Measure Upper Bounds for Nodal Sets of Eigenfunctions of the
bi-Harmonic Operator

Abstract: In this article, we consider eigenfunctions $u$ of the bi-harmonic operator, i.e., $\Delta^2 u = \lambda^2 u$ on $\Omega$ with some homogeneous linear boundary conditions. We assume that $\Omega \subseteq \mathbb{R}^n$ ($n \geq 2$) is a $C^\infty$ bounded domain, $\partial \Omega$ is piecewise analytic and $\partial \Omega$ is analytic except a set $\Gamma \subseteq \partial \Omega$ which is a finite union of some compact $(n-2)$ dimensional submanifolds of $\partial \Omega$. The main result of this paper is that the measure upper bounds of the nodal sets of the eigenfunctions is controlled by $\sqrt{\lambda}$. We first define a frequency function and a doubling index related to these eigenfunctions. With the help of establishing the monotonicity formula, doubling conditions and various a priori estimates, we obtain that the $(n-1)$ dimensional Hausdorff measures of nodal sets of these eigenfunctions in a ball are controlled by the frequency function and $\sqrt{\lambda}$. In order to further control the frequency function with $\sqrt{\lambda}$, we first establish the relationship between the frequency function and the doubling index, and then separate the domain $\Omega$ into two parts: a domain away from $\Gamma$ and a domain near $\Gamma$, and develop iteration arguments to deal with the two cases respectively.

Key Words: Eigenfunctions, bi-harmonic operator, frequency, doubling conditions, doubling index, measure estimates, nodal sets.

Mathematics Subject Classification(2010): 58E10, 35J30.

1 Introduction

In this paper, we focus on the eigenvalue problem \( \triangle^2 u = \lambda^2 u \) in \( \Omega \), where \( \triangle \) is the Laplacian operator. We always assume that \( \Omega \subseteq \mathbb{R}^n (n \geq 2) \) is a bounded domain and \( \partial \Omega \) is of \( C^\infty \) piecewise analytic and \( \partial \Omega \) is analytic except a set \( \Gamma \subseteq \partial \Omega \) which is a finite union of some \( (n-2) \)-dimensional submanifolds of \( \partial \Omega \). Through this paper, we always consider the following homogeneous boundary condition:

\[
B_j u = 0, \quad j = 1, 2, \quad \text{on} \quad \partial \Omega,
\]

where \( B_j u = \sum_{|\alpha| \leq 3} a_{\alpha,j}(x) D^\alpha u(x) \) on \( \partial \Omega \), and we also assume that the constants \( a_{\alpha,j}(x) \) are all \( C^\infty \) and piecewise analytic on \( \partial \Omega \), and analytic on \( \partial \Omega \setminus \Gamma \).

In 1979, F.J. Almgren in [1] introduced the frequency concept for the harmonic functions. Then in 1986 and 1987, N. Garofalo and F.H. Lin in [6] and [7] established the monotonicity formula for the frequency functions and the doubling conditions for solutions of uniformly linear elliptic equations of second order, and obtained the unique continuation property of such solutions. In 1991, F.H. Lin in [13] investigated the measure estimates of nodal sets of solutions to some uniformly linear elliptic equations of second order. In 2000, Q. Han, R. Hardt and F.H. Lin in [8] showed the structure of the nodal sets of solutions for a class of uniformly linear elliptic equations of higher order. It is pointed out that the nodal sets of solutions to higher order elliptic equations are very different from those of solutions to second order elliptic equations. For uniformly linear elliptic operators of second order, Hausdorff measures of critical zero sets of solutions are at most \( n-2 \) dimensional. But for uniformly linear elliptic operators of higher order, this conclusion is not always true. In fact, it is showed in [8] that, if \( u \) is a solution of an \( l \)-th order homogeneous uniformly elliptic equation, then the set \( \{ x \in \mathbb{R}^n | u(x) = 0, |\nabla u(x)| = 0, \cdots, |\nabla^{l-2} u(x)| = 0 \} \) may be \( n-1 \) dimensional, and the set \( \{ x \in \mathbb{R}^n | u(x) = 0, |\nabla u(x)| = 0, \cdots, |\nabla^{l-1} u(x)| = 0 \} \) must be at most \( n-2 \) dimensional. The latter set is called the singular set of those solutions. In 2003, Q. Han, R. Hardt and
F.H.Lin in [8] investigated the structures and measure estimates of singular sets of solutions to uniformly linear elliptic equations of higher order. In 2014, the authors in [20] gave the measure estimates of nodal sets for bi-harmonic functions.

On the other hand, there have been a number of very interesting and intensive results on nodal sets for eigenfunctions to elliptic operators. S.T.Yau conjectured that, for a Laplacian eigenfunction \( u \), i.e., \( u \) satisfies the equation

\[
\triangle u + \lambda u = 0
\]

on a compact \( n \) dimensional Riemannian manifold without boundary, it holds that

\[
c \lambda^{1/2} \leq \mathcal{H}^{n-1}(\{u(x) = 0\}) \leq C \lambda^{1/2},
\]

where \( \mathcal{H}^{n-1}(\{u(x) = 0\}) \) denotes the \((n-1)\) dimensional Hausdorff measure of the nodal set \( \{u = 0\} \) on the whole manifold, \( C \) is an absolute positive constant independent of \( \lambda \) and \( u \). This conjecture was proved for real analytic manifolds by Bruning and Yau independently in two dimensional case, and by H.Donnelly and C.Fefferman in [4] in higher dimensional case. For \( C^\infty \) manifolds, the following upper bound

\[
\mathcal{H}^{n-1}(\{u = 0\}) \leq C \lambda^{3/4}
\]

was proved by H.Donnelly and C.Fefferman in [5] in two dimensional case and R.T.Dong gave a very different proof for the same bound in [3] by introducing a second order frequency function. The upper bound was refined to \( C \lambda^{3/4-\epsilon} \) by A.Logunov and E.Melinkov in [17]. For the high dimensional case, the estimate

\[
\mathcal{H}^{n-1}(\{u = 0\}) \leq C \lambda^{\alpha \sqrt{n}}
\]

was given by R.Hardt and L.Simon in [9]. In 2016, A.Logunov in [18] improved the upper bound to \( C \lambda^\alpha \) for some \( \alpha > 1/2 \).

There are also a large number of papers concerning the lower bounds for the measure of nodal sets of Laplacian eigenfunctions (see for example [2], [4], [19].)
For eigenfunctions of higher order equations, the related results are very limited. I. Kukavica in [12] gave the optimal upper measure bound of nodal sets for eigenfunctions of higher order elliptic operators in the analytic case. The eigenfunctions can be extended pass through the boundary of $\Omega$ because the operator and the boundary $\partial \Omega$ are assumed to be analytic in that paper. And then the growth order of an eigenfunction can be estimated and the measure upper bound of its nodal set can be derived. In this paper, we do not assume that the boundary $\partial \Omega$ is totally analytic. In this case, the method in [12] cannot be used directly. So first we will define a frequency function related to an eigenfunction and establish the monotonicity formula, doubling conditions, and various estimates. As a result, we will further derive a measure upper bound of the nodal set of an eigenfunction, where the bound contains the corresponding eigenvalue $\lambda$ and the frequency function. Next we will derive an upper bound for the frequency function, whose center is away from the nonanalytic part $\Gamma \subseteq \partial \Omega$, with the help of the doubling index of the bi-harmonic eigenfunction in a ball. We also construct an iteration scheme to control the frequency function and extend the eigenfunction $u$ to outside of $\Omega$ by passing through the part of the boundary $\partial \Omega$ away from $\Gamma$. These lead to prove the upper bound for the measure of the nodal set of the eigenfunction $u$ in the domain $\Omega \setminus T_{R_0}(\Gamma)$ for some suitable domain $T_{R_0}(\Gamma) = \{ x \in \overline{\Omega} : \text{dist}(x, \Gamma) < R_0 \}$, where $R_0$ is some suitable positive constant depending only on $n$ and $\Omega$. Finally, we locally establish an upper bound of the doubling index near the points in the nonanalytic parts by applying the upper bound of the frequency function in $\Omega$. And then by using an iteration method, we can get the desired estimation of the nodal set of $u$ near $\Gamma$.

More precisely, in order to get the upper bound for the frequency function, we first start to derive an upper bound for the frequency function centered at some point $y_0 = (\bar{x}, 0)$ with $\bar{x} \in \Omega$ satisfying that the function value $|u(\bar{x})|$ is suitable large. Then from an iteration argument, the relationship between the frequency function and the doubling index, the “changing center” property for the frequency function, and the dou-
bling conditions, we can get the upper bound for the frequency function centered at some point away from $\Gamma$. Then by the similar iteration argument again, we can get the upper bound for the frequency function at any point away from $\Gamma$. For the frequency centered near $\Gamma$, we start from some point away from $\Gamma$, whose doubling index is controlled by $\sqrt{\lambda}$. Then by using the iteration arguments, the analytically extending of $u$, the relationship between the frequency function and the doubling index, and the doubling conditions, we can get the upper bound for the frequency function centered near $\Gamma$. Actually one notes that the bound for the frequency function may go to infinity when the corresponding center tends to the nonanalytic part $\Gamma$. However, because the dimension of $\Gamma$ is $(n-2)$, and the upper bound for the frequency function goes to infinity not very fast as the center of the frequency function tends to $\Gamma$, the measure for the nodal set of $u$ in a domain near $\Gamma$ can be obtained by using the iteration method.

The main result of this paper is as follows.

**Theorem 1.1.** Let $u$ be a solution to the following boundary value problem:

\[
\begin{align*}
\Delta^2 u &= \lambda^2 u \quad \text{in} \quad \Omega, \\
B_j u &= 0, \quad j = 1, 2, \quad \text{on} \quad \partial \Omega,
\end{align*}
\]

where $B_j, j = 1, 2$ are linear boundary operators defined as $B_j u = \sum_{|\alpha| \leq 3} a_{\alpha,j}(x) D^\alpha u(x)$ on $\partial \Omega$, where $a_{\alpha,j}(x)$ are all $C^\infty$ and piecewise analytic on $\partial \Omega$, and analytic on $\partial \Omega \setminus \Gamma$.

Then the measure of nodal set of $u$ has the following estimate:

\[
\mathcal{H}^{n-1}(\{x \in \Omega | u(x) = 0\}) \leq C \sqrt{\lambda},
\]

where $C$ is a positive constant depending only on $n$, $\Omega$ and the boundary operators $B_j$, $j = 1, 2$.

The rest of this paper is organized as follows. In the second section, we give the definition of a frequency function related to bi-harmonic eigenfunctions and show some interesting properties including the monotonicity formula and some estimates for the
frequency function. In the third section, we obtain some doubling conditions and show the “changing center” property for the monotonicity formula. In the fourth section, we give a measure estimate of nodal sets of eigenfunctions in $\Omega(R_0, \Gamma)$. Here $\Omega(R_0, \Gamma) \subseteq \overline{\Omega}$ and the distance of $\Omega(R_0, \Gamma)$ and $\Gamma$ is greater than some constant $R_0$ depending only on $n$ and $\Omega$. Finally in the last section, we give the measure estimate of the nodal set of the eigenfunction $u$ near the nonanalytic set $\Gamma$.

2 Frequency function

We rewrite the equation $\Delta^2 u = \lambda^2 u$ as the following forms:

\[
(\Delta - \lambda) u = v,
\]
\[
(\Delta + \lambda) v = 0.
\]

Let $g(x, x_{n+1}) = u(x)e^{\sqrt{\lambda} x_{n+1}}$ and $h(x, x_{n+1}) = v(x)e^{\sqrt{\lambda} x_{n+1}}$. Thus we have

\[
(\Delta - 2\lambda) g = h,
\]
\[
\Delta h = 0,
\]

where $g$ and $h$ are all considered as functions of $n+1$ dimensional variable $y = (x, x_{n+1})$.

Then we define the frequency function centered at $y_0$ as follows:

\[
N(y_0, r) = \frac{\int_{B_r(y_0)} (|\nabla g|^2 + |\nabla h|^2 + gh + 2\lambda g^2) \, dy}{\int_{\partial B_r(y_0)} (g^2 + h^2) \, d\sigma},
\]

(2.1)

where $d\sigma$ is the $n$ dimensional Hausdorff measure on $\partial B_r(y_0)$. We use the notation

\[
D_1(y_0, r) = \int_{B_r(y_0)} |\nabla g|^2 \, dy, \quad D_2(y_0, r) = \int_{B_r(y_0)} |\nabla h|^2 \, dy,
\]
\[
D_3(y_0, r) = \int_{B_r(y_0)} gh \, dy, \quad D_4(y_0, r) = 2\lambda \int_{B_r(y_0)} g^2 \, dy,
\]
\[
H_1(y_0, r) = \int_{\partial B_r(y_0)} g^2 \, d\sigma, \quad H_2(y_0, r) = \int_{\partial B_r(y_0)} h^2 \, d\sigma,
\]
\[ D(y_0, r) = D_1(y_0, r) + D_2(y_0, r) + D_3(y_0, r) + D_4(y_0, r), \]
\[ H(y_0, r) = H_1(y_0, r) + H_2(y_0, r). \]

Then the frequency function can be written as
\[ N(y_0, r) = r \frac{D(y_0, r)}{H(y_0, r)} = r \frac{D_1(y_0, r) + D_2(y_0, r) + D_3(y_0, r) + D_4(y_0, r)}{H_1(y_0, r) + H_2(y_0, r)}, \]
and it is also easy to check that
\[ N(y_0, r) = r \int_{\partial B_r(y_0)} (gg_n + hh_n) d\sigma \]
where \( g_n \) and \( h_n \) mean \( \nabla g \cdot -\vec{n} \) and \( \nabla h \cdot -\vec{n} \) respectively, and \( \vec{n} \) is the outer unit normal vector on \( \partial B_r(y_0) \).

Such a frequency function has following properties.

**Lemma 2.1.** If the vanishing orders of \( g \) and \( h \) at point \( y_0 \) are \( k \) and \( l \) respectively, then it holds that
\[ \lim_{r \to 0^+} N(y_0, r) = \min \{ k, l \}. \]  
(2.3)

**Proof.** Without loss of generality, we may assume that \( y_0 = 0 \). Because the vanishing order of \( g \) at the origin is \( k \), we have
\[ g(y) = P_k(y) + o(|y|^k), \]
where \( P_k(y) \) is a homogeneous polynomial of degree \( k \). Similarly, we have
\[ h(y) = P_l(y) + o(|y|^l), \]
where \( P_l(y) \) is a homogeneous polynomial of degree \( l \). In the polar coordinate system \( (r, \theta) = (r_1, \theta_2, \cdots, \theta_n) \), \( P_k(y) \) and \( P_l(y) \) can be written as the following forms.
\[ P_k(y) = r^k \phi(\theta), \quad P_l(y) = r^l \psi(\theta). \]
Then from (2.2), we have

\[
N(0, r) = \frac{r \int_{\partial B_r} (gg_n + hh_n) d\sigma}{\int_{\partial B_r} (g^2 + h^2) d\sigma}
\]

\[
= \frac{\int_{\partial B_r} (k r^{2k+n} \phi^2(\theta) + lr^{2l+n} \psi^2(\theta) + o(r^{2k+n}) + o(r^{2l+n})) d\sigma}{\int_{\partial B_r} (r^{2k+n} \phi^2(\theta) + r^{2l+n} \psi^2(\theta) + o(r^{2k+n}) + o(r^{2l+n})) d\sigma}.
\]

Letting \( r \to 0^+ \), we have the desired result. \( \square \)

**Lemma 2.2.** The frequency defined in (2.1) has the following lower bound:

\[
N(y_0, r) \geq -\frac{r^2}{8(n+1)\lambda}.
\]  

(2.4)

**Proof.** Without loss of generality, we may assume that \( y_0 = 0 \). Then

\[
\int_{B_r(0)} gh \, dy \leq 2\lambda \int_{B_r(0)} g^2 \, dy + \frac{1}{8\lambda} \int_{B_r(0)} h^2 \, dy.
\]

Because \( h \) is a harmonic function, we have

\[
\int_{B_r(0)} h^2 \, dy \leq \frac{r}{n+1} \int_{\partial B_r(0)} h^2 \, d\sigma,
\]

which can be seen in \([10]\). So

\[
N(0, r) \geq \frac{r \int_{B_r(0)} (|\nabla g|^2 + |\nabla h|^2) \, dy - \frac{r}{8(n+1)\lambda} \int_{\partial B_r(0)} h^2 \, d\sigma}{\int_{\partial B_r(0)} (g^2 + h^2) \, d\sigma}
\]

\[
\geq -\frac{r^2}{8(n+1)\lambda},
\]

which is the desired result. \( \square \)

Now we will show the monotonicity formula.

**Theorem 2.3.** Let \( \lambda > 1 \). Then there exist positive constants \( C_0 \) and \( C \) depending only on \( n \), such that if \( N(y_0, r) \geq C_0 \) then

\[
\frac{d \ln N(y_0, r)}{dr} \geq -C
\]  

(2.5)

for \( r \leq 1 \).
Proof. Let $y_0 = 0$. Note that
\[
\frac{d \ln N(0, r)}{dr} = -\frac{1}{r} + \sum_{i=1}^{4} \frac{D'_i(0, r)}{D(0, r)} - \sum_{j=1}^{2} \frac{H'_j(0, r)}{H(0, r)}.
\]

First we calculate the term $D'_1(0, r)$.
\[
D'_1(0, r) = \int_{\partial B_r(0)} |\nabla g|^2 d\sigma
= \int_{\partial B_r(0)} |\nabla g|^2 \cdot \frac{y}{r} \cdot \frac{y}{r} d\sigma
= \frac{1}{r} \int_{B_r(0)} \text{div} \left( |\nabla g|^2 \frac{y}{r} \right) dy
= \frac{n}{r} \int_{B_r(0)} |\nabla g|^2 dy + \frac{2}{r} \int_{B_r(0)} \nabla g \cdot \nabla g \cdot \frac{y}{r} dy
= \frac{n-2}{r} D_1(0, r) + 2 \int_{\partial B_r(0)} g^2 d\sigma - \frac{2}{r} \int_{B_r(0)} (h + 2\lambda g) \nabla g \cdot \frac{y}{r} dy.
\]

Here $d\sigma$ means the $n-1$ dimensional Hausdorff measure on $\partial B_r(0)$. Similarly, we have
\[
D'_2(0, r) = \frac{n-2}{r} D_2(0, r) + 2 \int_{\partial B_r(0)} h^2 d\sigma.
\]

For $D'_3(0, r)$ and $D'_4(0, r)$, we have
\[
D'_3(0, r) = \int_{\partial B_r(0)} ghd\sigma = \frac{1}{r} \int_{B_r(0)} \text{div}(ghy) dy
= \frac{n-2}{r} D_3(0, r) + \frac{1}{r} \left( \int_{B_r(0)} h \nabla g \cdot y dy + \int_{B_r(0)} g \nabla h \cdot y dy + 2 \int_{B_r(0)} gh dy \right),
\]
and
\[
D'_4(0, r) = 2\lambda \int_{\partial B_r(0)} g^2 d\sigma
= \frac{n-2}{r} D_4(0, r) + \frac{2\lambda}{r} \left( \int_{B_r(0)} 2g \nabla g \cdot y dy + 2 \int_{B_r(0)} g^2 dy \right).
\]
So

\[-D'(0, r) = \frac{n-2}{r}D(0, r) + 2 \int_{\partial B_r(0)} \left( g_n^2 + h_n^2 \right) d\sigma \]

\[- \frac{1}{r} \int_{B_r(0)} h \nabla g \cdot dy + \frac{1}{r} \int_{B_r(0)} g \nabla h \cdot dy \]

\[+ \frac{2}{r} \int_{B_r(0)} ghdy + \frac{4\lambda}{r} \int_{B_r(0)} g^2 dy \]

\[\geq \frac{n-2}{r}D(0, r) + 2 \int_{\partial B_r(0)} \left( g_n^2 + h_n^2 \right) d\sigma \]

\[- \int_{B_r(0)} |h| \nabla g|dy - \int_{B_r(0)} |g| \nabla h|dy - \frac{1}{4r\lambda} \int_{B_r(0)} h^2 dy. \]

For the term \(\int_{B_r(0)} |h| \nabla g|dy\) and \(\int_{B_r(0)} |g| \nabla h|dy\), we have

\[\int_{B_r(0)} |h| \nabla g|dy \leq \frac{r}{2} \int_{B_r(0)} |\nabla g|^2 dy + \frac{1}{2r} \int_{B_r(0)} h^2 dy,\]

and

\[\int_{B_r(0)} |g| \nabla h|dy \leq \frac{r}{2} \int_{B_r(0)} |\nabla h|^2 dy + \frac{1}{2r} \int_{B_r(0)} g^2 dy.\]

Now we consider the term \(\int_{B_r(0)} g^2 dy\). Note that \(\Delta g = h + 2\lambda g\), we can separate \(g = \overline{g} + \underline{g}\), where \(\overline{g}\) and \(\underline{g}\) satisfy that

\[
\begin{cases}
\Delta \overline{g} = h + 2\lambda g & \text{in } B_r(0), \\
\overline{g} = 0 & \text{on } \partial B_r(0),
\end{cases}
\]

and

\[
\begin{cases}
\Delta \underline{g} = 0 & \text{in } B_r(0), \\
\underline{g} = g & \text{on } \partial B_r(0).
\end{cases}
\]

Write the term \(\int_{B_r(0)} g^2 dy\) as follows:

\[\int_{B_r(0)} g^2 dy \leq 2 \int_{B_r(0)} \overline{g}^2 dy + 2 \int_{B_r(0)} \underline{g}^2 dy.\]

Now we consider \(\overline{g}\) and \(\underline{g}\). Because

\[\int_{B_r(0)} \Delta \overline{g} \cdot \overline{g} dy = \int_{B_r(0)} h \overline{g} dy + 2\lambda \int_{B_r(0)} \overline{g}^2 dy + 2\lambda \int_{B_r(0)} \overline{g} \underline{g} dy,\]
it holds that
\[
2\lambda \int_{B_r(0)} g^2 \, dy = -2\lambda \int_{B_r(0)} gg \, dy - \int_{B_r(0)} hg \, dy + \int_{B_r(0)} \Delta g \cdot g \, dy
\leq 4\lambda \int_{B_r(0)} g^2 \, dy + \lambda \int_{B_r(0)} g^2 \, dy + \frac{1}{2\lambda} \int_{B_r(0)} h^2 \, dy
+ \frac{\lambda}{2} \int_{B_r(0)} g^2 \, dy - \int_{B_r(0)} |\nabla g|^2 \, dy
\leq \frac{3\lambda}{2} \int_{B_r(0)} g^2 \, dy + 4\lambda \int_{B_r(0)} g^2 \, dy + \frac{1}{2} \int_{B_r(0)} h^2 \, dy.
\]

So
\[
\int_{B_r(0)} g^2 \, dy \leq 8 \int_{B_r(0)} g^2 \, dy + \frac{1}{\lambda^2} \int_{B_r(0)} h^2 \, dy.
\]

Because \(g\) and \(h\) both are harmonic functions, we have
\[
\int_{B_r(0)} g^2 \, dy \leq \frac{r}{n+1} \int_{\partial B_r(0)} g^2 \, d\sigma,
\]

and
\[
\int_{B_r(0)} h^2 \, dy \leq \frac{r}{n+1} \int_{\partial B_r(0)} h^2 \, d\sigma.
\]

By the above arguments, we have that
\[
D'(0, r) \geq \frac{n-2}{r} D(0, r) + 2 \int_{\partial B_r(0)} \left( g_n^2 + h_n^2 \right) d\sigma
- \frac{r}{2} \int_{B_r(0)} \left( |\nabla g|^2 + |\nabla h|^2 \right) \, dy
- CH(0, r),
\]

where \(C\) is a positive constant depending only on \(n\).

On the other hand, from the assumption that \(N(0, r) \geq C_0\), where \(C_0\) is a constant to be determined, we have
\[
H(0, r) \leq r \frac{D(0, r)}{C_0}.
\]

So
\[
D'(0, r) \geq \frac{n-2}{r} D(0, r) + 2 \int_{\partial B_r(0)} \left( g_n^2 + h_n^2 \right) dy - \frac{Cr}{C_0} D(0, r) - \frac{1}{2} \int_{B_r(0)} \left( |\nabla g|^2 + |\nabla h|^2 \right) dy.
\]

11
Also note that
\[
D(0, r) = \int_{B_r(0)} \left( |\nabla g|^2 + |\nabla h|^2 + hg + 2\lambda g^2 \right) dy
\]
\[
\geq \int_{B_r(0)} \left( |\nabla g|^2 + |\nabla h|^2 \right) dy - \frac{1}{8\lambda} \int_{\partial B_r(0)} h^2 d\sigma
\]
\[
\geq \int_{B_r(0)} \left( |\nabla g|^2 + |\nabla h|^2 \right) dy - \frac{r}{8(n+1)\lambda} \int_{\partial B_r(0)} H(0, r)
\]
\[
\geq \int_{B_r(0)} \left( |\nabla g|^2 + |\nabla h|^2 \right) dy - \frac{1}{8(n+1)C_0\lambda} D(0, r).
\]

By choosing \(C_0 = 1/(n+1)\), we have
\[
D(0, r) \geq \frac{8}{9} \int_{B_r(0)} \left( |\nabla g|^2 + |\nabla h|^2 \right) dy.
\]

So
\[
D'(0, r) \geq \frac{n-2}{r} D(0, r) + 2 \int_{\partial B_r(0)} \left( g_n^2 + h_n^2 \right) d\sigma - CD(0, r).
\]

By some direct calculation, we have
\[
H'(0, r) = \frac{n-2}{r} H(0, r) + 2 \int_{\partial B_r(0)} \left( hh_n + gg_n \right) d\sigma.
\]

So
\[
\frac{d \ln N(0, r)}{dr} \geq -Cr,
\]

which is just the result we want. \(\square\)

From this “monotonicity formula”, the following corollary can be got easily.

**Corollary 2.4.** Let \(\lambda > 1\). Then for any \(0 < r_1 < r_2 \leq 1\), we have

\[
N(0, r_1) \leq C \max \{C_0, N(0, r_2)\}.
\]

Moreover, if for any \(r \in (r_1, r_2)\), it holds that \(N(0, r) > C_0\), then

\[
N(0, r_2) \geq C' N(0, r_1).
\]
Here $C_0$ is the same constant as in Theorem\ref{theo:2.3}. $C$ and $C'$ are positive constants depending only on $n$.

**Proof.** Let $I = \{ r \in (0, r_2) | N(0, r) > C_0 \}$. Then $I$ is a union of at most countable number of intervals $(a_i, b_i)$, with $N(0, a_i) = C_0$, $N(0, b_i) = C_0$ if $b_i \neq r_2$. If $r_1 \in (a_i, b_i)$ with $b_i \neq r_2$, then from Theorem\ref{theo:2.3} it holds that

$$\ln \frac{N(0, b_i)}{N(0, r_1)} = \int_{r_1}^{b_i} d \ln N(0, \rho) \geq -C(r_2 - r_1).$$

So

$$N(0, r_1) \leq C_0 e^{C(r_2 - r_1)} \leq CC_0.$$

If $r_1 \in (a_i, b_i)$ with $B_i = r_2$, then by the same arguments, we have

$$\ln \frac{N(0, r_2)}{N(0, r_1)} = \int_{r_1}^{r_2} d \ln N(0, \rho) \geq -C(r_2 - r_1),\quad (2.8)$$

and thus

$$N(0, r_1) \leq CN(0, r_2).$$

Then we get the first result, i.e., (2.6).

If for any $r \in (r_1, r_2)$, it holds that $N(0, r) > C_0$, then $r_1$ and $r_2$ must be in the same interval $(a_i, b_i)$. So from (2.6), the second result can be got directly. $\square$

### 3 Doubling conditions

In this section, we show the doubling conditions based on the monotonicity formula. First we can show the following doubling condition including both $g$ and $h$.

**Lemma 3.1.** Let $\lambda > 1$. Then for any $0 < r_1 < r_2 < 1$, it holds that

$$\int_{\partial B_{r_2}(y_0)} (g^2 + h^2) d\sigma \leq \left( \frac{r_2}{r_1} \right)^{C \max(N(y_0, r_2), C_0)} \int_{\partial B_{r_1}(y_0)} (g^2 + h^2) d\sigma,\quad (3.1)$$

13
\[
\int_{B_{r_2}(y_0)} (g^2 + h^2) dy \leq \left( \frac{r_2}{r_1} \right)^{C \max \{N(y_0, r_2), C_0 \}} \int_{B_{r_1}(y_0)} (g^2 + h^2) dy, \tag{3.2}
\]
and
\[
\int_{\partial B_{r_2}(y_0)} (g^2 + h^2) d\sigma \geq \left( \frac{r_2}{r_1} \right)^{C_{\min \{N(y_0, r_2), C_0 \}}} \int_{\partial B_{r_1}(y_0)} (g^2 + h^2) d\sigma, \tag{3.3}
\]
where \( C_0 \) is the same constant as in Theorem 2.3. \( C, C', \bar{C} \) and \( \bar{C}' \) are all positive constants depending only on \( n \).

Proof. We only need to prove (3.1) and (3.3). The inequality (3.2) and (3.4) can be easily deduced from (3.1) and (3.3). Without loss of generality, we assume that \( y_0 \) is the origin. Define
\[
\bar{H}(\rho) = \int_{\partial B_{\rho}(0)} (g^2 + h^2) d\sigma = \frac{1}{\omega_n \rho^n} \int_{\partial B_{\rho}} (g^2 + h^2) d\sigma, \tag{3.5}
\]
where \( \omega_n \) is the Hausdorff measure of an \( n \) dimensional unit sphere. It is easy to check that
\[
\frac{d \ln \bar{H}(0, \rho)}{d\rho} = \frac{2N(0, \rho)}{\rho}. \tag{3.6}
\]
So from Theorem 2.3 and Corollary 2.4, it holds that
\[
\int_{r_1}^{r_2} \frac{2N(0, \rho)}{\rho} d\rho = \max_{\rho \in [r_1, r_2]} \{N(0, \rho)\} \ln \frac{r_2}{r_1} \leq C \max \{C_0, N(0, r_2)\} \ln \frac{r_2}{r_1}.
\]
So we have
\[
\bar{H}(r_2) \leq \left( \frac{r_2}{r_1} \right)^{C \max \{C_0, N(0, r_2)\}} \bar{H}(r_1).
\]
On the other hand, it also holds that
\[
\int_{r_1}^{r_2} \frac{2N(0, \rho)}{\rho} d\rho \geq \min_{\rho \in [r_1, r_2]} \{N(0, \rho)\} \ln \frac{r_2}{r_1}.
\]
So we also have

\[ \bar{H}(r_2) \geq \left( \frac{r_2}{r_1} \right) \min_{\rho \in \mathbb{N}(0, r)} \bar{H}(r_1). \]

Thus we get the desired result. \( \square \)

Basing on this doubling condition, we can prove the following doubling condition only for \( g \).

**Lemma 3.2.** Let \( \lambda > 1 \) and \( 0 < r < 1 \). Then

\[
\int_{B_r(y_0)} g^2 \, dy \leq \left( \frac{1}{r^4} + \lambda^2 \right) 2^C \max\{C_0, N(y_0, r)\} \int_{B_{2r}(y_0)} g^2 \, dy, \tag{3.7}
\]

where \( C \) is a positive constant depending only on \( n \).

In order to prove this doubling condition, we need the following interior estimation.

**Lemma 3.3.** Let \( \lambda > 1 \). Then for \( 0 < r < 1/2 \), we have

\[
\int_{B_r(y_0)} h^2 \, dy \leq C \left( \frac{1}{r^4} + \lambda^2 \right) \int_{B_r(y_0)} g^2 \, dy, \tag{3.8}
\]

where \( C \) is a positive constant depending only on \( n \).

**Proof.** Without loss of generality, let \( y_0 = 0 \). Let \( \phi \) be the cut-off function satisfying that

\[
\phi = 1 \text{ in } B_r; \quad \phi = 0 \text{ outside } B_r; \quad 0 \leq \phi \leq 1; \quad |\nabla \phi| \leq c/r; \quad |\nabla^2 \phi| \leq c/r^2,
\]

where \( c > 1 \) is a positive constant depending only on \( n \). Define a test function \( \psi \) as follows:

\[
\psi = e^{1 - \frac{1}{\phi}} \in (0, 1) \text{ if } \phi > 0, \quad \psi = 0 \text{ if } \phi = 0. \tag{3.9}
\]
Then, up to a limit, it also holds that

\[
\frac{\psi}{\phi^k} = 0 \quad \text{if} \quad \phi = 0 \quad (3.10)
\]

for any positive constant \( k \). From the equation \( \triangle g = h + 2\lambda g \), we have

\[
\int_{B_r(0)} \triangle g h \psi dy = \int_{B_r(0)} h^2 \psi dy + 2\lambda \int_{B_r(0)} gh \psi dy. \quad (3.11)
\]

First calculate the left hand side.

\[
\int_{B_r(0)} \triangle g h \psi dy = \int_{B_r(0)} g \triangle(h \psi) dy
\]

\[
= \int_{B_r(0)} g \triangle h \psi dy + 2 \int_{B_r(0)} g \nabla h \nabla \psi dy + \int_{B_r(0)} gh \psi dy.
\]

Because

\[
\triangle h = 0, \quad \nabla \psi = \psi \cdot \nabla \phi, \quad \triangle \psi = \psi \left( \frac{|\nabla \phi|^2}{\phi^2} - \frac{2|\nabla \phi|^2}{\phi^3} + \frac{\triangle \phi}{\phi^2} \right),
\]

we have

\[
\int_{B_r(0)} \triangle g h \psi dy = 2 \int_{B_r(0)} g \psi \frac{1}{\phi^2} \nabla h \cdot \nabla \psi dy + \int_{B_r(0)} gh \psi \left( \frac{|\nabla \phi|^2}{\phi^4} - \frac{2|\nabla \phi|^2}{\phi^3} + \frac{\triangle \phi}{\phi^2} \right) dy.
\]

From (3.11), we have

\[
\int_{B_r(0)} h^2 \psi dy = \int_{B_r(0)} \triangle g h \psi dy - 2\lambda \int_{B_r(0)} gh \psi dy
\]

\[
\leq 2 \int_{B_r(0)} g \psi \frac{1}{\phi^2} \nabla h \nabla \psi dy + \int_{B_r(0)} gh \psi \left( \frac{|\nabla \phi|^2}{\phi^4} - \frac{2|\nabla \phi|^2}{\phi^3} + \frac{\triangle \phi}{\phi^2} \right) dy
\]

\[
+ 2\lambda^2 \int_{B_r(0)} g^2 \psi dy + \frac{1}{2} \int_{B_r(0)} h^2 \psi dy.
\]

Because \( \triangle h = 0 \), we have

\[
\int_{B_r(0)} \triangle h \psi \phi^k dy = 0.
\]
Thus
\[
\int_{B_r(0)} |\nabla h|^2 \psi \phi^4 dy + \int_{B_r(0)} h \nabla h \cdot \nabla \phi \psi \left( \phi^2 + 4 \phi^3 \right) dy = 0. \tag{3.12}
\]

So
\[
\int_{B_r(0)} |\nabla h|^2 \psi \phi^4 dy = -\int_{B_r(0)} h \nabla h \nabla \phi \psi \left( \phi^2 + 4 \phi^3 \right) dy \tag{3.13}
\leq 5 \int_{B_r(0)} h |\nabla h| |\nabla \phi| \psi^2 dy
\leq \frac{1}{2} \int_{B_r(0)} |\nabla h|^2 \psi \phi^4 dy + 18 \int_{B_r(0)} h^2 \psi |\nabla \phi|^2 dy. \tag{3.14}
\]

Thus
\[
\int_{B_r(0)} |\nabla h|^2 \psi \phi^4 dy \leq \frac{36c^2}{r^2} \int_{B_r(0)} h^2 \psi dy.
\]

So
\[
\int_{B_r(0)} g \nabla \phi \nabla h \frac{1}{\phi^4} dy \leq \frac{r^2}{144c^2} \int_{B_r(0)} |\nabla h|^2 \psi \phi^4 dy + \frac{36c^2}{r^2} \int_{B_r(0)} g^2 \psi \frac{1}{\phi^8} |\nabla \phi|^2 dy
\leq \frac{1}{4} \int_{B_r(0)} h^2 \psi dy + \frac{36c^4}{r^4} \int_{B_r(0)} g^2 \psi \frac{1}{\phi^8} dy.
\]

On the other hand, we also have
\[
2\lambda \int_{B_r(0)} gh \psi \leq \frac{1}{8} \int_{B_r(0)} h^2 \psi dy + 8\lambda^2 \int_{B_r(0)} g^2 \psi dy,
\]
and
\[
\int_{B_r(0)} gh \psi \left( \frac{|\nabla \phi|^2}{\phi^4} - 2 \frac{|\nabla \phi|^2}{\phi^3} + \frac{\Delta \phi}{\phi^2} \right) dy \leq \frac{4c^2}{r^2} \int_{B_r(0)} |g||h| \psi \frac{1}{\phi^4} dy
\leq \frac{1}{16} \int_{B_r(0)} h^2 \psi dy + \frac{64c^4}{r^4} \int_{B_r(0)} h^2 \psi \frac{1}{\phi^8} dy.
\]

Put these inequalities into (3.12), it holds that
\[
\int_{B_r(0)} h^2 \psi dy \leq 10\lambda^2 \int_{B_r(0)} g^2 \psi dy + \frac{100c^4}{r^4} \int_{B_r(0)} g^2 \psi \frac{1}{\phi^8} dy.
\]

From (3.9) and (3.10), we know that $0 \leq \psi \leq 1$ when $0 \leq \phi \leq 1$, $\psi = 1$ when $\phi = 1$, $\psi = 0$ when $\phi = 0$, and $\psi / \phi^k = 0$ when $\phi = 0$ for any positive integer $k$. So we have
\[
\int_{B_r(0)} h^2 dy \leq C \left( \lambda^2 + \frac{1}{r^4} \right) \int_{B_r(0)} g^2 dy,
\]

17
where $C$ is a positive constant depending only on $c$ and $n,$ and thus only on $n$. That is just the desired result. □

Now we will present the proof of Lemma 3.2.

**Proof of Lemma 3.2.**

Without loss of generality, we assume that $y_0$ is the origin. Then by using Lemma 3.3 and Lemma 3.1, we have

\[
\int_{B_r(0)} g^2 dy \leq \int_{B_r(0)} (g^2 + h^2) dy \\
\leq 2^{C_{\max\{N(0,r),C_0\}}} \int_{B_{r/2}(0)} (g^2 + h^2) dy \\
\leq 2^{C_{\max\{N(0,r),C_0\}}} \left(\lambda^2 + \frac{1}{r^4}\right) \int_{B_{r/2}(0)} g^2 dy,
\]

which is the desired result.

\[\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad\quad}\]
Proof. If for some \( r \geq \frac{1}{2}(r_0 - |p|) \), it holds that \( N(p, r) \leq C_0 \), then from Corollary 2.4 we can get that
\[
N(p, \rho) \leq C N(p, r) \leq C C_0,
\]
which is the desired result. So in the following of the proof, we always assume that \( N(0, r) > C_0 \) for any \( r \geq \frac{1}{2}(r_0 - |p|) \).

For any \( p \in B_{\frac{1}{2}r_0}, \) it holds that
\[
\bar{B}_{\frac{3}{4}r_0}(p) \subseteq \bar{B}_{r_0}, \quad \bar{B}_{\frac{1}{2}r_0} \subseteq \bar{B}_{\frac{1}{2}r_0}(p).
\] (3.17)

Thus from Lemma 3.1, we have
\[
\int_{\bar{B}_{\frac{3}{4}r_0}(p)} (g^2 + h^2)dy \leq \left( \frac{4}{3} \right)^{n+1} \int_{B_{r_0}} (g^2 + h^2)dy
\]
\[
\leq 4^{C_{\max\{C_0, N(0, r_0)\}}} \int_{\bar{B}_{\frac{1}{2}r_0}} (g^2 + h^2)dy
\]
\[
\leq 4^{C_{\max\{C_0, N(0, r_0)\}}} \int_{\bar{B}_{\frac{1}{2}r_0}(p)} (g^2 + h^2)dx. \quad (3.18)
\]

Now we will show that
\[
\int_{\partial B_{\frac{3}{8}r_0}(p)} (g^2 + h^2)dy \leq 4^{C_{\max\{C_0, N(0, r_0)\}}} \int_{\partial B_{\frac{1}{2}r_0}(p)} (g^2 + h^2)dx. \quad (3.19)
\]

In fact,
\[
\int_{B_{\frac{1}{8}r_0}(p)} (g^2 + h^2)dy \geq \int_{B_{\frac{1}{8}r_0}(p) - B_{\frac{3}{8}r_0}(p)} (g^2 + h^2)dy
\]
\[
= \int_{\frac{3}{8}r_0}^{\frac{1}{8}r_0} \omega_n r^n \int_{\partial B_r(p)} (g^2 + h^2)d\sigma dr.
\]

Because
\[
\ln \frac{\int_{\partial B_r(p)} (g^2 + h^2)d\sigma}{\int_{B_{\frac{3}{8}r_0}(p)} (g^2 + h^2)d\sigma} = 2 \int_{\frac{3}{8}r_0}^{r} \frac{N(p, \rho)}{\rho} d\rho
\]
\[
\geq 2C_0 \ln \frac{r}{\frac{3}{8}r_0},
\]
So
\[
\int_{B_{\frac{3}{4} r_0}(p)} (g^2 + h^2)dy \geq \int_{\frac{3}{4} r_0}^{\frac{4}{5} r_0} \omega_n \frac{8r}{5 r_0} e^{2C_0} dr \int_{\partial B_{\frac{3}{4} r_0}(p)} (g^2 + h^2)d\sigma \\
= C r_0^{n+1} \int_{\partial B_{\frac{3}{4} r_0}(p)} (g^2 + h^2)d\sigma,
\]
which means that
\[
\int_{B_{\frac{3}{4} r_0}(p)} (g^2 + h^2)dy \geq C \int_{\partial B_{\frac{3}{4} r_0}(p)} (g^2 + h^2)d\sigma. \tag{3.20}
\]

On the other hand,
\[
\int_{B_{\frac{3}{4} r_0}(p)} (g^2 + h^2)dy = \int_{0}^{\frac{4}{5} r_0} \omega_n r^n \int_{\partial B_r(p)} (g^2 + h^2)d\sigma dr.
\]

Because
\[
\ln \frac{\int_{\partial B_{\frac{3}{4} r_0}(p)} (g^2 + h^2)d\sigma}{\int_{\partial B_r(p)} (g^2 + h^2)d\sigma} = \int_{r}^{\frac{4}{5} r_0} \frac{2N(p, \rho)}{\rho} d\rho \geq -C \frac{(\frac{4}{5} r_0 - r)^3}{\lambda}.
\]

Thus
\[
\int_{\partial B_r(p)} (g^2 + h^2)d\sigma \leq 2\pi (\frac{4}{5} r_0 - r)^3 \int_{\partial B_{\frac{3}{4} r_0}(p)} (g^2 + h^2)d\sigma \\
\leq 2C r_0^3 \int_{\partial B_{\frac{3}{4} r_0}(p)} (g^2 + h^2)d\sigma.
\]

So
\[
\int_{B_{\frac{3}{4} r_0}(p)} (g^2 + h^2)dy \leq C \int_{\partial B_{\frac{3}{4} r_0}(p)} (g^2 + h^2)d\sigma. \tag{3.21}
\]

It also holds that
\[
\int_{B_{\frac{1}{2} r_0}(p)} (g^2 + h^2)dy \leq \int_{B_{r}(0)} (g^2 + h^2)dy \tag{3.22}
\leq 2C \max(\text{max}(C_0, N(0, r))) \int_{B_{\frac{1}{2} r_0}(p)} (g^2 + h^2)dy \\
\leq 2C \max(\text{max}(C_0, N(0, r))) \int_{B_{\frac{1}{2} r_0}(p)} (g^2 + h^2)dy.
\]
From (3.20), (3.21) and (3.22), we can get the inequality (3.19) directly.

Note that
\[
\frac{d}{dr} \ln \int_{\partial B_r(p)} (g^2 + h^2)d\sigma = \frac{2N(p,r)}{r},
\]
we have
\[
\ln \frac{\int_{B_{\frac{r}{2}}(p)} (g^2 + h^2)d\sigma}{\int_{B_{r_0}(p)} (g^2 + h^2)d\sigma} = \int_{r_0}^{\frac{r}{2}} \frac{N(p,\rho)}{\rho} d\rho \geq CN(p, \frac{1}{2}r_0).
\]
Thus from (3.19), we have
\[
N(p, \frac{1}{2}r_0) \leq C \max \left\{ C_0, N(0, \frac{5}{8}r_0) \right\},
\]
which is the desired result. \( \square \)

4 Measure estimates of the nodal sets away from non-analytic parts

In this section, we will give a measure estimate of the nodal set for an eigenfunction \( u \) in a subset of \( \Omega \) away from \( \Gamma \), the non-analytic part of \( \partial \Omega \). We divide our task into two steps. First we will show the measure upper bounds for the nodal set of \( u \) in some small balls in terms of the frequency function. Then we will give the upper bound for the frequency function.

4.1 Nodal set in a ball

In order to get an upper bound of the measure of the nodal set of an eigenfunction \( u \) in some small ball, we need to estimate an upper bound of the \( L^\infty \) norm of \( u \).

Lemma 4.1. Let \( u \) and \( v \) satisfy
\[
\Delta u + \lambda u = v, \\
\Delta v - \lambda v = 0,
\]

21
in $B_1(0)$, and assume $\lambda > 1$. Then, for any $r \in (0, 1)$ and $t > 1$ and $tr < 1$, we have

$$
\|u\|_{L^t(B_r(0))} \leq C \left( \frac{\lambda^{\frac{1}{2}k}}{r^{\frac{n}{2}+1}} (\|u\|_{W^{1,2}(B_r(0))} + \|v\|_{L^2(B_r(0))}) \right),
$$

(4.1)

where $C$ is a positive constant depending only on $n$ and $t$.

Proof. From the equation

$$
\triangle u + \lambda u = v,
$$

the standard interior estimates of elliptic equations, we have that,

$$
\|u\|_{W^{k,2}(B_r(0))} \leq C \left( \frac{\sqrt[k]{\lambda}}{r^k} \|u\|_{W^{k-1,2}(B_{r^k}(0))} + \|v\|_{W^{k-1,2}(B_{r^k}(0))} \right)
$$

for any positive integer $k > 0$, where $\kappa > 1$ and $C$ is a positive constant depending only on $n$ and $\kappa$. On the other hand, from the standard elliptic estimation and $\triangle v = \lambda v$, it also holds that

$$
\|v\|_{W^{k,2}(B_r(0))} \leq C \left( \frac{\sqrt[k]{\lambda}}{r^k} \|v\|_{L^2(B_{r^k}(0))} \right),
$$

where $C > 0$ depends only on $n$ and $\kappa$. From the above inequalities, we have that

$$
\|u\|_{W^{k,2}(B_r(0))} \leq C \left( \frac{\sqrt[k]{\lambda}}{r^k} \|u\|_{W^{k-1,2}(B_{r^k}(0))} + \|v\|_{W^{k-1,2}(B_{r^k}(0))} \right)
$$

$$
\leq C \left( \frac{\sqrt[k]{\lambda}}{r^k} \|u\|_{W^{k-1,2}(B_{r^k}(0))} + \frac{\sqrt[k]{\lambda}}{r^k} \|v\|_{W^{k-1,2}(B_{r^k}(0))} + \|v\|_{W^{k-1,2}(B_{r^k}(0))} \right)
$$

$$
\leq C \left( \frac{\sqrt[k]{\lambda}}{r^k} \|u\|_{L^2(B_{r^k}(0))} + \sum_{j=0}^{k-1} \left( \frac{\sqrt[k]{\lambda}}{r^k} \|v\|_{W^{k-1,2}(B_{r^k}(0))} \right) \right)
$$

$$
\leq C \left( \frac{\sqrt[k]{\lambda}}{r^k} \|u\|_{L^2(B_{r^k}(0))} + k \left( \frac{\sqrt[k]{\lambda}}{r^k} \right)^{k-1} \|v\|_{L^2(B_{r^k}(0))} \right)
$$

$$
\leq Ck \left( \frac{\sqrt[k]{\lambda}}{r^k} \right)^k \left( \|u\|_{L^2(B_{r^k}(0))} + \|v\|_{L^2(B_{r^k}(0))} \right).
$$

Then from the Sobolev’s imbedding theorem and let $t = k^k$ for $k = [n/2] + 1$, we can get the desired result. \qed
Remark 4.2. From the relationship of \( u \) and \( g \), and the doubling condition for \( g \), it is easy to check that for any \( 0 < r_1 < r_2 < \sqrt{2}/2 \), it holds that

\[
\int_{B_{r_2}(y_0)} u^2 \, dx \leq \left( \frac{\sqrt{2}r_2}{r_1} \right)^{C \max\{N(0, \sqrt{2}r_2), C_0\} + \sqrt{2}r_2 - \ln(r_2 - r_1)} \int_{B_{r_1}(y_0)} u^2 \, dx,
\]

where \( y_0 = (x_0, 0) \) and \( C \) is a positive constant depending only on \( n \). That is because \( B_{r_2}(x_0) \times (-r_2, r_2) \subseteq B_{\sqrt{2}r_2}(y_0) \), \( B_{r_1}(y_0) \subseteq B_{r_1}(x_0) \times (-r_1, r_1) \), and the following estimates:

\[
\int_{B_{r_2}(x_0)} u^2 \, dx = \frac{2 \sqrt{2} e^{2 \sqrt{r_2}}}{e^{4 \sqrt{r_2} - 1}} \int_{B_{r_2}(y_0) \times (-r_2, r_2)} g^2 \, dy \leq \frac{2 \sqrt{2} e^{2 \sqrt{r_2}}}{e^{4 \sqrt{r_2} - 1}} \int_{B_{\sqrt{2}r_2}(y_0)} g^2 \, dy \leq \frac{2 \sqrt{2} e^{2 \sqrt{r_2}}}{e^{4 \sqrt{r_2} - 1}} \left( \frac{\sqrt{2}r_2}{r_1} \right)^{C \max\{N(0, \sqrt{2}r_2), C_0\}} \left( \lambda^2 + \frac{1}{(\sqrt{2}r_2 - r_1)^4} \right) \int_{B_{r_1}(y_0)} g^2 \, dy \leq \frac{2 \sqrt{2} e^{2 \sqrt{r_2}}}{e^{4 \sqrt{r_2} - 1}} \left( \frac{\sqrt{2}r_2}{r_1} \right)^{C \max\{N(0, \sqrt{2}r_2), C_0\}} \left( \lambda^2 + \frac{1}{(r_2 - r_1)^4} \right) \int_{B_{r_1}(x_0)} u^2 \, dx \leq \frac{\sqrt{2}r_2}{r_1} \left( \frac{\sqrt{2}r_2}{r_1} \right)^{C \max\{N(0, \sqrt{2}r_2), C_0\} + \sqrt{2}r_2 - \ln(r_2 - r_1)} \int_{B_{r_1}(x_0)} u^2 \, dx.
\]

Basing on the monotonicity formula and the doubling conditions in Remark 4.2, we can get an upper bound for the Hausdorff measure of the nodal set of \( u \) in some small ball.

Theorem 4.3. Let \( \lambda > 1 \) and \( u \) be an eigenfunction of \( B_{r_0}(0) \) with \( \lambda^2 \) the corresponding eigenvalue and \( r_0 < 1 \). Then we have the following estimate of the \((n - 1)\) dimensional Hausdorff measure of the nodal set of \( u \) in \( B_{\frac{r_0}{4}}(0) \) with a fixed \( 0 < r < r_0/4 \):

\[
\mathcal{H}^{n-1} \left( \{ x : u(x) = 0 \} \cap B_{\frac{r_0}{4}}(0) \right) \leq C \left( \max\{N(0, r_0), C_0\} + \ln \lambda + \sqrt{\lambda r - \ln r} \right)^{n-1},
\]

where \( C \) is a positive constant depending only on \( n \).
Proof. Without loss of generality, we may assume that
\[ \int_{B_{\sqrt{2}/2}(0)} u^2 \, dx = 1. \]
Then from Remark 4.2 and Theorem 3.5, and note that for any \( p \in B_{r/16}(0) \),
\[ B_{r/16}(p) \subseteq B_{3r/16}(0) \subseteq B_{\sqrt{2}r/2}(0), \quad B_{r/16}(0) \subseteq B_{3r/16}(p), \]
it holds that,
\[ \int_{B_{r/16}(p)} u^2 \, dx \geq 2^{-\left\{ \max \{ N((0,0), \sqrt{2}r/2, C_0) + \sqrt{r-\ln r} \} \right\}} \int_{B_{3r/16}(p)} u^2 \, dx \]
\[ \geq 2^{-\left\{ \max \{ N((0,0), \sqrt{2}r/2, C_0) + \sqrt{r-\ln r} \} \right\}} \int_{B_{r/16}(0)} u^2 \, dx \]
\[ \geq 2^{-\left\{ \max \{ N((0,0), 1/2, r, C_0) + \sqrt{r-\ln r} \} \right\}} \int_{B_{r/16}(0)} u^2 \, dx \]
\[ \geq 2^{-\left\{ \max \{ N((0,0), 1/2, r, C_0) + \sqrt{r-\ln r} \} \right\}} 2^{-\left\{ \max \{ N((0,0), r, C_0) + \sqrt{r-\ln r} \} \right\}} \int_{B_{\sqrt{2}r/2}(0)} u^2 \, dx \]
\[ \geq 2^{-\left\{ \max \{ N((0,0), r, C_0) + \sqrt{r-\ln r} \} \right\}}. \]

Here we have used the doubling condition in the first and fourth inequalities, and the “changing center property” for the frequency function in the third inequality.

The above inequality shows that, for any \( p \in B_{r/4}(0) \), there exists some point \( x_p \in B_{r/16}(p) \), such that
\[ |u(x_p)| \geq 2^{-\left\{ \max \{ N((0,0), r, C_0) + \sqrt{r-\ln r} \} \right\}}. \quad (4.4) \]
Choose \( p_i \in \partial B_{r/4}(0), i = 1, 2, \cdots, n \) on the \( i \)-th axis. Then from (4.4) we get that there exist points \( x_{pi} \in B_{r/16}(p_i), i = 1, 2, \cdots, n \) satisfy (4.4). On the other hand, from Lemma
and Lemma 3.3, we have

\[
\|u\|_{L^\infty(B_r(0))} \leq C \frac{\lambda^{2/5}}{r^{2/5}} (\|u\|_{L^2(B_{5r/4}(0))} + \|\nu\|_{L^2(B_{5r/4}(0))})
\]

\[
\leq C \frac{\lambda^{2/5}}{r^{2/5}} (\|u\|_{L^2(B_{5r/4}(0))} + 2 C \sqrt{r} \|h\|_{L^2(B_{5r/4}(0))})
\]

\[
\leq C \frac{\lambda^{2/5}}{r^{2/5}} (\|u\|_{L^2(B_{5r/4}(0))} + 2 C (\sqrt{r} + \ln \lambda - \ln r) \|g\|_{L^2(B_{5r/4}(0))})
\]

\[
\leq C \frac{\lambda^{2/5}}{r^{2/5}} (\|u\|_{L^2(B_{5r/4}(0))} + 2 C (\sqrt{r} + \ln \lambda - \ln r) \|u\|_{L^2(B_{5r/4}(0))})
\]

\[
\leq 2 C (\max\{N(0, 4r), C_0\} + \sqrt{r} + \ln \lambda - \ln r) \left( \int_{B_{5r/4}(0)} u^2 \, dx \right)^{\frac{1}{2}}.
\]

In the above estimates, we have used \( \lambda > 1 \), the assumption that \( 4r < r_0 \) and the monotonicity formula for the frequency function. Thus we arrive at

\[
\|u\|_{L^\infty(B_r(0))} \leq 2 C (\max\{N(0, r_0), C_0\} + \sqrt{r} + \ln \lambda - \ln r).
\]

(4.5)

Let

\[ f_i(\omega, t) = u(x_{p_i} + t\omega), \quad \omega \in \mathbb{S}^{n-1}, \quad t \in (-\frac{5}{8} r, \frac{5}{8} r), \quad i = 1, 2, \cdots, n, \]

where \( \mathbb{S}^{n-1} \) means the unit sphere on \( \mathbb{R}^n \). Then \( x_{p_i} + t\omega \subseteq B_r(0) \). Then from (4.5), we have that

\[
|f_i(\omega, t)| \leq \|u\|_{L^\infty(B_r(0))} \leq 2 C (\max\{N(0, r_0), C_0\} + \sqrt{r} - \ln r).
\]

On the other hand, from (4.4), we have

\[
|f_i(\omega, 0)| = |u(x_{p_i})| \geq 2^{-C (\max\{N(0, r_0), C_0\} + \sqrt{r} - \ln r)}.
\]

Then from Lemma 2.3.2 in [10], we have that

\[
\mathcal{H}^0 \left( \left\{ t \in (-\frac{5}{8} r, \frac{5}{8} r) : u(x_{p_i} + t\omega) = 0 \right\} \right) \leq C \left( \{N(0, r_0), C_0\} + \ln \lambda + \sqrt{\lambda r} - \ln r \right). \]

(4.6)

Thus from the integral geometric formula (see [14], [10]), and the fact that

\[
B_{r/16}(0) \subseteq \cap_{i=1}^n B_{5r/8}(x_{p_i}),
\]

...
we have
\[ \mathcal{H}^{n-1}\left(\{x \in B_{r/\pi}(0) : u(x) = 0\}\right) \leq C \left(N(0, r_0), C_0\right) + \ln \lambda + \sqrt{\lambda r - \ln r} r^{n-1}, \] (4.7)
which is the desired result. \(\Box\)

4.2 Upper bound for the frequency function

We first give the definition of the “doubling index”, which is borrowed from [17] and [18] and will be used to help us to give an upper bound for the frequency function.

**Definition 4.1.** For \( B_{r}(y_0) \subseteq \Omega \times \mathbb{R}, \) define
\[ \bar{N}(y_0, r) = \log_2 \frac{\max_{B_{r}(y_0)} |g|}{\max_{B_{r}^{2}(y_0)} |g|}. \] (4.8)

We now give the relationship between the frequency function and the doubling index.

**Lemma 4.4.** Let \( y_0 = (x_0, 0), B_{4r}(x_0) \subseteq \Omega. \) Assume that \( \lambda > 1 \) is large enough such that \( \log_2 \lambda \geq C_0 \) and \( C_0 \) is the constant in Theorem 2.3. Then it holds that
\[ \bar{N}(y_0, r) \leq C \left(\ln \lambda - \ln r + N(y_0, 2r)\right), \] (4.9)
and
\[ N(y_0, \frac{r}{2}) \leq C' \left(\ln \lambda - \ln r + \bar{N}(y_0, r)\right), \] (4.10)
where \( C \) and \( C' \) are positive constants depending only on \( n. \) Here
\[ g(y) = g(x, x_{n+1}) = u(x)e^{-\sqrt{\lambda }x_{n+1}} \]
is defined in Section 2.

**Proof.** Note that \( \Delta g = h + 2\lambda g \) and \( \Delta h = 0. \) So from the standard interior estimate of \( g \) and \( h, \) and note that \( g \) is a function defined in a subset of \( \mathbb{R}^{n+1}, \) we have
\[ \|g\|_{L^{\infty}(B_{r}(y_0))} \leq C \frac{\lambda^{\frac{n+1}{2}}}{r^{\frac{n+1}{2}+1}} \left(\|g\|_{L^{2^{2}}(B_{2r}(y_0))} + \|h\|_{L^{2}(B_{2r}(y_0))}\right). \]
From Lemma 3.3

\[ \|h\|_{L^2(B_r(x_0))} \leq C \left( \frac{1}{r^2} + \lambda \right) \|g\|_{L^2(B_{2r}(x_0))}. \]

So

\[ \|g\|_{L^2(B_r(x_0))} + \|h\|_{L^2(B_r(x_0))} \leq C \left( \frac{1}{r^2} + \lambda \right) \|g\|_{L^\infty(B_{2r}(x_0))} \frac{2.55}{r^2}, \]

i.e.,

\[ \|g\|_{L^\infty(B_{2r}(x_0))} \geq C \frac{1}{\left( \frac{1}{r^2} + \lambda \right)} (\|g\|_{L^2(B_r(x_0))} + \|h\|_{L^2(B_r(x_0))}). \]

Thus we have

\[ \tilde{N}(y_0, r) = \log_2 \frac{\max_{B_{2r}(y_0)} |g|}{\max_{B_r(y_0)} |g|} \]

\[ \leq \log_2 C \frac{\int_{B_{2r}(y_0)} (g^2 + h^2) dy}{r^{\frac{2.55}{2.55}} \left( \int_{B_r(y_0)} (g^2 + h^2) dy \right)^{\frac{2}{2.55}}} \]

\[ \leq C (\ln \lambda - \ln r) + \frac{1}{2} \log_2 \frac{\int_{B_{2r}(y_0)} (g^2 + h^2) dy}{\int_{B_r(y_0)} (g^2 + h^2) dy}, \]

where \( C \) is a suitable large positive constant depending only on \( n, \Omega \) and \( B_j, j = 1, 2 \). From the doubling condition, i.e., Lemma 3.1 we have

\[ \log_2 \frac{\int_{B_{2r}(y_0)} (g^2 + h^2) dy}{\int_{B_r(y_0)} (g^2 + h^2) dy} \leq C \max \{N(y_0, 2r), C_0\}. \]

It tells us that

\[ \tilde{N}(y_0, r) \leq C (\ln \lambda - \ln r + \max \{N(y_0, 2r), C_0\}), \]

where \( C \) is a positive constant depending only on \( n \). By the similar arguments, we also
have that
\[ \tilde{N}(y_0, r) = \log_2 \max_{B_r(y_0)} \frac{\max_{B_{2r}(y_0)} |g|}{\max_{B_{2r}(y_0)} |g|} \]
\[ \geq \log_2 C \frac{r^{\frac{n}{2}} (1 + \epsilon)}{r^{\frac{n+1}{2}}} \left( \int_{B_{2r}(y_0)} (g^2 + h^2) dy \right)^{\frac{1}{2}} \]
\[ \geq C (\ln r - \ln \lambda) + \frac{1}{2} \log_2 \frac{\int_{B_{2r}(y_0)} (g^2 + h^2) dy}{\int_{B_{2r}(y_0)} (g^2 + h^2) dy}. \]

Then also from Lemma 3.1 it holds that
\[ \tilde{N}(g, B_r(y_0)) \geq C (\ln r - \ln \lambda + \min_{\rho \in [5r/8, 7r/8]} N(y_0, \rho)). \]

If for any \( \rho \in [5r/8, 7r/8], N(y_0, \rho) \geq C_0 \), then from the monotonicity formula, i.e., Theorem 2.3, we have
\[ \tilde{N}(g, B_r(y_0)) \geq C (\ln r - \ln \lambda + N(y_0, r/2)), \]
and this implies that
\[ N(y_0, r/2) \leq C (N(y_0, r) + \ln \lambda - \ln r). \]

If for some \( \rho_0 \in [5r/8, 7r/8], N(y_0, \rho_0) \leq C_0 \), then also from Theorem 2.3, we have
\[ N(y_0, r/2) \leq C \max \{N(y_0, \rho_0), C_0\} \leq CC_0 \leq C (\tilde{N}(y_0, r) + \ln \lambda - \ln r), \]
if \( \lambda \) is large enough. Thus we can get the result we need. \( \square \)

Now we will go to establish the upper bound for the frequency function. We first prove the following two lemmas.
Lemma 4.5. Let $\Omega$ be a bounded domain in $\mathbb{R}^n$. Assume that $\partial \Omega$ is of $C^\infty$. Let $u$ be a solution of the eigenvalue problem $\Delta^2 u = \lambda^2 u$ in $\Omega$ with the boundary conditions (4.1.1) and define $T_r(\partial \Omega) = \{ x \in \overline{\Omega} : \text{dist}(x, \partial \Omega) \leq r \}$. Then we have

$$\|u\|_{L^2(T_r(\partial \Omega))} \leq \frac{1}{2} \|u\|_{L^2(\Omega)},$$

(4.11)

where $r^* = C_1 \lambda^{-(n+2)/2} < 1$, and $C_1$ is a positive constant depending only on $n$, $\Omega$ and the boundary operators $B_j$, $j = 1, 2$.

Proof. First we have the following global $L^\infty(\Omega)$ estimate of $u$:

$$\|u\|_{L^\infty(\Omega)} \leq C \lambda^{\frac{2n}{n+2}} \|u\|_{L^2(\Omega)},$$

(4.12)

where $C$ is a positive constant depending only on $n$, $\Omega$ and the boundary operators $B_j$, $j = 1, 2$. Thus

$$\|u\|_{L^2(T_r(\partial \Omega))} \leq C \|u\|_{L^\infty(\Omega)} \left( \mathcal{H}^n(T_r(\partial \Omega)) \right)^{\frac{1}{2}} \leq C \lambda^{\frac{2n}{n+2}} \|u\|_{L^2(\Omega)} \left( \mathcal{H}^{n-1}(\partial \Omega) r \right)^{\frac{1}{2}} \leq C \lambda^{\frac{2n}{n+2}} \|u\|_{L^2(\Omega)} \frac{r}{2} \leq \frac{1}{2} \|u\|_{L^2(\Omega)},$$

if $0 < r \leq C_1 \lambda^{-(n+2)/2}$ for some suitable constant $C_1$ depending only on $n$, $\Omega$, $\mathcal{H}^{n-1}(\partial \Omega)$, and the boundary operators $B_j$, $j = 1, 2$. That is the desired result. □

Because $\partial \Omega$ is analytic except the set $\Gamma$, one can extend the function $u$ out of $\Omega$ except a neighborhood of $\Gamma$. Thus we have the following conclusion.

Lemma 4.6. Let $T_r(\Gamma) = \{ x \in \overline{\Omega} : \text{dist}(x, \Gamma) \leq r \}$ be the $r$ tubular type domain containing $\Gamma$. Let $x \in \overline{\Omega} \setminus T_{\tilde{r}}(\Gamma)$, where $\tilde{r} = \lambda^{-d} < 1$ for some positive constant $d$. Then for any $\tau \in (0, 1)$ there exists a positive constant $C$ depending only on $n$, $\Omega$, $d$, and $B_j$, $j = 1, 2$, such that for any $1 \geq r \geq \tilde{r}$, $u$ can be analytically extended into the set $B_{\tau r}(x) \setminus \Omega$, and

$$\|u\|_{L^\infty(B_{\tau r}(x))} \leq e^{C \sqrt{\tau}} \|u\|_{L^2(B_{\lambda^{-d} r}(\Gamma))}.$$  

(4.13)
Proof. Because \( x \in \Omega \setminus T_r(\Gamma) \) with \( r \geq \tilde{r} \), we know that \( \text{dist}(x, \Gamma) > r \). So from the standard elliptic estimate, the Sobolev’s embedding theorem and the fact that \( \partial \Omega \) is of \( C^\infty \) and compact, we know that there exists a positive constant \( C \) depending only on \( n, \Omega, B_j, j = 1, 2 \), but independent of \( x \), such that for any fixed multi-index \( \alpha \),

\[
|D^\alpha u(x)| \leq C \frac{\lambda^{|\alpha|/2 + \frac{n+2}{2}}}{r^{|\alpha|+1+\frac{1}{2}}} \|u\|_{L^2(B_r(\cdot) \cap \Omega)}.
\]

Because \( u \) is analytic in some neighborhood of \( x \), the Taylor power series of \( u \) at point \( x \) is convergent in \( B_{\tau r}(x) \) for any \( \tau \in (0, 1) \). So

\[
\|u\|_{L^\infty(B_{\tau r}(x))} \leq \sum_{k=0}^{\infty} \frac{1}{k!} |D^k u(x)| (\tau r)^k.
\]

\[
\leq C \sum_{k=0}^{\infty} \frac{k!}{k!} (\tau \sqrt{\lambda})^k \frac{\lambda^{\frac{n+2}{2}}}{r^{\frac{n+1}{2}}} \|u\|_{L^2(B_r(\cdot) \cap \Omega)}.
\]

\[
\leq e^{C(\tau \sqrt{\lambda} + \ln \lambda - \ln r)} \|u\|_{L^2(B_r(\cdot) \cap \Omega)}.
\]

\[
\leq e^{C \sqrt{\lambda}} \|u\|_{L^2(B_r(\cdot) \cap \Omega)}.
\]

In the last inequality in the above, we have used the fact that \( r \geq \tilde{r} = \lambda^{-d}, \ln \lambda < \sqrt{\lambda} \) for \( \lambda \) large enough, and \( C \) is a positive constant depending only on \( n, \Omega, d \) and \( B_j, j = 1, 2 \), but independent of \( x \) because \( \partial \Omega \) is of \( C^\infty \) and compact. That is the desired result. \( \square \)

Now we begin to show an upper bound for the frequency function.

**Theorem 4.7.** Let \( u \) be an eigenfunction in \( \Omega \) with the boundary condition \((1.1)\). Then, there exists a positive constant \( R_0 \) depending only on \( n \) and \( \Omega \), such that for any \( x \in \Omega(R_0, \Gamma) = \Omega \setminus T_{R_0}(\Gamma) \) and \( 0 < r < R_0/2 \), it holds that

\[
N(y, r) \leq C \sqrt{\lambda}.
\]

(4.14)

Here \( y = (x, 0) \) and the positive constants \( C \) depends only on \( n, \Omega \) and \( B_j, j = 1, 2 \).

**Proof.** Without loss of generality, we may assume that \( \|u\|_{L^2(\Omega)} = 1 \). Then from Lemma 4.5 we know that \( \|u\|_{L^2(\Omega \setminus T_r(\partial \Omega))} \geq \frac{1}{2} \) with \( r^* = C_4 \lambda^{-(n+2)/2} \) is the same radius as in
Lemma 4.5 Moreover, the function $u$ is analytic at any point of the set $\Omega(r^*, \partial\Omega) = \Omega \setminus T(r^*, \partial\Omega)$.

Let $\bar{x}$ denote a maximum point of $|u|$ in $\Omega(r^*, \partial\Omega)$ and define $y_0 = (\bar{x}, 0)$. From the $L^\infty$ estimation of $u$, we have

$$
\|u\|_{L^\infty(B_{r^*}(\bar{x}))} \leq \|u\|_{L^\infty(\Omega)} \leq C\lambda^{n/2} \|u\|_{L^2(\Omega)} \leq e^{C\ln \lambda}.
$$

On the other hand,

$$
|u(\bar{x})| = \|u\|_{L^\infty(\Omega(r^*, \partial\Omega))} \geq \frac{1}{(\mathcal{H}^n(\Omega))^2} \|u\|_{L^2(\Omega(r^*, \partial\Omega))} \geq \frac{1}{2 (\mathcal{H}^n(\Omega))^2}.
$$

Then the doubling index of $g$ centered at $y_0$ with radius $r_0 = r^*$ can be bounded as follows:

$$
\tilde{N}(y_0, r_0) = \log_2 \max_{y \in B_{r_0}(y_0)} \frac{|g(y)|}{\max_{y \in B_{r_0/2}(y_0)} |g(y)|} \max_{y \in B_{r_0}(y_0)} |g(y)| \
\leq \log_2 \frac{|g(y_0)|}{|g(y_0)|} e^{\sqrt{\lambda} r_0} \max_{x \in B_{r_0}(\bar{x})} |u(x)| \
\leq \log_2 \frac{|u(\bar{x})|}{|u(\bar{x})|} e^{C\ln \lambda} \leq C\sqrt{\lambda} r_0 + \log_2 \frac{e^{C\ln \lambda}}{C} \
\leq C(\sqrt{\lambda} r_0 + \ln \lambda).
$$

From Lemma 4.4 we have

$$
N(y_0, \frac{r_0}{2}) \leq C(\sqrt{\lambda} r_0 + \ln \lambda - \ln r_0).
$$

Thus from Theorem 3.3 for any point $p \in B_{r_0}^\#(y_0)$,

$$
N(p, \frac{r_0}{8}) \leq C(\sqrt{\lambda} r_0 + \ln \lambda - \ln r_0),
$$

and thus from Lemma 4.4 again,

$$
\tilde{N}(p, \frac{r_0}{16}) \leq C(\sqrt{\lambda} r_0 + \ln \lambda - \ln r_0).
$$
Then from the fact that \( y_0 \in B_{r_0/16}(p) \), we have
\[
\max_{B_{32}(p)} |g| \geq \max_{B_{\frac{r_0}{16}}(p)} |g| e^{-C(\sqrt{r_0} + \ln \lambda - \ln r_0)}
\geq |u(\bar{x})| e^{-C(\sqrt{r_0} + \ln \lambda - \ln r_0)}
\geq e^{-C(\sqrt{r_0} + \ln \lambda - \ln r_0)}.
\]

Choose \( x_1 \in B_{r_0/16}(\bar{x}) \) be the point such that
\[
\text{dist}(x_1, \partial \Omega) = \max_{x \in B_{r_0/16}(\bar{x}) \cap \Omega} \text{dist}(x, \partial \Omega),
\]
and let \( y_1 = (x_1, 0) \in B_{r_0/16}(y_0) \). Then from the above inequalities, we have
\[
\max_{B_{32}(y_1)} |g| \geq \max_{B_{\frac{r_0}{16}}(y_1)} |g| \geq e^{-C(\sqrt{r_0} + \ln \lambda - \ln r_0)}.
\]

Let \( r_1 = r_0 + \frac{r_0}{16} \), then \( \text{dist}(x_1, \partial \Omega) \geq r_0 + r_0/16 = r_1 \). Thus \( B_{r_1}(x_1) \subseteq \Omega \). From the \( L^\infty \) estimation of \( u \) in \( \Omega \) again, we have
\[
\|u\|_{L^\infty(B_{r_1}(x_1))} \leq e^{C \ln \lambda}.
\]

Thus it holds that
\[
N(y_1, r_1) = \log_2 \max_{y \in B_{r_1}(y_1)} |g(y)| \leq \log_2 \max_{y \in B_{r_1}(y_1)} |g(y)| e^{\sqrt{r_1}} \max_{x \in B_{r_1}(x_1)} |u(x)|
\leq \log_2 \frac{e^{\sqrt{r_1}} \max_{x \in B_{r_1}(x_1)} |u(x)|}{e^{-C(\sqrt{r_0} + \ln \lambda - \ln r_0)}}
\leq \sqrt{r_1} + \log_2 \frac{e^{C \ln \lambda}}{e^{-C(\sqrt{r_0} + \ln \lambda - \ln r_0)}}
\leq C(\sqrt{\lambda(r_0 + r_1)} + \ln \lambda - \ln r_0).
\]

Then from Lemma 4.4, we have
\[
N(y_1, r_1/2) \leq C(\sqrt{\lambda(r_0 + r_1)} + \ln \lambda - \ln r_0 - \ln r_1).
\]

32
Applying the same argument with replacing $r_0$ by $r_1$, we have for $r_2 = r_1 + \frac{r_0}{10}$, $y_2 = (x_2, 0)$, where $x_2 \in \Omega(r_0, \partial \Omega)$ and

$$\text{dist}(x_2, \partial \Omega) = \max_{x \in B_{r_1/10}(x_1) \cap \Omega(r_0, \partial \Omega)} \text{dist}(x, \partial \Omega),$$

it holds that

$$\bar{N}(y_2, r_2) \leq C(\ln \lambda - \ln r_0 - \ln r_1 + \sqrt{\lambda}(r_0 + r_1 + r_2)),$$

and thus

$$N(y_2, r_2/2) \leq C(2 \ln \lambda - \ln r_0 - \ln r_1 - \ln r_2 + \sqrt{\lambda}(r_0 + r_1 + r_2)).$$

Let $\delta = \frac{17}{16}$. Choose $R_0$ to be a suitable small positive constant depending only on $n$ and $\Omega$ but independent of $\lambda$, such that the following conditions hold:

1. $R_0$ satisfies that $\mathcal{H}^n(T_{R_0}(\partial \Omega)) \leq \frac{1}{100} \mathcal{H}^n(\Omega)$;
2. For any fixed $r \leq R_0$, it holds that, $\forall x \in \partial \Omega(r, \partial \Omega)$, there exists unique point $x' \in \partial \Omega$, such that $\text{dist}(x, x') = r$;

Repeat the same argument for $k$ times, such that $r_{k-1} < R_0$, and $r_k \geq R_0$. Then

$$R_0 \leq r_k = \delta^k r_0 = C_1 \delta^k \lambda^{-\frac{\lambda^k}{2}},$$

and

$$R_0 \geq r_{k-1} = C_1 \delta^{k-1} \lambda^{-\frac{\lambda^k}{2}}.$$

These show that $k \leq \bar{C} \ln \lambda$, where $\bar{C}$ is a positive constant depending only on $R_0$, $C_1$ and $n$. Thus we have, $x_k \in \Omega(R_0, \partial \Omega)$, $y_k = (x_k, 0)$, and

$$\bar{N}(y_k, r_k) \leq C(\ln^2 \lambda - k \ln r_0 - (1 + 2 + \cdots + (k - 1)) \ln \delta + \sqrt{\lambda}r_0(1 + \delta + \delta^2 + \cdots + \delta^{k-1})) \leq C(\ln^2 \lambda + \sqrt{\lambda}r_0(\delta^{k+1} - 1)/(\delta - 1)) \leq C(\ln^2 \lambda + \sqrt{\lambda}r_0\delta^{k+1}) \leq C \sqrt{\lambda},$$

33
if \( \lambda \) is large enough such that \( \ln \lambda < \sqrt{\lambda} \). These imply that

\[
\bar{N}(y_k, R_0) \leq C \sqrt{\lambda}.
\] (4.15)

Now we will consider the upper bound for the doubling index centered at \( y = (x, 0) \) for any fixed point \( x \in \Omega(R_0, \Gamma) \). Because \( x_k \) and \( x \) can be connected by some curve in \( \Omega(R_0, \Gamma) \) whose length is bounded by some positive constant depending only on \( \Omega \), the upper bound for the doubling index centered at \( y \) with radius \( R_0 \) can be obtained by the similar iteration arguments as above in finite many steps, and the number of the iteration steps depends only on \( \Omega \) and \( \text{dist}(x_k, x) \). In fact, from Lemma 4.6, we know that for \( \tilde{y}_1 = (\tilde{x}_1, 0) \) with \( \tilde{x}_1 \in \overline{B}_{\tau R_0/4}(y_k) \cap \Omega(R_0, \Gamma) \), where \( \tau \in (0, 1) \), it holds that

\[
\|g\|_{L^\infty(B_{\tau R_0}(\tilde{y}_1))} \leq e^{C \sqrt{\tau R_0}}\|u\|_{L^\infty(B_{\tau R_0}(\tilde{y}_1))} \leq e^{C \sqrt{\tau}}\|u\|_{L^2(B_{R_0}(\tilde{x}_1) \cap \Omega)}.
\]

On the other hand, because \( B_{\tau R_0/4}(y_k) \subseteq B_{\tau R_0/2}(\tilde{y}_1) \), we have, from (4.15),

\[
\|g\|_{L^\infty(B_{\tau R_0/2}(\tilde{y}_1))} \leq \|g\|_{L^\infty(B_{\tau R_0/4}(y_k))} \leq e^{C \sqrt{\tau}}\|u\|_{L^2(B_{R_0}(\tilde{x}_1))} \geq e^{C \sqrt{\tau}}\|u\|_{L^2(B_{R_0}(\tilde{x}_1) \cap \Omega)}.
\]

Thus from the above inequalities, we have

\[
\bar{N}(\tilde{y}_1, R_0) \leq C(\sqrt{\lambda} + \sqrt{\tau} R_0) \leq C \sqrt{\lambda}.
\]

Then by repeating the finite steps whose number depends only on \( R_0 \) and \( \Omega \), we can get the desired result by using Lemma 4.4 and Theorem 2.3. \( \square \)

Combining Theorem 4.7 and Theorem 4.3, and note that we have already extended \( u \) outside \( \Omega \) except a neighborhood of \( \Gamma \) in Lemma 4.6, we can get that
Theorem 4.8. Let $\Omega(R_0, \Gamma) = \Omega \setminus T_{R_0}(\Gamma)$, where $R_0$ is the same positive constant as in Theorem 4.7. Then
\[ H^{n-1}(\{x \in \Omega(R_0, \Gamma) : u(x) = 0\}) \leq C \sqrt{\lambda}. \] (4.16)
Here $C$ is a positive constant depending only on $n$, $\Omega$ and the boundary operators $B_j$, $j = 1, 2$.

5 Measure estimates of nodal sets near $\Gamma$

In this section, we begin to consider the domain including the nonanalytic set $\Gamma$.

Lemma 5.1. Let $x \in \Omega \setminus \Gamma$, and $r = \text{dist}(x, \Gamma) > 0$. Then the eigenfunction $u$ can be extended analytically into $B_{\sigma r}(x)$ for any $\sigma \in (0, 1)$, and satisfies that
\[ \|u\|_{L^\infty(B_{\sigma r}(x))} \leq e^{C(\sqrt{\lambda} \ln r)}\|u\|_{L^2(B_r(x) \cap \Omega)}, \] (5.1)
where $C$ is a positive constant depending only on $n$, $\Omega$ and $B_j$, $j = 1, 2$.

Proof. From the proof of Lemma 4.6, it is known that, $\forall x \in \Omega \setminus \Gamma$ and any $\sigma \in (0, 1)$,
\[ \|u\|_{L^\infty(B_{\sigma r}(x))} \leq e^{C(\sqrt{\lambda} \ln r)}\|u\|_{L^2(B_r(x) \cap \Omega)}, \]
where $C$ is a positive constant depending only on $n$, $\Omega$ and $B_j$, $j = 1, 2$. Because $\ln \lambda < \sqrt{\lambda}$ when $\lambda$ large enough, the desired result is hold. \qed

By the same iteration argument in the proof of Theorem 4.7, we have that

Lemma 5.2. Let $u$ be an eigenfunction for the bi-harmonic operator with boundary conditions (1.1). Let $x \in T_{R_0}(\Gamma) \setminus \Gamma$ and denote $\bar{r} = \text{dist}(x, \Gamma)$, where $R_0$ is the same constant as in Theorem 4.7. Then for any $r \in (0, \bar{r})$, it holds that
\[ N(x, r) \leq C(-\sqrt{\lambda} \ln r + \ln^2 r). \] (5.2)
Here $C$ is a positive constant depending only on $n$, $\Omega$ and $B_j$, $j = 1, 2$. 

35
Proof. For any \(x_0^* \in \Omega\) with \(\text{dist}(x_0^*, \Gamma) = R_0\), from Theorem 4.7, we have already known that
\[
\tilde{N}(x_0^*, r) \leq C \sqrt{\lambda}
\]
for any \(r < R_0\). Let \(\sigma\) be a constant in \((0, 1)\). Because \(\Gamma\) is compact, we know that
\[
T_{R_0}(\Gamma) \setminus T_{(1-\varepsilon)R_0}(\Gamma) \subseteq \bigcup_{x^* \in \Omega, \text{dist}(x^*, \Gamma) = R_0} B_{\sigma R_0/16}(x^*),
\]
where \(\varepsilon = \theta \sigma / 16\) and \(\theta \in (0, 1)\) is a positive constant depending only on \(\Omega\) and \(\Gamma\). Let \(R_1 = (1 - \varepsilon)R_0\). Then for any \(x_1^* \in \Omega\) such that \(\text{dist}(x_1^*, \Gamma) = R_1\), there exists some point \(x_0^* \in \Omega\) with \(\text{dist}(x_0^*, \Gamma) = R_0\) such that \(x_1^* \in B_{\sigma R_0/16}(x_0^*)\).

Thus \(\|u\|_{L^\infty(B_{\sigma R_1/4}(x_1^*))} \geq e^{C \sqrt{\lambda}} \|u\|_{L^\infty(B_{\sigma R_0/8}(x_0^*))}\).

Thus for \(y_1^* = (x_1^*, 0)\), it holds that
\[
\|g\|_{L^\infty(B_{\sigma R_1/2}(y_1^*))} \geq e^{C \sqrt{\lambda}} \|u\|_{L^\infty(B_{\sigma R_0/8}(x_0^*))^\Omega}.\]

On the other hand, from Lemma 5.1, we have
\[
\|u\|_{L^\infty(B_{\sigma R_1/2}(y_1^*))} \leq e^{C(\sqrt{\lambda} - \ln R_1)} \|u\|_{L^\infty(B_{\sigma R_0/8}(x_0^*))^\Omega}.\]

Thus
\[
\|u\|_{L^\infty(B_{\sigma R_1/2}(y_1^*))} \leq e^{C(\sqrt{\lambda} - \ln R_1)} \|u\|_{L^\infty(B_{\sigma R_0/8}(x_0^*))^\Omega}.\]

From the above inequalities and the relationship between \(u\) and \(g\), we have
\[
\tilde{N}(y_1^*, \sigma R_1) \leq C(\sqrt{\lambda} - \ln R_1 + \sqrt{\lambda} R_1).\]
Repeat these arguments for $k$ times such that $R_{k-1} \geq r$ and $R_k < r$. Then we have that for $y = (x, 0)$,

$$\tilde{N}(y, \sigma \bar{r}) \leq C \tilde{N}(y'_k, R_k)$$

$$\leq C (k \sqrt{\lambda} - (\ln R_1 + \cdots + \ln R_k) + \sqrt{\lambda}(R_1 + \cdots + R_k))$$

$$\leq C \left( k \sqrt{\lambda} - k \ln R_0 - (1 + 2 + \cdots + k) \ln(1 - \epsilon) + \sqrt{\lambda} R_0 \frac{1 - (1 - \epsilon)^k}{1 - (1 - \epsilon)} \right)$$

$$\leq C (k \sqrt{\lambda} - k \ln R_0 + k^2 + R_0 \sqrt{\lambda}).$$

From $R_{k-1} \geq r$ and $R_k < r$, we have that

$$(1 - \epsilon)^{k-1} R_0 \geq r,$$

and

$$(1 - \epsilon)^k R_0 < r.$$

These show that

$$k \leq -C \ln r$$

for some positive constant $C$ depending only on $n$, $\Omega$, $\Gamma$, and $R_0$. Thus we have

$$\tilde{N}(x, \sigma r) \leq C (k \sqrt{\lambda} - k \ln R_0 + k^2 + R_0 \sqrt{\lambda})$$

$$\leq C (- \ln r \sqrt{\lambda} + \ln^2 r + R_0 \sqrt{\lambda})$$

$$\leq C (- \ln r \sqrt{\lambda} + \ln^2 r).$$

Because $\sigma$ can be chosen as any number in $(0, 1)$, we can get the desired result. \qed

Now we can establish the measure upper bound of the nodal set of $u$ near the boundary $\partial \Omega$.

**Theorem 5.3.** Let $u$ be an eigenfunction of the bi-harmonic operator on a $C^\infty$ bounded domain $\Omega \subseteq \mathbb{R}^n$ with the boundary condition $B_j u = 0$, $j = 1, 2$ on $\partial \Omega$, and the corresponding eigenvalue is $\lambda^2$. Also suppose that $\partial \Omega$ is piecewise analytic and $\partial \Omega \setminus \Gamma$ is
analytic, where $\Gamma \subseteq \partial \Omega$ is a finite union of some $(n-2)$ dimensional submanifolds of $\partial \Omega$. Then for $\lambda$ large enough, we have the following measure estimate:

$$\mathcal{H}^{n-1}\left(\{x \in T_{R_0}(\Gamma) \cap \Omega : u(x) = 0\}\right) \leq C \sqrt[4]{\lambda}, \quad (5.3)$$

where $C$ is a positive constant depending only on $n$, $\Omega$, $B_j$, $j = 1, 2$ and $R_0$. Here $R_0$ is the same positive constant as in Theorem 4.7.

**Proof.** First consider the nodal set in $(T_{R_0}(\Gamma) \setminus T_{R_0/2}(\Gamma)) \cap \Omega$. One can use finitely many balls with radius $\sigma R_0$ to cover the set $(T_{R_0}(\Gamma) \setminus T_{R_0/2}(\Gamma)) \cap \Omega$. Here $\sigma$ is the same positive constant as in Lemma 5.1. The number of these balls is $C/R_0^{n-2}$, where $C > 0$ depends only on $n$ and $\Omega$, and is independent of the radius $R_0$. Because $u$ is analytic in $(T_{R_0}(\Gamma) \setminus T_{R_0/2}(\Gamma)) \cap \Omega$, and the upper bound for the frequency function in this case is $C(\sqrt[4]{\lambda} - \ln \lambda \ln R_0 - \ln^2 R_0)$ from Lemma 5.2, we have

$$\mathcal{H}^{n-1}\left(\{x \in (T_{R_0}(\Gamma) \setminus T_{R_0/2}(\Gamma)) \cap \Omega : u(x) = 0\}\right) \leq C(-\ln R_0 \sqrt[4]{\lambda} + \ln^2 R_0) R_0^{n-1} \cdot \frac{1}{R_0^{n-2}} \leq C(-R_0 \ln R_0 \sqrt[4]{\lambda} + R_0 \ln^2 R_0).$$

Now we consider the nodal set in $(T_{R_0/2}(\Gamma) \setminus T_{R_0/4}(\Gamma)) \cap \Omega$. One can also use finitely many balls with radius $\sigma R_0/2$ to cover the set $(T_{R_0/2}(\Gamma) \setminus T_{R_0/4}(\Gamma)) \cap \Omega$, and the number of these balls is $C/(R_0/2)^{n-2}$ with $C > 0$ depends only on $n$ and $\Omega$. Then we can get the measure of the nodal set in this domain as follows.

$$\mathcal{H}^{n-1}\left(\{x \in (T_{R_0/2}(\Gamma) \setminus T_{R_0/4}(\Gamma)) \cap \Omega : u(x) = 0\}\right) \leq C\left(-\ln \frac{R_0}{2} \sqrt[4]{\lambda} + \ln^2 \frac{R_0}{2} \frac{R_0^{n-1}}{2} \right) \cdot \frac{1}{(R_0/2)^{n-2}} \leq C\left(-\frac{R_0}{2} \ln \frac{R_0}{2} \sqrt[4]{\lambda} + \frac{R_0}{2} \ln^2 \frac{R_0}{2}\right).$$
Continue this argument step by step. By the iteration method, we have that

\[ H^{n-1}(\{x \in T_0(\Gamma) \cap \Omega : u(x) = 0\}) \leq \sum_{j=0}^{\infty} H^{n-1}(\{x \in B_{R_0/2j}(\Gamma) \setminus B_{R_0/2j+1}(\Gamma) \cap \Omega | u(x) = 0\}) \]

\[ \leq CR_0 \left( \sum_{j=0}^{\infty} \frac{j \ln 2 - \ln R_0}{2^j} \sqrt{\lambda} + \sum_{j=0}^{\infty} \frac{1}{2^j} \ln^2 R_0 \right) \]

\[ \leq CR_0 \left( \sqrt{\lambda} \sum_{j=0}^{\infty} \frac{j}{2^j} + \sum_{j=0}^{\infty} \frac{j^2}{2^j} \right) \]

\[ \leq C \sqrt{\lambda}, \]

where the last inequality used the assumption that \( \lambda \) large enough. That is the desired result.

\[ \square \]

From Theorem 5.3 and Theorem 4.8, we can get the desired upper bound estimate of the nodal set of \( u \) in \( \Omega \).

**Theorem 5.4.** Let \( u \) be an eigenfunction satisfies the boundary condition (1.1) and \( \lambda^2 \) be the corresponding eigenvalue. Assume that \( \Omega \) is a \( C^\infty \) bounded domain, \( \partial \Omega \) is piecewise analytic, and \( \partial \Omega \setminus \Gamma \) is analytic, where \( \Gamma \subseteq \partial \Omega \) is a finite union of some \( (n-2) \) dimensional submanifolds of \( \partial \Omega \). Then

\[ H^{n-1} \{x \in \Omega | u(x) = 0\} \leq C \sqrt{\lambda}, \]

(5.4)

where \( C \) is a positive constant depending only on \( n, \Omega \) and the boundary operators \( B_j \), \( j = 1, 2 \).

**Remark 5.5.** Note that the \( C^\infty \) property for \( \partial \Omega \) and the coefficients of the boundary operators \( B_j \), \( j = 1, 2 \), are only used in the \( L^\infty \) estimation of \( u \) and the uniform \( L^\infty \) estimation of \( D^\alpha u \) for any fixed multi-index \( \alpha \). Thus we may only assume that \( \partial \Omega \) is piecewise analytic and \( C^{(\alpha+1)/2} \) continuous, and \( \partial \Omega \setminus \Gamma \) is analytic.

**Remark 5.6.** If we assume that

\[ ||u||_{L^\infty(\Omega)} \leq e^{C \sqrt{T}} ||u||_{L^2(\Omega)}, \]

(5.5)
then the smooth condition for the domain $\Omega$ can be weakened further. In fact, if $(5.5)$ holds, then we only need that $\Omega$ is bounded, $\partial \Omega$ is continuous and piecewise analytic, and $\partial \Omega \setminus \Gamma$ is analytic. Because the $C^{(n+1)/2}$ continuity property for $\partial \Omega$ in Remark 5.5 is only used in the estimation of $L^\infty$ norm of $u$. Moreover, if one of the boundary conditions in $(1.1)$ is $u = 0$ on $\partial \Omega$, then the condition $(5.5)$ can also be omitted. The reason is that, under these assumptions, the upper bounds for the $L^\infty$ norms of $u$ and $D^\alpha u$ in $\Omega$ are

$$\|u\|_{L^\infty(\Omega)} \leq C \lambda^{\frac{n+1}{4}} \|u\|_{L^2(\Omega)}$$

and

$$|D^\alpha u(x)| \leq C \lambda^{\frac{|\alpha|}{2}} \|u\|_{L^2(B_r(x) \cap \Omega)}$$

respectively, provided that $\partial \Omega$ is bounded and continuous. This case contains a lot of usual domains. For instance, a polygon in two dimensional case, a polyhedron in three dimensional case, etc.
