AMPLE PAIRS

ENRIQUE CASANOVAS, AMADOR MARTIN-PIZARRO AND DANIEL PALACIN

Abstract. We show that the ample degree of a stable theory with trivial forking is preserved when we consider the corresponding theory of belles paires, if it exists. This result also applies to the theory of \( H \)-structures of a trivial theory of rank 1.

INTRODUCTION

The dichotomy principle, formulated by Zilber and at the base of many key applications of Geometric Model Theory to Diophantine Geometry, establishes a division line on the geometry of the minimal sets in a given theory: either the lattice of algebraically closed sets (in \( T^{eq} \)) is modular or an algebraically closed field can be interpreted. The dichotomy principle does not hold for strongly minimal sets, as shown by Hrushovski, who developed a general method \([11, 12]\) to produce \( \omega \)-stable theories with prescribed geometries in terms of underlying dimension functions, which agree with Morley rank on the resulting theories. Despite the exotic behaviour of the geometry of his \( ab \ initio \) example, it satisfies a weakening of the modularity principle, which in itself prevents an infinite field to be interpretable \([13]\). Motivated by this, Pillay \([14]\) and Evans \([8]\) introduced the ample hierarchy of stable theories, in order to provide finer division lines on the analysis of the geometry of strongly minimal sets. According to this hierarchy, motivated by the incidence relation in the euclidean space of the flags of affine subspaces of increasing dimension, from one point to a hyperplane, the \( ab \ initio \) construction is of low complexity, whereas algebraically closed fields or the free non-abelian group \([18]\) lie at the very top.

Little is known about preservation theorems for ampleness. In recent work, Carmona \([7]\) studied the ample degree of a sufficiently saturated model of simple theory of rank 1, equipped with a distinguished predicate for a dense codense independent subset. Any two such structures are elementarily equivalent and their common theory is an example of an \( H \)-structure, as introduced by Berenstein and Vassiliev \([6]\). He showed that it is preserved whenever the degree of ampleness is at least 2. However, an \( H \)-structure of a 1-based theory of rank 1 need no longer be 1-based. This marks a major difference with respect to Poizat’s belles paires of models of a stable theory \([16]\) (or more generally, lovely pairs of a simple theory \([4]\)), which remain 1-based if the departing theory is \([4, \text{Proposition 7.7}]\).

In this short note, we explore such preservation results for belles paires. Imaginaries represent the first obstacle. For non-1-ampleness (or equivalently 1-basedness)...
of belles paires, the proof in [4] uses a reformulation of it, weakly linear, which does not mention imaginaries. However, we do not know of a such a formulation of ampleness, for degree at least 2. Notice that the theory of belles paires does not have geometric elimination of imaginaries as soon as an infinite group can be defined (or interpreted) in the departing theory [15]. In order to circumvent this obstacle, we will only consider pairs of a theory with trivial forking, which prevents the existence of definable infinite groups. We originally thought that this assumption would only play a minor role, in order to work with real sets in the definition of ampleness. However triviality becomes crucial in the proofs. The question remains thus open, whether generally the theory of belles paires preserves ampleness.

1. Trivialities

From now on, fix a complete theory $T$ with in a language $L$. To avoid dealing with hyperimaginaries and bounded closures, we will assume that the theory $T$ is stable, though the statements (and their proofs) hold for $T$ simple with the appropriate modifications. We work inside a sufficiently saturated (and strongly homogeneous) model of $T$, which embeds any model of $T$ as a small elementary substructure.

We first recall the following definitions from [9]:

**Definition 1.1.** The theory $T$ is trivial if, whenever the tuples $a$, $b$ and $c$ are pairwise independent over a small set of parameters $D$, then they are $D$-independent. Likewise, a stationary type $p$ over $E$ is trivial, if whenever the tuples $a$, $b$ and $c$, each consisting of realisations of $p|D$, are pairwise independent over $D \supset E$, then they are $D$-independent.

The theory $T$ is totally trivial if, whenever $a \mid \uparrow_D b$ and $a \mid \uparrow_D c$, then $a \mid \uparrow_D b, c$.

Although the above two notions are different, they agree whenever $T$ has finite Lascar rank [9]. Notice that our local version of triviality strengthens the original one from [3]. Clearly, local triviality is preserved under nonforking extensions and restrictions.

Let us first remark the following easy observation:

**Remark 1.2.** Given a stationary trivial type $p$ over $E$ and some $T^{eq}$-algebraically closed set of parameters $D \supset E$, suppose that $b$ is algebraic over $D, a$, where $a$ is a tuple of realisations of $p|D$. Then $tp(b/D)$ is also trivial.

**Proof.** Let $D_1 \supset D$ be given and consider three pairwise $D_1$-independent tuples $b_1$, $b_2$ and $b_3$ of realisations of the non-forking extension of $tp(b/D)$ to $D_1$. We may assume that $D_1 = D$ and each $b_i$ is algebraic over $D, a_i$, where $a_i$ is a tuple of realisations of $p|D$.

By successively taking nonforking extensions, we may assume the following independences hold:

\[
\begin{align*}
a_1 & \downarrow_{D, b_1} b_2, b_3, \\
a_2 & \downarrow_{D, b_2} a_1, b_3 \
a_3 & \downarrow_{D, b_3} a_2, a_1.
\end{align*}
\]

In particular, the tuples $a_1$, $a_2$ and $a_3$ are pairwise $D$-independent, so they are $D$-independent, as a set. Thus, so are $b_1$, $b_2$ and $b_3$. □

**Fact 1.3.** [5, Corollary 5.1.8] Consider a stationary type $tp(a/D)$ whose Lascar rank has Cantor normal form:
We may therefore assume that

\[ \omega^{\alpha_1} \cdot n_1 + \cdots + \omega^{\alpha_k} \cdot n_k, \]

with \( \alpha_1 > \ldots > \alpha_k \) and \( n_k \neq 0 \). There are (possibly imaginary) elements \( a = a_1, \ldots, a_k \), with \( a_{i+1} \) algebraic over \( D, a_i \) for \( i < k \), and

\[ U(a/Da_i) = \sum_{j<i} \omega^{\alpha_j} \cdot n_j \text{ and } U(a_k/D) = \sum_{j=1}^k \omega^{\alpha_j} \cdot n_j \]

In particular, the element \( a_k \) is algebraic over \( D, a \) and has Lascar rank \( \omega^{\alpha_k} \cdot n_k \).

Recall that, if a stationary type \( p \) over \( D \) has Lascar rank in Cantor normal form

\[ \omega^{\alpha_1} \cdot n_1 + \cdots + \omega^{\alpha_k} \cdot n_k, \]

with \( \alpha_1 > \ldots > \alpha_k \) and \( n_k \neq 0 \), then it is non-orthogonal to a type of Lascar rank \( \omega^{\alpha_k} \): there is a realisation \( a \) of the non-forking extension of \( p \) to some set \( C \) and a stationary type \( \text{tp}(b/C) \) of Lascar rank \( \omega^{\alpha_k} \) such that

\[ a \mathrel{\not\mathrel{\mathcal{L}}} C b. \]

In [9, Proposition 2], it is shown that a superstable theory is trivial if and only if all the regular types in \( T^{eq} \) are trivial. A detailed study of the proof yields an improvement of the above result, without assuming superstability, but solely working with a fixed trivial type of ordinal-valued Lascar rank. However, observe that our local definition of triviality is more restrictive than Goode’s definition. We believe the following result is probably well-known but could not find any references:

**Proposition 1.4.** Let \( T \) be a stable (possibly non-superstable) theory and \( p = \text{tp}(a/D) \) be a stationary trivial type whose Lascar rank has Cantor normal form:

\[ \omega^{\alpha_1} \cdot n_1 + \cdots + \omega^{\alpha_k} \cdot n_k. \]

There is some realisation \( a \) of the non-forking extension of \( p \) to some set \( C \) and an imaginary element \( e \) algebraic over \( C, a \) such that \( \text{tp}(e/C) \) has Lascar rank \( \omega^{\alpha_k} \).

In particular, the type \( p \) is non-orthogonal to a type of rank \( \omega^{\alpha_k} \).

**Proof.** Set \( n = n_k \) and \( \alpha = \alpha_k \), and suppose \( n \geq 2 \). Remark 1.2 and Fact 1.3 allow us to assume that \( U(p) = \omega^n \cdot n \). By the above, there is a realisation \( a \) of the non-forking extension of \( p \) to some set \( C \) and a stationary type \( \text{tp}(b/C) \) of Lascar rank \( \omega^n \) such that

\[ a \mathrel{\not\mathrel{\mathcal{L}}} C b. \]

Set \( b' = \text{Cb}(a/C,b) \), which is not not algebraic over \( C \), because of the dependence \( a \mathrel{\not\mathrel{\mathcal{L}}} C b \). Notice that \( a \mathrel{\not\mathrel{\mathcal{L}}} C b' \), since \( a \mathrel{\not\mathrel{\mathcal{L}}} C b' \). As \( b' \) lies in \( \text{acl}^{eq}(C,b) \), its rank \( U(b'/C) \) is bounded by \( \omega^n \). If \( U(b'/C) < \omega^n \), then it contradicts the Lascar inequalities:

\[ \omega^n \cdot n = U(a/C) \leq U(a/C,b') \oplus U(b'/C) < \omega^n \cdot n. \]

We may therefore assume that \( b = b' \) is algebraic over a finite segment of a Morley sequence of \( \text{tp}(a/C,b) \), so its type \( \text{tp}(b/C) \) is also trivial, by Remark 1.2.

Set \( e = \text{Cb}(b/C,a) \), which lies in \( \text{acl}^{eq}(C,a) \setminus \text{acl}^{eq}(C) \), for \( a \mathrel{\not\mathrel{\mathcal{L}}} C b \). Thus \( a \mathrel{\not\mathrel{\mathcal{L}}} C e \). As above, a straight-forward application of the Lascar inequalities yields that \( U(e/C) \geq \omega^n \).
Let us now show that \( U(e/C) = \omega^\alpha \), which will be done in two steps: First, we show that \( U(e/C) < \omega^\alpha \cdot 2 \). Second we will prove the actual equality \( U(e/C) = \omega^\alpha \).

Since \( U(e/C) \geq \omega^\alpha \), write \( U(e/C) = \omega^\alpha + \beta \), for some ordinal \( \beta \). Choose a finite initial segment \( b_1, \ldots, b_{2m} \) of a Morley sequence of \( \text{stp}(b/C, a) \) such that \( e \) is algebraic over \( b_1, \ldots, b_m \). Notice that \( e \) is also algebraic over \( b_{m+1}, \ldots, b_{2m} \) by indiscernibility. Thus, the sequence \( b_1, \ldots, b_{2m} \) cannot be \( C \)-independent, since \( e \) is not algebraic over \( C \). Triviality of \( \text{tp}(b/C) \) implies that

\[
\beta \leq \alpha < \omega^\alpha, \quad \beta + 1 < \omega^\alpha + \alpha.
\]

Hence, the Lascar inequalities yield the following:

\[
U(e/C) \leq U(b_1, \ldots, b_m/C) \leq U(b_1/C) \oplus \bigoplus_{i=1}^{m-1} U(b_{i+1}/C, b_1, \ldots, b_i) < \omega^\alpha \cdot 2.
\]

Thus \( \beta < \omega^\alpha \). By Fact \( 3 \) there is some element \( e' \) in \( \text{acl}^{eq}(C, e) \subset \text{acl}^{eq}(C, a) \) such that \( U(e'/C) = \beta < \omega^\alpha \). Since \( U(a/C) = \omega^\alpha \cdot n \), we have that \( a \downarrow_\alpha e' \), so \( e' \) must be algebraic over \( C \), that is, the ordinal \( \beta \) is 0. We conclude that the element \( e \) has rank \( \omega^\alpha \), as desired.

\[ \square \]

2. Ampleness

As in the previous section, let \( T \) be a complete stable theory in a language \( \mathcal{L} \). We first recall the definition of 1-basedness, CM-triviality and \( n \)-ampleness [14 8]:

**Definition 2.1.** The theory \( T \) is 1-based if for every pair of algebraically closed subsets \( A \subset B \) in \( T^{eq} \), and every real tuple \( c \), we have that \( \text{Cb}(c/A) \) is algebraic over \( \text{Cb}(c/B) \). Equivalently, for every \( T^{eq} \)-algebraically closed set \( A \) and every real tuple \( c \), the canonical base \( \text{Cb}(c/A) \) is algebraic over \( c \).

The theory \( T \) is CM-trivial if for every pair of algebraically closed subsets \( A \subset B \) in \( T^{eq} \), and every real tuple \( c \), if \( \text{acl}^{eq}(Ac) \cap B = A \), then \( \text{Cb}(c/A) \) is algebraic over \( \text{Cb}(c/B) \).

The theory \( T \) is called \( n \)-ample if there are \( n + 1 \) real tuples satisfying the following conditions (possibly working over parameters):

\[ (a) \quad \text{acl}^{eq}(a_0, \ldots, a_i) \cap \text{acl}^{eq}(a_0, \ldots, a_{i-1}, a_{i+1}) = \text{acl}^{eq}(a_0, \ldots, a_{i-1}) \quad \text{for every} \quad 0 \leq i < n, \]

\[ (b) \quad a_{i+1} \downarrow a_i a_0, \ldots, a_{i-1} \quad \text{for every} \quad 1 \leq i < n, \]

\[ (c) \quad a_n \not\in a_0. \]

By inductively choosing models \( M_i \supseteq a_i \) such that

\[ M_i \downarrow M_0, \ldots, M_{i-1}, a_i+1, \ldots, a_n, \]

we can replace, in the definition of \( n \)-ampleness, all tuples by models. This was already remarked in [13 Corollary 2.5] in the case of CM-triviality. Likewise, if the theory \( T \) is 1-based, resp. CM-trivial or \( n \)-ample, the corresponding conclusion holds whenever the tuples are imaginary.

Every 1-based theory is CM-trivial. A theory is 1-based if and only if it is not 1-ample; it is CM-trivial if and only if it is not 2-ample [14]. Observe that \( n \)-ampleness implies \( (n-1) \)-ampleness. Thus, ampleness establishes a strict hierarchy (see [17 1 3]) among stable theories, according to which both (pure) algebraically
closed fields \[14\] and the free non-abelian group \[18\] are \( n \)-ample for every natural number \( n \).

We now give an alternative characterisation of ampleness, which will be useful in the last section:

**Proposition 2.2.** The theory \( T \) is \( n \)-ample if and only if there are \( n + 1 \) tuples satisfying the following conditions (possibly working over parameters):

1. \( \text{acl}^q(a_i, i \leq n \text{ even}) \cap \text{acl}^q(a_i, i \leq n \text{ odd}) = \text{acl}^q(\emptyset) \),
2. \( a_{i+1} \subseteq a_i \cap a_0, \ldots, a_{i-1} \) for every \( 1 \leq i < n \),
3. \( a_n \subseteq a_0 \).

Furthermore, we may assume that the above tuples are real and enumerate small models.

**Proof.** Suppose first that the tuples \( a_0, \ldots, a_n \) witness \( n \)-ampleness. They clearly satisfy conditions (1) and (3), so we need only prove condition (2). Set \( X_0 = \text{acl}^q(\emptyset) \) and

\[ X_k = \text{acl}^q(a_i : i \leq k \text{ even}) \cap \text{acl}^q(a_i : i \leq k \text{ odd}) \]

for \( 1 \leq k \leq n \).

It suffices to show that \( X_k = X_{k-1} \), by induction on \( k \). It clearly holds for \( k = 1 \). Fix \( k \geq 2 \), which we may assume to be even, without loss of generality. Thus

\[ X_k = \text{acl}^q(a_i : i \leq k \text{ even}) \cap \text{acl}^q(a_i : i \leq k - 1 \text{ odd}) \]

\[ \subseteq \text{acl}(a_i : i \leq k \text{ even}) \cap \text{acl}^q(a_0 \ldots a_{k-1}) \]

\[ \subseteq \text{acl}(a_0 \ldots a_{k-2} a_k) \cap \text{acl}^q(a_0 \ldots a_{k-1}) \]

\[ \subseteq \text{acl}^q(Aa_0 \ldots a_{k-2}) \]

by condition 2.1 (4). Both transitivity and condition 2.1 (4) yield that

\[ a_{k-1} a_k \subseteq a_0 \ldots a_{k-3}, \]

so

\[ a_k \subseteq a_0 \ldots a_{k-3}. \]

In particular, we have that

\[ X_k \subset \text{acl}^q(a_i : i \leq k \text{ even}) \cap \text{acl}^q(a_0 \ldots a_{k-2}) \]

\[ \subseteq \text{acl}^q(a_i : i \leq k - 1 \text{ even}). \]

Hence \( X_k \subset \text{acl}^q(a_i : i \leq k - 1 \text{ odd}) \cap \text{acl}^q(a_i : i \leq k - 1 \text{ even}) = X_{k-1} \), as desired.

Suppose now the tuples \( a_0, \ldots, a_n \) satisfy conditions (1), (2) and (3). Set:

- \( b_n = a_n \) and \( b_{n-1} = a_{n-1} \);
- \( b_i = \text{acl}^q(a_i a_{i+1}) \cap \text{acl}^q(a_i a_{i+2}) \) for \( 0 \leq i \leq n - 2 \);
- \( A_0 = \text{acl}^q(b_0) \cap \text{acl}^q(b_1) \).

Notice that

\[ a_n \ldots a_{i+1} \subseteq a_0 \ldots a_{i-1}, \]
for every $1 \leq i < n$ by transitivity and condition (3). Since $a_i \subseteq b_i \subseteq \text{acl}^\text{eq}(a_{i+1} \ldots a_n)$ and $b_j \subseteq \text{acl}^\text{eq}(a_j \ldots a_{i-1}b_i)$ for $j < i$, we have that

$$b_{i+1} \models_{A_0, b_i} b_0 \ldots b_{i-1}.$$ 

Now,

$$A_0 \subseteq \text{acl}^\text{eq}(a_i : i \leq n \text{ even}) \cap \text{acl}^\text{eq}(a_i : i \leq n \text{ odd}) = \text{acl}^\text{eq}(\emptyset),$$

so $b_n \not\subseteq b_0$, as $b_n = a_n$ and $a_0 \subseteq b_0$, by condition 2.4 (4).

We need only prove 2.1 (1) for the $b_i$'s. Observe that

$$\text{acl}^\text{eq}(b_i b_{i+1}) \cap \text{acl}^\text{eq}(b_i b_{i+2}) = \text{acl}^\text{eq}(b_i),$$

so in particular,

$$\text{acl}^\text{eq}(b_0) = \text{acl}^\text{eq}(b_0 b_1) \cap \text{acl}^\text{eq}(b_0 b_2).$$

Given $1 \leq i < n - 1$, since $b_{i+2} b_{i+1} \models_{b_i} b_0 \ldots b_{i-1}$, we conclude that

$$\text{acl}^\text{eq}(b_0 \ldots b_i) = \text{acl}^\text{eq}(b_0 \ldots b_{i+1}) \cap \text{acl}^\text{eq}(b_0 \ldots b_{i+2}),$$

by [4, Fact 2.4].

Using a similar trick as in [1, Remarks 2.3 and 2.5], we can replace the obtained $b_i$'s by real tuples enumerating small models: consider recursively for each $i$ a model $M_i$ containing some representative of $b_i$ such that

$$M_i \models_{b_i} M_0 \ldots M_{i-1} b_{i+1} \ldots b_n.$$ 

Clearly $M_n \not\subseteq M_0$, for each $b_i$ is contained in $M_i$. A straightforward application of transitivity yields that $M_{i+1} \models_{M_i} M_0 \ldots M_{i-1}$ for $1 \leq i < n$.

It remains hence to see that the models $M_0, \ldots, M_n$ satisfy condition (4). To do so, consider some arbitrary index $i$ with $1 \leq i < n$ and assume, without loss of generality, that it is odd. It is easy to see that

$$\text{acl}^\text{eq}(M_j, b_k : j \leq i, k > i \text{ odd}) \cap \text{acl}^\text{eq}(M_j, b_k : j \leq i, k > i \text{ even})$$

is contained in

$$\text{acl}^\text{eq}(M_j, b_k : j < i, k > i \text{ odd}) \cap \text{acl}^\text{eq}(M_j, b_k : j < i, k > i \text{ even}),$$

which gives that $\text{acl}^\text{eq}(M_i : i \text{ even}) \cap \text{acl}^\text{eq}(M_i : i \text{ odd}) = \text{acl}^\text{eq}(\emptyset)$, as desired.

\[\square\]

3. Theories of Pairs

From now on, let $T$ denote a complete stable theory in a language $\mathcal{L}$. We will furthermore assume, for the sake of the presentation, that $T$ has geometric elimination of imaginaries (otherwise consider $T^\text{eq}$).

We first provide a uniform approach to both belles pairs as well as $H$-structures of rank 1 theories, isolating their common features. Consider the expansion $\mathcal{L}_p = \mathcal{L} \cup \{P\}$ of the language $\mathcal{L}$ by a unary predicate $P$, which will be interpreted by an infinite proper subset. Work inside a sufficiently saturated (strongly homogenous) $\mathcal{L}_p$-structure $M$, which is also a model of $T$. We will not distinguish between $P$ and its interpretation $P^M$.

**Definition 3.1.** A subset $A \subseteq M$ is special if $A \models_{P \cap A} P$.
In the terminology of [4], special subsets correspond to \( P \)-independent subsets. Furthermore, if we interpret \( P \) as a dense independent set, in the sense of \( H \)-structures of a stable theory of rank 1 [6], a subset is special if and only if it contains its \( H \)-basis, by minimality and the fact that the elements of \( H \) are geometrically independent.

**Definition 3.2.** A complete \( \mathcal{L}_P \)-theory \( T_P \) extending \( T \) is a **theory of pairs** of \( T \) if it is stable and any sufficiently saturated (and strongly homogeneous) model \( M \) of \( T_P \) satisfies the following conditions:

1. Given a complete \( n \)-ary \( \mathcal{L} \)-type \( p \) over a small special subset \( A \subset M \), there is a realisation \( b \) of \( p \) with \( b \upharpoonright A \)

2. Two special subsets \( A \) and \( B \) of \( M \) have the same type if and only if they have both the same \( \mathcal{L} \)-type and the same quantifier-free \( \mathcal{L}_P \)-type, that is, there is an \( \mathcal{L} \)-elementary map which maps \( A \) to \( B \) and \( P \cap A \) to \( P \cap B \).

3. Algebraically closed subsets in \( T_P \) are special. Moreover, the algebraic closure in \( T_P \) of a special subset \( A \) coincides with its \( \mathcal{L} \)-algebraic closure.

4. Non-forking independence in \( T_P \) for special subsets \( A \) and \( B \) over a common \( \mathcal{L}_P \)-algebraically closed substructure \( C \) is characterised as follows:

\[
A \downarrow_C B \iff \begin{cases} 
A \downarrow_{C,P} B \\
A \downarrow_{C,P} B
\end{cases}
\]

5. If \( T \) is trivial, then \( T_P \) has geometric elimination of imaginaries as well.

Notice that condition (4), though not explicitly stated for \( H \)-structures in [4], is a straightforward adaptation of the proof of [4, Proposition 7.3]. Condition (5), which holds for belles paires (see [13]), is trivial for \( H \)-structures of theories of rank 1, for they always eliminate imaginaries geometrically, regardless whether \( T \) is trivial or not (see [4, Remark 5.14]).

A result on preservation of ampleness was obtained in [4] for \( H \)-structures of a rank 1 theory: for \( n \geq 2 \), the base theory \( T \) is \( n \)-ample if and only if the theory of the pair is. In [4, Proposition 7.7], it was shown that the theory of belles paires of a stable theory \( T \) is 1-based whenever \( T \) is. Indeed, it suffices to show that \( T_P \) is **weakly 1-based** [4, Definition 2.3]: that is, given a tuple \( a \) over a model \( N \), there is some \( a' \models tp_P(a/N) \) such that \( a' \downarrow_{P,N} a \) and \( a' \downarrow_{P,N} a \). The advantage of this formulation is that no imaginaries appear and one reduces the question to a situation in \( T \), by using the characterisation of independence in Definition 2.2 [4]. Unfortunately, we do not know of an imaginary-free equivalent definition for higher degrees of ampleness. As noticed in [15], as soon as an infinite group is definable in \( T \), then the theory of belles paires does not have geometric elimination of imaginaries. For particular stable theories, such as the theory of algebraically closed fields, or more generally, almost strongly minimal theories with infinite \( acl(\emptyset) \), there is a
suitable expansion of the language $L_P$ by geometric sorts in order to obtain geometric elimination of imaginaries. However, the characterisation of independence in Definition 3.2 does not hold for imaginary subsets.

We will now provide a result on preservation of ampleness assuming that the theory $T$ is trivial. Recall that $T$ is fixed complete stable trivial theory with geometric elimination of imaginaries, and work inside a sufficiently saturated (strongly homogeneous) model of an associated theory of pairs $T_P$ of $T$, which we assume exists.

**Lemma 3.3.** Given special subsets $A$ and $B$ with a common $L_P$-algebraically closed substructure $C$, the following equivalence holds:

$$A \perp_c B \iff A \perp_c B.$$  

Furthermore, if $T$ is totally trivial, then $A \cup B$ is again special.

**Proof.** We need only prove that $A \perp_{C,P} B$, whenever $A \perp C B$. Since $A$ is special and contains $C$, we have that

$$A \perp_{C,P \cap A,P \cap B} P.$$  

Similarly, the independence $B \perp_{C,P \cap A,P \cap B} P$ holds. Since $A \perp C B$, we have that

$$A \perp_{C,P \cap A,P \cap B} B.$$  

Triviality of $T$ yields that

$$A \perp_{C,P \cap A,P \cap B} B, P,$$

which implies $A \perp_{C,P} B$, as desired.

If $T$ is totally trivial, then the independences $A \perp_{P \cap A,P \cap B} P$ and $B \perp_{P \cap A,P \cap B} P$ imply that

$$A \cup B \perp_{P \cap A,P \cap B} P,$$

so $A \cup B$ is special. $\square$

**Theorem 3.4.** Let $T_P$ be a theory of pairs of a trivial stable theory $T$. For any natural number $n$, the theory $T$ is $n$-ample if and only if $T_P$ is.

**Proof.** Suppose first that the real tuples $a_0, \ldots, a_n$ witness that $T$ is $n$-ample over some set of parameters, which we assume to be empty. By condition 3.2 (1), we may assume that

$$a_0, \ldots, a_n \perp P.$$  

In particular, any subcollection of $a_0, \ldots, a_n$ is special, so the algebraic closures in $T_P$ and $T$ coincide. By Lemma 3.3, so does forking (in $T_P$ and $T$). In particular, the tuples $a_0, \ldots, a_n$ witness that $T_P$ is $n$-ample.

For the converse, suppose $T$ is not $n$-ample. By Proposition 2.2, let $a_0, \ldots, a_n$ be given with:

(a) $acl_P(a_i, i \leq n \text{ even}) \cap acl_P(a_i, i \leq n \text{ odd}) = acl_P(\emptyset)$,

(b) $a_{i+1} \perp_{a_i} a_0, \ldots, a_{i-1}$ for every $1 \leq i < n$.  

We may assume that each \( a_i \) is \( \mathcal{L}_P \)-algebraically closed, hence special. By Lemma \ref{lem:ample_pairs}, we need only to show that \( a_n \downarrow a_0 \) in \( T \).

The independence \( a_{i+1} \downarrow P_{a_i} a_0, \ldots, a_{i-1} \) implies that

\[
\text{acl}_P(a_{i+1}, a_i) \downarrow_{a_i} \text{acl}_P(a_0, \ldots, a_i),
\]

so Lemma \ref{lem:ample_pairs} yields that

\[
\text{acl}_P(a_{i+1}, a_i) \downarrow_{a_i} \text{acl}_P(a_0, \ldots, a_i),
\]

and particularly

\[
a_{i+1} \downarrow_{\text{acl}_P(\emptyset), a_i} a_0, \ldots, a_{i-1}.
\]

Furthermore,

\[
\text{acl}(a_i, i \leq n \text{ even}) \cap \text{acl}(a_i, i \leq n \text{ odd}) \subset
\text{acl}_P(a_i, i \leq n \text{ even}) \cap \text{acl}_P(a_i, i \leq n \text{ odd}) = \text{acl}_P(\emptyset).
\]

Working over \( \text{acl}_P(\emptyset) \), we have that \( a_n \downarrow a_0 \), since \( T \) is \( n \)-ample, as desired. \( \square \)

Remark 3.5. If \( T \) is totally trivial, we can conclude that \( T_P \) has the same degree of amplifiedness as \( T \), without using Proposition \ref{prop:ample_pairs}. Indeed, if the tuples \( a_0, \ldots, a_n \) are special and satisfy

\(\begin{align*}
&\text{(a) } \text{acl}_P(a_0, \ldots, a_i) \cap \text{acl}_P(a_0, \ldots, a_{i-1}, a_{i+1}) = \text{acl}_P(a_0, \ldots, a_{i-1}) \text{ for every } 0 \leq i < n, \\
&\text{(b) } a_{i+1} \downarrow P_{a_i} a_0, \ldots, a_{i-1} \text{ for every } 1 \leq i < n,
\end{align*}\)

then any subtuple \( a_0, \ldots, a_i \) is again special, by Lemma \ref{lem:ample_pairs}, so we conclude directly that \( a_n \downarrow a_0 \), because \( T \) is not \( n \)-ample.

We will now conclude with some examples illustrating the above result.

Example 3.6. Let \( T \) be the theory of a free pseudoplane, a (bicolored) infinite branching graph with no (non-trivial) loops. This theory is \( \omega \)-stable, totally trivial not 2-ample but 1-ample, and has weak elimination of imaginaries \cite[Proposition 2.1]{ref1}. The theory \( T_P \) of belles paires of \( T \) is axiomatised by the following elementary properties:

- The universe is a free pseudoplane.
- Every element of \( P \) has infinitely many direct neighbours in \( P \), and every reduced path between elements of \( P \) is contained in \( P \).
- Given an element \( a \) in a finite subset \( A \), there is some element \( b \) connected to \( a \) with \( b \notin P \cup A \).

It is very easy to see that an \( \aleph_0 \)-saturated model of the above theory is again a belle paire. It suffices to note that every finite set is contained in a finite superset \( A \) such that \( A \cup P \) is nice in the terminology of \cite{ref2}, that is, closed under reduced paths. Thus, the theory \( T_P \) is stable and is a theory of pairs in the sense of Definition \ref{def:pair}. In particular, Theorem \ref{thm:ample_pairs} yields that \( T_P \) is 1-ample but not 2-ample.

Likewise, a similar argument yields that the theory of belles paires of the free pseudospace \cite{ref1} is 2-ample but not 3-ample. Furthermore, if we consider the free \( n \)-dimensional pseudospace \cite{ref1} (or more generally, free orthogonal buildings \cite{ref2}), which are stable \( n \)-ample but not \( (n+1) \)-ample with weak elimination of imaginaries.
and totally trivial, a similar axiomatisation of the theory of belles paires can be obtained. It suffices to consider the bi-interpretable structure consisting of the space of flags, where there are no reduced loops. In particular, Theorem 5.4 yields that the theory of belles paires of free $n$-dimensional pseudospaces is $n$-ample but not $(n + 1)$-ample.

Example 3.7. We will now consider a trivial but not totally trivial stable theory, which first appeared in [9].

Consider the theory $T$ of a two-sorted structure $(A, B)$ with a binary function $\sigma$ from $A \times B$ to $B$ such that any $\sigma(a, \cdot)$ induces a bijection on $B$. Thus, we can talk about inverses of elements of $A$ by considering the inverse of $\sigma(a, \cdot)$. However, note that $A$ is neither closed under inverses nor has a group structure. A word of elements (and their inverses) of $A$ is reduced if it is the empty word or does not contain a subword of the form $a \cdot a^{-1}$. We require that the bijection of every non-trivial reduced word has no fixed points on $B$. One can regard the second sort $B$ as a binary (directed) graph with edges labelled by elements of $A$. Namely, two elements $x$ and $y$ in $B$ are connected by an edge labelled by $a$ in $A$ if and only if $\sigma(a, x) = y$. A subset $D$ of $(A, B)$ is nice if $D \cap A$ and $D \cap B$ are both non-empty and the path of a reduced word between two elements of $D \cap B$ is contained in $D \cap A$, and the reduced word is contained in $D \cap A$.

The theory of the above structure is complete, since the quantifier-free type of a nice set implies its type. It is $\omega$-stable with weak elimination of imaginaries, and forking independence can be easily described for nice sets $D_1$, $D_2$ and $D_3$ with $D_3 \subset D_1 \cap D_2$:

$$D_1 \perp_{D_3} D_2 \iff \begin{cases} D_1 \cap D_2 \cap A \subset D_3 \cap A, \text{ and} \\ \text{Every reduced path between an element of } D_1 \cap B \\ \text{and an element of } D_2 \cap B \text{ factors through } D_3 \cap B. \end{cases}$$

This theory is trivial yet not totally trivial. However, it resembles the free pseudo-plane, for it is 1-ample but not 2-ample. Since the theory is 2-dimensional [9], it does not have the finite cover property [10, Corollary 4]. Therefore the theory of belles paires is axiomatisable and a theory of pairs in the sense of Definition 3.2.

By Theorem 3.4, the theory of belles paires is 1-ample, but not 2-ample.
