0 & u_1 & u_2 \\
0 & 1 & u_0 & u_1 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1
\end{pmatrix}.
\]
Elements of $A$ are of the form $\gamma = \text{diag}(e^a, e^a, e^{-a}, e^{-a})$ with $a \in \mathbb{R}$. And elements $g \in M$ are of the form (A.5.4) with $B \in \text{SL}(2, \mathbb{R})$. So elements of $UAM \cdot \varphi$ are of the form (A.5.14)
\[
\nu \gamma g \cdot H_{\varphi}^{1,0} = \text{span}_\mathbb{C}\{ e_3 + u_1 e_1 + u_0 e_2 - \sqrt{-1} e^{2a}(B_1 \cdot B_2 e_1 + B_2 \cdot B_2 e_2), e_4 + u_2 e_1 + u_1 e_2 - \sqrt{-1} e^{2a}(B_1 \cdot B_1 e_1 + B_1 \cdot B_2 e_2) \}.
\]
Here $B_1$ and $B_2$ are the first and second rows of $B$, respectively, and $B_i \cdot B_j$ denotes the dot product. As in the proof of Claim A.5.8, comparing (A.5.14) with (A.5.11) we see that $\tilde{\theta}(\sqrt{-1} y_1, \ldots, \sqrt{-1} y_8)$ will lie in $UAM \cdot \varphi$ if and only if it lies in $AM \cdot \varphi$. (That is, $u_i = 0$.) Equivalently, if we can solve (A.5.15)
\[
r(y) = e^{2a} B_1 \cdot B_2, \quad p(y) = e^{2a} B_2 \cdot B_2 \quad \text{and} \quad q(y) = e^{2a} B_1 \cdot B_1
\]
for $a$ and $B$ (in terms of $y$). Moreover, $\tilde{\theta}(\sqrt{-1} y_1, \ldots, \sqrt{-1} y_8)$ will lie in a $(P, K)$-Siegel domain when $y_j > 0$ if and only if $B(y)$ is bounded (for this will then force $e^{2a(y)} \to \infty$ as $y_j \to \infty$).

To see that this will fail in general, consider the case that $\sigma = \text{span}_{\mathbb{R}^+}\{ \hat{N}_1, \hat{N}_2 \}$. That is, $p = (p_1, p_2) = (0, 1)$ and $q = (q_1, q_2) = (1, 0)$, and $r_1 = r_2 = 0$. Then $r(y) = 0$ implies $B_1(y)$ and $B_2(y)$ are orthogonal, and $B(y) = 1$ implies $1 = \|B_1(y)\| \cdot \|B_2(y)\|$. Then
\[
\|B_1(y)\|^4 = \frac{\|B_1(y)\|^2}{\|B_2(y)\|^2} = \frac{q(y)}{p(y)} = \frac{y_1}{y_2}
\]
may be arbitrarily large regardless of a lower bound on the $y_j$. That is, there exists no lower bound $c > 0$ so that $\theta(\sqrt{-1} y_1, \sqrt{-1} y_2)$ lies in a $(P, K)$-Siegel domain when $y_j > c$. This example extends to the general case that $s > 1$ and some $r_i = 0$. □

Appendix B. Positivity of the Hodge vector bundle

B.1. Introduction. The purpose of this appendix is to give, without formal proofs which will appear elsewhere, three properties of the canonically extended Hodge vector bundle $F_e \to \overline{B}$, and to formulate some interesting questions related to these results. The underlying issues are these:

The Hodge vector bundle is semi-positive, but almost never positive. Just how much positivity does it have? What positivity is there for bundles naturally constructed from it? What information does the Hodge vector bundle carry beyond that in the Hodge line bundle?
One measure of the positivity of the Hodge vector bundle is its curvature form. Another is its numerical dimension $n(F_e)$. This is a quantity defined purely in terms of its Chern classes; it may be computed from $F_e$’s curvature forms. In general the word “positivity” suggests “sections,” so yet another measure of positivity is its Kodaira dimension $\kappa(F_e)$. All these quantities will be defined below. Informally stated, one result is

**Theorem B.1.1.** We have $\kappa(F_e) \leq n(F_e)$. (And we conjecture that equality holds under the assumption of finite monodromy in (B.6.2) below. This assumption is satisfied if $F_e \to \mathcal{B}$ is globally generated.)

The theorem and conjecture are discussed in §§ B.5–B.6.

For the second result, we assume that the end piece $\Phi_{*,n}$ of the differential of the VHS is generically injective. Then we have

**Theorem B.1.2.** (i) $\text{Proj}(\Lambda e \otimes F_e)$ exists and has dimension equal to $\dim \mathcal{P}F_e$.

(ii) The bundle $F_e$ captures some of the extension data of the limiting mixed Hodge structures over $\mathcal{B}\setminus \mathcal{B}$.

The precise meaning of (ii) will be explained in §B.8.

Metric positivity often arises as follows: There is a Hermitian vector bundle $G \to X$ and a holomorphic bundle mapping

$$A : TX \to \text{Hom}(E, G)$$

such that the curvature form is given by

$$\Theta_E(e, \xi) = \|A(\xi)e\|^2,$$

where $\| \cdot \|^2$ is the metric in $G$. When (B.1.3) holds we have $\Theta_E \geq 0$, and the linear algebra properties of (B.1.3a) translate into positivity properties of the curvature form.

**Remark B.1.4.** The property (B.1.3) is functorial. If it is satisfied for triples $(E_1, G_1, A_1)$ and $(E_2, G_2, A_2)$, then it is also holds for the triple $(E, G, A)$ given by $E = E_1 \otimes E_2$, $G = (G_1 \otimes E_2) \oplus (E_1 \otimes G_2)$ and $A(\xi)(e_1 \otimes e_2) = (A_1(\xi)e_1 \otimes e_2) + (e_1 \otimes A_2(\xi)e_2)$. It follows that

$$A(\xi)(e_1 \otimes e_2) = \Theta_{E_1}(e_1, \xi)\|e_2\|^2 + \|e_1\|^2\Theta_{E_2}(e_2, \xi) = \|A_1(\xi)e_1\|^2\|e_2\|^2 + \|e_1\|^2\|A_2(\xi)e_2\|^2.$$

In this case, the condition that there exists $x \in X$ and $e \in E_x$ so that $A_x(e) : T_xX \to G_x$ is injective (cf. the hypothesis of Theorem B.1.5(b)) is the statement that

$$(A_{1,x}(e_1) \otimes \text{Id}_{E_y}) \oplus (\text{Id}_{E_1} \otimes A_{2,x}(e_2)) : T_xX \to (G_{1,x} \otimes E_{2,x}) \oplus (E_{1,x} \otimes G_{2,x})$$

is injective. This suggests that passing to tensor products, or direct summands of such, may make semi-positive bundles “more positive”. As illustrations of this principle, we have the following result.

---

26As noted in (1.3.4), the curvature of the Hodge vector bundle has the form (B.1.3) where $A$ is the end piece $\Phi_{*,n}$ of the differential of the period mapping.
Theorem B.1.5. Assume that the curvature of \( E \to X \) is of the form (B.1.3).

(a) If there exists \( x \in X \) so that \( A_x : T_xX \to \text{Hom}(E_x, G_x) \) is injective, then \( \det E = \bigwedge^r E \) is big.

(b) If there exists \( x \in X \) and \( e_1, \ldots, e_r \in E_x \) so that
\[
A_x(e_1, \ldots, e_r) : T_xX \to \bigoplus \text{Sym}^{r-1} E_x \otimes G_x \to G_x
\]
is injective, then \( S^r E \) is big.

We note the obvious symmetry: In (B.1.3a) we may consider \( A \) as a map \( TX \otimes E \to G \), and (a) and (b) of the theorem correspond to injectivity assumptions on each of the two factors \( TX \) and \( E \), respectively. The proof of the theorem is sketched in §B.2. A consequence of Theorem B.1.5(b) is

Theorem B.1.6. When the weight \( n = 1, 2 \), the HT-SBB completion \( \overline{M} \) is log canonical.

In §B.9 we will indicate an argument for the weaker (than Theorem B.1.6) result

Theorem B.1.7. If \( \Phi_{*,n} \) is injective at one point, then \( \Omega_B^d(\log Z) \) is big, where \( d = \dim B \).

Theorem B.1.6 can be extended to higher weights, but we shall not take this up here. There are are number of similar, stronger results in the literature (cf. [Bru16b] and the references cited there; cf. also [Bru16a, BKT13, Zuo00]). Our main points are (1) to give a result describing a property of the HT-SBB completion, and (2) to indicate that the property that the curvature matrix be of the form \( \Theta_E = -A^\wedge A \), with \( A \) given by (B.1.3a), suggests that the measure of positivity of \( E \to X \) be expressed by the linear algebra properties of \( A \). As will be discussed elsewhere, this can lead to alternative, and perhaps simpler, arguments of how “positivity produces sections.”

For a holomorphic vector bundle \( E \to X \) over a smooth projective variety there are three main notions of positivity: metric, numerical and cohomological. We shall review the first two in §§B.2 & B.4 respectively. The last one is equivalent to weak positivity, a notion that is due to Vieweg and has been used extensively by him and others in connection with the Iitaka conjecture and related questions (cf. [Vie83a, Vie83b, Kol87] for some classical references); we shall not discuss this topic here.

B.2. Metric positivity. Given a holomorphic vector bundle \( E \to X \) over a complex manifold, uniquely associated to a Hermitian metric in the bundle is the Chern connection with associated curvature

\[
\Theta_E \in A^{1,1}(\text{End} E)
\]
(cf. [Dem12]). The associated curvature form is defined for \( x \in X \) and \( e \in E_x, \xi \in T_xX \) by

\[
\Theta_E(e, \xi) = \langle (\Theta_E(e), e), \xi \wedge \overline{\xi} \rangle.
\]

The vector bundle \( E \to X \) is positive if there exists a metric whose curvature form satisfies

\[
\Theta_E(e, \xi) > 0
\]
for $e, \xi$ non-zero. We should say “$E \to X$ is metrically positive,” but will omit the “metrically” since this is the main form of positivity we shall be concerned with.

We shall say that $E \to X$ is semi-positive if we have

$$\Theta_E(e, \xi) \geq 0.$$ 

We sometimes write $\Theta_E > 0$ and $\Theta_E \geq 0$ for positivity and semi-positivity, respectively.

A central issue is: For Hodge-theoretic purposes positivity is often too strong and semi-positivity is too weak. One desires a notion that is computationally useful and which has significant geometric consequences.

**Sketch of the proof of Theorem B.1.5(a).** Assume that the curvature of $E \to X$ is of the form (B.1.3). If there exists $x \in X$ so that $A_x : T_xX \to \text{Hom}(E_x, G_x)$ is injective, then $\Theta_{\det E} = \text{Tr} \Theta_E$ is positive on a Zariski open set. The result then follows from [Dem12]. □

**Sketch of the proof of Theorem B.1.5(b).** Let $\omega_r$ represent $c_1(\mathcal{O}_{\mathbb{P}SE}(1))$. At $[e_1 \cdots e_r] \in (\mathbb{P}SE)_x$ and for $\xi \in T_xX$, we have

$$\langle \omega, \xi \wedge \bar{\xi} \rangle = \sum_j \|A(\xi \otimes e_j)\|^2 \|e_1 \cdots \hat{e_j} \cdots e_r\|^2 > 0,$$

The result then again follows from [Dem12]. □

**Remark B.2.1.** To prove Theorem B.1.6 we need to extend the above argument to take into account the singularities of $A$ along $Z$. This is similar to, but simpler than, the singularity analysis given in §5.

**B.3. Interpretation of the curvature form.** Associated to $E \to X$ is the projective bundle $\mathbb{P}E \to X$ with fibres $(\mathbb{P}E)_x = \mathbb{P}E_x^* = 1$-dimensional quotients of $E_x$. Points in $(\mathbb{P}E)_x$ will be denoted by $(x, [\ell])$ where $\ell \in E_x^*$. The tautological bundle $\mathcal{O}_{\mathbb{P}E}(1)$ has fibres $\mathcal{O}_{\mathbb{P}E}(1)_{(x,[\ell])} = E_x/\ell^\perp$. For all $m \geq 0$ we have

$$\pi_*\mathcal{O}_{\mathbb{P}E}(m) = S^m E.$$

A metric in $E \to X$ induces one in $\mathcal{O}_{\mathbb{P}E}(1)$, and we denote by $\omega$ the corresponding curvature form. Then restriction of $\omega$ to a fibre is the Fubini-Study form which is positive. Using this property of $\omega$ the vertical tangent space to the fibres

$$V_{(x,[\ell])} := \ker\{\pi_* : T_{(x,[\ell])}\mathbb{P}E \to T_xX\}$$

has a horizontal complement

$$V^\perp_{(x,[\ell])} = H_{(x,[\ell])} \xrightarrow{\sim} T_xX.$$

Decomposing

$$\omega = \omega_V + \omega_H$$

into its vertical and horizontal components we may identify $\omega_H$ with the curvature form. More precisely, using the metric to identify $E_x^* \cong E_x$ and letting $[e] \in \mathbb{P}E_x$ correspond to
$[\ell] \in \mathbb{P}E_x^{\ast}$ normalized to have $\|e\| = 1$, we have for the value $\omega(\xi) = \langle \omega, \xi \wedge \xi \rangle$ of $\omega$ on $\xi \in H(x,[\ell])$ the formula

$$\omega(\xi) = \Theta_E(e, \xi).$$

As a consequence

$$\Theta_E > 0 \implies \mathcal{O}_{PE}(1) \text{ is ample.}$$

B.4. Numerical positivity. We will consider polynomials $P(c_1, \ldots, c_r) \in \mathbb{Q}[c_1, \ldots, c_r]$ that are weighted by setting $\deg c_i = i$. The cone $\mathcal{C}$ of positive polynomials in $\mathbb{Q}[c_1, \ldots, c_r]$ is defined in [Gri69] and [Laz04], page 119.

Definition B.4.1. A rank $r$ holomorphic vector bundle $E \to X$ over a smooth projective variety is numerically positive if

$$P(c_1(E), \ldots, c_r(E)) > 0$$

for all $P \in \mathcal{C}$ with $\deg P \leq \dim X$. $E \to X$ is numerically semipositive if we have

$$P(c_1(E), \ldots, c_r(E)) \geq 0.$$

The strict inequality means

$$\int_Z P(c_1(E), \ldots, c_r(E)) > 0$$

for all subvarieties $Z \subset X$ with $\dim Z = \deg P$, and similarly for the inequality $\geq 0$. From 8.39 in [Laz04] we have

$$\Theta_E > 0 \implies E \text{ is numerically positive.}$$

For our purposes we will use the result [Gri69]

$$\Theta_E > 0 \implies E \text{ is numerically semi-positive.}$$

Definition B.5.1. Suppose that $\Theta_E \geq 0$. Then the numerical dimension $n(E)$ of $E \to X$ is defined by $\omega^{n(E)+1} \equiv 0$ and

$$\omega^{n(E)} \not\equiv 0$$

on an open set.

Then $\omega \geq 0$ and $n(E)$ is equal to the numerical dimension of $\mathcal{O}_{PE}(1)$ in the sense of [Dem12, Bru16b]. We note that if $r = \text{rank } E$, then

- $n(E) \geq r - 1$;
- $n(E) = \dim X + r - 1$ if and only if $\mathcal{O}_{PE}(1)$ is big.
The numerical dimension \( n(E) \) may be defined in terms of the Chern classes of \( E \to X \) in the following way (cf. [Gri69, BKT13, Bru16b]). Noting that in de Rham cohomology we have
\[
\pi_*c_1(\mathcal{O}_{\mathbb{P}E}(1)) = \left( \frac{i}{2\pi} \right) \omega,
\]
there are weighted degree \( k \) Segre polynomials \( S_k(c_1, \ldots, c_k) \in \mathbb{C} \) such that
\[
\pi_*c_1(\mathcal{O}_{\mathbb{P}E}(1))^{r-1+k} = S_k(c_1(E), \ldots, c_r(E)) \geq 0.
\]
Then \( n(E) \) is defined by
\[
S_k(c_1(E), \ldots, c_r(E)) = 0 \quad \text{for} \quad k > n(E) - r + 1 \quad \text{and}
\]
\[
S_{n(E)-r+1}(c_1(E), \ldots, c_r(E)) \neq 0.
\]

Assume now that \( \Theta_E \) is given by (B.1.3b) and define
\[
\rho(E) = \begin{cases} 
\dim \text{Im}\{\xi \to A(\xi) \cdot e\} \text{ for general } \\
x \in X, e \in E_x \text{ and variable } \xi \in T_xX
\end{cases}
\]

**Proposition B.5.2.** \( n(E) = r - 1 + \rho(E) \).

**Proof.** This follows from (B.3.1) and
\[
\omega^{r-1+k} = \omega_Y^{r-1} \wedge \omega_H^{k} + \text{(terms involving } \omega_Y^\ell \text{ for } \ell < r - 1). \quad \square
\]

As previously noted, one wants an implication “positivity implies sections.” For line bundles \( L \to X \) over a compact complex manifold \( Y \) a standard measure of the amount of sections of powers of \( L \) is given by the Kodaira dimension \( \kappa(L) \). It is known ([Dem12]) that
\[
\kappa(L) \leq n(L)
\]
and that in general equality does not hold (loc. cit.). The examples where equality fails of which we are aware involve some aspect of flat bundles; we will return to this below.

**Definition B.5.4.** Assuming \( \mathcal{O}_{\mathbb{P}E}(1) \geq 0 \), the **Kodaira dimension** of \( E \to X \) is defined by
\[
\kappa(E) = \kappa(\mathcal{O}_{\mathbb{P}E}(1)).
\]

From (B.5.3) we have
\[
\kappa(E) \leq n(E).
\]

However, there is no general lower bound on \( \kappa(E) \); there exist \( E \) with any \( n(E) < r - 1 + \dim X \) and with \( \kappa(E) = -\infty \).

Ideally one would like numerical criteria that imply a lower bound on \( \kappa(E) \).\footnote{We note that by a result of Fulton there is no numerical criterion for ampleness of \( E \) (cf. [Laz04]).}

**Proposition B.5.5.** Suppose that we have \( f : Y \to X \) and a line bundle \( L \to Y \) with \( E = f_*L \). Let \( r = \text{rank } E \) and define
\[
E^{(r)} = f_*(L^r).
\]
Then if \( \dim X = d \) we have

\[
c_1(E)^d > 0 \implies \kappa(L^{(mr)}) \geq d \text{ for } m \gg 0.
\]

**Idea of the proof.** We have \( \det E \subset \otimes^r E \) giving

\[
\left( \det E \right)^m \subset S^m(\otimes^r E) = S^m(f_*L \otimes \cdots \otimes f_*L) \xrightarrow{\mu} f_*L^{mr}
\]

where \( \mu \) is the point-wise multiplication map of sections along the fibres of \( Y \xrightarrow{f} X \). The map is non-trivial because it is non-zero on decomposable tensors in \( S^m(f_*L \otimes \cdots \otimes f_*L) \). □

**B.6. Foliation defined by a semi-positive bundle.** The question is:

*Given a semi-positive holomorphic vector bundle \( E \rightarrow X \), how is one going to produce sections of \( \mathcal{O}_{PE}(m) \rightarrow PE \)?*

Suppose there are sections that give a regular map \( f : PE \rightarrow P^N \) with \( f^*\mathcal{O}_{P^N}(1) = \mathcal{O}_{PE}(m) \). Then \( \dim f(PE) = n(E) \), and on any fibre \( f^{-1}(p) \) the restriction

\[
\omega\big|_{f^{-1}(p)} = 0.
\]

This suggests that we consider the integral varieties of the exterior differential system (EDS) \( \omega = 0 \).

Given a non-negative (1,1) form \( \varphi \) on a complex manifold \( Y \) the EDS \( \varphi = 0 \) was studied by Bedford-Kalka [BK77] and Sommer [Som59] and used by Kollár in [Kol87]. They showed that on an open set \( \varphi = 0 \) defines a foliation whose leaves are complex analytic subvarieties. In general this foliation is only \( C^\infty \). In our situation we have the

**Proposition B.6.1.** Assume that the curvature of \( E \rightarrow X \) has the form (B.1.3b). Then

(i) the EDS \( \omega = 0 \) defines a complex analytic foliation \( \mathcal{F} \);

(ii) over the open set where \( \mathcal{F} \) is a sub-bundle of \( TP_E \) the leaves \( W \subset PE \) of \( \mathcal{F} \) are étalé over \( X \); and

(iii) along any such leaf the corresponding line sub-bundle of \( \pi^*E \rightarrow W \) is flat.

**Sketch of the argument.** Let \((x, \eta) \in (PE)_x = PE^*_x \). Since \( \omega > 0 \) in the fibres of \( PE \rightarrow X \), the null space \( \omega = 0 \) projects isomorphically to the subspace

\[
\text{Ker}\{T_xX \rightarrow \eta \otimes G_x\} \subset T_xX
\]

which implies (i) and (ii). For (iii), since the curvature form \( \omega|_W = 0 \) the line bundle \( \mathcal{O}_{PE}(1)|_W \) is flat. □

It follows that locally \( W \) projects isomorphically to a closed subvariety \( \pi(W) \subset X \). Analytic continuation around a closed path in \( \pi(W) \) induces a monodromy action on \( W \).

**Definition B.6.2.** We shall say that the monodromy of \( E \rightarrow W \) is finite if the above monodromy action is finite on connected components of the leaves \( W \) of \( \mathcal{F} \).
The examples in [Dem12] where $\Theta_E \geq 0$ and $\kappa(E) = -\infty$ do not have finite monodromy. In the case of finite monodromy a plausibility argument may be given that the quotient $\mathbb{P}E/\mathcal{F}$ is a compact analytic variety and some $\mathcal{O}_{\mathbb{P}E}(m)$ is trivial on the connected components of $\mathbb{P}E \to \mathbb{P}E/\mathcal{F}$. Using a Stein factorization would then lead to Theorem [B.1.1]

**B.7. Examples.**

**Example B.7.1.** We will take $X = G(k,n) = \text{Grassmanian of } k$-planes and $E = S^*$ the dual of the universal sub-bundle. For a $k$-plane $\Lambda \subset \mathbb{C}^n$ the fibre $S^*_\Lambda = \Lambda^*$. Points of $\mathbb{P}E$ are $(\Lambda, [v])$ where $v \in \Lambda$, and the fibre $\mathcal{O}_{\mathbb{P}E}(1)_{(\Lambda,[v])}$ is $\mathbb{C}v$. The global sections of $E \to G(k,n)$ span the fibres. The same is true of $\mathcal{O}_{\mathbb{P}E}(1) \to \mathbb{P}E$, and the resulting map $f : \mathbb{P}E \to \mathbb{P}^{n-1}$ is the tautological one $f(\Lambda,[v]) = [v] \in \mathbb{P}^{n-1}$.

For $p \in \mathbb{P}^{n-1}$, the fibre $f^{-1}(p) = \{k\text{-planes } \Lambda \text{ with } p \in \Lambda \} \cong G(k-1,n-1)$.

The Kodaira dimension $\kappa(E) = n - 1$.

**Remark B.7.2.** The analysis in this example extends to any globally generated vector bundle $E \to X$. The monodromy in the leaves of $\omega = 0$ is trivial in this case.

**Example B.7.3.** We consider the Hodge vector bundle $F \to B$ for a VHS of weight $n = 2$. We leave aside the issue of the singularities that arise over $\overline{B} \setminus B$ for the canonical extension. Then $F \subset \nabla$ where $\nabla \to B$ is the local system with flat metric given by $(v,w) = Q(v,\bar{w})$ for local sections $v,w$ of $\mathcal{O}_B(\nabla)$. If the metric were positive definite, then $F$ would have negative curvature and the $(1,1)$ form $\omega$ on $\mathbb{P}F$ would be positive along the fibres and negative in the horizontal direction. But due to the alteration of signs in the second Hodge-Riemann bilinear relations, the usual sign rules are reversed and $\omega_H$ is also positive.

**Example B.7.4.** In the geometric case of a VHS the differential $\Phi_*$ may be computed cohomologically via the usual Kodaira-Spencer type mechanism. For families of curves the relevant map is $T_bB \to \text{Hom}(H^0(\Omega^1_{C_b}), H^1(\mathcal{O}_{C_b}))$.

For example, for $B = \mathcal{M}_g$ one obtains the estimate $\kappa(F_c) \leq 2g - 1$.

We suspect that equality holds, but this seems to require dealing with the monodromy issue. (The same estimate holds for the Hodge bundle over $\mathcal{A}_g$.)
B.8. The Hodge vector bundle may detect discrete extension data.

Proposition B.8.1. On a subvariety \( Y \subset Z^*_I \) along which the period mapping \( \Phi_I \) is constant, the extended Hodge bundle \( F_{e,I} \to Y \) is flat. It may however have non-trivial monodromy.

Proof. \( F_{e,I} \) is filtered by \( W^\bullet(N_I) \cap F_{e,I} \). The Gauss-Manin connection \( \nabla \) acting on \( V_m \) preserves \( W^\bullet(N_I) \), and on the associated graded to \( W^\bullet(N_I) \cap F_{e,I} \). It follows that \( \nabla \) preserves \( F_{e,I} \subset O_Y(V) \).

\( \square \)

Example B.8.2. On an algebraic surface \( S \) suppose we have a smooth curve \( \tilde{C} \) of genus \( g(\tilde{C}) \geq 2 \), and that through each pair of distinct points \( p, q \in \tilde{C} \) there is a unique rational curve meeting \( \tilde{C} \) at two points.

Suppose moreover that along the diagonal \( D \subset \tilde{C} \times \tilde{C} \) the \( \mathbb{P}^1 \) becomes simply tangent. Then \( \tilde{C} + \mathbb{P}^1 \) is a nodal curve, and for \( m \gg 0 \) the pluricanonical map given by \( |m\omega_{\tilde{C} + \mathbb{P}^1}| \) contracts the \( \mathbb{P}^1 \) and we obtain an irreducible stable curve \( C_{p,q} \) with arithmetic genus \( p_a(C_{p,q}) = 3 \).

As \( \mathbb{P}^1 \) becomes tangent we obtain a cusp.

The extension data for the MHS is given (cf. [Car80]) by

\[ \text{AJ}_{\tilde{C}}(p - q) \in J(\tilde{C}). \]

When we turn around \( p = q \) we interchange \( p, q \); after base change \( t \to t^2 \) the extension class is well defined locally. Globally, it is another story.

The vector space \( H^0(\omega_{C_{p,q}}) \), which is the fibre of the canonically extended Hodge bundle, has the 2-dimensional fixed subspace \( H^0(\Omega^1_{\tilde{C}}) \) and variable 1-dimensional quotient represented by a differential of the third kind \( \varphi_{p,q} \in H^0(\Omega^1_{\tilde{C}}(p + q)) \). As \( p \to q \) the differential \( \varphi_{p,q} \) tends to a differential of the second kind \( \varphi_{2p} \in H^0(\Omega^1_{\tilde{C}}(2p)) \). For the global monodromy over \( Y = \tilde{C} \times \tilde{C} \setminus D \), the extension class is given for \( \psi \in H^0(\Omega^1_{\tilde{C}}) \) by

\[ \psi \to \int_p^q \psi \mod \text{periods}. \]

The action of \( \pi_1(Y) \) on \( H_1(\tilde{C}, \{p, q\}) \) may be shown to give an infinite subgroup of \( H_1(\tilde{C}, \mathbb{Z}) \), which implies the assertion.
Claim B.8.3. The Hodge vector bundle may detect continuous extension data.

Here continuous extension data means the extension classes that arise in the induced filtration of $F_e \to Y$ where there is a VLMHS over $Y$ with $F_e$ the Hodge vector bundle.

Example B.8.4. We let $\tilde{C}$ be a smooth curve with $g(\tilde{C}) \geq 2$ and $p \in \tilde{C}$ a fixed point. We construct a family $C_q, p \in \tilde{C}$, of stable curves as follows.

- For $q \neq p$ we identify $p, q$

  ![Diagram](B.8.5)

- For $p = q$, we obtain a curve

In this way we obtain a VMHS parametrized by $\tilde{C}$ and with trivial monodromy.

For the filtration on the canonically extended Hodge bundle there is a fixed part

$$W_1(N) \cap F_e^1 \cong H^0(\Omega_C^1),$$

and a variable part whose quotient is

$$W_2(N) \cap F_e^1 / W_1(N) \cap F_e^1 = \begin{cases} \mathbb{C} \varphi_{p,q} & \text{for } q \neq p \\ \mathbb{C} \varphi_{E,r} & \text{for } q = p. \end{cases}$$

The notation means that $\varphi_{E,r}$ is the differential of the third kind on the normalization of $E$ and with residues at $\pm 1$ at the two points over the node. Since there is no monodromy we may normalize the $\varphi_{p,q}$ and $\varphi_{E,r}$.

Combining we have over $\tilde{C}$ an exact sequence

$$0 \to H^0(\Omega_{\tilde{C}}^1) \otimes O_{\tilde{C}} \to F_e \to O_{\tilde{C}} \to 0$$

with non-trivial extension class

$$e = \text{“Identity”} \in H^1(O_{\tilde{C}}) \otimes H^0(\Omega_{\tilde{C}}^1).$$
B.9. **Idea underlying proof of Theorem B.1.7**. There are two aspects of the argument. One is a positivity property over $B$, where the necessary positivity is obtained by passing to summands of the tensor products of semi-positive bundles as indicated in Remark B.1.4. The second involves the singularities of the curvature along $B \setminus B$. Here we shall only deal with the first; the second will be treated elsewhere using [CKS86] and arguments from the literature and from Section 5 above that are based on that reference.

We shall sketch the argument in the cases of weights $n = 1, 2$. In both cases the triple $(E, G, A)$ in (B.1.3) may be taken to be 

\[ E = F^n =: F, \quad G = F^{n-1}/F^n \quad \text{and} \quad A = \Phi_{n,*}. \]

Starting from this we shall pass to summands of tensor products.

**The case $n = 1$.** We have

\[ A : TB \to \text{Hom}^* (F, F^*) = S^2 F^*. \]

For $B = A_g$, this mapping is an isomorphism and we shall make this identification. Using the notation from Theorem B.1.5, we have

**Lemma B.9.1.** For $X = A_g$ and $E = T^* X$, let $\omega$ be the $(1,1)$–form representing $c_1(O_{PE}(1))$. At a general point of $P_E$ we have $\omega^{\dim PE} \neq 0$.

As an application of the lemma, we have the following.

**Lemma B.9.2.** For $B \subset A_g$, $E_B := T^* B$ and $\omega_B = c_1(O_{PE_B}(1))$, we have $(\omega_B)^{\dim PE_B} \neq 0$ at a general point of $P_E B$.

This may be used to prove the following result.

**Proposition B.9.3 (Brunebarbe [Bru16b]).** The bundle $S^2 F_e \simeq \Omega^{1}_{B}(\log Z)$ is big.

Arguments that are by now fairly standard (cf. [Zuo00], [Bru16a, BKT13]) may be used to deduce Theorem B.1.7 from Proposition B.9.3.

**Proof of Lemma B.9.2**. Assume that Lemma B.9.1 holds. Then Lemma B.9.2 follows from the fact that curvatures increase on quotient bundles, and $\Omega^1_{B}$ is a quotient of $\Omega^1_{A_g|B}$.

**Sketch of the proof of Lemma B.9.1**. The point is to have the situation (B.1.3), and to use linear algebra to infer the result following the heuristic of Remark B.1.4.

The general linear algebraic situation is as follows: We are given a vector space $W$ with a non-degenerate alternating bilinear form that is used to identify $W \simeq W^*$. There is a natural map

\[ \sigma : S^2 W^* \to \text{Hom}(S^2 W, W^* \otimes W) \]

obtained from the symmetrization of the contraction mapping $(W^* \otimes W^*) \otimes (W \otimes W) \to W^* \otimes W$. We want to show that for a general $Q \in S^2 W^*$, $\sigma(Q) \in \text{Hom}(S^2 W, W^* \otimes W)$ is injective. Using Proposition B.5.2, this is what is needed to show that $\omega > 0$ at a
general point of $\mathbb{P}T^*A_g$. As may be checked in coordinates, $\sigma(Q)$ is injective when $Q$ is a nonsingular quadric.

Remark B.9.4. From the argument we see that $\omega$ has some degeneracy, which implies that $S^2\Omega_B^1(\log Z)$ is not, in general, ample over $B$.

The case $n = 2$.

Lemma B.9.5. For the canonically extended Hodge bundle $F_e \to \overline{B}$, $S^2F_e$ is big.

Sketch of proof. As before, the crucial point is to show that for $\omega$, the $(1, 1)$–form representing $c_1(\mathcal{O}_{\mathbb{P}S^2F}(1))$, we have

(B.9.6) $\omega^{\dim \mathbb{P}S^2F} \neq 0$ at a general point.

The argument is then completed by showing that $\omega$ extends from $\mathbb{P}S^2F$ to a closed $(1, 1)$–current on $\mathbb{P}S^2F_e$ that represents $c_1(\mathcal{O}_{\mathbb{P}S^2F_e}(1))$ and for which the exterior power $\omega^{\dim \mathbb{P}S^2F_e}$ is integrable (cf. [Kol87]). Again, as before, this comes down to a linear algebra property that we now isolate.

Let $T, W, U$ be vector spaces for which we have an injective linear map $A : T \to \text{Hom}(W, U)$. Suppose that there is on $U$ a non-degenerate, symmetric bilinear form; this yields an identification $U \simeq U^\ast$. Thinking of $A$ as a $T^\ast$–valued element of $\text{Hom}(W, U)$, we then have $\imath_A : U \to W^\ast$ and $\imath_A \wedge A \in \text{Hom}(W, W^\ast)$. We assume the integrability condition $\imath_A \wedge A = 0$ is satisfied. For such $A \in \text{Hom}(T \otimes W, U)$ we have the induced $S^2A \in \text{Hom}(T \otimes S^2W, W \otimes U)$ (cf. Remark B.1.4). The linear algebra condition needed to establish (B.9.6) is: For general $Q \in S^2W$, the composite map $\sigma(Q) : T \to T \otimes Q \overset{A}{\to} W \otimes U$ is injective. In fact the composite map is obtained from

\[
\begin{array}{ccc}
T & \xrightarrow{\sigma(Q)} & W \otimes U \\
\downarrow & & \downarrow \\
W^\ast \otimes U & \xrightarrow{\cdot Q} & W \otimes U
\end{array}
\]

by contracting with $Q$ in the first factor. Therefore it is injective when $Q$ is a nonsingular quadric. \hfill \Box

References

28In fact, integrability is not needed here, but will be used in the proof of Theorem B.1.7. This argument is somewhat lengthy and will be given elsewhere.
