Supperdiffusions for certain nonuniformly hyperbolic systems

Luke Mohr       Hong-Kun Zhang*

September 8, 2018

Abstract

We investigate superdiffusion for stochastic processes generated by nonuniformly hyperbolic system models, in terms of the convergence of rescaled distributions to the normal distribution following the abnormal central limit theorem, which differs from the usual requirement that the mean square displacement grow asymptotically linearly in time. We construct a martingale approximation that follows the idea of Doob’s decomposition theorem. We obtain an explicit formula for the superdiffusion constant in terms of the fine structure that originates in the phase transitions as well as the geometry of the configuration domains of the systems. Models that satisfy our main assumptions include chaotic Lorentz gas, Bunimovich stadia, billiards with cusps, and can be apply to other nonuniformly hyperbolic systems with slow correlation decay rates of order $O(1/n)$.

Keywords: nonstandard central limit theorem, nonuniformly hyperbolic systems, first return time.

1 Introduction and main results

1.1 Introduction

One of the most fundamental mechanisms in nonequilibrium physical systems is the diffusion process. Although random processes have been used to model diffusion based on Einstein’s seminal work on Brownian motion \cite{20}, it has been realized recently that many simple deterministic dynamical systems resemble diffusion to some extent. The theory of dynamical systems has its origin in classical and statistical mechanics through the works of Poincaré and Boltzmann. One of the key aims of statistical mechanics is to relate the microscopic properties of a fluid to the transport coefficient which leads to diffusion on a macroscopic scale. These include diffusion coefficients, viscosity, and heat conduction. Being the simplest physical systems resembling diffusion \cite{7}, deterministic billiards have attracted much attention since Sinai’s seminal work \cite{37}. Limiting laws in classical hyperbolic systems are better understood and proved or almost proved in quite a few cases. However, only recently have these laws become a main focus of study for nonuniformly hyperbolic systems, so the development of new techniques to prove limiting laws is of great mathematical interest.

There are many physically-motivated variations on billiards, such as Lorentz gas, Bunimovich Stadia, etc.; see \cite{37,5,6,8,9,15,30,36} for detailed descriptions. These systems were proved to be hyperbolic, ergodic, and mixing. Many mixing systems have slow (polynomial) mixing rates which cause weak statistical properties; this situation commonly arises in nonuniformly hyperbolic systems. The central limit theorem may fail and affect the convergence to a Brownian motion in a proper space-time limit (weak-invariance principle) and many other useful approximations by stochastic processes that play crucial roles in statistical mechanics. Such systems exemplify a delicate transition from regular behavior to chaos. For this reason, they have attracted considerable interest in mathematical physics during the past 20 years; see \cite{11,2,10,11,13,16,20,23,28,32,35,40,41} and the references therein.

It is somewhat challenging to study hyperbolic systems with singularities, including chaotic billiards. One main reason is that these systems may have singularities that lead to an unpleasant fragmentation of the phase space. More precisely, any unstable manifold may expand locally, but the singularities may cut its images into many pieces. Some of the resulting pieces are a much smaller size than the original ones, and this requires a long time to recover. Moreover, the differential of the map can also be unbounded and/or have unbounded distortion, which aggravates the analysis.

Let \((T, \mathcal{M}, \mu_M)\) be an ergodic transformation of a probability space \((\mathcal{M}, \mu_M, \mathcal{F})\), with \(\mathcal{M}\) a \(d\)-dimensional Riemannian manifold and \(\mathcal{F}\) the Borel \(\sigma\)-algebra on \(\mathcal{M}\). We assume the map \(T : \mathcal{M} \rightarrow \mathcal{M}\) preserves a mixing probability measure \(\mu_M\) on the \(\sigma\)-algebra \(\mathcal{F}\). One can study the statistical properties of a real-valued observable function \(f\) on \(\mathcal{M}\) by defining the sequence of random variables \(X_i = f \circ T^i, i \geq 1\); this sequence is dependent but identically distributed due to the invariance of \(\mu_M\). One intuitive line of inquiry is to study whether classical probability limiting theorems, such as the central limit theorem, are satisfied for this process. It is often the case that as long as the system in question exhibits sufficiently chaotic behavior one may expect such limiting theorems to hold.

Much attention is now shifting to open questions concerning nonuniformly hyperbolic systems with decay rates of correlations as slow as of order \(O(n^{-1})\). Indeed, the central limit theorem has been proved for a variety of these systems, see for example the works of Bálint, Chernov, Dolgopyat, Gouëzel, Liverani, Markarian, Szász, and Varjú \cite{2,3,15,30,36}. The techniques for two-dimensional hyperbolic systems that have been previously utilized are often quite system specific and require geometric calculations based on the particular dynamical system being considered. In this paper, we utilize a martingale difference decomposition technique which can be used to prove the Central Limit Theorem (CLT) for a wide variety of nonuniformly hyperbolic systems. In addition to the new martingale approximation method for hyperbolic systems, we also go beyond previous research, including \cite{2,3,30}, by (i) proving the CLT for processes \(\{f \circ T^n\}\) generated by more general observables, that are only required to be Hölder continuous on stable manifolds; (ii) we are able to explicitly compute the supperdiffusion constants for Sinai billiards on torus with finite number of free flight channels; (iii) the method developed in this paper is not restricted to billiards, but can also be applied for other non uniformly hyperbolic systems.

Our main goal for this paper is to develop central limit theorems for certain nonuniformly hyperbolic systems with slow correlation decay rates of order \(O(n^{-1})\). The stochastic processes generated by these systems exhibit the super-diffusion phenomenon. The main tools we use in our proofs are martingale approximation and the martingale central limit theorem, which are presented in depth by Hall and Heyde in \cite{27} and Helland in \cite{28}. One advantage of our methods is that we will, in many cases, be able to give explicit expressions for the super-diffusion constants. Additionally, we find that our proposed methods are applicable to a wide variety of hyperbolic systems. Our goal
is that this will lead to a more unified approach to studying the statistical properties of nonuniformly hyperbolic systems with slow decay of correlations.

One major advantage of studying martingales is that, while they are not generally independent sequences of random variables, their dependence is “weak enough” that it is possible to generalize results for the i.i.d. case to martingales with certain additional properties. Furthermore, the following result due to Doob [24] gives the study of the statistical properties of martingales even greater significance.

**Doob’s decomposition theorem.** Let $(\Omega, \mathcal{F}, \mathbb{P})$ be a probability space, $\{\mathcal{F}_n\}_{n \in \mathbb{N}}$ a filtration of $\mathcal{F}$, and $\{X_n\}_{n \in \mathbb{N}}$ an adapted stochastic process with $\mathbb{E}|X_n| < \infty$ for all $n \in \mathbb{N}$. Then there exists a martingale $\{M_n\}_{n \in \mathbb{N}}$ and an integrable predictable process $\{A_n\}_{n \in \mathbb{N}}$ starting with $A_1 = 0$ such that $X_n = M_n + A_n$ for every $n \in \mathbb{N}$. This decomposition is unique almost surely.

Note that a process $\{A_n\}_{n \in \mathbb{N}}$ is predictable if $A_n$ is $\mathcal{F}_{n-1}$-measurable for every $n \geq 2$. The above result illustrates the usefulness of studying the statistical properties of martingales. If a stochastic process is adapted to a filtration and each random variable in that process is integrable, then showing the central limit theorem for that stochastic process may reduce to proving an associated martingale central limit theorem, as long as the process $\{A_n\}_{n \in \mathbb{N}}$ is, in a sense, negligibly small.

### 1.2 Abnormal CLT for certain stationary Processes

Let $(\Omega, \mathcal{F}, \mathbb{P})$ be a probability space, with $\mathcal{F}$ being a $\sigma$-algebra. Let $\{\mathcal{F}_n, n \geq 0\}$ be an increasing filtration with

$$\mathcal{F}_0 \subset \cdots \subset \mathcal{F}_{n-1} \subset \mathcal{F}_n \subset \mathcal{F}.$$ 

We assume $\{X_n, n \geq 0\}$ is a sequence of stationary random variables that is adapted to the filtration $\{\mathcal{F}_n, n \geq 0\}$.

We first make some specific assumptions on the stochastic process $\{X_n\}$.

**(A1)** Assume $X_0$ has infinite variance, and $\mathbb{E}(X_0) = 0$. Let $H(t) := \text{Var}(X_0I_{|X_0|<t})$, we assume $H(t)$ is a slowly varying function at infinity, i.e., for all $c > 0$, $\lim_{t \to \infty} H(ct)/H(t) = 1$. Let $c_n \in (0, +\infty)$, with $\lim c_n \to \infty$, such that

$$\lim_{n \to \infty} n\mathbb{P}(|X_1| \geq c_n) = 0, \quad \lim_{n \to \infty} \frac{c_n}{\sqrt{nH(c_n)}} = 0. \quad (1)$$

We define $X_{n,k} = X_k \cdot I_{|X_k|<c_n}$ for any $n \geq 1$ and $k = 0, \cdots, n$.

**(A2)** There exists $\theta \in (-1, 1)$ such that for any $n \geq 0$, $k = 1, \cdots, n$,

$$\mathbb{E}(X_{n,k}|\mathcal{F}_{k-1}) = \theta X_{n,k-1} + \mathcal{E}_{n,k-1}, \quad (2)$$

where $\mathcal{E}_{n,k} \in \mathcal{F}_{k-1}$ is a stationary process such that $\mathbb{E}(\mathcal{E}_{n,0}^2) < \infty$, $\mathbb{E}(|X_{n,0}\mathcal{E}_{n,0}|) < \infty$ and

$$\sum_{k=0}^{n-1} (n-k)\text{Cov}(\mathcal{E}_{n,0}, \mathcal{E}_{n,k}) = O(n).$$

**Theorem 1.** Let $\{X_n, n \geq 0\}$ be a stationary process that satisfies assumptions (A1)-(A2). Then the following sequence converges:

$$\frac{X_1 + \cdots + X_n}{\sqrt{nH(c_n)(1+\theta)/(1-\theta)}} \overset{d}{\to} \mathcal{N}(0, 1) \quad (3)$$

(in distribution). Here, $\mathcal{N}(0, 1)$ is a standard normal distribution, and $\theta, c_n$ are chosen according to (A1)-(A2).

Next we prove the Invariance Principle. Let $J = [0, 1]$. Let $D(J)$ be the space of right continuous (with left limits ) real valued functions on $J$, endowed with the Skorohod $J_1$ topology: that is, for any small $\rho > 0$, we say two functions $u$ and $v$ in $D(J)$ are $\rho$-close if there exists $\lambda : [0, 1] \to [0, 1]$ such that

1. $\lambda(0) = 0, \lambda(1) = 1$, and $\lambda$ is increasing;
(2) \( \forall t \in [0,1], |\lambda(t) - t| \leq \rho; \)
(3) \( \forall t \in [0,1], |u(\lambda(t)) - v(\lambda(t))| \leq \rho. \)

We define a random function such that for any \( t \in [0,1], n \geq 1, \)
\[
W_n(X, t) = \sum_{k=1}^{[tn]} \frac{X_k}{\sqrt{nH(c_n)}}
\]
and we denote \( W \) as the standard Brownian motion on \( D(J). \)

**Theorem 2.** Suppose that \( X_n \) satisfies assumptions (A1)-(A2). Then \( W_n(X, \cdot) \rightarrow \sqrt{\frac{1-\delta}{1+\delta}} W(\cdot) \) weakly on \( D(J) \) as \( n \rightarrow \infty. \)

Proofs of Theorem 1 and Theorem 2 can be found in Section 2.

### 1.3 Abnormal CLT for Dynamical Systems

We consider a dynamical system \((T, \mathcal{M}, \mu_M)\) and assume that the map \( T \) is hyperbolic with singularity \( S \subset \mathcal{M}, \) as defined by Katok and Strelcyn [29], and \( \mu_M \) is a mixing SRB measure. To investigate the statistical properties of \((T, \mathcal{M}, \mu_M)\), we introduce an induced system \((F, M)\). Let \( \mathcal{D} = \bigcup_{i \in I} \Omega_i \) (card \( I < \infty \)) be a finite union of some connected components of \( \mathcal{M} \setminus S. \) For any \( x \in \mathcal{D} \), let
\[
\mathcal{R}(x) = \min\{n \geq 1 : T^n(x) \in \mathcal{D}, \ T^m(x) \notin S, \ m = 1, \ldots, n-1\}
\]
be the first return time function. We denote by \( \mathcal{N}_1 \subset \mathcal{D} \) the set of points that never return to \( \mathcal{D} \). For each \( n \geq 1, \) the “level” set \( \mathcal{D}_n = \{\mathcal{R}(x) = n\} \subset \mathcal{D} \) is open, and if \( \mathcal{D}_n \neq \emptyset \) then \( T^n \) is a diffeomorphism of \( \mathcal{D}_n \) onto \( T^n(\mathcal{D}_n) \subset \mathcal{D} \).

We denote by \( F \) the first return map, i.e.,
\[
F(x) = T^n(x) \quad \forall x \in \mathcal{D}_n, \ n \geq 1.
\]

It is easy to see that \( F \) is a diffeomorphism of the open set \( \mathcal{D}^+ = \bigcup_{n \geq 1} \mathcal{D}_n \) onto the open set \( \mathcal{D}^- = \bigcup_{n \geq 1} T^n(\mathcal{D}_n). \) The inverse map \( F^{-1} \) is defined on \( \mathcal{D}^- \subset \mathcal{D} \) and maps it back to \( \mathcal{D}^+. \) Let \( M = \overline{\mathcal{D}} \) denote the closure of \( \mathcal{D} \), and for each \( n \geq 1 \) let
\[
M_n = \overline{\mathcal{D}_n}.
\]

We set
\[
S_1 = M \setminus \mathcal{D}^+ = \mathcal{N}_1 \cap \partial \mathcal{D}
\]
and
\[
S_{-1} = M \setminus \mathcal{D}^- = \mathcal{N}_{-1} \cap \partial \mathcal{D},
\]
where \( \mathcal{N}_{-1} \subset \mathcal{D} \) denotes the set of points that never return to \( \mathcal{D} \) under the iterations of \( T^{-1}. \) We assume that both \( S_1 \) and \( S_{-1} \) are finite or countable unions of smooth compact curves. The sets \( S_{\pm 1} \) play the role of singularities for the induced maps \( F^{\pm 1}. \) We assume that the map \( F \) restricted to any level set \( \mathcal{D}_n \) can be extended by continuity to its boundary \( \partial \mathcal{D}_n, \) but the extensions to \( \partial \mathcal{D}_n \cap \partial \mathcal{D}_m \) for \( n \neq m \) need not agree.

We assume that \( \mu_M(\mathcal{D}) > 0. \) By the ergodicity of \( \mu_M \) we have
\[
M = \bigcup_{n \geq 1} \bigcup_{m=0}^{n-1} T^m M_n \quad (\text{mod} \ 0).
\]

The first return map \( F \) preserves the measure \( \mu_M \) conditioned on \( M; \) we denote it by \( \mu. \) We note that \( \int_M \mathcal{R} d\mu = \mu_M(M)^{-1} \) by the Kac theorem. The measure \( \mu \) is ergodic, and we assume that it is also mixing.

We assume the support of \( \mu \) has a measurable foliation \( \mathcal{W}^u \) of unstable manifolds of the map \( F, \) such that for any \( W^u \in \mathcal{W}^u \) and any \( x, y \in W^u, \) we have
\[
d(F^{-n}(x), F^{-n}(y)) < C\eta^n,
\]
for some constant $C > 0$ and $\eta \in (0, 1)$.

Assume $\mathcal{F}$ is the Borel $\sigma$-algebra on the region $M \subset \mathbb{R}^2$. Let $\mathcal{A}_0 = \sigma(\mathcal{R})$ be the smallest $\sigma$-algebra generated by the return time function $\mathcal{R}$, or equivalently, generated by a (finite or) countable partition $\{\Omega_n, n \geq 1\}$ of $M \setminus S_1$. We define the $\sigma$-algebra $\mathcal{F}_0 = \sigma(\mathcal{R} \circ F^k, k \leq 0)$, and let $\mathcal{F}_{-1}$ be the trivial $\sigma$-algebra. We define, for $n \geq 1$

$$\mathcal{F}_n = \sigma(\mathcal{R} \circ F^k, k \in (-\infty, n]).$$

(9)

One can check that $\{\mathcal{F}_n, n \geq 0\}$ is an increasing filtration with

$$\mathcal{F}_{n-1} \subset \mathcal{F}_n \subset \mathcal{F}.$$

To get a clear picture of $\mathcal{F}_0$, note that any unstable manifold $W^u \in \mathcal{F}_0$. Indeed $\mathcal{F}_0$ is the smallest $\sigma$-algebra generated by the foliation $W^u$, any observable that is constant on each unstable manifold must belong to $\mathcal{F}_0$. In particular, one can check that for the return time function $\mathcal{R} \circ F^n \in \mathcal{F}_n$, for $n \geq 0$.

For any observable $f : M \to \mathbb{R}$ with finite expectation, we define $E_n(f) = E(f|\mathcal{F}_n)$ and its induced function $\tilde{f} : M \to \mathbb{R}$ such that $\tilde{f}(x) = f(x) + \cdots + f(T^{n-1}x)$ for any $x \in M_n$. For any observable function $f$ on $M$, we denote by $S_nf$ and $S_n\tilde{f}$ the Birkhoff sums of $f$ and the induced function $\tilde{f}$, respectively:

$$S_nf = f + f \circ T + \cdots + f \circ T^{n-1}, \quad \text{and} \quad S_n\tilde{f} = \tilde{f} + \tilde{f} \circ F + \cdots + \tilde{f} \circ F^{n-1}.$$

(10)

To prove the central limit theorem for the process $\{\tilde{f} \circ F^n\}$, we need to introduce the class of observables that we will use to study statistical properties. For any $\gamma \in (0, 1)$, let $\mathcal{H}_\gamma$ be the set of all functions $g \in L_\infty(M, \mu_M)$ such that for any $x, y \in M$,

$$|g(x) - g(y)| \leq \|g\|_\gamma d(x, y)^\gamma,$$

(11)

where

$$\|g\|_\gamma := \sup_{x, y \in M} \frac{|g(x) - g(y)|}{d(x, y)^\gamma} < \infty.$$

If $\|g\|_\infty < \infty$, we also define

$$\|g\|_{c_\gamma} := \|g\|_\infty + \|g\|_\gamma.$$

(12)

**Theorem 3.** Let $f \in \mathcal{H}_\gamma$ with exponent $\gamma \in (0, 1)$. We assume the process $X_n = E_n(\tilde{f} \circ F^n) - E(\tilde{f})$ satisfies assumptions (A1)-(A2), and the process $\xi_{n,k} := (\tilde{f} \cdot I_{|f| \leq c_n} - E_0(\tilde{f} \cdot I_{|f| \leq c_n})) \circ F^k$ satisfies

(A3) $\sum_{k=0}^{m-1}(m-k)Cov(\xi_{n,0} : \xi_{n,k}) = O(m)$, for any $m \leq n$.

Then the following sequence converges in distribution as $n \to \infty$:

$$\frac{S_n\tilde{f} - n\mu(\tilde{f})}{\sqrt{\frac{2}{1-\theta} \cdot nH(c_n)}} \overset{d}{\to} \mathcal{N}(0, 1).$$

(13)

Here $\theta, c_n$ are chosen as in (A1)-(A2).

Next we prove the Invariance Principle and form a random function such that

$$W_n(\tilde{f}, F, \mu, t) = \sum_{k=1}^{[m]} \frac{\tilde{f} \circ F^k - \mu(\tilde{f})}{\sqrt{nH(c_n)}},$$

(14)

where we denote $W$ as the standard Brownian motion on $D(J)$.

**Theorem 4.** Let $f \in \mathcal{H}_\gamma$ with exponent $\gamma \in (0, 1)$. We assume the process $X_n = E_n(\tilde{f} \circ F^n) - E(\tilde{f})$ and $\{\xi_{n,k}\}$ satisfy assumptions (A1)-(A3). Then

$$W_n(\tilde{f}, F, \mu, \cdot) \overset{\text{weakly}}{\to} \sqrt{\frac{2}{1-\theta}} \cdot W(\cdot)$$

(15)

weakly on $D(J)$ as $n \to \infty$. 

5
More generally, we have the following results for the original system \((M, T, \mu_M, f)\) with \(f : M \to \mathbb{R}\). For any observable \(f : M \to \mathbb{R}\) with finite expectation, we denote the induced system by \((M, F, \mu)\) and the induced function by \(\tilde{f} : M \to \mathbb{R}\).

**Theorem 5.** Let \(f\) be an observable on \(M\) where \(f \in \mathcal{H}_\gamma\) with exponent \(\gamma \in (0, 1)\). We assume the process \(X_n = E_n(f \circ F^n) - E(\tilde{f})\) and \(\{\xi_{n,k}\}\) satisfy assumptions (A1)-(A3). Then

\[
W_n(f, T, \mu_M, \cdot) \Rightarrow \sqrt{\mu_M(M)} \frac{1+\theta}{1-\theta} \cdot W(\cdot)
\]

weakly on \(D(J)\) as \(n \to \infty\).

As a consequence of the above invariance principle, we have the following central limit theorem.

**Theorem 6.** For any observable \(f \in H_\gamma\) with \(\gamma \in (0, 1)\), we assume assumptions (A1)-(A3). Then the following sequence converges in distribution:

\[
\frac{f + \cdots + f \circ T^{n-1} - n \mu_M(f)}{\sqrt{\frac{1+\theta}{1-\theta} \cdot n H(c_n) \mu_M(M)}} \xrightarrow{d} \mathcal{N}(0, 1).
\]

The convergence in (16) means precisely that for any \(z \in \mathbb{R}\),

\[
\mu_M \left( \frac{S_n f - n \mu_M(f)}{\sqrt{\frac{1+\theta}{1-\theta} \cdot n H(c_n) \mu_M(M)}} < z \right) \to \int_{-\infty}^{z} \frac{1}{\sqrt{2\pi}} e^{-\frac{x^2}{2}} dx,
\]

as \(n \to \infty\). Since the map \((T, \mu_M)\) is mixing, the limit law (16) holds if we replace \(\mu_M\) with any probability measure that is absolutely continuous with respect to \(\mu_M\); see Section 4.2 in [25].

An analogue of Theorem 6 was proved for some billiard models where correlations decay as \(O(1/n)\) for the Bunimovich stadium, the Lorentz gas with infinite horizon, and billiards with cusps; see [2, 3, 36]. The main goal of this paper is to provide a new method using martingale approximation, and performing a simplified and unified study on the central limit theorem for systems with similar properties. Moreover, Theorem 6 provides the precise formula for the diffusion constants (i.e. coefficient of the term \(n \ln n\)). In particular, this allows us to obtain the diffusion constant for Lorentz gas with infinite horizon, which is new to our knowledge.

**Proposition 7.** Theorem 6 follows from Theorem 5.

The proof of Proposition 7 can be found in Section 4. Thus, it is enough for us to prove Theorem 5 for the induced systems.

In Section 2, we prove a central limit theorem for mixing stationary processes by using martingale approximations. These are inspired by and have direct applications to the nonuniformly hyperbolic systems we subsequently study in-depth. The processes have weak dependence and special assumptions on their conditional expectations that arise naturally in these systems. Theorem 5 and Theorem 6 are proved in Section 3. Section 5 lists some sufficient conditions for estimating diffusion coefficients that will be used in our applications. In Section 6, we study certain classes of nonuniformly hyperbolic billiards and show that we can apply the main results, especially Theorem 13 to each of these systems. Although we only concentrate on stadia, billiards with cusps, and semi-dispersing billiards, the main theorems have legitimate applications to rather general hyperbolic systems.

Throughout this paper we will use the following conventions: positive and finite global constants whose value is unimportant will be denoted by \(c, c_1, c_2, \ldots\) or \(C, C_1, C_2, \ldots\), etc. These letters may denote different values in different equations throughout the paper. Let \(d(.)\) be the distance function on \(\overline{M} \times \overline{M}\) induced by the Riemannian metric in \(M\). For any smooth curve \(W\) in \(M\), we denote by \(|W|\) its Lebesgue length. For any measurable set \(A \subset M\), we denote \(1_A\) as the indicator function of the set \(A\). Given two sequences \(A_n\) and \(B_n\), we use the notation \(A_n \asymp B_n\) to indicate that there exists two uniform constants \(C_1 < C_2\) such that \(C_1 B_n < A_n < C_2 B_n\).
2 Proof of Theorem 1 and Theorem 2

2.1 Martingale approximations

In this section, we consider the stationary process \{X_n\} adapted to the filtration \{\mathcal{F}_n\}, with \mathbb{E}(X_n) = 0. We say that a random variable \( X \) belongs to the domain of attraction of the normal distribution if there exists \( b_n > 0 \) such that

\[
\frac{X_1 + \cdots + X_n}{b_n} \rightarrow \mathcal{N}(0,1)
\]

in distribution as \( n \rightarrow \infty \).

Note that assumption (A1) provides a sufficient condition for the stationary process \{X_n\} to be in the domain of attraction of the normal distribution with \( a_n = 0 \), so our first goal is to find \( b_n \).

We let \( I_A \) denote the indicator of an event \( A \). To overcome the difficulty of the infinite variance property, we next define a triangular array \{\( X_{n,k} : n \geq 1, k = 0, \ldots, n \}\) adapted to \{\( \mathcal{F}_{n,k}, n \geq 1, k = 0, \ldots, n \}\), such that

\[
X_{n,k} = (X_k - I_{|X_k| < c_n}), \quad \mathcal{F}_{n,k} = \mathcal{F}_k.
\]

Clearly, for each \( n \geq 0 \), the row of random variables \{\( X_{n,k}, k = 0, \ldots, n \)\} are identically distributed with

\[
\text{Var}(X_{n,k}) = H(c_n).
\]

The sequence \{\( X_{n,k}, k = 0, \ldots, n \)\} is said to admit a co-boundary if there is a stationary sequence of martingale differences \( Z_k \) and another stationary process \( d_k \) for which \( X_{n,k} = Z_k + d_k - d_{k-1} \) for all \( k = 1, \ldots, n \), in which case

\[
S_n = M_n + Y_n, \quad S_n = \sum_{k=1}^{n} X_{n,k}, \quad M_n = \sum_{k=1}^{n} Z_k, \quad \text{and} \quad Y_n = d_n - d_0.
\]

Here, \( M_n \) is a martingale. Next, we construct a simple martingale difference approximation for the process \{\( X_n \)\}.

**Lemma 8.** There exists a strictly stationary, ergodic martingale difference process array \( \{Z_{n,k}, n \geq 1, k = 1, \ldots, n\} \) with respect to the filtration \( \{\mathcal{F}_n, n \geq 0\} \) such that \( X_{n,k} = Z_{n,k} + Y_{n,k} \), with \( Y_{n,k} := \mathbb{E}(X_{n,k} | \mathcal{F}_{k-1}) \).

**Proof.** We define, for \( n \geq 1 \) and \( k = 1, \ldots, n \),

\[
Y_{n,k} := \mathbb{E}(X_{n,k} | \mathcal{F}_{k-1}).
\]

Then \( \{Y_{n,k}, k = 1, \ldots, n\} \) is a predictable process adapted to the filtration \( \{\mathcal{F}_{k-1}, k = 1, \ldots, n\} \). We also define a stationary sequence

\[
Z_{n,k} = X_{n,k} - \mathbb{E}(X_{n,k} | \mathcal{F}_{k-1}.
\]

(18)

In addition, we define \( Z_{0,0} = X_0 \). One can check that this process is stationary. Note that, in the probability space \((\Omega, \mathcal{F}, \mathcal{F}), \{Z_{n,k}, k = 1, \ldots, n\}\) is adapted to the filtration \( \{\mathcal{F}_k, k \geq 0\} \). Moreover, we have

\[
\mathbb{E}(Z_{n,k} | \mathcal{F}_{k-1}) = \mathbb{E}(X_{n,k} - \mathbb{E}(X_{n,k} | \mathcal{F}_{k-1}) | \mathcal{F}_{k-1})
\]

\[
= \mathbb{E}(X_{n,k} | \mathcal{F}_{k-1}) - \mathbb{E}(\mathbb{E}(X_{n,k} | \mathcal{F}_{k-1}) | \mathcal{F}_{k-1}) = 0.
\]

Thus, \( \{Z_{n,k}\} \) is a martingale difference sequence array. The ergodicity of \( \{Z_{n,k}\} \) follows from that of \( \{X_n\} \).

Moreover, we can check that for any \( n \in \mathbb{Z}, k = 1, \ldots, n \), we have

\[
X_{n,k} = Z_{n,k} + Y_{n,k}.
\]

\[
\square
\]

By Lemma 8, \( \{Z_{n,k}, n \geq 1, k = 1, \ldots, n\} \) is a strictly stationary, ergodic martingale difference array with respect to the filtration \( \{\mathcal{F}_k, k \geq 0\} \). Moreover, by the stationary property and assumption (A2), we have for any \( k \geq 1 \) that

\[
\mathbb{E}(X_{n,k+1} | \mathcal{F}_k) = \theta X_{n,k} + \epsilon_{n,k}.
\]

(19)

We define the partial sums

\[
S_n = \sum_{i=1}^{n} X_{n,i}
\]

7
and

$$M_n = \sum_{i=1}^{n} Z_{n,i}.$$ 

We then have

$$(1 - \theta)S_n = M_n + \theta(X_{n,0} - X_{n,n}) + \sum_{k=0}^{n-1} \xi_{n,k}. \quad (20)$$

Our next goal is to investigate the CLT for the martingale difference \( \{Z_{n,k}\} \). The following lemma was proved by McLeish in [34].

**Lemma 9.** Let \( \{\tilde{Z}_{n,k}\} \) be a martingale difference array adapted to the filtration array \( \{\mathcal{F}_{n,k}\} \). For \( n \to \infty \), assume there exists \( \sigma > 0 \) such that:

1. \( \mathbb{E}(\max_{1 \leq k \leq n} |\tilde{Z}_{n,k}|^2) \to 0; \)
2. \( \sum_{k=1}^{n} \tilde{Z}_{n,k}^2 \to \sigma^2, \) in probability.

Then \( \tilde{Z}_{n,1} + \cdots + \tilde{Z}_{n,n} \to \mathcal{N}(0, \sigma^2) \) in distribution.

In order to relax the requirement to a martingale difference sequence with infinite variance we need to prove an abnormal central limit theorem.

**Proposition 10.** Let \( \{Z_{n,k}\} \) be a martingale difference array defined as in (18) and adapted to the filtration array \( \{\mathcal{F}_{n,k}\} \). Then, for \( n \to \infty \) and any \( k = 1, \ldots, n \),

$$\frac{Z_{n,1} + \cdots + Z_{n,n}}{\sqrt{(1 - \theta^2)nH(c_n)}} \to \mathcal{N}(0, 1)$$

in distribution.

**Proof.** To apply the last lemma, we choose \( c_n \) according to (1) and define an array

$$\tilde{Z}_{n,k} = \frac{Z_{n,k}}{\sqrt{nH(c_n)}}$$

for \( n \geq 1 \) and \( k = 1, \ldots, n \). We claim that \( \tilde{Z}_{n,k}, n \geq 1, k = 1, \ldots, n \) is a martingale difference array that satisfies the assumptions of Lemma 9. Let \( \mathcal{F}_{n,k} = \mathcal{F}_k \) for any \( n \geq 1 \) and \( k = 1, \ldots, n \). Clearly, \( \tilde{Z}_{n,k} \) is \( \mathcal{F}_{n,k} \) measurable and, for each fixed \( n \geq 1 \), \( \{\tilde{Z}_{n,k}, k = 1, \ldots, n\} \) is a martingale difference sequence. Moreover,

$$|\tilde{Z}_{n,k}|^2 = \frac{1}{nH(c_n)} (|X_{n,k} - \mathbb{E}(X_{n,k} | \mathcal{F}_{k-1})|^2).$$

By assumption, we know that \( \mathbb{E}(|\tilde{Z}_{n,k}|^2) < \infty \).

We claim that, for any stationary triangular array \( \eta_{n,k} \) with finite mean,

$$\lim_{n \to \infty} \frac{1}{n} \mathbb{E}\left( \max_{1 \leq k \leq n} \eta_{n,k} \right) = 0. \quad (21)$$

To prove this claim, first choose a large \( N > 1 \). We denote

$$\eta_{n,k} = \eta_{n,k} \cdot 1_{\eta_{n,k} < N} + \eta_{n,k} \cdot 1_{\eta_{n,k} \geq N}$$

and \( \xi_{n,k} = \eta_{n,k} \cdot 1_{\eta_{n,k} > N} \). Note that

$$\mathbb{E}\left( \max_{1 \leq k \leq n} \xi_{n,k} \right) = \int_{0}^{\infty} \mathbb{P}\left( \max_{1 \leq k \leq n} \xi_{n,k} > x \right) \, dx$$

$$\leq \sum_{k=1}^{n} \int_{0}^{\infty} \mathbb{P}(\xi_{n,k} > x) \, dx$$

$$= n \int_{0}^{\infty} \mathbb{P}(\xi_{n,1} > x) \, dx = n \mathbb{E}(\xi_{n,1}).$$
Thus, we have
\[
\frac{1}{n} E \left( \max_{1 \leq k \leq n} \eta_{n,k} \right) \leq \frac{N}{n} + E(\xi_{n,1}) = \frac{N}{n} + E(\eta_{n,1} \cdot I_{\eta_{n,1} > N}).
\]
Since \(E(\eta_{n,1}) < \infty\), and we can choose \(N\) to be arbitrarily large, the right hand side of the above equation approaches 0 as \(n \to \infty\). This completes the proof of claim (21).

Now, take \(\eta_{n,k} = Z_{n,k}^2 / H(c_n)\). Then \(E(\eta_{n,k}) < \infty\) and
\[
\lim_{n \to \infty} \frac{1}{n} E \left( \max_{1 \leq k \leq n} \eta_{n,k} \right) = 0.
\]
Therefore,
\[
E \left( \max_{1 \leq k \leq n} \tilde{Z}_{n,k}^2 \right) = \frac{1}{n} E \left( \max_{1 \leq k \leq n} \eta_{n,k} \right) \to 0
\]
as \(n \to \infty\), which implies that \(E(\max_{1 \leq k \leq n} \tilde{Z}_{n,k}^2)\) is uniformly bounded and verifies item 1 of Lemma 9.

Note that (19) implies that, for any \(k \geq 0\),
\[
E(X_{n,k+1}|\mathcal{F}_k) = \theta X_{n,k} + \varepsilon_{n,k}.
\]
We then have
\[
nH(c_n) E(\tilde{Z}_{n,k+1}^2) = E(E_k(\tilde{Z}_{n,k+1}^2))
\]
\[
= E(E_k(X_{n,k+1}^2 - 2X_{n,k+1}E_k(X_{n,k+1}) + E_k(X_{n,k+1})^2))
\]
\[
= E(X_{n,k+1}^2) - E(E_k(X_{n,k+1})^2)
\]
\[
= E(X_{n,k+1}^2) - E((\theta X_{n,k} + \varepsilon_{n,k})^2)
\]
\[
= (1 - \theta^2)H(c_n) + C_{n,k},
\]
where we use the fact that \(H(c_n) = E(X_{n,k}^2) = E(X_{n,k+1}^2)\), and we have denoted
\[
C_{n,k} = 2\theta E(\varepsilon_{n,k} \cdot X_{n,k}) + E(\varepsilon_{n,0}^2) + 2\theta E(\varepsilon_{n,0} \cdot X_0 \cdot I_{|X_0| < c_n}) + E(\varepsilon_{n,0}^2).
\]
It follows from (A2) that \(C_{n,k}\) is uniformly bounded. This leads to the following equality:
\[
\sum_{k=1}^{n} E(\tilde{Z}_{n,k}^2) = E \left( \sum_{k=1}^{n} E_k(\tilde{Z}_{n,k}^2) \right) = (1 - \theta^2) + \frac{\sum_{k=0}^{n-1} C_{n,k}}{nH(c_n)},
\]
which implies that, as \(n \to \infty\),
\[
\sum_{k=1}^{n} \tilde{Z}_{n,k}^2 \to 1 - \theta^2 > 0
\]
in mean. Therefore, the sequence also converges in probability. This verifies item 2. of Lemma 9.

We can now apply Lemma 7 and obtain that, as \(n \to \infty\),
\[
\sum_{k=1}^{n} \tilde{Z}_{n,k} \to N(0, 1 - \theta^2)
\]
in distribution.

\[\square\]

2.2 Proof of Theorem 1 and Theorem 2

Let \(\{Z_{n,k}, n \geq 0, k = 1, \ldots, n\}\) be the martingale difference array defined as in (13). We denote by \(M_n = Z_{n,1} + \cdots + Z_{n,n}\) the corresponding martingale adapted to the filtration \(\{\mathcal{F}_n, n \geq 1\}\). Now we can use Proposition 10 which implies that, as \(n \to \infty\),
\[
\frac{M_n}{\sqrt{(1 - \theta^2)nH(c_n)}} \to N(0, 1)
\]
in distribution.

According to assumptions (A1)-(A2), we know that the partial sum \( S_n \) of \( \{X_{n,k}, k = 1, \ldots, n\} \) can be written in terms of a martingale \( M_n \) and an error term:

\[
S_n := X_{n,1} + \cdots + X_{n,n} = \sum_{i=1}^{n} \mathbb{E}(X_{n,i}|\mathcal{F}_{i-1}) + Z_{n,1} + \cdots + Z_{n,n} = M_n + \theta \sum_{i=0}^{n-1} X_{n,i} + \sum_{i=0}^{n-1} \mathcal{E}_{n,i}. \tag{23}
\]

This implies that

\[
(1 - \theta)S_n = M_n + \sum_{i=0}^{n-1} \mathcal{E}_{n,i} + \theta(X_{n,n} - X_{n,0}). \tag{24}
\]

Therefore, as \( n \to \infty \),

\[
\frac{(1 - \theta)S_n + \theta(X_{n,n} - X_{n,0}) - \sum_{i=0}^{n-1} \mathcal{E}_{n,i}}{\sqrt{(1 - \theta^2)nH(c_n)}} = \frac{M_n}{\sqrt{(1 - \theta^2)nH(c_n)}} \to \mathcal{N}(0, 1) \tag{25}
\]

in distribution.

One can easily check that

\[
\frac{\theta(X_{n,n} - X_{n,0})}{\sqrt{(1 - \theta^2)nH(c_n)}} \to 0
\]

in \( L_1 \) and, thus, also in distribution. Moreover, we claim that

\[
\frac{1}{\sqrt{(1 - \theta^2)nH(c_n)}} \sum_{i=0}^{n-1} \mathcal{E}_{n,i} \to 0
\]

in distribution. We use assumption (A2), which implies that

\[
\text{Var} \left( \sum_{i=0}^{n-1} \mathcal{E}_{n,i} \right) = n \text{Var}(\mathcal{E}_{n,0}) + 2 \sum_{k=1}^{n-1} (n - k) \text{Cov}(\mathcal{E}_{n,0} \cdot \mathcal{E}_{n,k}) = \mathcal{O}(n).
\]

Furthermore, \( \lim_{n \to \infty} H(c_n) = \infty \) since \( X_0 \) has infinite variance. This implies that

\[
\frac{1}{\sqrt{(1 - \theta^2)nH(c_n)}} \sum_{i=0}^{n-1} \mathcal{E}_{n,i} \to 0
\]

in \( L_2 \).

We have shown that

\[
\frac{(1 - \theta)S_n}{\sqrt{(1 - \theta^2)nH(c_n)}} \to \mathcal{N}(0, 1)
\]

in distribution. This implies that

\[
\frac{S_n}{\sqrt{nH(c_n)(1 + \theta)/(1 - \theta)}} \to \mathcal{N}(0, 1)
\]

in distribution. In particular, this also implies that

\[
\frac{1}{\sqrt{nH(c_n)(1 + \theta)/(1 - \theta)}} \sum_{k=1}^{n} X_k \cdot (I_{|X_k| < c_n}) \to \mathcal{N}(0, 1)
\]

in distribution.

Note that, by (1),

\[
\sum_{k=1}^{n} \mathbb{P}(X_k \neq X_k \cdot (I_{|X_k| < c_n})) \leq \sum_{k=1}^{n} \mathbb{P}(|X_0| > c_n) = n \mathbb{P}(|X_0| > c_n) \to 0
\]
as \( n \to \infty \). By the Borel-Cantelli Lemma, we have
\[
\mu(\mathcal{F}_n) = 0.
\]
Combining the above facts, we have show that
\[
\frac{1}{\sqrt{nH(c_n)(1 + \theta)/(1 - \theta)}} \sum_{k=1}^{n} X_k \to \mathcal{N}(0,1)
\]
in distribution, as \( n \to \infty \). This completes the proof of the Theorem 1.

To prove Theorem 2, we use the following Lemma by McLeish in [34].

**Lemma 11.** Suppose \( \tilde{Z}_{n,k} \) is a martingale difference array satisfying

(a) \( \lim_{n \to \infty} E(\max_{1 \leq k \leq [nt]} \tilde{Z}_{n,k}) = 0 \);
(b) \( \lim_{n \to \infty} \sum_{k=1}^{[nt]} \tilde{Z}_{n,k} = t \) for each \( t \in J \).

Then \( \mathcal{W}_n(\tilde{Z}, \cdot) \to W \) weakly on \( D(\mathcal{J}) \).

Let \( \{Z_{n,k}, n \geq 0, k = 1, \ldots, n\} \) be the martingale difference array defined as in [18]. We denote by \( M_n = Z_{n,1} + \cdots + Z_{n,n} \) the corresponding martingale adapted to the filtration \( \{\mathcal{F}_n, n \geq 1\} \).

Note that the two conditions in Lemma 11 are very similar to those of Lemma 9. Consequently, the verification of conditions (a) and (b) is almost identical to those in Lemma 9 which we will omit here. Thus, for \( n \to \infty \), we have \( \mathcal{W}_n(Z, t) \to W(t) \) weakly on \( D(\mathcal{J}) \):
\[
\mathcal{W}_n(Z, t) = \sum_{k=1}^{[nt]} \frac{Z_{n,k}}{\sqrt{n \text{Var}(Z_{n,k})}} = \frac{M_{[nt]}}{\sqrt{(1 - \theta^2)nH(c_n)}} \to W(t).
\]

Using (25), as \( n \to \infty \) we know that
\[
\mathcal{W}_n(X, t) = \sigma \sum_{k=1}^{[nt]} \frac{X_{n,k}}{n\sigma \text{Var}(X_{n,k})} \to \sigma W(t),
\]
weakly on \( D(\mathcal{J}) \) as \( n \to \infty \), where \( \sigma = \sqrt{\frac{1+\theta}{1-\theta}} \). This completes the proof of Theorem 2.

### 3 Proof of Theorem 3 and Theorem 4

We consider the filtration \( \{\mathcal{F}_n, n \geq 0\} \) as defined in [3] and its remark. For any observable \( f : \mathcal{M} \to \mathbb{R} \), we define its induced function \( \tilde{f} : \mathcal{M} \to \mathbb{R} \), such that
\[
\tilde{f}(x) = f(x) + \cdots + f(T^{n-1}x)
\]
for any \( x \in M_n \), with \( n \geq 1 \). Let \( E_k(\tilde{f}) = E(\tilde{f}|\mathcal{F}_k) \), for \( k \geq 0 \).

Let \( H(t) := \text{Var}(\tilde{f}, 1_{|f| < c}) \), we assume \( H(t) \) is a slowly varying function at infinity. Let \( c_n \in (0, +\infty] \), with \( \lim c_n \to \infty \), such that
\[
\lim_{n \to \infty} n\mathbb{P}(|\tilde{f}| \geq c_n) = 0, \quad \lim_{n \to \infty} \frac{c_n}{\sqrt{nH(c_n)}} = 0.
\]

Note that, by (1),
\[
\sum_{k=1}^{n} \mathbb{P}(\tilde{f} \circ F^k \neq \tilde{f} \circ F^k \cdot (1_{|f| < c_n})) \leq \sum_{k=1}^{n} \mathbb{P}(|\tilde{f}| > c_n) = n\mathbb{P}(|\tilde{f}| > c_n) \to 0
\]
as \( n \to \infty \). By the Borel-Cantelli Lemma, we have
\[
\mu(\tilde{f} \neq \tilde{f} \cdot 1_{|f| < c_n}, \text{ i.o.}) = 0.
\]
Combining the above facts, we have show that

\[ \frac{1}{\sqrt{nH(c_n)}} \sum_{k=1}^{n} \tilde{f} \circ F^k - \frac{1}{\sqrt{nH(c_n)}} \sum_{k=1}^{n} (\tilde{f} \cdot (I_{|f|<c_n})) \circ F^k \rightarrow 0 \]

convergence to zero in distribution, as \( n \to \infty \).

We define \( \hat{f}_{n,k} = (f \cdot \mathbf{1}_{|f|<c_n}) \circ F^k \) for any \( n \geq 1 \) and \( k = 0, \cdots, n \). Above analysis shows that it is enough to consider the central limit theorem for this triangle array.

We consider the stochastic process

\[ X_{n,k} := \mathbb{E}_k(\hat{f}_{n,k}) - \mu_M(\hat{f}_{n,k}) \]

for \( n \geq 0 \).

We first show that for any fixed \( n \geq 1 \), \( \{X_{n,k}, k = 0, \cdots, n\} \) is a stationary sequence.

**Lemma 12.** For \( n \geq 1 \) and any random variable \( h \in L_1(M, \mu) \),

\[ \mathbb{E}(h \circ F^n|\mathcal{F}_n) = \mathbb{E}(h|\mathcal{F}_0) \circ F^n. \]  

(28)

In particular, for any \( n \geq 1 \), \( \{X_{n,k}, k = 0, \cdots, n\} \) defines a stationary process.

**Proof.** For \( n \geq 1 \), any \( g \in \mathcal{F}_n \), and \( h \in L_1(M, \mu) \), the invariance of \( \mu \) and the fact that \( g \circ F^{-n} \in \mathcal{F}_0 \) implies that

\[ \mathbb{E}(\mathbb{E}(h|\mathcal{F}_0) \circ F^n \cdot g) = \mathbb{E}(\mathbb{E}(h|\mathcal{F}_0) \cdot g \circ F^{-n}) \]

\[ = \mathbb{E}(h \cdot g \circ F^{-n}|\mathcal{F}_0) \]

\[ = \mathbb{E}(h \cdot g \circ F^{-n}) \]

\[ = \mathbb{E}(h \circ F^n \cdot g). \]

Thus, by the definition of conditional expectation, we have shown that the expectation of \( h \circ F^n \) with respect to \( \mathcal{F}_n \) is \( \mathbb{E}(h \circ F|\mathcal{F}_0) \circ F^n \), which verifies (28).

Applying the above formula for \( h = \hat{f}_{n,0} - \mu(\hat{f}_{n,0}) \), we then obtain

\[ X_{n,k} = \mathbb{E}(h \circ F^k|\mathcal{F}_k) = \mathbb{E}(h|\mathcal{F}_0) \circ F^k = X_{n,0} \circ F^k. \]

\[ \square \]

Now we have shown that \( \{X_{n,k}, k = 0, \cdots, n\} \) is a sequence of identically distributed, stationary random variables. Note that

\[ \hat{f}_{n,0} + \cdots + \hat{f}_{n,0} \circ F^k - k \mu(\hat{f}) = X_{n,0} + \cdots + X_{n,k} + \xi_{n,0} + \cdots + \xi_{n,k}, \]  

(29)

where

\[ \xi_{n,k} = \hat{f}_{n,k} - \mathbb{E}_k(\hat{f}_{n,k}) = \hat{f}_{n,0} \circ F^k - \mathbb{E}_0(\hat{f}_{n,0}) \circ F^k = (\hat{f}_{n,0} - \mathbb{E}_0(\hat{f}_{n,0})) \circ F^k. \]

Note that \( \mathbb{E}_0(\hat{f}_{n,0}) \) is the conditional average of \( \hat{f}_{n,0} \) on each unstable manifold; i.e., for any \( W^u \in \mathcal{W}^u \), there exists \( x_u \in W^u \) such that for any \( x \in W^u \), \( \mathbb{E}_0(\hat{f}_{n,0})(x) = \hat{f}_{n,0}(x_u) \). Consequently, \( \xi_{n,0} \) can be represented as

\[ \xi_{n,0}(x) = \hat{f}_{n,0}(x) - \hat{f}_{n,0}(x_u), \]

with \( x_u \in W^u(x) \) for any \( x \in M \) such that \( W^u(x) \) exists.

We now claim that

\[ \frac{1}{\sqrt{(1-\theta^2)nH(c_n)}} \sum_{i=0}^{n-1} \xi_{n,i} \rightarrow 0 \]

in distribution. We use assumption (A3), which implies that

\[ \text{Var} \left( \sum_{i=0}^{n-1} \xi_i \right) = n \text{Var}(\xi_0) + 2 \sum_{k=1}^{n-1} (n-k) \text{Cov}(\xi_0 \cdot \xi_{n,k}) = O(n). \]
Thus, it follows from (29) and Theorem 1 that we have
\[ \frac{1}{\sqrt{\frac{1+\theta}{1-\theta} \cdot nH(c_n)}} \sum_{k=1}^{n} \tilde{f} \circ F^k \to N(0,1) \]
in distribution. This completes the proof of Theorem 3.

Next we prove Theorem 4. Without loss of generality, we assume \( \mu(\hat{f}) = 0 \). Let \( J = [0,1] \). Let \( D(J) \) be the space of right continuous real valued functions on \( J \), endowed with the Skorohod \( J_1 \) topology. Let \( X_{n,k} := E_n(\hat{f} \cdot \mathbf{1}_{|f|<c_n}) \circ F^k \), with \( n \geq 1, k = 0, \ldots, n \). We now consider a triangular array \( \{\tilde{X}_{n,k}, n \geq 1, k = 0, \ldots, n\} \), defined as
\[ \tilde{X}_{n,k} = \frac{X_{n,k}}{\sqrt{nH(c_n)}}. \]
Note that \( H(c_n) = \text{Var}X_{n,k} \). We define a random function
\[ W_n(X,t) = \sum_{k=1}^{[nt]} \tilde{X}_{n,k}. \]
Observe that \( W_n(X,\cdot) \) is a right continuous step function, a measurable element of \( D(J) \), and \( W_n(X,0) = 0 \). The object of the invariance principle is to show that \( W_n(X,\cdot) \) converges weakly to the standard Brownian motion process \( W \) on \( D(J) \).

Next, we consider the process \( Y_{n,k} := \tilde{f}_{n,0} \circ F^k \). We form a random function such that
\[ W_n(Y,t) = \sum_{k=1}^{[nt]} \frac{Y_{n,k}}{\sqrt{nH(c_n)}}. \]
It follows from (29) that
\[ \sum_{k=1}^{[nt]} Y_{n,k} = \sum_{k=1}^{[nt]} X_{n,k} + \sum_{k=1}^{[nt]} \xi_{n,k}. \]
Combining (A3) and Theorem 2, we obtain Theorem 4 which states that \( W_n(Y,\cdot) \to \sqrt{\frac{1+\theta}{1-\theta}} \cdot W \) weakly on \( D(J) \) as \( n \to \infty \).

4 Proof of Proposition 7.

For any piecewise H"older continuous observable \( f : \mathcal{M} \to \mathbb{R} \), we let \( \hat{f} \) be its induced function. Assume \( f \in \mathcal{H}_\gamma \), with \( \gamma \in (0,1) \), and we denote
\[ A_n = \sqrt{nH_f(c_n)} \]
where \( H_f(t) := E(\hat{f}^2 \mathbf{1}_{|\hat{f}|<t}) \). And \( S_n(\hat{f},t) = \sum_{k=1}^{[nt]} (\hat{f} \circ F^k - \mu(\hat{f})) \), then \( W_n(\hat{f},t) := S_n(\hat{f},t)/A_n \). Moreover, we denote \( S_n(f,t) = \sum_{k=1}^{[nt]} (f \circ T^k - \mu(f)) \). Theorem 4 implies that \( W_n(\hat{f},t) \) converges to the Brownian motion \( W \) in \( D(J) \). Taking a random time \( N(t) \), we consider whether or not the same limit holds for \( W_N(\hat{f},t) \).

To prove Proposition 7, we need the following lemma from Billingsley [4]-Theorem 14.4 about random change of time. Let \( N \) be a stopping time. We define \( W_N(\hat{f},t) \) by
\[ W_N(\hat{f},t)(\omega) = \frac{S_N(\hat{f},t)}{A_N}(\omega) = \frac{1}{\sqrt{N(\omega)H_f(c_N)}} \sum_{k=1}^{[N(\omega)t]} (\hat{f} \circ F^k(\omega) - \mu(\hat{f})). \]
Lemma 13. If \( N_n \) is a random index with \( N_n/n \to a \) in probability, where \( a > 0 \) is a positive constant, then \( W_n(f, t) \to \sigma \cdot W(t) \) for some \( \sigma > 0 \) implies that \( W_{N_n}(f, t) \to \sigma \cdot W(t) \), as \( n \to \infty \).

We now prove Proposition 13. Define a measure \( \nu \) on \( M \) such that \( \frac{d\nu}{d\mu}(x) = n \mu_M(M) \) for any \( x \in M_n \). Clearly, (33) holds with respect to the measure \( \nu \). Given \( n > 1 \), we fix \( n' = \lfloor n/\mu(M) \rfloor \). Let

\[ n''(x) = 1 + \sum_{j=0}^{[n]} 1_{M}(f \circ T^j(x)), \quad \forall n \geq 1, \]

then \( n'' \) is the number of returns within \( n \) iterations under \( T \), and \( n'' \) is a stopping time with respect to the filtration \( \{\mathcal{F}_n\} \). Thus, by Lemma 13, we have

\[ W_{n''}(\hat{f}, t) \to \frac{1}{1+\theta} \cdot W(t) \quad (33) \]
in \( D(J) \).

Moreover it implies that \( S_{n''}(\mathcal{R}, t) \leq nt \leq S_{n''}(\mathcal{R}, t) \). Let \( \hat{A}_n = \sqrt{nH_{\mathcal{R}}(c_n)} \).

Apply Lemma 13 to \( \mathcal{R} \) for the stopping time \( n'' \), we know that for \( n \to \infty \),

\[ \frac{S_{n''}(\mathcal{R}, t)}{A_{n''}} \to \frac{1}{1+\theta} \cdot W(t). \]

This implies that \( \frac{(\nu'(n')-\nu'(n''))\mu(\mathcal{R})}{A_{n''}} \to \frac{1+\theta}{1+\theta} \cdot W(t) \) as \( n \to \infty \). Thus \( \{\nu'(n')-\nu'(n'')\mu(\mathcal{R})\} \) is tight, which implies that for any \( \varepsilon > 0 \), there exists \( C > 0 \) such that

\[ \nu(|n' - n''| \leq CA_{n''}) \geq 1 - \varepsilon. \]

Note that for \( n \) large, \( n' > n'' \), thus as \( n \to \infty \),

\[ I_{1,n} := \frac{S_n(f, t) - S_{n''}(f, t)}{A_n} = \frac{S_{n'}(\hat{f}, t) - S_{n''}(\hat{f}, t)}{A_n} = \frac{S_{n'}(\hat{f}, t) - S_{n''}(\hat{f}, t)}{A_{n'} - A_{n''}}, \quad \frac{A_{n'} - A_{n''}}{A_n} \to 0. \]

Next, we have

\[ S_n(f, t) - S_{n''}(f, t) \leq \|f\|_{\infty} (nt - S_{n''}(\mathcal{R}, t)) \]

Note that \( S_{n''}(\mathcal{R}, t) \leq nt \), thus \( |nt| - S_{n''}(\mathcal{R}, t) = k \) implies that \( T^{\lfloor nt \rfloor}(x) \in T^k(M_m) \) for some \( m > k \). Then

\[ \mu((|nt| - S_{n''}(\mathcal{R}, t))) \leq \sum_{m \geq k} \mu(M_m) \leq Ck^{-2}. \]

As a result the following process also converges to zero in probability as \( n \to \infty \):

\[ I_{2,n} := \frac{S_n(f, t) - S_{n''}(\hat{f}, t)}{A_n} \leq \frac{\|f\|_{\infty} |nt| - S_{n''}(\mathcal{R}, t)}{A_n} \to 0. \quad (34) \]

Combining the above facts as well as Theorem 13, we have shown the convergence holds with respect to the measure \( \nu \),

\[ \frac{S_n(f, t)}{A_n} = \frac{S_n(\hat{f}, t)}{A_n} + \frac{S_n'(\hat{f}, t) - S_{n'}(\hat{f}, t)}{A_n} + \frac{S_n(f, t) - S_{n''}(\hat{f}, t)}{A_n} \to \frac{\sqrt{1+\theta} \mu_M(M)}{1-\theta} \cdot W(t) \quad (35) \]
as \( n \to \infty \).

Next we consider the measure \( \mu_M \). Since \( M \) can be built into a tower based on \( M \) with height function \( \mathcal{R} \), \( (M, \nu) \) can be viewed as isometric to the space \( (\hat{M}, \mu_M) \). For any \( x \in \hat{M} \), let \( \pi : \hat{M} \to M \) be the projection onto the base along trajectories. For any Holder function \( f : \hat{M} \to M \), if \( x \in \hat{M} \setminus M \) and \( \min\{k \geq 1 : T^k x \in M\} = i \) then \( x \) belongs to the \( i \)-th level of the tower. For any \( n > 1 \), \( t \in (0, 1] \) and \( x \in M \), let \( n'' \) be the number of returns to the base \( M \) within \( |nt| \) iterations along the trajectory of \( x \). Then according to (34), the following sequence converges to zero in probability:

\[ \frac{S_n(f, t) - S_n(f \circ \pi, t)}{A_n} \leq \frac{\|f\|_{\infty} n - S_{n''}(\mathcal{R} \circ \pi, t)}{A_n} \to 0. \]
Then
\[
\frac{S_n(f, t)}{A_n} = \frac{S_n(f \circ \pi, t)}{A_n} + \frac{S_n(f, t) - S_n(f \circ \pi, t)}{A_n} \to \sqrt{\mu_{\mathcal{H}}(M)} \frac{1 + \theta}{1 - \theta} W(t)
\]
in $D(J)$ as $n \to \infty$.

5 Sufficient conditions for estimating diffusion coefficients

The limiting law (10) can be interpreted in physical terms as \textit{superdiffusion}, and the constant factors in the denominator refer to the so-called superdiffusion constant, which plays an important role in physics. Next, we introduce a set of new conditions, under which the superdiffusion constant can be characterized more specifically. These conditions can be applied to hyperbolic attractors. Later, we apply this theorem to all dynamical systems considered in this paper.

(B1) Let $f \in \mathcal{H}$, with exponent $\gamma \in (0, 1)$. Assume there exist $N > 0$ and a set of real numbers $A_f = \{a_1, \cdots, a_N\}$, and for each $n \geq 1$, the level set $M_n$ is decomposed into $N$ connected sets $M_n = \bigcup_{k=1}^N M_{n,k}$. Let $U_{n,k} = \bigcup_{m=n}^\infty M_{m,k}$. We now define a function
\[
J_f = \sum_{k=1}^N a_k \cdot R \cdot I_{U_{1,k}}.
\]
Assume there exists an observable $E = E(f)$, such that the induced function $\tilde{f}$ satisfies:
\[
\tilde{f}(x) = J_f(x) + E(x)
\]

(B2) Assume there exists $c_{M,f} > 0$ such that
\[
c_{M,f} = \lim_{n \to \infty} n^2 \mu(|J_f| \geq n).
\]

(B3) Assume there exists $\theta \in (-1, 1)$ such that
\[
E((J_f \cdot I_{|J_f| < c_n}) \circ F|\mathcal{F}_0) = \theta \cdot J_f \cdot I_{|J_f| < c_n} + \mathcal{E}_{n,0},
\]
where $\mathcal{E}_{n,0} \in \mathcal{F}_0$.

(B4) Suppose $\{\tilde{g}_{n,k}, n \geq 1, k = 0, \cdots, N\}$, for each $n \geq 1$, each $k = 0, \cdots, n$, $\tilde{g}_{n,k}$ is an induced function by some $g_{n,k} \in \mathcal{H}$, and $\tilde{g}_{n,k} \leq c_n$. Then for any $k = 1, \cdots, 2 \ln n$, we have
\[
|\mu(\tilde{g}_{n,k} \circ F^k \cdot \tilde{g}_{n,k}) - \mu(g_{n,k})^2| \leq C \theta^k \ln n;
\]
and for $k = 2 \ln n, \cdots, n$,
\[
|\mu(\tilde{g}_{n,k} \circ F^k \cdot \tilde{g}_{n,k}) - \mu(\tilde{g}_{n,k})^2| \leq C \theta^k/2.
\]
where $\theta \in (0, 1)$ is a constant.

Remark: Note that (B1) and (B4) implies that
\[
\Var\left(\sum_{k=0}^{n-1} E_{n,k}\right) < Cn
\]
for some uniform constant $C > 0$, where $E_{n,k} = (E \cdot I_{\mathcal{G} < c_n}) \circ F^k$, and $c_n = \sqrt{n \ln \ln n}$.

Furthermore, (B3) and (B4) imply that
\[
\sum_{k=1}^{n-1} (n - k) \text{Cov}(\mathcal{E}_{n,0} \cdot \mathcal{E}_{n,0} \circ F^k) = \mathcal{O}(n).
\]
Theorem 14. Let $f$ be a H"older continuous function on $\mathcal{M}$ with exponent $\gamma \in (0,1)$ and $\mu_M(f) = 0$. If (B1)-(B4) hold, then
\[
\frac{\tilde{f} + \cdots + \tilde{f} \circ F^{n-1}}{\sqrt{\frac{1+\theta}{1-\theta} \cdot c_{M,f} \cdot n \ln n}} \overset{d}{\to} N(0,1) \tag{43}
\]
converges in distribution, as $n \to \infty$. Moreover, the CLT holds for $\{f \circ T^n\}$:
\[
\frac{f + \cdots + f \circ T^{n-1}}{\sqrt{\frac{1+\theta}{1-\theta} \cdot \mu_M(M) \cdot c_{M,f} \cdot n \ln n}} \overset{d}{\to} N(0,1) \tag{44}
\]
converges in distribution, as $n \to \infty$.

Proof. Assume (B1)-(B4) hold. We define $X_n = J_f \circ F^n$. Since $J_f$ is constant on each level set of $\mathcal{R}$, and $\mathcal{R} \circ F^n \in \mathcal{F}_n$, clearly, $X_n$ is also $\mathcal{F}_n$-measurable. Thus we have the following decomposition:
\[
\tilde{f} + \cdots + \tilde{f} \circ F^{n-1} = (X_0 + \cdots + X_n) + \sum_{k=0}^{n-1} E \circ F^k
\]
We define $E_{n,k} = (E \cdot I_{\mathcal{R} < c_n}) \circ F^k$, for $n \geq 1$, and $k = 0, \cdots, n$. Moreover, we claim that
\[
\frac{1}{\sqrt{n \ln n}} \sum_{i=0}^{n-1} E_{n,0} \circ F^i \to 0
\]
in distribution, as $n \to \infty$.

We use assumption (B1) and (B4), which implies that
\[
\text{Var} \left( \sum_{i=0}^{n-1} E_{n,0} \circ F^i \right) \leq C n
\]
for a uniform constant $C > 0$. This implies that
\[
\frac{1}{\sqrt{n \ln n}} \sum_{i=0}^{n-1} E_{n,0} \circ F^i \to 0
\]
in $L_2$, as $n \to \infty$.

Next it suffices to verify conditions (A1)-(A2) for the process $\{X_n\}$. Note that
\[
\mathbb{E}(J_f^2 I_{|J_f| < t}) = \sum_{k=1}^{N} a_k^2 \cdot \mathbb{E}(\mathcal{R}^2 \cdot I_{x \in U_{1,k} : |a_k| \mathcal{R}(x) < t})
\]
\[
= 2 \sum_{k=1}^{N} a_k^2 \left( \frac{t}{|a_k|} \right) \sum_{s=1}^{\infty} s \mu(U_{s,k}).
\]
where $U_{s,k} = \bigcup_{m=k}^{\infty} M_{m,k}$. Since $\mathbb{E}(J_f^2 I_{|J_f| < t}) \to \infty$ as $t \to \infty$. By L’Hospital’s rule and (B2), we get
\[
\lim_{t \to \infty} \frac{\mathbb{E}(J_f^2 I_{|J_f| < t})}{\ln t} = \lim_{t \to \infty} \sum_{k=1}^{N} \frac{2a_k^2 \cdot \int_{0}^{t/|a_k|} s \mu(U_{s,k}) \, ds}{\ln t}
\]
\[
= \lim_{t \to \infty} \sum_{k=1}^{N} 2t^2 \cdot \mu(U_{t/a_k,k})
\]
\[
= \lim_{t \to \infty} 2t^2 \mu(|J_f| \geq t) = 2c_{M,f}. \tag{45}
\]
We choose a positive increasing sequence \( \{c_n\} \) such that \( c_n = \sqrt{n \ln \ln n} \). Clearly, we have \( \lim_{n \to \infty} c_n = \infty \) and the following holds:

\[
\lim_{n \to \infty} n \mu(|J_f| > c_n) = 0 \quad \text{and} \quad \lim_{n \to \infty} \frac{c_n}{\sqrt{n \mathbb{E}(J_f^2 | |J_f| < c_n)}} = 0. \tag{46}
\]

It follows from the above analysis that

\[
\lim_{n \to \infty} \frac{\mathbb{E}(J_f^2 | |J_f| < c_n)}{\ln n} = \lim_{n \to \infty} n^2 \mu(|J_f| \geq n) = c_{M,f}. \tag{47}
\]

This relation also tells us that in order to estimate the variance of the variance \( J_f \cdot 1_{|J_f| < c_n} \), it is enough to estimate the tail distribution of the random variable \( \mu(|J_f| \geq n) \). We denote \( a_M := \max\{a_k, k = 1, \cdots, N\} \) as the largest value that \( J_f \) can take. Note that for any \( t > 0 \)

\[
(|J_f| > t/a_M) \supseteq (|J_f| > t) \supseteq (|J_f| > a_M t). \tag{48}
\]

Combining with (47), we know that for some constant \( C > 0 \):

\[
\mu(R \geq n) \leq Cn^{-2}. \tag{49}
\]

**Claim:** We claim that for any \( n \geq 1 \),

\[
\lim_{n \to \infty} \frac{\mathbb{E}(J_f^2 : 1_{|J_f| > \mathbb{E}(J_f)| < c_n})}{\ln n} = \lim_{n \to \infty} \frac{\mathbb{E}(J_f^2 : 1_{|J_f| < c_n})}{\ln n}. \tag{50}
\]

To prove this claim, we first get the following estimation for any \( b \geq 0 \). Note that

\[
\lim_{n \to \infty} \frac{\mathbb{E}(J_f^2 : 1_{|J_f| < c_n + b})}{\ln n} = \lim_{n \to \infty} \frac{2}{\ln n} \int_{c_n}^{c_n + b} s \mu(|J_f| > s) ds \leq \lim_{n \to \infty} \frac{2(c_n + b)}{\ln n} \mu(c_n < |J_f| < c_n + b) \leq \lim_{n \to \infty} \frac{2(c_n + b)}{\ln n} \mu(|J_f| > c_n) = 0,
\]

where we have used (47) in the last step estimation.

Combining with the above facts, we have

\[
\lim_{n \to \infty} \frac{\mathbb{E}(J_f^2 : 1_{|J_f| > \mathbb{E}(J_f)| < c_n})}{\ln n} = \lim_{n \to \infty} \frac{\mathbb{E}(J_f^2 : 1_{|J_f| < c_n} + \mathbb{E}(J_f) < c_n + \mathbb{E}(J_f)})}{\ln n} = \lim_{n \to \infty} \frac{\mathbb{E}(J_f^2 : 1_{|J_f| < c_n} + \mathbb{E}(J_f) < c_n + \mathbb{E}(J_f)})}{\ln n} + \lim_{n \to \infty} \frac{\mathbb{E}(J_f^2 : 1_{|J_f| < c_n} + \mathbb{E}(J_f) < c_n + \mathbb{E}(J_f)})}{\ln n}
\]

This finishes the claim (50).

In addition, we can check that

\[
\lim_{n \to \infty} \frac{\mathbb{E}(J_f - \mathbb{E}(J_f))^2 : 1_{|J_f - \mathbb{E}(J_f)| < c_n})}{\ln n}
\]

\[
= \lim_{n \to \infty} \frac{\mathbb{E}(J_f^2 : 1_{|J_f - \mathbb{E}(J_f)| < c_n})}{\ln n} + \lim_{n \to \infty} \frac{\mathbb{E}(J_f^2 - 2J_f \mathbb{E}(J_f) : 1_{|J_f - \mathbb{E}(J_f)| < c_n})}{\ln n}
\]

\[
= \lim_{n \to \infty} \frac{\mathbb{E}(J_f^2 : 1_{|J_f| < c_n})}{\ln n}.
\]
This allows us to bypass the complication of subtracting the expectation of \( J_t \) in the above limit in our estimations. Thus (B2) implies that

\[
\lim_{n \to \infty} \frac{\mathbb{E}((J_f - \mathbb{E}(J_f))^2 \cdot \mathbb{I}_{|J_f - \mathbb{E}(J_f)| < c_n})}{\ln n} = 2c_{M,f},
\]

which verifies (A1).

Since (B3) and (B4) imply (A2), we get that

\[
\frac{\hat{f} + \cdots + \hat{f} \circ F^{n-1} - n\mu(f)}{\sqrt{\frac{1+n}{n} \cdot c_{M,f} \cdot n \ln n}} \overset{d}{\to} \mathbb{N}(0,1)
\]

converges in distribution as \( n \to \infty \) by Theorem 3.

Combining with Theorem 6, we know that the CLT holds for \( \{f \circ T^n\} \):

\[
\frac{\hat{f} + \cdots + f \circ T^{n-1} - n\mu_M(f)}{\sqrt{\frac{1+n}{n} \cdot c_{M,f} \cdot \mu_M(M) \cdot n(\ln n)}} \overset{d}{\to} \mathbb{N}(0,1)
\]

converges in distribution, as \( n \to \infty \).

\[\square\]

6 Application to nonuniformly hyperbolic systems

6.1 Introduction of nonuniformly hyperbolic billiards

Let \( D \subset \mathbb{R}^2 \) be a bounded open connected domain whose boundary is a finite union of \( C^3 \) compact curves:

\[
\partial D = \Gamma_1 \cup \cdots \cup \Gamma_l.
\]

\( D \) is called a billiard table and \( \Gamma_1, \ldots, \Gamma_l \) are its walls. To generate dynamics, we let a point-like particle move inside the billiard table with unit velocity. Upon colliding with a wall, the particle bounces instantaneously such that its angle of incidence is equal to its angle of reflection. These dynamics are referred to as the billiard flow on \( D \). The billiard flow induces a first return map \( T \) to \( \partial D \) often referred to as the billiard map. We will be studying the discrete-time dynamics of the billiard map and its associated statistical properties.

Assume that \( \partial D \) has a counterclockwise orientation. By construction, we have

\[
T : \partial D \times [-\pi/2, \pi/2] \to \partial D \times [-\pi/2, \pi/2].
\]

The coordinates of the billiard map are given by \((r, \varphi)\), where \( r \) is an arc length parameter on the boundary of the billiard table and \( \varphi \) is the angle of reflection relative to the normal direction. It is known that the billiard map preserves a probability measure on the collision space \( M = \partial D \times [-\pi/2, \pi/2] \) given by

\[
d\mu_M = c_\mu \cos \varphi \, dr \, d\varphi,
\]

where \( c_\mu = (2|\partial D|)^{-1} \) is the normalizing constant.

The dynamics of the billiard map are completely determined by the shape of the table. In rectangles and ellipses, for instance, the dynamics are completely integrable. Sinai introduced the first class of chaotic billiards in 1970 \[37\]. In fact he showed that if \( \partial D \) is convex inwards and has no cusps, then the system is hyperbolic, ergodic, mixing, and K-mixing. Since then, many other classes of chaotic billiards have been studied; see for example the works of Bunimovich \[5, 6\], Markarian \[31\], and Wojtkowski \[39\]. We will focus on billiards which are nonuniformly hyperbolic. Although the central limit theorem has previously been proved in some of the cases we investigate, we believe that our methods have two advantages: they can be applied to a wide variety of dynamical systems and will give us a strong understanding of the variance of the normal distribution in the central limit theorem. To achieve this, we will be utilizing the theorems developed above which rely largely on the application of the martingale central limit theorem to the problem at hand.

The billiards in this chapter are nonuniformly hyperbolic and have polynomial rates of mixing. This slow mixing rate causes the classical central limit theorem to fail. It is therefore advantageous to construct a map induced by
the billiard map which enjoys an exponential decay of correlations. In certain billiards this can be accomplished by considering a subset $M \subset M$ in which we ignore “nonessential collisions;” these are sets in the phase space which contribute to the nonuniformity of the hyperbolicity. The classification of these collisions depends on the billiard table we are considering, so we will leave the specifics for subsequent sections. We can define a return time function $\mathcal{R} : M \to \mathbb{N}$ by

$$\mathcal{R}(x) = \min \{ m \geq 1 : T^m x \in M \}$$

and an induced billiard map $F : M \to M$ by

$$F(x) = T^{\mathcal{R}(x)}(x).$$

Note that $\mathcal{R}$ can be extended to $M$ almost surely as defined in (1). Furthermore, we define $m$-cells $M_m$ in $M$ as

$$M_m = \{ x \in M : \mathcal{R}(x) = m \}.$$  

The induced dynamical system preserves the probability measure $\mu$ on $M$, where $\mu(A) = \mu_M(A)/\mu_M(M)$ for any $A \in \mathcal{M}$.

Note that the collection of $m$-cells $\{M_m\}_{m=1}^\infty$ is an infinite partition of $M$ into disjoint sets, each with positive probability. We define $\mathcal{F}_0 = \sigma(\mathcal{R})$ to be the $\sigma$-algebra generated by $\mathcal{R}$, and $\mathcal{F}_n = \sigma(\mathcal{R} \circ F^n, -\infty < m \leq n)$ to be the smallest $\sigma$-algebra generated by $\mathcal{R} \circ F^n$ with $m \leq n$.

To determine the diffusion constant $\sigma_2$ specifically, the following subsections will exhibit nonclassical central limit theorems for $\tilde{f}$, associated with any H"older continuous function $f : M \to \mathbb{R}$ on various billiard phase spaces; i.e., we will show that

$$\lim_{n \to \infty} \frac{1}{\sqrt{n \ln n}} \sum_{i=0}^{n-1} \left[ \tilde{f} \circ F^i - n\mu_M(\tilde{f}) \right] \to \mathcal{N}(0, \sigma_2^2),$$

where $\sigma_2^2$ is a constant which depends on the shape of the table being studied. The main reason that we concentrate on $\tilde{f}$ is that the CLT for the process $\{ \tilde{f} \circ F^n \}$ follows from that of $\{ f \circ F^n \}$, as indicated by Proposition 7.

This is an amazing result on the tables we study for several reasons. It is possible for trajectories of the billiard to become stuck in arbitrarily long sequences of “nonessential collisions,” that is, many iterations may occur in $M \setminus M$. Consequently, the return time map $\mathcal{R}$ is unbounded in these systems. Furthermore, $m$-cells in these billiards have measure $\mu(M_m) \asymp m^{-3}$. This means that $\mathcal{R}$ has infinite variance:

$$\mu(\mathcal{R}^2) = \sum_{m=1}^\infty m^2 \mu(M_m) \asymp \sum_{m=1}^\infty m^{-1}.$$  

Although a trajectory (under $T$) may become stuck in an arbitrarily large number of nonessential collisions, the central limit theorem indicates that this is highly atypical. However, this possibility does contribute to the nonstandard scaling factor found in the theorem. We see that the extra $\sqrt{\ln n}$ leads to the variance of the average being $\sigma_2^2 n^{-1} \ln n$ as opposed to the classical $\sigma_2^2 n^{-1}$. Clearly, the variance in our case converges to zero more slowly, meaning that the convergence of the time average of $\mathcal{R}$ to its space average is also slower.

We next review the concept of a standard pair and state a growth lemma. For an unstable curve $W$ and a probability measure $\nu_0$ on the Borel $\sigma$-algebra of $W$, we say that the pair $(W, \nu_0)$ is a standard pair if $\nu_0$ is absolutely continuous with respect to the Lebesgue measure, $\text{d}W$, induced by the curve length, with density function $f(x) := \text{d}\nu_0/\text{d}W(x)$ satisfying

$$| \ln f(x) - \ln f(y) | \leq C_{W}(x, y)^{\gamma_0}.$$  

Here the $\gamma_0$ exponent is the Hölder exponent which appears in the distortion bound for the map $F$. Also, $C_{W}(x, y)$ is the distance between $x$ and $y$ measured along the smooth curve $W$.

The notion of a standard pair was studied by Chernov and Dolgopyat in [12]. In particular, they considered families of standard pairs $\mathcal{G} = \{ (W_\alpha, \nu_\alpha) : \alpha \in \mathcal{A} \}$ where $\mathcal{A} \subset [0,1]$. Let $\mathcal{W} = \{ W_\alpha | \alpha \in \mathcal{A} \}$. We call $\mathcal{G}$ a standard family if $W$ is a measurable foliation of a measurable subset of $M$, and there exists a finite Borel measure $\lambda_\mathcal{G}$ on $\mathcal{A}$, which defines a measure $\nu$ on $M$ by

$$\nu(B) := \int_{\mathcal{A}} \nu_\alpha(B \cap W_\alpha) \, d\lambda_\mathcal{G}(\alpha)$$  

for all measurable sets $B \subset M$. In the following, we denote a standard family by $\mathcal{G} = (W, \nu)$. 

\begin{align}
\text{(52)}
| \ln f(x) - \ln f(y) | \leq C_{W}(x, y)^{\gamma_0}.
\end{align}
Define a function \( Z \) on standard families, such that for any standard family \( \mathcal{G} = (W, \nu) \),
\[
Z(\mathcal{G}) := \frac{1}{\nu(M)} \int_{\mathcal{A}} |W_\alpha|^{-1} \lambda_\alpha(d\alpha). \tag{54}
\]

For any unstable curve \( W \in \mathcal{W} \), any \( x \in W \), and any \( n \geq 1 \), let \( W^k(x) \) be the smooth unstable curve in \( F^kW \) that contains \( F^kx \). We define \( r_k(x) \) as the minimal distance between \( F^kx \) and the two end points of \( W^u(F^kx) \).

The following Growth Lemma was proved in [20, Lemma 6].

**Lemma 15** (Growth Lemma). Let \( \mathcal{G} = (W, \nu) \) be a standard family such that \( Z(\mathcal{G}) < \infty \). Then for any \( \epsilon > 0 \),
\[
\nu(r_k(x) < \epsilon) \leq C_0 \epsilon Z(F^k\mathcal{G}) \leq C_1 (\theta^{k-1} Z(\mathcal{G}) + C_2) \epsilon
\]
where \( C_0 > 0, C_1 > 0, C_2 > 0 \) and \( \theta \in (0, 1) \) are constants.

For \( \gamma \in (0, 1) \), let \( \mathcal{H}_\gamma \) be the set of bounded functions \( f \in \mathcal{L}_\infty(M, \mu) \) for which there exists an integer \( n_0 \geq 1 \), such that for any connected component \( A \in \sigma(\mathcal{R} \circ F^{n_0}) \) and any \( x, y \in A \),
\[
|f(x) - f(y)| \leq \|f\|_\gamma \text{dist}(x, y)^\gamma, \tag{55}
\]
with
\[
\|f\|_\gamma := \sup_{A \in \sigma(\mathcal{R} \circ F^{n_0})} \sup_{x, y \in A} \frac{|f(x) - f(y)|}{\text{dist}(x, y)^\gamma} < \infty.
\]

Here \( \sigma(\mathcal{R} \circ F^{n_0}) \) is the \( \sigma \)-algebra generated by the random variable \( \mathcal{R} \circ F^{n_0} \). For every \( f \in \mathcal{H}_\gamma \), we define
\[
\|f\|_{C^\gamma} := \|f\|_\infty + \|f\|_\gamma. \tag{56}
\]

It was shown in [20] Theorem 3] that for \( f, g \in \mathcal{H}_\gamma \), and any integer \( k \), the correlations of \( f \) and \( g \circ F^k \) satisfy:
\[
\text{Cov}(f, g \circ F^k) := |\mu(f \cdot g \circ F^k) - \mu(f) \mu(g)| \leq C \|f\|_{C^\gamma} \|g\|_{C^\gamma} \theta^k \tag{57}
\]
where \( C > 0 \) and \( \theta \in (0, 1) \) are constants.

For a fixed large constant \( C_p \geq 0 \), any standard family \( \mathcal{G} \) with \( Z(\mathcal{G}) < C_p \) will be called a proper family. The following was proved in [20 Theorem 2].

**Lemma 16** (Equidistribution). If \( \mathcal{G} = (W, \nu) \) is a proper family, then for any \( g \in \mathcal{H}_\gamma \), with \( \gamma \in (0, 1) \),
\[
|F^m \nu(g) - \nu(g)| \leq C \|g\|_{C^\gamma} \theta^m \tag{58}
\]
where \( C > 0 \) is a constant.

We note here that in the sections that follow we are presenting examples of applications that demonstrate that our main theorems hold, since in most cases the central limit theorem has been proved for the following billiards. This was done by Bálint and Gouëzel for stadia [3], by Bálint, Chernov, and Dolgopyat in the case of dispersing billiards with cusps [2], and by Szász and Varjú in the case of Lorentz gas with infinite horizon [30]. We believe that our method is applicable to a wide variety of systems and will be useful in determining relevant variances and diffusion coefficients in those systems; we intend to demonstrate this claim in subsequent sections.

### 6.2 Maps with linear spreading property

In this subsection, we consider three types of systems which generate stochastic processes with the linear spreading property as defined below.

We say that a dynamical system has the **linear spreading property** for the one-step transition if the following three conditions are true for large enough \( m, n \):

1. **(L1)** Assume that there exists \( \beta > 1 \) such that \( FM_n \) only intersects those cells \( M_n \) with index \( n \in \mathcal{B}_m := [m/\beta + c_1, \beta m + c_2] \) for some constants \( c_1, c_2 > 0 \). We also assume that
\[
\theta := \frac{2 \ln \beta}{\beta - \beta^{-1}} < 1; \tag{59}
\]
(L2) Assume there exist \( c_M > 0 \) such that the measure
\[
\lim_{m \to \infty} m^2 \mu(\mathcal{R}(x) > m) = c_M;
\]

(L3) Assume the cell \( M_m \) has length \( \sim m^{-1} \) and width \( \sim m^2 \), then transition probability from \( M_m \) to \( M_n \) satisfies
\[
p_{m,n} = \mu(M_n|F(M_m)) = \frac{c_0 m}{n^2} + c(m,n)m^{-2},
\]
for any \( i \geq 1 \), where \( c_0 = [\beta - \beta^{-1}]^{-1} \) is the normalizing constant and \( c(m,n) \) is uniformly bounded.

(L4) Assume for \( k = 1, \cdots, n-1 \), for \( x \) belongs to any unstable manifold \( W^u \subset M_n \), the unstable manifolds \( T^kW^u \) at \( T^kx \) are expanded under \( T \) by a factor \( 1 + \lambda_k \), with
\[
\lambda_k = \frac{C}{k} + o(n^{-1}).
\]

We first prove the Hölder continuity of \( \tilde{f} \). We now estimate the Hölder norm of \( \tilde{f} \), for any \( f \in \mathcal{H}_\gamma \).

**Lemma 17.** For any \( \gamma \in (0,1) \), any \( f \in \mathcal{H}_\gamma \), any \( n \geq 1 \), any \( x, y \in M_n \), the induced function \( \tilde{f} \) has Hölder norm satisfies the following condition:
\[
|\tilde{f}(x) - \tilde{f}(y)| \leq C\|f\|_\gamma n^{1+\gamma}d(x,y)^\gamma
\]
where \( C = C(\gamma) > 0 \) is a constant.

**Proof.** For any \( n \geq 1 \), any \( x, y \in M_n \),
\[
|\tilde{f}(x) - \tilde{f}(y)| \leq \sum_{k=0}^{n-1} \|f\|_\gamma d(T^k x, T^k y)^\gamma
\]
The images \( \{T^k(M_n), k = 1, \cdots, n-1\} \) keep stretching in the unstable direction and shrinking in the stable direction, as \( k \) increases, thus we can assume that \( x, y \) lie on one unstable curve \( W \subset M_n \). By (L4), for \( k = 1, \cdots, n-1 \), the unstable manifolds \( T^kW \) at \( T^kx \) are expanded under \( T \) by a factor \( 1 + \lambda_k \), with \( \lambda_k \sim 1/k \).

We know that the length of \( FM_n \) is of order \( O(n^{-1}) \). Using the fact that \( FW \) is stretched in \( FM_n \), thus its length satisfies
\[
|FW| \leq Cn^{-1}
\]
Moreover, by the distortion bound, we have for \( m \in [1, n-1] \),
\[
d(T^k m, T^m y) \leq C_1 d(x,y) \prod_{l=1}^k (1 + \lambda_l)
\]
for some constant \( C_1 > 0 \). Combining with (61) and (63), we get,
\[
d(T^m x, T^m y) \leq Cmd(x,y)
\]
Combining the above facts, we have
\[
|\tilde{f}(x) - \tilde{f}(y)| \leq \sum_{k=0}^{n-1} \|f\|_\gamma d(T^k x, T^k y)^\gamma
\]
\[
\leq \|f\|_\gamma C_1 d(x,y)^\gamma n^{1+\gamma}.
\]
This implies that \( \tilde{f} \) has Hölder norm of order \( n^{1+\gamma} \). 

\( \Box \)
We then prove a lemma, which verifies (B4).
Let $M_{i,j} = \cup_{m=i}^{j} M_m$ be the union of cells with indices satisfying $1 \leq i \leq j$. Denote

$$f_{i,j} := \tilde{f} \cdot I_{M_{i,j}} - \mu(\tilde{f} \cdot I_{M_{i,j}})$$

**Proposition 18** (Exponential decay of correlations for $f_{i,j}$). Let $\tilde{f}$ be an induced function on $M$, and $f_{i,j}$ is as defined above for any $1 \leq i \leq j < \sqrt{n \ln n}$. Then for all $k \leq 2 \ln n$,

$$|\mu(f_{i,j} \circ F^k \cdot \tilde{f}_{i,j}) - \mu(f_{i,j})^2| \leq C \ln n \cdot \theta^k,$$

where $\theta \in (0, 1)$ is a constant. On the other hand, for $k \geq 2 \ln n$,

$$|\mu(f_{i,j} \circ F^k \cdot \tilde{f}_{i,j}) - \mu(f_{i,j})^2| \leq C \theta^{k/2}.$$

**Proof.** For any set $M_m$ in $M_{i,j}$, we foliate it into unstable curves that stretch completely from one side to the other. Let $\{W_\beta, \beta \in \mathcal{A}, \lambda\}$ be the foliation, and $\lambda$ the factor measure defined on the index set $\mathcal{A}$. This enables us to define a standard family, denoted as $\hat{S}_{i,j} = (M_{i,j}, \mu_{i,j})$, where $\mu_{i,j} := \mu|_{M_{i,j}}$.

Our first step in proving the decay of correlations is to estimate the $Z$ function of $F^k \hat{S}_{i,j}$. According to assumption (L3), $FM_m$ is a strip that has length $\sim m^{-1}$ and width $\sim m^{-2}$. Also, by construction, the density of $\mu_{i,j}$ is of order 1 on $FM_m$. Thus we obtain for $j < \infty$,

$$Z(F \hat{S}_{i,j}) = \mu(M_{i,j})^{-1} \int_{\beta \in \mathcal{A}} |FW_\beta|^{-1} \lambda_{\hat{S}_{i,j}}(d\beta)$$

$$\leq C \mu(M_{i,j})^{-1} \cdot \sum_{m=i}^{j} m^{-2}$$

$$= C_1 \epsilon^2 \cdot i^{-1} = C_1 i.$$

Note that for any large $m \leq l$, we have

$$\mu(FM_{i,j} \cap M_{m,l}) \leq F_\ast \mu_{i,j}(r < \epsilon_{m,l})$$

where $\epsilon_{m,l}$ is approximately the length of the smallest cell in $M_{m,l}$, which is of order $m^{-2}$. Using Lemma 16, we have that

$$\mu(F^k(M_{i,j}) \cap M_{m,l}) \leq F_\ast \mu_{i,j}(r < \epsilon_{m,l})$$

$$\leq C' (\theta^{-1} Z(F \hat{S}_{i,j}) + C'' \epsilon_{m,l} \mu(M_{i,j}))$$

$$\leq C(C_1 \|f\|_\infty \theta^{-1} i + C'' m^{-2} i^{-2})$$

(66)

For any fixed large $k$, we truncate $f_{i,j}$ at two extra levels, with $i \leq p < q \leq j$, which will be chosen later, i.e.

$$f_{i,j} = f_{i,p} + f_{p,q} + f_{q,j}$$

The function $f_{i,q} = f_{i,p} + f_{p,q}$ is bounded with $\|f_{i,q}\|_{\infty} \leq C\|f\|_\infty q$, and Hölder norm $\|f_{i,q}\|_\gamma \leq C\|f\|_\gamma q^{1+\gamma}$. Thus by (67), we know that

$$\mu(f_{i,q} \circ F^k f_{i,q}) \leq C \|f_{i,q}\|_C^2 \theta^k + \mu(f_{i,q})^2 \leq C q^{2+2\gamma} \theta^k + O(q^{-2})$$

(67)

where we used the fact that

$$\mu(f_{i,q}) = -\mu(f_{q,j}) = O(q^{-1})$$
Next we estimate

$$\mu(\hat{f}_{i,p}, \hat{f}_{q,j} \circ F^k) \leq C \|f\|_\infty^2 \sum_{m=i}^{p} \sum_{l=q}^{j} m \cdot l \cdot \mu(M_l \cap F^k M_m)$$

$$= C \|f\|_\infty^2 \sum_{m=i}^{p} \sum_{l=q}^{j} m \cdot \mu(M_l \cap F^k M_m)$$

$$= C \|f\|_\infty^2 \sum_{m=i}^{p} \sum_{l=q}^{j} \left( \sum_{s=q}^{j} \mu(M_s \cap F^k M_m) + \sum_{s=q}^{j} \mu(M_s \cap F^k M_m) \right)$$

$$= C \|f\|_\infty^2 \sum_{m=i}^{p} \sum_{l=q}^{j} \left( q \cdot \mu(M_{q,j} \cap F^k M_m) + \sum_{s=q}^{j} \mu(M_{s,j} \cap F^k M_m) \right)$$

$$+ C \|f\|_\infty^2 \sum_{i=1}^{m} \left( q \cdot \mu(M_{q,i} \cap F^k M_{i,p}) + \sum_{s=q}^{j} \mu(M_{s,j} \cap F^k M_{i,p}) \right)$$

$$= C \|f\|_\infty^2 \left( (C_1 \|f\|_\infty \vartheta^{k-1} i + C''') q^{-1} i^{-1} + \sum_{s=q}^{j} (C_1 \|f\|_\infty \vartheta^{k-1} i + C''') s^{-2} i^{-1} \right)$$

$$+ C \|f\|_\infty^2 \sum_{i=1}^{m} \left( (C_1 \|f\|_\infty \vartheta^{k-1} t + C''') t^{-2} q^{-1} + \sum_{s=q}^{j} (C_1 \|f\|_\infty \vartheta^{k-1} t + C''') s^{-2} t^{-2} \right)$$

Then one can check that

$$\mu(\hat{f}_{i,p}, \hat{f}_{q,j} \circ F^k) = O(q^{-1}(C_1 \vartheta^k \ln p + C_2 i^{-1}))$$

(68)

Similarly, we can show that

$$\mu(\hat{f}_{q,j}, \hat{f}_{i,p} \circ F^k) = O(q^{-1}(C_1 \vartheta^k \ln j + C_2 q^{-1}))$$

(69)

Next, we estimate

$$\mu(\hat{f}_{p,j}, \hat{f}_{p,j} \circ F^k) \leq C \|f\|_\infty^2 \sum_{m=p}^{j} \sum_{l=p}^{j} m \cdot l \cdot \mu(M_l \cap F^k M_m)$$

$$= C \|f\|_\infty^2 \sum_{i=1}^{p} \left( p \cdot \mu(M_{p,j} \cap F^k M_{p,j}) + \sum_{s=p}^{j} \mu(M_{s,j} \cap F^k M_{p,j}) \right)$$

$$+ C \|f\|_\infty^2 \sum_{i=1}^{p} \left( p \cdot \mu(M_{p,j} \cap F^k M_{i,j}) + \sum_{s=p}^{j} \mu(M_{s,j} \cap F^k M_{i,j}) \right)$$

$$= C \|f\|_\infty^2 \left( (C_1 \|f\|_\infty \vartheta^{k-1} p + C''') p^{-2} + \sum_{s=p}^{j} (C_1 \|f\|_\infty \vartheta^{k-1} p + C''') s^{-2} p^{-1} \right)$$

$$+ C \|f\|_\infty^2 \sum_{i=1}^{p} \left( (C_1 \|f\|_\infty \vartheta^{k-1} t + C''') t^{-2} p^{-1} + \sum_{s=p}^{j} (C_1 \|f\|_\infty \vartheta^{k-1} t + C''') s^{-2} t^{-2} \right)$$

Then one can check that

$$\mu(\hat{f}_{p,j}, \hat{f}_{p,j} \circ F^k) = O(p^{-1} \vartheta^k \ln j + p^{-2}) = O(p^{-1} \vartheta^k \ln n + p^{-2})$$

(70)
Combining the above estimations, we have
\[ \mu(\tilde{f}_{i,j}, \tilde{f}_{i,j} \circ F^k) \leq C_1 \vartheta^k (q^{2+2\gamma} + p^{-1} \ln n) + C_2 p^{-1} \]

Now we choose \( q = \vartheta^{-k/d}, p = \sqrt{q} \), where \( d = 6(1 + \gamma) \). Then above estimations implies that
\[ \mu(\tilde{f}_{i,j}, \tilde{f}_{i,j} \circ F^k) \leq C_1 \vartheta^k \ln n, \]
where \( \vartheta = \vartheta^{2/3} \). Note that for \( k > 2 \ln n \),
\[ \vartheta^k \ln n = \vartheta^{k/2} \vartheta^{k/2} \ln n \leq \vartheta^{k/2} \ln n \ln |\ln \theta| \leq \vartheta^{k/2}. \]

In this subsection we will show that it follows from Theorem 14 that the CLT holds for certain observable \( f \) on dynamical systems with the linear spreading property.

**Proposition 19.** For any observable \( f \) on \( M \), assume \( \tilde{f} \in \mathcal{H}_\gamma \) for some \( \gamma \in (0,1) \). Assume \((B1)\) holds, with \( J_f = I_f \mathcal{R} \), such that \( I_f \neq 0 \) is a constant. Moreover we assume the induced map \((F, M)\) satisfies \((L1)-(L4)\). Then the CLT holds:
\[ \lim_{n \to \infty} n \mu_M(\{ x \in M : \mathcal{R} \geq n \}) = 1 \]
converges in distribution, as \( n \to \infty \), where
\[ \sigma_f^2 := \lim_{n \to \infty} n \mu_M(\{ x \in M : \mathcal{R} \geq n \}) = \frac{1+\theta}{1-\theta} \cdot c_M. \]

In addition, we have
\[ \lim_{n \to \infty} n \mu_M(\{ x \in M : \mathcal{R} \geq n \}) = 1 \]
converges in distribution, as \( n \to \infty \), where
\[ \sigma_f = I_f \sqrt{\mu_M(M)} \cdot \tilde{\sigma}_R. \]
(2) Note that if \( f = 1 - \mu(\mathbb{R})I_M \), then \( \tilde{f} = \mathbb{R} - \mu(\mathbb{R}) \), with \( I_f = 1 \), so the diffusion constants for the processes \( \{ f \circ T^n \} \) and \( \{ \tilde{f} \circ F^n \} \) are given by:
\[
\sigma^2_f = \frac{1 + \theta}{1 - \theta} \cdot \lim_{n \to \infty} n\mu_M(x \in M : \mathbb{R} \geq n), \quad \sigma^2_{\tilde{f}} = \frac{\sigma^2_f}{\mu_M(M)}.
\]
This implies that heavier tail for \( \mathbb{R} \) implies faster diffusion for these processes. Note that \( N_n := I_M(x) + \cdots + I_M(T^{n-1}x) \) is the number of returns to \( M \) within \( n \) iterations under \( T \), with \( \mu_M(N_n) = n\mu_M(M) \). Thus the CLT for \( f \) implies that for any \( z > 0 \),
\[
\mu_M \left( \frac{N_n - \mu_M(N_n)}{\mu_M(M)\sigma_{\tilde{f}}\sqrt{n\ln n}} > z \right) \to \int_z^{+\infty} \frac{1}{\sqrt{2\pi}e^{-z^2/2}} dx,
\]
as \( n \to \infty \).

(3) Note that for any \( x \in M_n, \frac{\tilde{f}}{\mathbb{R}(x)} = I_f + E(x)/n \), which implies that
\[
I_f = \lim_{n \to \infty} \frac{\tilde{f}}{n} = \lim_{n \to \infty} \frac{f(x) + \cdots + f(T^{n-1}x)}{n}.
\]
As \( n \to \infty \), the sequence \( f(x), \ldots, f(T^{n-1}x) \) accumulates to the set \( \mathbb{R}^{-1}(\infty) \) in the phase space. Thus \( I_f \) can be viewed as the “average value” of \( f \) in the set \( \mathbb{R}^{-1}(\infty) \). Thus processes \( \{ f \circ T^n \} \) generated by \( f \) with more weight on \( \mathbb{R}^{-1}(\infty) \) will have faster diffusion. This property holds for all dynamical systems with the algebraic spreading property \( \text{(L1)-(L3)} \). Examples include Bunimovich stadia and Skewed stadia.

Next we give the proof of Proposition \[13\] 

Proof. We define \( J_f = I_f \mathbb{R} \), with \( I_f \neq 0 \) being a constant. Define
\[
X_n := J_f \circ F^n - \mu(J_f), \quad n \geq 0.
\]
Next we will show that if a system has the linear spreading property, then the process \( \{ X_n \} \) satisfies \( \text{(B2-B3)} \).

We choose a positive increasing sequence \( \{ c_n \} \) such that \( c_n = \sqrt{n \ln n} \); then, \( \lim_{n \to \infty} c_n = \infty \). Now \( \text{(B2)} \) follows from \( \text{(L2)} \):
\[
\lim_{t \to \infty} \frac{\mathbb{E}(J_f^2 \cdot I_{|J_f| < c_n})}{\ln n} = \lim_{n \to \infty} \frac{n^2 \mu(|J_f| > n)}{\ln n} = \lim_{t \to \infty} n^2 I_f^2 \mu(\mathbb{R} > n) = c_M I_f^2.
\]

Next, we verify condition \( \text{(B3)} \). Since \( \{ \mathbb{R} \circ F^n \} \) is stationary, it is enough to calculate the initial one-step conditional expectations. For \( m \) large, we have
\[
\mathbb{E}(\mathbb{R} \circ F(x)|\mathbb{R}(x) = m) = \sum_{n \in B_m} n \cdot \left( \frac{c_n m}{n^2} + c(m, n)m^{-2} \right) I_{M_m}(x) = \left( 2m \frac{\ln \beta}{\beta - 1} + \sum_{n \in B_m} c(m, n)nm^{-2} \right) I_{M_m}(x) = (\beta m + e_m)I_{M_m},
\]
where \( e_m = \sum_{n \in B_m} c(m, n)nm^{-2} \leq C_e \). Let \( a = \mu(\mathbb{R}) \). We define \( X_{n,0} = (\mathbb{R} - a) \cdot I_{\mathbb{R} < c_n + a} \) and
\[
\mathbb{E}_{n,0} = \mathbb{E}((\mathbb{R} - a) \cdot I_{\mathbb{R} < c_n + a}) \circ F|\mathbb{R} - \theta(\mathbb{R} - a) \cdot I_{\mathbb{R} < c_n + a} = \sum_{m = 1}^{c_n + a} e_m I_{M_m} - a \mathbb{E}(I_{\mathbb{R} < c_n + a} \circ F|\mathbb{R} - \theta \cdot I_{\mathbb{R} < c_n + a}).
\]
Note that \( \mathbb{E}_{n,0} \) is uniformly bounded and \( \sigma(\mathbb{R}) \)-measurable. This verifies \( \text{(B3)} \).

Now the CLT follows from Theorem \[14\] .

Next, we study two systems that have the linear spreading property. More precisely, we will verify conditions \( \text{(B1), (L1)-(L4)} \), and the fact that for any Holder observables \( f \) on \( \mathcal{M} \), \( c_M f = I_f \cdot c_M \) for these systems.
6.2.1 Stadia

The stadium billiard table, introduced by Bunimovich in 1974 [5], is comprised of two equal semicircles which are connected by two parallel lines. Let \( l > 0 \). We consider a region in the plane delimited by two semicircles of radius 1, joined by two horizontal segments of length \( l \), tangent to the semicircles. To a point on the boundary of this set and a vector pointing inwards, we associate an image by the usual billiard reflection law. This defines the stadium billiard map \( T : M \to M \). This map admits a unique absolutely continuous invariant probability measure \( \mu_M \). A point in the phase space \( x \in M \) is given by \( (r, \varphi) \) where \( r \in [0, 2\pi + 2l] \) is the position on the boundary, and \( \varphi \in [-\pi/2, \pi/2] \) is the angle with respect to the normal to this boundary at \( r \). The invariant measure \( \mu_M \) is given by

\[
d\mu_M(r, \varphi) = \frac{\cos \varphi \, dr \, d\varphi}{4(\pi + 1)}.
\]

Dynamics on the stadium have been shown to be nonuniformly hyperbolic, ergodic, and mixing; for some discussion of these facts see [9, 10, 15]. Chernov and Zhang proved in [19] that correlations in stadia decay polynomially, in fact, they decay as \( \mathcal{O}(1/n) \). As a consequence, billiards in stadia do not satisfy the classical central limit theorem.

The induced billiard map on stadia is discussed extensively in [15]. We let \( M \subset \mathbb{R} \) consist only of first collisions at focusing arcs and let the induced billiard map \( F : M \to M \) and return time function \( \mathcal{R} : M \to \mathbb{N} \) be defined as previously mentioned. Note that \( M \) consists of two identical parallelograms with sides bounded by \( \varphi = \pm \pi/2 \) and two line segment with slope \( d\varphi/dr = -1/2 \). So by symmetric property, the \( \mu_M \) measure of \( M \)

\[
\mu_M(M) = \frac{4}{4(\pi + 1)} \int_0^\pi \int_0^{r/2} \cos \varphi \, d\varphi \, dr = \frac{2}{\pi + 1}.
\]

Note that the measure of the set \( M \) was incorrectly calculated in Formula (3) of reference [3], with \( \mu_M(M) = \frac{\pi}{2(\pi + 1)} \). Apparently, \( \frac{\pi}{2(\pi + 1)} \) is the measure of the two rectangles corresponding to all collision points on the two straight sides of the stadium.

Note that the stadium billiard has 4 singular points based on the two arcs, each of which has infinite free flight in the unfolding space of the table (by removing the straight sides). This implies that \( \{M_n\} \) has exactly 4 converging subsequences, denoted as \( M_n = \bigcup_{k=1}^4 M_{n,k} \). We also denote \( M_{n,3} := M_{n,1} \) for convenience of notations. For \( x \in M_n \), its image will hit the flat sides of the stadia \( n - 1 \) times before hitting another arc. Also note that the collision angle along the trajectory \( T_k x, k = 1, \cdots, n - 1 \), is invariant. By symmetric property of the table, one can check that the entire set \( \bigcup_{m \geq n} \bigcup_{k=1}^{m-1} T_k M_m \) is squeezed between two lines with equation

\[
\sin \varphi = \frac{1}{2n} + Cn^{-2} \quad \text{and} \quad \sin \varphi = -\frac{1}{2n} + Cn^{-2}
\]

for some uniform constant \( C > 0 \). One can check that

\[
\mu_M(x \in M : \mathcal{R} \geq n) = \frac{1}{2} \sum_{m \geq n} \sum_{k=0}^{m-1} \mu_M(T_k M_m) + \mathcal{O}(n^2)
\]

\[
= \frac{1}{4(\partial D)} \int_{r \in A} \int_{\frac{\pi}{2n} + Cn^{-2}}^{\frac{\pi}{2n}} d\sin \varphi \, dr + \mathcal{O}(n^2) = \frac{1^2}{4n(\pi + 1)} + \mathcal{O}(n^2).
\]

Thus

\[
c_M = \lim_{n \to \infty} n^2 \mu_M(x \in M : \mathcal{R} \geq n)
\]

\[
= \frac{1}{\mu_M(M)} \lim_{n \to \infty} n \mu_M(x \in M : \mathcal{R} \geq n) = \frac{1^2}{4(\pi + 1)\mu_M(M)}.
\]

This verifies (L2).

It was shown in [5, 15, 18] that \( Fx \in M_n \) for any \( x \in M_m \), where \( n \in B_m := \lfloor m/3 + c_1, 3m + c_2 \rfloor \) for some constants \( c_1, c_2 > 0 \). Moreover, for condition (L1) we have

\[
\theta := \frac{3 \ln 3}{4} = 0.824 < 1.
\]

(78)
It was shown in [8,9] that if \( x \in M_m \), then \( Fx \in M_k \) for some \( m/3 + o(1) \leq k \leq 3m + o(1) \) and that we have the transition probability
\[
\mu(Fx \in M_k | x \in M_m) = \frac{3m}{8k^2} + O\left(\frac{1}{m^2}\right)
\]
which verifies (L3). It was proved in [15], Chapter 8, that if \( k = 1, \cdots, n - 1 \), for \( x \) belongs to any unstable manifold \( W^u \subset M_n \), the unstable manifolds \( T^kW^u \) at \( T^kx \) are expanded under \( T \) by a factor \( 1 + \lambda_k \), with \( \lambda_k = \frac{C}{k} + o(n^{-1}) \). This verifies (L4).

Let \( f \) be a piecewise Hölder continuous on \( M \) with Hölder exponent \( \gamma \in (0,1) \) and we assume \( \mu_M(f) = 0 \). Here we also assume \( f \) is Hölder continuous on a small neighborhood of the set \( \{(r,0) : r \in A\} \). Next define \( I_f \) such that
\[
I_f = \frac{1}{2I} \int_{r \in A} f(r,0) \, dr.
\]
Note that for any fixed \( k = 1, \ldots, 4 \), any \( x \in M_{n,k} \), its forward images \( T^i x = (r_i, \varphi_i) \) will only hit uniformly on the flat sides, for \( i = 1, \ldots, n - 1 \), with
\[
\varphi_i = \varphi_1 = \frac{2I}{2n} + O(n^{-2})
\]
and
\[
|r_i - r_{i-1}| = \frac{2I}{n} + O(n^{-2}).
\]
Since the Riemann integral approximation of \( I_f \) can be obtained by sampling \( f(r, \varphi_1) \) with respect to the uniform partition of each interval \( r \in [0,1] \) and \( r \in [1 + \pi, \pi + 2\pi] \); using the Hölder continuity of \( f \), one can show that for \( n \) large, any \( x \in M_{n,i} \), we denote \( f(T^kx) = (r_k, \varphi_1) \), then
\[
|f(r_k,0) - f(r_k, \varphi_1)| \leq C\|f\|_\gamma n^{-\gamma}
\]
This implies that
\[
|1_f - \frac{1}{n} \sum_{k=0}^{n-1} f \circ T^k(x)| \leq C\|f\|_\gamma n^{-\gamma},
\]
where \( \gamma \in (0,1) \) is the Hölder exponent of \( f \). Note that \( I_f \) does not depend on \( k \). This implies that we can define \( J_f = \int I_fR \). Moreover, there exists a function \( E = E(f) \), such that for any \( x \in M_n \),
\[
\tilde{f}(x) = \sum_{k=0}^{n-1} f \circ T^k(x) = J_f(x) + E(x),
\]
where \( E = O(R^{1-\gamma}) \). We define \( E_{n,k} = (E \cdot I_{\mathbb{R} < c_n}) \circ T^k \), for \( n \geq 1 \), and \( k = 0, \ldots, n - 1 \). Note that
\[
E_{n,k} \leq Cc_n^\gamma = C(n \ln \ln n)^{\frac{2}{3}}.
\]
This verifies (B1).

Now it follows that \( 139 \) holds with
\[
\frac{1 + \theta}{1 - \theta} = \frac{4 + 3 \ln 3}{4 - 3 \ln 3}.
\]
(79)

Therefore, the stadium satisfies conditions (L1)-(L3) and all assumptions of Proposition [19] are satisfied. Combining the above facts and Proposition [19] we have proved the following results.

**Theorem 20.** Let \( f \) be a piecewise Hölder observable on \( M \) with \( \mu_M(f) = 0 \) and \( \tilde{f} \in \mathcal{H}_\gamma \), such that \( f \) is Hölder continuous on a small neighborhood of the singular set \( \{(r,0) : r \in A\} \). Assume \( \int_{r \in A} f(r,0) \, dr \neq 0 \). Then the sequence
\[
\tilde{f} + \cdots + \tilde{f} \circ F^{n-1} \quad \frac{d}{\tilde{f} \sqrt{n \ln n}} \Rightarrow \mathcal{N}(0,1)
\]
(80)

27
converges in distribution, as \( n \to \infty \), with
\[
\sigma_f^2 = \frac{4 + 3 \ln 3}{4 - 3 \ln 3} \cdot \frac{(\int_{r \in A} f(r,0) \, dr)^2}{32}.
\]
Moreover,
\[
\frac{f + \ldots + f \circ T^{n-1}}{\sigma_f \sqrt{n \ln n}} \to \mathcal{N}(0,1)
\]
converges in distribution, as \( n \to \infty \), with
\[
\sigma_f^2 = \frac{4 + 3 \ln 3}{4 - 3 \ln 3} \cdot \frac{(\int_{r \in A} f(r,0) \, dr)^2}{16(\pi + 1)}.
\]

6.2.2 Skewed stadia

We now turn our attention to the skewed (or drivebelt) stadia. These tables are constructed by connecting a major arc \( \Gamma_1 \) with central angle \( \theta_0 \in (\pi,3\pi/2) \) and a minor arc \( \Gamma_2 \) with central angle \( \theta_1 \in (0,\pi/2) \) by two straight lines of length \( l \). We assume both arcs have radius 1. These billiards were introduced by Bunimovich in [5], where he also established their hyperbolicity and ergodicity. More recently, [19] proved that skewed stadia have polynomial decay of correlations. We will use facts from both references in our analysis.

By unfolding the table, we can first consider the phase space \( \mathcal{M} \) to be made up only of collisions with the arcs. Unlike straight stadia, using this method produces billiards with finite horizon since the lines used to connect arcs are not parallel.

The billiard map \( T : \mathcal{M} \to \mathcal{M} \) admits a unique absolutely continuous invariant probability measure \( \mu_M \). A point in the phase space \( x \in \mathcal{M} \) is given by \((r,\varphi)\) where \( r \in [0,l] \) is the position on the boundary, with \( |\partial \mathcal{D}| = \theta_0 + \theta_1 + 2l \), and \( \varphi \in [-\pi/2,\pi/2] \) is the angle with respect to the normal to this boundary at \( r \). The invariant measure \( \mu_M \) is given by
\[
d\mu_M(r,\varphi) = \frac{\cos \varphi \, dr \, d\varphi}{2|\partial \mathcal{D}|}.
\]

We let \( M \) be the set of all first collisions with a given arc, so that \( M_m \) is made up of points which collide with the same arc \( m \) times. In [17], the induced space \( \mathcal{M} \) and the structure of the associated \( m \)-cells described in detail. We let the induced billiard map \( F : \mathcal{M} \to \mathcal{M} \) and return time function \( \mathcal{R} : \mathcal{M} \to \mathbb{N} \) be defined as previously mentioned. Note that \( \mathcal{M} \) is the union of two parallelograms, one corresponds to the smaller arc, the other to the larger arc, we call them small and big parallelograms, respectively. The large parallelogram has sides bounded by \( \varphi = \pm \pi/2 \) and two line segment with slope \( d\varphi/dr = -1/2 \); and the small parallelogram has sides bounded by \( \varphi = \pm \pi/2 \) and two line segment with slope \( d\varphi/dr = -1/2 \). Thus the measure of \( M \) satisfies
\[
\mu_M(M) = \frac{1}{2|\partial \mathcal{D}|} \int_{\theta_0}^{\theta_1} \int_{(\theta_0-\pi/2)/2}^{(\pi-r)/2} \cos \varphi \, d\varphi \, dr + \frac{1}{2|\partial \mathcal{D}|} \int_{\theta_0}^{\theta_1} \int_{(\theta_0-\pi/2)/2}^{(\pi-r)/2} \cos \varphi \, d\varphi \, dr
\]
\[
= \frac{1}{2|\partial \mathcal{D}|} (\sin \theta_0 + \sin \theta_1).
\]

We define the \( r \)-coordinate such that \( r = 0 \) at one end point of the major arc, and \( r = \theta_0 \) at the other end point. Let \( A = [0,\theta_0-\pi] \cup [\pi,\theta_0] \). Note that there exist two symmetric families of vectors \( A_1 := \{(r,0) : r \in [0,\theta_0-\pi]\} \) and \( A_2 := \{(r,0) : r \in [\pi,\theta_0]\} \), such that \( TA_1 = A_2 \) and \( TA_2 = A_1 \). Moreover, any \( x \in A_1 \cup A_2 \), its trajectory passes through the center of the major arc, and reflects from one-side of \( \Gamma_1 \) to the other side. Note that Skewed stadia is similar to the Bunimovich Stadia, in particularly, the verification of (L3)-(L4) are the same, so we will only concentrate on (L1)-(L2).

To estimate the constant \( c_M \) in (L2), we need to estimate the measure of the set \( (\mathcal{R} \geq n) \). Note that for \( x \in M_n \), its image will hit the set \( A_1 \cup A_2 \) for \( n-1 \) times before exiting to other part of the boundary. Also note that the collision angle along the trajectory \( T^k x, k = 1, \ldots, n-1 \), is invariant. Thus the set \( \cup_{k=1}^{n-1} T^k M_n \) is squeezed between by a line with equation
\[
\sin \varphi = \frac{\theta_0 - \pi}{n} + Cn^{-2}
\]
for some constant $C > 0$ and the line $\varphi = 0$. Thus
\[
\mu_M(x \in M : \mathcal{R} \geq n) = \frac{1}{4|\partial D|} \int_{r \in A} \left( \frac{\theta_0 - \pi}{n} + Cn^{-2} \right) dr = \frac{(\theta_0 - \pi)^2}{2n|\partial D|} + \mathcal{O}(n^{-2}).
\]
This implies that
\[
e_M = \lim_{n \to \infty} n^2 \mu(x \in M : \mathcal{R} \geq n)
= \frac{1}{\mu_M(M)} \lim_{n \to \infty} n \mu_M(x \in M : \mathcal{R} \geq n) = \frac{(\theta_0 - \pi)^2}{2|\partial D| \mu_M(M)}.
\]

The skewed stadium enjoys many of the same properties as the straight stadium; for instance, the induced billiard map $F$ has exponential decay of correlations and the measure of an $m$ cell is $\mu(M_m) \asymp m^{-3}$. However, for a point $x \in M_m$ we have that $Fx \in M_n$, where
\[
\frac{1}{n} m - \mathcal{O}(1) \leq n \leq 7m + \mathcal{O}(1).
\]
Note that there are 4 families of subsequences in $M'_n \subset M_n$, $n \geq 1$ that accumulate at the tangential vectors of the two arcs. These subsequences have smaller order of measure $\mu(M'_n) = \mathcal{O}(n^{-1})$. Consequently, we will ignore these points in below estimations as one can check that they do not contribute to abnormal central limit theory.

Although points still spread linearly in $m$, we see that they can travel further than those in straight stadia. This wider range affects the normalizing constant present in the transition probabilities between cells, and we have
\[
\mu(Fx \in M_n | x \in M_m) = \frac{7m}{48n^2} + \mathcal{O}\left(\frac{1}{m^2}\right).
\]
Therefore, skewed stadia are linear spreading, and we have the CLT \((L1)\) with
\[
\sigma^2 = \frac{24 + 7\ln 7}{24 - 7\ln 7}.
\]
This verifies \((L1)\).

For skewed stadia, we define the set $A_1 \cup A_2 \subset \{ x \in M : \mathcal{R}(x) = \infty \}$ consist of the family of two-periodic points whose trajectories passing through the diameter of the major arc. In addition, we define $A = \{ r : (r, 0) \in A_1 \cup A_2 \}$ as the range of $r$-coordinates of these periodic points. For any piecewise Hölder observable $f$ on $M$ with $\mu_M(f) = 0$ and $f \in \mathcal{H}_\gamma$, such that $\int_{r \in A} f(r, 0) dr \neq 0$ and $f$ is Hölder continuous on a small neighborhood of the singular set $\{(r, 0) : r \in A \}$.

We define $I_f$ such that
\[
I_f = \frac{1}{2(\theta_0 - \pi)} \int_{r \in A} f(r, 0) dr.
\]
Note that for any $n$ large, any $x \in M_n \setminus M'_n$, the forward images $T^kx = (r_k, \varphi_k)$ will only hit evenly on the two end sides of $\Gamma_k, k = 1, \ldots, n - 1$, accumulating to points in $A_1 \cup A_2$, as $n \to \infty$. In particular, we have
\[
\varphi_k = \varphi_1 = \frac{2|A_1|}{n} + \mathcal{O}(n^{-2}).
\]
Also note that the collisions at the curves $A_1$ and $A_2$ alternate, thus
\[
r_k = r_1 + (k - 1)\varphi_1 = r_1 + \frac{2(k - 1)|A_1|}{n} + \mathcal{O}((k - 1)n^{-2})
\]
for $k = 1, \ldots, n - 2$. Since $\varphi_k = \varphi_1$, for $k = 1, \ldots, n - 1$, we define
\[
\tilde{f}(r_k) = f(r_k, \varphi_1).
\]
Since the Riemann integral approximation of $I$ is obtained by uniform partition of each interval $[0, \theta_0 - \pi]$ and $[\pi, \theta_0]$, by the Hölder continuity of $f$ one can show that for $n$ large, any $x \in M_n$,

$$
\bar{f}(x) = \sum_{k=0}^{n-1} f \circ T^k(x) = \sum_{k=0}^{n-1} \bar{f}(r_k)
$$

$$
= \sum_{k=0}^{n-1} \bar{f}(r_1 + \frac{2(k-1)\lfloor A_1 \rfloor}{n} + O((k-1)n^{-2}))
$$

$$
= \frac{n}{\lfloor A_1 \rfloor + \lfloor A_2 \rfloor} \int_{A_1 \cup A_2} f(r, \varphi) dr + E(x),
$$

where $E = O(R^{1-\gamma})$. Here we used the fact that the function $f$ is Hölder continuous with exponent $\gamma$ in the variables $(r, \varphi)$ on a small neighborhood of $A_1 \cup A_2$. This verifies (B1). Combining the above facts and Proposition 19 we have proved the following theorem.

**Theorem 21.** Let $f \in \mathcal{H}_\gamma$, with $\mu_M(f) = 0$ and $f \in \mathcal{H}_\gamma$, such that $f$ is Hölder continuous on a small neighborhood of the singular set $\{(r, 0) : r \in A\}$. Assume $I_f \neq 0$, then the sequence

$$
\frac{f + \cdots + f \circ T^{n-1} - n\mu_M(f)}{\sigma_f \sqrt{n \ln n}} \xrightarrow{d} N(0, 1)
$$

(85)

converges in distribution, as $n \to \infty$, with

$$
\sigma_f ^2 = \frac{24 + 7 \ln 7}{24 - 7 \ln 7} \cdot \frac{\left(\int_{r \in A} f(r, 0) \, dr\right)^2}{8|\partial D|}
$$

6.3 **Billiards with algebraic spreading property**

Let $f$ be a Hölder continuous function on $M$ with exponent $\gamma \in (0, 1)$. Assume (B1) and (B2) hold. More precisely, there exist $N > 0$ and a set of finite real numbers $A_f = \{a_1, \cdots, a_N\}$, and for each $n \geq 1$, the level set $M_n$ is decomposed into $N$ connected sets $M_n = \bigcup_{k=1}^{N} M_{n,k}$. Let $U_{n,k} = \bigcup_{m=n}^{\infty} M_{m,k}$. We now define a function

$$
J_f = \sum_{k=1}^{N} a_k R \cdot I_{U_{1,k}}.
$$

(86)

Assume there exists an observable $E = E(f)$, such that the induced function $\bar{f}$ satisfies:

$$
\bar{f}(x) = J_f(x) + E(x)
$$

with the property that $\text{Var}(\sum_{k=0}^{n-1} E_{n,k}) < Cn$ for some uniform constant $C > 0$, where $E_{n,k} = (E \cdot I_{\mathbb{R} \leq c_n}) \circ F^k$, and $c_n = \sqrt{n \ln n}$. Moreover, (B2) implies that there exists $c_M > 0$ such that

$$
\lim_{m \to \infty} m^2 \mu(|J_f| \geq m) = c_M.
$$

In this subsection, we first list some sufficient conditions (G1)-(G2) for dynamical systems to guarantee the algebraic spreading property, which is defined for $k \in [1, N]$:

(G1) Assume that for $m$ large, any $x \in M_{m,k}$, $Fx$ must belong to $M_{n,k}$, with index $n \in \mathcal{B}_m = [c_1 \sqrt{m}, c_2 m^2]$, for some constants $c_1 > 0, c_2 > 0$.

(G2) Assume the transition probability $p_{n,m,k}$ from $M_{n,k}$ to $M_{m,k}$ satisfies

$$
\sum_{n \in \mathcal{B}_m} np_{n,m,k} = \mathcal{O}(\sqrt{m}).
$$

(87)
Proposition 23. For any continuous observable \((f)\) and \(X_{n,k} = (X_n \cdot |X_n| < c_n) \circ F^k\) for \(k = 0, \ldots, n\), and \(H(c_n) = \text{Var}(X_{n,k})\), where \(c_n = \sqrt{n \ln n}\). It follows from similar argument that if the induced system \((F, M)\) satisfies (G1)-(G2), then the process \(\{X_n\}\) satisfies (A1)-(A2). Next we verify condition (A2).

Let us first assume (G2) holds. We have, for any \(k = 1, \ldots, N\), any \(m\) large,

\[
\mathbb{E}((a_k \cdot I_{a_k \cdot R < c_n}) \circ F(x)|\mathcal{R}(x) = m) = \sum_{n \in \mathbb{N}_m} a_k n p_{n, m, k} I_{M_m}(x) \cdot I_{a_k \cdot R < c_n}(F x) = c_m I_{M_m},
\]

where \(c_m = O(\sqrt{m})\). This implies that we can take \(\theta = 0\) and \(\varepsilon_{n,0} = \sum c_m^2\).

Thus, we have

\[
\mathbb{E}(\varepsilon_{n,0} \cdot X_{n,0}) = \sum_{k=1}^{c_n} k \cdot e_k \mu_\mathcal{M}(M_k) < C \sum_{k=1}^{c_n} k^{3/2} k^{-3} < C_1,
\]

where \(C, C_1 > 0\) are uniform constants. This verifies (A2).

For any \(n \geq 1\), \(\varepsilon_{n,0}\) is bounded by \(c_m^2\) and is piecewise constant on \(M\). It follows from results in [20] that \(\varepsilon_{n,0}\) enjoys exponential decay of correlations under the induced map \(F\). More precisely, there exists \(\theta_1 \in (0, 1)\) and constant \(C > 0\) such that

\[
\text{Cov}(\varepsilon_{n,0} \circ F^i \cdot \varepsilon_{n,0}) \leq C \varepsilon_{n,0} \theta_1^i.
\]

This implies that there exists \(C_2 > 0\) such that

\[
\sum_{i=1}^{n} (n - i) \text{Cov}(\varepsilon_{n,0} \circ F^i \cdot \varepsilon_{n,0}) \leq C_2 n.
\]

Combining the above facts, we have proved the following lemma.

**Lemma 22.** For algebraic spreading processes satisfy (B1)-(B2) and (G1)-(G2), condition (B3) holds with \(\theta = 0\).

Thus, it is sufficient to verify (B1)-(B2) and (G1)-(G2) to get the CLT according to Theorem 14.

**Proposition 23.** For any continuous observable \(f\) on \(M\), assume \(\hat{f} \in \mathcal{H}_\gamma\) for some \(\gamma \in (0, 1)\) satisfies (B1)-(B2). Moreover we assume the induced map \((F, M)\) satisfies (G1)-(G2). Then the CLT holds:

\[
\frac{f + \cdots + f \circ T^{n-1} - n \mu_\mathcal{M}(f)}{\sqrt{c_n \mu_\mathcal{M}(M) n \ln n}} \Rightarrow \mathcal{N}(0, 1)
\]

converges in distribution, as \(n \to \infty\).

Next, we study two systems that have the property of algebraic spreading.

### 6.3.1 Dispersing billiards with cusps

Here we consider billiards with cusps, where the table is made of three curves, in which two identical curves touch tangentially at a point \(p\) that forms a cusp. The table is constructed such that the tangent line of the two symmetric boundary at \(p\) is perpendicular to the third curve.

The decay rates of correlations for billiards with cusps was first studied in [10]. It is known that the billiard map on these tables is hyperbolic and ergodic; however, the hyperbolicity is nonuniform. As a result, correlations decay polynomially. In fact, it was proved in [13] that the rate of mixing is \(\leq \text{const} \cdot n^{-1}\). Recently, it was shown by Balint, Chernov, and Dolgopyat in [2] that a central limit theorem does hold in these systems for Hölder continuous functions; we again restrict our attention to the return time map.

On these tables the dynamics are nonuniformly hyperbolic when trajectories become trapped in a cusp for a large number of iterations. We wish to remove these collisions from our consideration, so for simplicity, we have assumed our table has only one cusp at point \(p\) with arclength parameter \(r = 0\). We construct the subset \(M \subset M\) by

\[
M = M \setminus \{(r, \varphi) : r \in \partial \mathcal{D} \setminus (\Gamma_1 \cup \Gamma_2)\}.
\]

31
Note that $M$ consists collisions on the complement of $\Gamma_1 \cup \Gamma_2$.

The cell $M_n$ (where $n$ is large) is made by trajectories that go deep into the cusp and after exactly $m1$ bounces off its walls exit it. We use the results and notation of [2]. Let a cusp be made by two boundary components $\Gamma_1, \Gamma_2$. Choose the coordinate system such that the equations of $\Gamma_i$ with equation $T_i$ respectively. We denote $A_i$ as proved in [2].

\[ \int \]

where we used the fact that $i$ is the end point of both $\Gamma_1$ and $\Gamma_2$, thus the coordinate $r$ takes two values at the cusp $p$, which we denote as $r', r''$, respectively. We denote $A_1 = \{(r', \varphi), \varphi \in [-\pi/2, \pi/2]\}$ and $A_2 = \{(r'', \varphi), \varphi \in [-\pi/2, \pi/2]\}$ as the two vertical boundaries in $M$ at the corner point $p$.

We let the induced billiard map $F : M \to M$ and return time function $R : M \to \mathbb{N}$ be defined as previously mentioned. Note that $M$ consists of all collisions on $\partial D \setminus (\Gamma_1 \cup \Gamma_2)$, thus the measure of $M$ satisfies

\[
\mu_M(M) = \frac{1}{2|\partial D|} \int_0^{\pi/2} \cos \varphi d\varphi dr = \frac{|\partial D| - |\Gamma_1| - |\Gamma_2|}{|\partial D|}. \tag{91}
\]

To prove the CLT, we need to check conditions $(\text{G1})$-$(\text{G2})$ and $(\text{B1})$-$(\text{B2})$.

To estimate the constant $c_M$ in $(\text{B2})$, we need to estimate the measure of the set $(R \geq n)$. Note that the collision angle along the trajectory $T^k x$, $k = 1, \cdots, n - 1$, is invariant. Thus the set $\bigcup_{k=1}^{n-1} T^k M_n$ is squeezed between by a line with equation

\[ r^2 = \frac{C}{n^2 \cos \varphi} + o(n^{-2}) \]

for some constant $C > 0$ and the line $\varphi = 0$. Thus

\[
\mu_M(x \in M : R \geq n) = \frac{1}{4|\partial D|} \int_{-\pi/2}^{\pi/2} \left( \frac{1}{\sqrt{n \cos \varphi}} + o(n^{-2}) \right) \cos \varphi d\varphi
\]

\[ = \frac{1}{4|\partial D|n} \int_{-\pi/2}^{\pi/2} \sqrt{\cos \varphi} d\varphi + o(n^{-1}) \]

\[ = \frac{\bar{a}}{2|\partial D|n} + o(n^{-1}), \]

where we used the fact that

\[
\int_{-\pi/2}^{\pi/2} \sqrt{\cos \varphi} d\varphi = 2\bar{a}
\]

as proved in [2].

Now we let $n \to \infty$ to get

\[
c_M = \lim_{n \to \infty} n \mu_M(x \in M : R \geq n) = \frac{\bar{a}}{2|\partial D|}. \tag{92}
\]

Let $f$ be a piecewise Hölder observable on $M$ with $\mu_M(f) = 0$ and $\tilde{f} \in \mathcal{H}$, such that $f$ is Hölder continuous on a small neighborhood of the singular set $A_1 \cup A_2$. Using [2], we can get the estimation on the sum for $x \in M_n$,

\[ S_n f(x) = \sum_{k=1}^{n} f(r_k, \varphi_k) = I_f R(x) + E(x), \]

where $(r_k, \varphi_k)$ are the standard coordinates of the reflection points, and

\[ I_f = \frac{\int_{-\pi/2}^{\pi/2} (f(r', \varphi) + f(r'', \varphi)) \sqrt{\cos \varphi} d\varphi}{4\bar{a}} \]

as well as

\[ E(x) \leq C R(x)^{1-\gamma/2} \]

32
Theorem 24. 

Let \( f \in \mathcal{H}_r \), with \( \mu_{\mathcal{H}_r}(f) = 0 \) and \( f \) is Hölder continuous on a small neighborhood of the singular set \( A_1 \cup A_2 \). We assume \( \int_{-\pi/2}^{\pi/2} (f(r', \varphi) + f(r'', \varphi)) \sqrt{\cos \varphi} \, d\varphi \neq 0 \), then the sequence

\[
\frac{f + \cdots + f \circ T^{n-1} - n\mu_{\mathcal{H}_r}(f)}{\sqrt{\sigma_f^2 \cdot n \ln n}} \xrightarrow{d} \mathcal{N}(0, 1)
\]

converges in distribution, as \( n \to \infty \), where

\[
\sigma_f^2 = \frac{\left( \int_{-\pi/2}^{\pi/2} (f(r', \varphi) + f(r'', \varphi)) \sqrt{\cos \varphi} \, d\varphi \right)^2}{8a|\partial \mathcal{D}|}.
\]

Note that in [2], the authors also proved the CLT for piecewise Hölder observable function \( f \) with discontinuity contained in the singular set of \( T^{\pm k} \), for some \( k \geq 1 \). The improvement here is that we only require that \( f \in \mathcal{H}_r \) is Hölder continuous on any stable manifolds, and \( f \) is Hölder continuous on a small neighborhood of the singular set \( \{(r, 0) : r \in A\} \). This improvement allows us to include more examples of processes \( \{f \circ T^n\} \). One such example is that we can take a union of stable manifolds \( \mathcal{W}^s \), and a small neighborhood \( U \) of \( A_1 \cup A_2 \), such that \( f = \mathbf{1}_{\mathcal{W}^s} + \mathbf{1}_U \). Then we still can apply the above CLT for this process \( \{f \circ T^n\} \).

6.3.2 Semi-dispersing billiards

Billiards in a rectangle with a finite number of obstacles removed are known as semi-dispersing billiards. We consider a rectangle \( \mathbf{R} \) with dimensions \( I_1 \) by \( I_2 \), and place a finite number of obstacle \( \mathbf{B} = \cup_{i=1}^{N} \mathbf{B}_i \) in the rectangle. The table is obtained by removing these three obstacles \( \mathcal{D} = \mathbf{R} \setminus \mathbf{B} \).

The phase space \( \mathcal{M} \) is made of finite number of connected components. We define the reduced phase space \( \mathcal{M} \) as made up only of collisions with the convex obstacles. We let \( \mathcal{R} : \mathcal{M} \to \mathbb{N} \) be defined as the first return time function that defines the induced map. Note that \( \mathcal{M} \) consists all collisions on \( \partial \mathcal{B} \). Thus the measure \( \mu_{\mathcal{M}} \) satisfies

\[
\mu_{\mathcal{M}}(\mathcal{M}) = \frac{|\partial \mathcal{B}|}{|\partial \mathcal{D}|}.
\]

The induced map \( F : M \to M \) is then equivalent to the well-studied Lorentz gas billiard map on a torus with infinite horizon [17], which is known to have exponential decay of correlations; see [15]. More precisely, the particle can move freely parallel to a unit lattice vector without ever colliding with a scatterer; this property is called infinite horizon. The structure of the m-cells \( M_m = \{x \in M : \mathcal{R}(x) = m\} \) is examined thoroughly in [8] [9] [15]; we will make use of some of the facts presented in those references. It was proved by Szász and Varjú in [36] that a non-classical central limit theorem is satisfied in this billiard. It was proved in [19] that this system has a decay of correlations bounded by const \( \cdot n^{-1} \).

We will consider three configurations of the semidispersing billiards.
Thus we have the following estimations:

Case I: Semidispersing billiard with one channel of free flights

To simplify the geometry, we first put one convex obstacle \( B_1 \) at the center of the rectangle, and two quarter disks \( B_2, B_3 \) centered at the two adjacent end points of the rectangle. See Figure 1(a). For this type of billiards, there is only one channel of free flight in the unfolding space of the billiard table by removing all flat sides of the boundary.

We define the \( r \)-coordinate such that \( r = 0 \) at one end point of the rectangle. We denote \( A \) as the range of \( r \)-coordinates for all 2-periodic points \((r, 0)\), whose trajectory are parallel to the horizontal channel, see Figure 1(a). Note that \( |A|/2 \) is the width of the free flight channel. We now define

\[
I_f = \frac{\int_{r \in A} f(r, 0) \, dr}{|A|}.
\]

For any \( n \geq 1 \), for any \( x \in M_n \), its trajectory is contained in the horizontal channel in the unfolding space. Let \( J_f := I_f \mathcal{R} \). Clearly, \( J_f \) satisfies condition (B1). Moreover, similar to the stadia case, we can get the estimation on the sum for \( x \in M_n \),

\[
\hat{f}(x) = \sum_{k=1}^{n} f(r_k, \varphi_k) = J_f(x) + E(x),
\]

where \((r_k, \varphi_k)\) are the standard coordinates of the reflection points, and

\[
E(x) \leq C \mathcal{R}(x)^{1-\gamma/2}
\]

for some uniform constant \( C > 0 \). This verifies (B1).

To estimate the constant \( c_M \), we need to estimate the measure of the set \( \mathcal{R} > n \).

Note that for \( x \in M_n \), its image will hit the boundary set with \( r \)-coordinates in \( A \) for \( n-1 \) times before exiting the associated channel. Also note that the collision angle along the trajectory \( T^k x \), \( k = 1, \ldots, n-1 \), is invariant. Thus the set \( \bigcup_{m=n}^{\infty} \bigcup_{k=1}^{m-1} T^k M_m \) is squeezed between by two parallel lines with equations:

\[
\sin \varphi = \pm \frac{|A|}{2n11} + o(n^{-2}).
\]

By symmetric property of the billiard table, we have

\[
\mu_M(x \in M : \mathcal{R} > n) = \frac{1}{4|\partial D|} \int_{r \in A} \left( \frac{|A|}{n11} + O(n^{-2}) \right) \, dr = \frac{|A|^2}{4n^2 |\partial D|} + O(n^{-2}).
\]

Note that

\[
\mu_M(x \in M : \mathcal{R} > n) = \sum_{k=0}^{n-1} \mu(F^k (x \in M : \mathcal{R} > n)) = n \mu_M(x \in M : \mathcal{R} > n).
\]

This implies that

\[
\mu_M(x \in M : \mathcal{R} > n) = \frac{1}{n} \cdot \mu_M(x \in M : \mathcal{R} > n) = \frac{|A|^2}{4n^2 |\partial D|} + O(n^{-3}).
\]

Thus we have the following estimations:

\[
H(n) = \mathbb{E}(J_f^2 \mathbb{I}_{|J_f| < n}) = I_f^2 \sum_{m=1}^{n} m^2 \mu(M_m) = 2I_f^2 \sum_{m=1}^{n} m \mu(M_m).
\]

Now we let \( n \to \infty \) to get (B2),

\[
c_M \mu_M(M) = \lim_{n \to \infty} \frac{\mu_M(M) H(c_n)}{\ln n} = \frac{I_f^2 |A|^2}{I_f |\partial D|}.
\]

Many properties of the \( m \)-cells and of the induced billiard map in the semi-dispersing case are quite similar to those in billiards with cusps. In particular, the measure of each \( m \)-cell is again \( \mu(M_m) \approx m^{-3} \), and as a result we
once more have that the expectation of the return time map \( R \) is finite. It is also known that for a point \( x \in M_m \) we have \( Fx \in M_n \), where

\[ O(\sqrt{m}) < n < O(m^2). \]

Moreover, for the transition probabilities between cells, we have for admissible \( n \) that

\[ p_{n,m} := \mu(Fx \in M_n | x \in M_m) \geq \frac{m + n}{n^3}. \]

From this it is clear that semi-dispersing billiards are square spreading. Note that

\[ \sum_{n=\sqrt{m}}^{m^2} n \mu(Fx \in M_n | x \in M_m) = O(\sqrt{m}). \]

We have, for any \( m \) large,

\[ \mathbb{E}((I_f R \cdot 1_{I_f R < c_n}) \circ F(x)|R(x) = m) = \sum_{n \in \mathbb{N}} I_f \sum_{n=\sqrt{m}}^{m^2} n \mu(Fx \in M_n | x \in M_m) \cdot 1_{M_m}(x) = \epsilon_m 1_{M_m}(x), \quad (96) \]

where \( \epsilon_m = O(\sqrt{m}) \). This implies that we can take \( \theta = 0 \) and \( \epsilon_{n,0} = \sum_{m=1}^{\epsilon_m} \epsilon_m 1_{M_m} \). This verifies (B3).

Next, we will prove (B4).

Let \( M_{i,j} = \cup_{m=i}^{j} M_m \) be the union of cells with indices satisfying \( 1 \leq i \leq j \). Denote

\[ f_{i,j} := f_i \cdot 1_{M_{i,j}} - \mu(f_i \cdot 1_{M_{i,j}}) \]

**Proposition 25** (Exponential decay of correlations for \( f_{i,j} \)). Let \( f_i \) be an induced function on \( M \), and \( f_{i,j} \) is as defined above for any \( 1 \leq i \leq j \leq \infty \). Then for all \( k \) sufficiently large,

\[ |\mu(f_{i,j} \circ F^k \cdot f_{i,j}) - \mu(f_{i,j})^2| \leq C \theta^k. \quad (97) \]

where \( \theta \in (0,1) \) is a constant.

**Proof.** For any set \( M_m \) in \( M_{i,j} \), foliate it into unstable curves that stretch completely from one side to the other. Let \( \{W_\beta, \beta \in A, \lambda \} \) be the foliation, and \( \lambda \) the factor measure defined on the index set \( A \). This enables us to define a standard family, denoted as \( S_{i,j} = (M_{i,j}, \mu_{i,j}) \), where \( \mu_{i,j} := \mu|_{M_{i,j}} \).

Our first step in proving the decay of correlations is to estimate the \( Z \) function of \( F^k S_{i,j} \). For semi-dispersing billiards, \( FM_m \) is a strip that has length \( \sim m^{-1/2} \) and width \( \sim m^{-2} \). Also, by construction, the singular set is close to grazing collisions, so the density of \( \mu_{i,j} \) is of order \( \sim m^{-1/2} \) on \( FM_m \). Thus we obtain for \( j \leq \infty \),

\[ Z(F S_{i,j}) = \mu(M_{i,j})^{-1} \int_{\beta \in A} |F W_\beta|^{-1} \lambda S_{i,j} (d\beta) \]

\[ \leq C \mu(M_{i,j})^{-1} \sum_{m=i}^{j} m^{1/2} \cdot m^{-3} \]

\[ = C_1 t^{1/2} \cdot t^{-3/2} = C_1 t^{1/2}. \]

Note that for any large \( m < l \), we have

\[ \mu(FM_{i,j} \cap FM_{m,l}) \leq F^* \mu_{i,j} (r < \epsilon_{m,l}) \]

where \( \epsilon_{m,l} \) is approximately the width of the smallest cell in \( M_{m,l} \), which is of order \( m^{-2} \). Using Lemma 10, we have that

\[ \mu(F^k(M_{i,j}) \cap M_{m,l}) = \mu(F^{m+1}(M_{i,j}) \cap FM_{m,l}) \]

\[ \leq F^* \mu_{i,j} (r < \epsilon_{m,l}) \]

\[ \leq C'(q^{k-1} Z(F S_{i,j}) + \epsilon_{m,l}) \mu(M_{i,j}) \]

\[ \leq C(C_1 ||f||_\infty q^{k-1} t^{1/2} + C'' \epsilon_{m,l} m^{-2} t^{-2}. \quad (98) \]

35
For any fixed large $k$, we truncate $\tilde{f}_{i,j}$ at two extra levels, with $i \leq p < q \leq j$, which will be chosen later, i.e.

$$\tilde{f}_{i,j} = \tilde{f}_{i,p} + \tilde{f}_{p,q} + \tilde{f}_{q,j}$$

The function $\tilde{f}_{i,q} = \tilde{f}_{i,p} + \tilde{f}_{p,q}$ is bounded with $\|\tilde{f}_{i,q}\|_\infty \leq C\|f\|_\infty q$, and Hölder norm $\|\tilde{f}_{i,q}\|_\gamma \leq C\|f\|_\gamma q^{1+\gamma}$. Thus by (57), we know that

$$\mu(\tilde{f}_{i,q} \circ F^k, \tilde{f}_{i,q}) \leq C\|\tilde{f}_{i,q}\|_\infty^2 \theta^k + \mu(\tilde{f}_{i,q})^2 \leq Cq^{2+2\gamma} \theta^k + O(q^{-2})$$

(99)

where we used the fact that

$$\mu(\tilde{f}_{i,q}) = -\mu(\tilde{f}_{q,j}) = O(q^{-1})$$

Next we estimate

$$\mu(\tilde{f}_{i,p}, \tilde{f}_{q,j} \circ F^k) \leq C\|f\|_\infty^2 \sum_{m=i}^j \sum_{l=q}^j m \cdot l \cdot \mu(M_l \cap F^k M_m)$$

$$= C\|f\|_\infty^2 \sum_{m=i}^j \sum_{l=q}^j \sum_{t=1}^m \sum_{s=1}^l \mu(M_t \cap F^k M_m)$$

$$= C\|f\|_\infty^2 \sum_{m=i}^j \sum_{l=q}^j \left( \sum_{t=1}^m \sum_{s=1}^l \mu(M_t \cap F^k M_m) + \sum_{s=q}^j \sum_{l=s}^j \mu(M_t \cap F^k M_m) \right)$$

$$= C\|f\|_\infty^2 \sum_{m=i}^j \left( q \cdot \mu(M_{q,j} \cap F^k M_m) + \sum_{s=q}^j \mu(M_{s,j} \cap F^k M_m) \right)$$

$$+ C\|f\|_\infty^2 \sum_{t=i}^p \left( q \cdot \mu(M_{q,t} \cap F^k M_{i,p}) + \sum_{s=q}^j \mu(M_{s,t} \cap F^k M_{i,p}) \right)$$

$$= C\|f\|_\infty^2 \left( (C_1\|f\|_\infty \theta^{k-1} - ^1/2 + C''') q^{-1} t^{-2} + \sum_{s=q}^j (C_1\|f\|_\infty \theta^{k-1} - ^1/2 + C''') s^{-2} t^{-2} \right)$$

$$+ C\|f\|_\infty^2 \sum_{t=i}^p \left( (C_1\|f\|_\infty \theta^{k-1} - ^1/2 + C''') q^{-1} t^{-2} + \sum_{s=q}^j (C_1\|f\|_\infty \theta^{k-1} - ^1/2 + C''') s^{-2} t^{-2} \right)$$

Then one can check that

$$\mu(\tilde{f}_{i,p}, \tilde{f}_{q,j} \circ F^k) = O(q^{-1}(C_1\theta^{k-1/2} + C_2))$$

(100)

Similarly, we can show that

$$\mu(\tilde{f}_{q,j}, \tilde{f}_{i,p} \circ F^k) = O(i^{-1}(C_1\theta^{k-1/2} + C_2))$$

(101)
Next, we estimate
\[
\mu(\tilde{f}_{p,j}, f_{p,j} \circ F^k) \leq C \|f\|_2^2 \sum_{m=p}^{\infty} \sum_{l=p}^{m} m \cdot l \cdot \mu(M_l \cap F^k M_m)
\]
\[
= C \|f\|_2^2 \sum_{i=1}^{p} \left( p \cdot \mu(M_{p,j} \cap F^k M_{p,j}) + \sum_{s=p}^{j} \mu(M_{s,j} \cap F^k M_{s,j}) \right)
\]
\[
+ C \|f\|_2^2 \sum_{i=1}^{p} \left( p \cdot \mu(M_{p,j} \cap F^k M_{t,j}) + \sum_{s=p}^{j} \mu(M_{s,j} \cap F^k M_{t,j}) \right)
\]
\[
= C \|f\|_2^2 \sum_{i=1}^{j} \left( (C_1 \|f\|_\infty \vartheta^{k-1} p + C'' p)^{-2} + \sum_{s=p}^{j} (C_1 \|f\|_\infty \vartheta^{k-1} p + C'' s^{-2} p^{-1}) \right)
\]
\[
+ C \|f\|_2^2 \sum_{i=1}^{j} \left( (C_1 \|f\|_\infty \vartheta^{k-1} t + C'' p)^{-2} + \sum_{s=p}^{j} (C_1 \|f\|_\infty \vartheta^{k-1} t + C'') s^{-2} t^{-2} \right)
\]

Then one can check that
\[
\mu(\tilde{f}_{p,j}, f_{p,j} \circ F^k) = O(p^{-2} (\vartheta^k p + C_1)) + O(p^{-1} \vartheta^k \ln p) \quad (102)
\]

Combining the above estimations, we have
\[
\mu(\tilde{f}_{i,j}, f_{i,j} \circ F^k) \leq C_1 \vartheta^k (q^{2+2\gamma} + p^{-1} \ln p) + C_2 p^{-1}
\]

Now we choose \( q = \vartheta^{-k/d}, \ p = \sqrt{q}, \) where \( d = 6(1 + \gamma). \) Then above estimations implies that
\[
\mu(\tilde{f}_{i,j}, f_{i,j} \circ F^k) \leq C_1 \vartheta^k
\]
where \( \theta = \vartheta^{2/3}. \)

Combining the above facts and Proposition 23, we have proved the following result.

Case II. Semidispersing billiards with \( N \) channels of free flights

Assume the semi-dispersing table has exactly \( N \) channels of free flights in the unfolding space of the billiard table by removing all flat sides of the boundary. For simplicity, we assume the table is a square with length \( l. \)

For any \( i \in \{1, \ldots, N\}, \) we consider the \( i \)-th channel in the unfolding space, which is defined as the unbounded region bounded by two parallel tangent lines \( l_1^i, l_2^i \) of the scatterers, such that any lines parallel to \( l_1^i \) in the channel will not touch any scatterers. Let \( \mathbf{x}_i \) be a tangent vector of the scatterers, such that its trajectory coincides with \( l_1^i. \) Note that \( T\mathbf{x}_i \) is based on a straight side of the square. Let \( \varphi_i \) be the collision angle of \( T\mathbf{x}_i, \) which is formed by the line \( l_1^i \) and the straight side of the square. Let \( l_2^i \) be the length of the segment of \( l_1^i \) in the rectangle. We also call \( \varphi_i \) the angle of the \( i \)-th channel.

We denote \( A_i, i = 1, \ldots, N \) as the range of \( r \)-coordinates on the boundary of the square, such that for any point \( (r, \varphi), \) with \( r \in A_i, \) its trajectory is parallel to the \( i \)-th channel. Note that \( |A_i|/2 \) is the width of the corresponding channel. We now define
\[
a_i = \frac{\int_{r \in A_i} f(r, \varphi) \, dr}{|A_i|}, \quad i = 1, \ldots, N.
\]

For any \( n \geq 1, \) we decompose \( M_n = \bigcup_{k=1}^{N} M_{n,k} \) into \( N \) components, such that for any \( x \in M_{n,k}, \) its trajectory is contained in the \( k \)-th channel in the unfolding space. Let
\[
U_{n,i} := \bigcup_{m \geq n} M_{m,i}
\]

37
be the collection of all collision vectors in $\mathcal{M}$, whose forward trajectories experience at least $n$-iterations in the $i$-th channel.

We now define

$$J_f := \sum_{i=1}^{N} a_i \cdot R \cdot I_{U_{n,i}}.$$  

Clearly, $J_f$ satisfies condition (B1). Moreover, similar to case I, we can get the estimation on the sum for $x \in M_{n,i}$,

$$\hat{f}(x) = \sum_{k=1}^{n-1} f(T^k x) = J_f(x) + E_i(x)$$

where

$$E_i(x) \leq C R(x)^{1-\gamma/2}$$

for some uniform constant $C > 0$.

To estimate the constant $c_M$, we need to estimate the measure of the set $U_{n,i}$. Note that for $x \in M_{n,i}$, its image will hit the boundary set with $r$-coordinates in $A_i$ for $n-1$ times before exiting the associated channel. Also note that the collision angle along the trajectory $T^k x$, $k = 1, \ldots, n-1$, is invariant. Thus the set $\cup_{m \geq n} \cup_{k=1}^{m-1} T^k M_{m,i}$ is squeezed between by two parallel lines with equations:

$$\sin \varphi = \sin \varphi_i \pm \frac{|A_i|}{2nI_{n}} + o(n^{-2}).$$

By the symmetric property of the billiard table, we have

$$\mu(U_{n,i}) = \frac{1}{4n|\partial D|} \int_{r \in A_i} \left( \frac{|A_i|}{m_i} + o(n^{-2}) \right) dr = \frac{|A_i|^2}{4n^2 I_{n} |\partial D|} + o(n^{-2}),$$

where we have used the fact that

$$\mu(\cup_{m \geq n} \cup_{k=1}^{m-1} T^k M_{m,i}) = \sum_{k=0}^{n-1} \mu_M(F^k U_{n,i}) = n \mu(U_{n,i}).$$
Note that
\[
c_M = \lim_{t \to \infty} \frac{E(J^2_f I_{|J_f|<t})}{2 \ln t} = \lim_{t \to \infty} t^2 \mu(|J_f| \geq t)
\]
\[
= \lim_{t \to \infty} \sum_{k=1}^N t^2 \cdot \mu(U_{t/a_k,k}) = \sum_{k=1}^N \frac{a_k^2 |A_k|^2}{4I_i|\partial D|\mu_{\mathcal{M}}(M)}
\]

Combining the above facts and Proposition 23, we have proved the following results.

**Theorem 26.** Assume the unfolding space of the semidispersing billiards has \(N\) channels of free flights. Let \(f \in \mathcal{H}\), be Hölder continuous on a small neighborhood of the singular set \(\{(r, \varphi_i) : r \in A_i, i = 1, \cdots, N\}\). Assume \(\sum_{k=1}^N (\int_{r \in A_i} f(r, \varphi_i) \, dr)^2 \neq 0\), then the sequence
\[
\frac{f + \cdots + f \circ T^{n-1} - n \mu(f)}{\sqrt{\sigma_f^2 \cdot n \ln n}} \xrightarrow{d} N(0, 1)
\]
converges in distribution, as \(n \to \infty\), with
\[
\sigma_f^2 = \sum_{i=1}^N \frac{(\int_{r \in A_i} f(r, \varphi_i) \, dr)^2}{4I_i|\partial D|}.
\]
