A POWER STRUCTURE OVER THE GROTHENDIECK RING OF GEOMETRIC DG CATEGORIES

ÁDÁM GYENGE

ABSTRACT. We prove the existence of an effective power structure over the Grothendieck ring of geometric dg categories. Using this power structure we show that the categorical zeta function of a geometric dg category can be expressed as a power with exponent the category itself. This implies a conjecture of Galkin and Shinder relating the motivic and categorical zeta functions of varieties. We also deduce a formula for the generating series of the classes of derived categories of the Hilbert scheme of points on smooth projective varieties. Moreover, our results show that the Heisenberg action on the derived category of the symmetric orbifold is an irreducible highest weight representation.

1. INTRODUCTION

A power structure over the Grothendieck ring of varieties $K_0(Var)$ was defined in [17]. It has turned out to be an effective tool in expressing certain generating functions associated to varieties, see e.g. [18]. Power structures have a deep connection with $\lambda$-ring structures. $K_0(Var)$ has a well-known $\lambda$-ring structure induced by the symmetric powers of varieties. These imply that the motivic zeta function of a variety has a particularly nice expression as a power with exponent the motive of the variety.

The derived category of coherent sheaves on a variety has been proposed as an analogue of the motive of a variety for a long time now [6]. In this analogy, semiorthogonal decompositions are the tools for the simplification of this “motive” similar to splitting by projectors in Grothendieck motivic theory. It has since then turned out that it is better to work with dg enhancements of these triangulated categories. In [10] it was shown that there is a motivic measure, i.e. a ring homomorphism

$$\mu: K_0(Var) \to K_0(gdg\text{-cat})$$

to a certain ring $K_0(gdg\text{-cat})$, which is the Grothendieck ring of geometric dg categories.

On the other hand, symmetric powers in $K_0(gdg\text{-cat})$ do not induce a $\lambda$-ring structure, but instead a 2-$\lambda$-ring structure [16]. For example, in a $\lambda$-ring $\text{Sym}^n(1) = 1$ for any integer $n$, whereas in a 2-$\lambda$-ring $\text{Sym}^n(1) = p(n)$, the number of partitions of $n$. A natural question is: does the 2-$\lambda$-ring structure on $K_0(gdg\text{-cat})$ imply the existence of a power structure on it? Our first main result is that this is indeed the case.

**Theorem 1.1.** There exists an effective power structure over the Grothendieck ring $K_0(gdg\text{-cat})$ of geometric dg categories.

This power structure is defined as a categorical analogue of the power structure on $K_0(Var)$, and shares many nice properties of it.

One of the difficulties with defining this power structure is that, contrary to a the case of varieties, the power of a dg category does not decompose trivially to strata indexed stabilizers under the action of the symmetric group. In particular, this makes it difficult to understand $\mu(X^n \setminus \Delta)$, where $X$ is a variety and $\Delta \subseteq X^n$ is the big diagonal in the product where at least two coordinates coincide. Our solution is to use the destackification method developed in [1], which realizes $\mu(X^n \setminus \Delta)$ as a semiorthogonal summand in a larger category.
The categorical zeta function of an object in $K_0(gdg\text{-}cat)$ collects the symmetric powers of the object into a generating function. The ring homomorphism $\mu$ turns out not to be a $\lambda$-ring homomorphism, and this implies that the expression of the categorical zeta function associated to a variety as a power is different from that of the motivic zeta function. Our second main result is that using our power structure on $K_0(gdg\text{-}cat)$, the categorical zeta function of a geometric dg category $\mathcal{M}$ can be expressed as a power with exponent the category itself.

Theorem 1.2.

$$Z_{\text{cat}}(\mathcal{M}, t) = \prod_{n=1}^{\infty} \left( \frac{1}{1 - q^n} \right)^{[\mathcal{M}]}.$$ 

Galkin and Shinder in [15] proved a relation between the motivic and the categorical zeta functions of varieties of dimensions 1 and 2, and they conjectured the same relationship to hold in any dimension. As an immediate corollary of Theorem 1.2 we get

Corollary 1.3. The Galkin-Shinder conjecture is true. Namely, for any variety $X$

$$Z_{\text{cat}}(\mu(X), t) = \prod_{n \geq 1} \mu(Z_{\text{mot}}(X, t^n)).$$

This result implies also a formula for the generating series of the classes of dg categories of the Hilbert scheme of points associated to a fixed smooth projective variety. Furthermore, our result also implies that the dg version of the categorical Heisenberg action of [22] on the derived category of the symmetric orbifold is an irreducible highest weight representation.

As the final draft of this paper was being prepared, the preprint [3] of Bergh, Gorchinskiy, Larsen, and Lunts appeared on the arXiv also proving the conjecture of Galkin and Shinder. Our proof seems to be different than theirs although it also uses Bergh’s destackification method as well as several results from [4, 2].

The structure of the paper is the following. In Section 2 we summarize the necessary notions and results about pretriangulated dg categories and actions of finite groups on them. In Section 3 we discuss semiorthogonal decomposition and specialize to the case of geometric dg categories. In Section 4, after recalling the definition of a power structure and the main properties of destackifications, we prove Theorem 1.1. In Section 5 we prove Theorem 1.2 and Corollary 1.3. The implications for Hilbert scheme of points and for the Heisenberg action on the derived category of the symmetric orbifold are given in Section 6.

Acknowledgement. The author would like to thank to Jim Bryan, Sabin Cautis, Eugene Gorsky, Sándor Kovács and Roberto Pirisi for helpful comments and discussions.

2. Preliminaries

2.1. Pretriangulated dg categories. The usefulness of dg enhancements of triangulated categories was first observed in [7]. We give here a brief summary of these. During the whole paper we fix an algebraically closed field $k$. All categories and functors that we will consider are assumed to be $k$-linear.

A dg category is a linear category $\mathcal{V}$ enriched in the monoidal category of complexes of $k$-vector spaces. This means that for any $A, B \in \text{Ob}(\mathcal{V})$ there is given a complex $\text{Hom}_\mathcal{V}(A, B)$. We denote by $H^\bullet(\mathcal{V})$ the $k$-linear category with the same objects as $\mathcal{V}$ and

$$\text{Hom}_{H^\bullet(\mathcal{V})}(A, B) = \bigoplus_i H^i \text{Hom}_\mathcal{V}(A, B).$$

$H^\bullet(\mathcal{V})$ is called the graded homotopy category of $\mathcal{V}$. Restricting to the 0-th cohomology of the Hom complexes one gets the homotopy category $H^0(\mathcal{V})$. 

The tensor product of dg categories $\mathcal{V}$ and $\mathcal{W}$ is defined as follows.

1. $\text{Ob}(\mathcal{V} \boxtimes \mathcal{W}) = \text{Ob}(\mathcal{V}) \times \text{Ob}(\mathcal{W})$; for $A \in \text{Ob}(\mathcal{V})$ and $B \in \text{Ob}(\mathcal{W})$ the corresponding object is denoted as $A \otimes B$.

2. $\text{Hom}(A \otimes B, A' \otimes B') = \text{Hom}(A, A') \otimes \text{Hom}(B, B')$ and the composition map is defined by $(f_1 \otimes g_1)(f_2 \otimes g_2) = (-1)^{\deg(g_1)\deg(f_2)}f_1f_2 \otimes g_1g_2$.

A dg functor between dg categories is a functor preserving the enrichment, i.e. inducing morphisms of Hom-complexes. A dg functor $F : \mathcal{V} \to \mathcal{W}$ is called a quasi-equivalence if $H^\bullet(F) : H^\bullet(\mathcal{V}) \to H^\bullet(\mathcal{W})$ is an equivalence of categories. Given dg categories $\mathcal{V}$ and $\mathcal{W}$ the set of covariant dg functors $\mathcal{V} \to \mathcal{W}$ form the objects of a dg category $\text{Fun}_{dg}(\mathcal{V}, \mathcal{W})$.

Let $DG(k) = C(k\text{-mod})$ be the dg category of complexes of $k$-vector spaces, or dg $k$-modules. We denote the dg category $\text{Fun}_{dg}(\mathcal{V}^{op}, DG(k))$ by $\text{mod}-\mathcal{V}$ and call it the category of dg $\mathcal{V}$-modules. This is a dg category with shift and cone functors, which are inherited from $DG(k)$. The Yoneda-embedding realizes the original dg category $\mathcal{V}$ as a full dg subcategory of $\text{mod}-\mathcal{V}$.

The pretriangulated hull $\text{Pre-Tr}(\mathcal{V})$ of $\mathcal{V}$ is the smallest full dg subcategory of $\text{mod}-\mathcal{V}$ that contains $\mathcal{V}$ and is closed under isomorphisms, direct sums, shifts, and cones. The perfect hull $\text{Perf}(\mathcal{V})$ of $\mathcal{V}$ is the full dg subcategory of $\text{mod}-\mathcal{V}$ consisting of semi-free dg modules that are homotopy equivalent to a direct summand of an object of the category $\text{Pre-Tr}(\mathcal{V})$. The homotopy category $H^0(\text{Pre-Tr}(\mathcal{V}))$ is denoted as $\text{Tr}(\mathcal{V})$.

A dg category $\mathcal{V}$ is called pretriangulated, if the embedding $\mathcal{V} \to \text{Pre-Tr}(\mathcal{V})$ is a quasi-equivalence. A dg category $\mathcal{V}$ is called strongly pretriangulated, if the embedding $\mathcal{V} \to \text{Pre-Tr}(\mathcal{V})$ is a dg equivalence. A dg category is called perfect, if $\mathcal{V} \to \text{Perf}(\mathcal{V})$ is a quasi-equivalence.

If $\mathcal{V}$ is a pretriangulated category, then $H^0(\mathcal{V})$ is naturally a triangulated category. Given a triangulated category $\mathcal{T}$, an enhancement of $\mathcal{T}$ is a pretriangulated category $\mathcal{V}$ with an equivalence $\epsilon : H^0(\mathcal{V}) \to \mathcal{T}$. If $(\mathcal{V}, \epsilon)$ is an enhancement of a triangulated category $\mathcal{T}$ then any strict full triangulated subcategory $S \subset \mathcal{T}$ has an enhancement given by the full dg subcategory of $\mathcal{V}$ of objects that go to objects of $S$ under $\epsilon$ together with the restriction of $\epsilon$ to the 0-th cohomology of this subcategory.

**Example 2.1.**

1. If $\mathcal{V}$ is any dg category, then $\text{Pre-Tr}(\mathcal{V})$ is pretriangulated, and hence $\text{Tr}(\mathcal{V})$ is triangulated.

2. If $\mathcal{A}$ is any $k$-linear abelian category, then $C(\mathcal{A})$, the category of complexes over $\mathcal{A}$ is pretriangulated.

**Example 2.2.**

1. Let $X$ be a scheme of finite type over $k$. Let $\mathcal{O}_X$-mod be the abelian category of all sheaves of $\mathcal{O}_X$-modules. Let $I(\mathcal{O}_X$-mod) be the full dg subcategory of $C(\mathcal{O}_X$-mod) consisting of h-injective complexes of injective objects. Then $I(\mathcal{O}_X$-mod) is pretriangulated, and the composition $\epsilon_{I(\mathcal{O}_X$-mod)} : H^0(I(\mathcal{O}_X$-mod)) $\to$ H^0(C(\mathcal{O}_X$-mod)) $\to$ $D(\mathcal{O}_X$-mod) is an equivalence [20, Thm. 14.3.1 (iii)]. Therefore, $I(\mathcal{O}_X$-mod) is a dg enhancement of $D(\mathcal{O}_X$-mod).

2. It is known that the subcategory $D_{qc}(X) \subset D(\mathcal{O}_X$-mod) of complexes with quasi-coherent cohomology is thick. In fact, $D_{qc}(X)$ is known to be equivalent to $D(Q\text{Coh}(X))$, where $Q\text{Coh}(X)$ is the category of quasi-coherent $\mathcal{O}_X$-modules. Denote by $I_{qc}(X) \subset I(\mathcal{O}_X$-mod) the appropriate enhancement of $D_{qc}(X)$.

3. Similarly, the subcategory $D_{pf}(X) \subset D_{qc}(X)$ consisting of perfect complexes is thick. Its enhancement is $I_{pf}(X) \subset I_{qc}(X)$. When $X$ is smooth, then $D_{pf}(X) = D^b(\text{Coh}(X))$, where $\text{Coh}(X)$ is the category of coherent $\mathcal{O}_X$-modules.

**Example 2.3.** Throughout the paper we will need to work with stacks and derived categories associated to them. We will restrict our attention to algebraic stacks of Deligne-Mumford type. Most importantly, we will investigate quotient stacks of the form
\[ X = [M/G], \text{ where } M \text{ is a scheme and } G \text{ is a finite group acting on it. In this case a sheaf on } X \text{ is the same as a } G\text{-equivariant sheaf on } M. \] The derived categories \( D_{qc}(X) \) and \( D_{pf}(X) \) can be defined analogously to Example 2.2. These have the enhancements \( I_{qc}(X) \) and \( I_{pf}(X) \) respectively. A good summary about the details of these constructions can be found in [4].

**Remark 2.4.** In the rest of the paper, except when noted otherwise, we will use the perfect version of the derived categories and their dg enhancements both for schemes and for DM stacks. To ease the notation, we will drop the subscript and write only \( D(X) = D_{pf}(X) \) (resp., \( D(X) = D_{pf}(X) \) and \( I(X) = I_{pf}(X) \)).

The main advantage of working with dg enhancements is that there is a very-well behaving product for them.

**Definition 2.5.** The completed tensor product of two pretriangulated categories \( V \) and \( W \) is defined by
\[
\hat{V} \boxtimes \hat{W} = \text{Perf}(V \boxtimes W)
\]
Again, to ease the notation, we will drop the hat from the notation of the completed tensor product and just write \( V \boxtimes W \).

**Example 2.6.** By [10, Theorem 5.5], if \( X_1, \ldots, X_n \) are smooth projective varieties, then \( I(X_1) \boxtimes \cdots \boxtimes I(X_n) \) is quasi-isomorphic to \( I(X_1 \times \cdots \times X_n) \). With exactly the same proof as in [10, Theorem 5.5] one can get the analogous result for DM stacks.

**2.2. 2-representations.** Suppose that \( G \) is a finite group such that \(|G|\) is invertible in \( k \). A 2-representation of \( G \) on a linear category \( V \) consists of the following data:

- (1) for each element \( g \in G \), a linear functor \( \rho(g): V \to V \);
- (2) for any pair of elements \((g, h)\) of a \( G \) an isomorphism of functors 
  \[ \phi_{g,h}: (\rho(g) \circ \rho(h)) \Rightarrow \rho(gh) \]
- (3) an isomorphism of functors 
  \[ \phi_1: \rho(1) \Rightarrow \text{Id}_V; \]

such that the following conditions hold:

- (4) for any \( g, h, k \in G \) we have 
  \[ \phi_{gh,k}(\phi_{g,h} \circ \rho(k)) = \phi_{g,hk}(\rho(g) \circ \phi_{h,k}); \]
- (5) \( \phi_{1,g} = \phi_1 \circ \rho(g) \) and \( \phi_{g,1} = \rho(g) \circ \phi_1 \).

**Definition 2.7.** Suppose we are given a 2-representation of \( G \) on \( V \). A \( G \)-equivariant object of \( V \) is a pair \((A, (\epsilon_g)_{g \in G})\), where \( A \in \text{Ob}(V) \) and \((\epsilon_g)_{g \in G}\) is a family isomorphisms 
\[ \epsilon_g: A \to \rho(g)A, \]

satisfying the following compatibility conditions:

- (1) for \( g = 1 \),
  \[ \epsilon_1 = \phi_{1,A}^{-1}: A \mapsto \rho(1)A; \]
- (2) for any \( g, h \in G \) the diagram
  \[
  \begin{array}{ccc}
  A & \xrightarrow{\epsilon_g} & \rho(g)(A) \\
  \downarrow{\epsilon_{gh}} & & \downarrow{\rho(g)(\epsilon_h)} \\
  \rho(gh)(A) & \xleftarrow{\phi_{g,h,A}} & \rho(g)(\rho(h)(A))
  \end{array}
  \]

is commutative.
A morphism of equivariant objects from \((A, (\epsilon_g)_{g \in G})\) and \((B, (\eta_g)_{g \in G})\) is a morphism \(f : A \to B\) compatible with the \(G\)-action. That is, a morphism for which all the following diagram is commutative:

\[
\begin{array}{ccc}
A & \xrightarrow{\epsilon_g} & \rho(g)(A) \\
\downarrow f & & \downarrow \rho(g)(f) \\
B & \xrightarrow{\eta_g} & \rho(g)(B).
\end{array}
\]

The category of \(G\)-equivariant objects in \(\mathcal{V}\) is denoted as \(\mathcal{V}^G\).

For a pretriangulated category \(\mathcal{V}\) with a \(G\)-action the category \(\mathcal{V}^G\) is not necessarily pretriangulated. But for a strongly pretriangulated category \(\mathcal{V}\), the category \(\mathcal{V}^G\) is always strongly pretriangulated [29, Proposition 3.7]. This is the case for the category \(I(X)\) associated to scheme.

**Example 2.8.** One can equip every linear category \(\mathcal{V}\) with the trivial \(G\)-action. That is, all \(\rho(g)\) and \(\phi_{g,h}\), as well as \(\phi_1\) are defined to be the identities. In this case a \(G\)-equivariant object in \(\mathcal{V}\) is the same as a representation of \(G\) in \(\mathcal{V}\), i.e. an object \(V \in \mathcal{V}\) and a homomorphism \(G \to \text{Aut}_\mathcal{V}(V)\).

**Example 2.9.** Let \(X\) be a scheme of finite type over \(k\) equipped with an action of \(G\). Let \(I_G(X)\) be the dg category of equivariant objects in \(I(X)\). Then \(I_G(X)\) is pretriangulated, and the composition \(\epsilon_{I_G(X)} : H^0(I_G(X)) \to H^0(C_G(O_X\text{-mod})) \to D_G(X)\) is an equivalence. It is known, that \(D_G(X) = D([X/G])\). Due to [12, Theorem 9.6], \(I_G(X) = (I(X))^G\), the category of \(G\)-equivariant objects in \(I(X)\).

2.3. **Symmetric powers.** Let \(\mathcal{V}\) be a pretriangulated category. The \(n\)-th tensor power of \(\mathcal{V}\) is \(\mathcal{V}^{\boxtimes n} = \mathcal{V} \boxtimes \cdots \boxtimes \mathcal{V}\) where there are \(n\) factors in the tensor product. The symmetric group \(S_n\) acts on \(\mathcal{V}^{\boxtimes n}\) by the transformation

\[
\sigma(A_1 \otimes \cdots \otimes A_n) = A_{\sigma^{-1}(1)} \otimes \cdots \otimes A_{\sigma^{-1}(n)},
\]

on the objects, and similarly on the Hom complexes. The \(n\)-th symmetric power \(\text{Sym}^n(\mathcal{V})\) is defined in [16] as the category of \(S_n\)-equivariant objects in \(\mathcal{V}^{\boxtimes n}\):

\[
\text{Sym}^n(\mathcal{V}) = (\mathcal{V}^{\boxtimes n})^{S_n}.
\]

**Example 2.10.** If \(X\) is a smooth projective variety, then \(\text{Sym}^n(I(X))\) is the dg category of \(S_n\)-equivariant complexes of injective \(O\)-modules on \(X^n\) which are bounded below and have bounded coherent cohomology. \(H^0(\text{Sym}^n(I(X))) = D([X^n/S^n]) = D_{S_n}(X^n)\) is the (bounded) derived category of \(S_n\)-equivariant complexes of coherent sheaves on \(X^n\).

3. **Semiorthogonal decompositions**

3.1. **Semiorthogonal decomposition of triangulated categories.** Let \(\mathcal{T}\) be a triangulated category. The triangulated envelope of a class of objects \(\mathcal{E} = (E_i)_{i \in I}\) is the smallest strictly full triangulated subcategory of \(\mathcal{T}\) that contains \(\mathcal{E}\). The right orthogonal \(\mathcal{E}^\perp\) is the full subcategory of \(\mathcal{T}\) whose objects \(A\) have the property \(\text{Hom}(E_i[n], A) = 0\) for all \(i\) and \(n\). Similarly, the left orthogonal \({}\mathcal{E}^\perp\) is the full subcategory of \(\mathcal{T}\) whose objects \(A\) have the property \(\text{Hom}(A, E_i[n]) = 0\) for all \(i\) and \(n\).

Let \(\mathcal{A} \subset \mathcal{T}\) be a strictly full triangulated subcategory. \(\mathcal{A}\) is called right admissible (resp. left admissible) if for every \(A \in \mathcal{T}\) there exists an exact triangle \(A_\mathcal{A} \to A \to A_{\mathcal{A}^\perp}\) (resp. \(A_{\mathcal{A}^\perp} \to A \to A_\mathcal{A}\)) with \(A_\mathcal{A} \in \mathcal{A}\) and \(A_{\mathcal{A}^\perp} \in \mathcal{A}^\perp\) (resp. \(A_{\mathcal{A}^\perp} \in \mathcal{A}^\perp\)). A subcategory is called admissible if it is both left and right admissible.

**Proposition 3.1.** Let \(\mathcal{T}\) be a triangulated category, \(\mathcal{A} \subset \mathcal{T}\) a strictly full triangulated subcategory. The following conditions are equivalent:
(a) \( A \) is right (resp. left) admissible in \( T \);
(b) the embedding functor \( i: A \rightarrow T \) has a right (resp. left) adjoint \( i^! \) (resp. \( i^* \)).

If these hold, then the compositions \( i^! \cdot i \) and \( i^* \cdot i \) are isomorphic to the identity functor on \( A \).

A semiorthogonal sequence in \( T \) is a sequence of admissible triangulated subcategories \( A_1, \ldots, A_n \) of \( T \) such that \( A_j \subset \perp A_i \) for \( j > i \). In addition, a semiorthogonal sequence is said to be full if it generates \( T \). In this case we call such a sequence a semiorthogonal decomposition of \( T \) and denote this as

\[ T = (A_1, \ldots, A_n). \]

**Lemma 3.2** \([8]\). If \( T = \langle A, B \rangle \) is a semiorthogonal decomposition, then \( A \) is left admissible and \( B \) is right admissible. Conversely, if \( A \subset T \) is left admissible, then \( T = \langle A, \perp A \rangle \) is a semiorthogonal decomposition, and if \( B \subset T \) is right admissible, then \( T = \langle B^\perp, B \rangle \) is a semiorthogonal decomposition.

There are some cases when a semiorthogonal decomposition is induced automatically on the category of equivariant objects.

**Proposition 3.3** \([24, \text{Proposition 3.3}]\). Let \( T \) be a triangulated category with a trivial action of a finite group \( G \). If \( T^G \) is also triangulated, then there is a completely orthogonal decomposition

\[ T^G = \langle T \otimes V_0, T \otimes V_1, \ldots, T \otimes V_n \rangle, \]

where \( V_0, \ldots, V_n \) is a list of the finite-dimensional irreducible representations of \( G \).

Let \( G \) be a finite abelian group which acts on a Karoubian linear category \( C \). Let \( G^\vee = \text{Hom}(G, k^*) \) be the dual group to \( G \). \( G^\vee \) acts on the category \( C^G \) by twisting: for any \( \chi \in G^\vee \) let

\[ \rho(\chi)((A, (\epsilon_g)_{g \in G})) = (A, (\epsilon_g)_{g \in G}) \otimes \chi = (A, (\epsilon_g \cdot \chi(g))_{g \in G}). \]

For \( \chi, \psi \in G^\vee \), the equivariant objects \( \rho(\chi)(\rho(\psi)((A, (\epsilon_g)_{g \in G}))) \) and \( \rho(\chi \psi)((A, (\epsilon_g)_{g \in G})) \) are the same. Let the isomorphisms

\[ \phi_{\chi, \psi}: \rho(\chi) \circ \rho(\psi) \xrightarrow{\sim} \rho(\chi \psi) \]

be the identities.

**Theorem 3.4** \([14, \text{Theorem 4.2}]\). Let \( G \) be a finite abelian group. Suppose that \( C \) is a Karoubian linear category and \( G \) acts on \( C \). Then

\[ (C^G)^{G^\vee} \cong C. \]

The following is a very important descent result for semiorthogonal decompositions.

**Theorem 3.5** \([13, \text{Theorem 6.2}]\). (1) Let \( X \) be a quasi-projective variety, \( G \) a finite group acting on \( X \), and let \( p_2 \) and \( a \) be the projection and action morphisms from \( G \times X \) to \( X \). Suppose a semiorthogonal decomposition

\[ D(X) = \langle A_1, \ldots, A_n \rangle \]

is given such that for any \( 1 \leq i < j \leq n \) and \( A_i, F_j \in A_j \) one has \( \text{Hom}(p_2^* F_j, a^* F_i) = 0 \). Let

\[ B_i = \{(A, (\epsilon_g)_{g \in G}) \in T^G \mid A \in A_i \} \]

be the full subcategory in \( T^G \) consisting of objects \( (A, (\epsilon_g)_{g \in G}) \) such that \( A \in A_i \). Then there is a semiorthogonal decomposition

\[ D(X)^G = \langle B_1, \ldots, B_n \rangle. \]
Remark 3.7. (1) We will often identify $D(U)$ with its image under $j_*$ in $D(X)$, and we will just write shortly the semiorthogonal decomposition as

$$D(X) = \langle D(U), D_Z(X) \rangle.$$ 

Version (2) is not mentioned in [13, Theorem 6.2] but the proof therein gives this stronger version as well.

For a scheme $X$ and a closed subscheme $Z \subset X$ we denote by $D_Z(X)$ the full subcategory of $D(X)$ of complexes whose cohomology sheaves have their support contained in $Z$.

Proposition 3.6. Let $X$ be a quasi-projective variety, $Z \subset X$ be a closed subvariety and $j : U = X \setminus Z \hookrightarrow X$ be the embedding of the complement of $Z$. Suppose that $D_Z(X) \subset D(X)$ is a right admissible subcategory. Then

1. there is a semiorthogonal decomposition

$$D(X) = \langle D_Z(X) \perp, D_Z(X) \rangle;$$

(2) there exists a functor $j_* : D(U) \to D(X)$ right adjoint to $j^* : D(X) \to D(U)$;

(3) moreover, $D_Z(X) \perp = j_* D(U)$.

Proof. (1) follows from Lemma 3.2.

To prove (2) and (3) we have to work with the quasi-coherent categories $D_{\mathcal{QC}}(X)$ and $D_{\mathcal{QC}}(U)$. It follows from (1) and [13, Lemma 4.2] that there also exists a semiorthogonal decomposition

$$D_{\mathcal{QC}}(X) = \langle D_{\mathcal{QC},Z}(X) \perp, D_{\mathcal{QC},Z}(X) \rangle,$$

such that $D_Z(X) = D_{\mathcal{QC},Z}(X) \cap D(X)$, $D_Z(X) \perp = D_{\mathcal{QC},Z}(X) \perp \cap D(X)$.

Moreover, in the quasi-coherent case there always exists a right adjoint $j_* : D_{\mathcal{QC}}(U) \to D_{\mathcal{QC}}(X)$ of the functor $j^* : D_{\mathcal{QC}}(X) \to D_{\mathcal{QC}}(U)$. This functor has $D_{\mathcal{QC},Z}(X)$ as its kernel [28, Section 3]. By adjunction, for any two objects $A \in D_{\mathcal{QC},Z}(X)$, $B \in D_{\mathcal{QC}}(U)$,

$$\text{Hom}(A, j_* B) = \text{Hom}(j^* A, B) = 0,$$

That is, $j_* D_{\mathcal{QC}}(U) \subseteq D_{\mathcal{QC},Z}(X) \perp$.

Let $F \in D_{\mathcal{QC},Z}(X) \perp$. Consider the natural morphism $F \to j_* j^* F$. This is an isomorphism on $U$. Therefore, the cone $M$ of this morphism is supported set theoretically on $Z$. It follows that each cohomology sheaf of $M$ is supported set theoretically on $Z$, i.e. $M \in D_{\mathcal{QC},Z}(X)$. Then, we have the following exact triangle in $D_{\mathcal{QC}}(X)$:

$$M[-1] \to F \to j_* j^* F \to M.$$ 

But since $M[-1] \in D_{\mathcal{QC},Z}(X)$ and $F \in D_{\mathcal{QC},Z}(X) \perp$ the first morphism can only be 0. In particular, $j_* j^* F = F \oplus M$. Composing $j_* j^*$ with the projection onto the first component yields to the identity. By definition, $j^* \circ j_* = id$ as well. By the uniqueness of adjoints, the composition $j_* \circ j^*$, when restricted to $D_{\mathcal{QC},Z}(X) \perp$, has to be the identity too, and $M = 0$. This shows that $D_{\mathcal{QC},Z}(X) \perp \subseteq j_* D_{\mathcal{QC}}(U)$. It also follows that perfect complexes are mapped to perfect complexes under $j_*$. Therefore, the adjoint also exists in the perfect case and $D_Z(X) \perp = j_* D(U)$.

□

Remark 3.7. (1) We will often identify $D(U)$ with its image under $j_*$ in $D(X)$, and we will just write shortly the semiorthogonal decomposition as

$$D(X) = \langle D(U), D_Z(X) \rangle.$$ 

(2) The statements of Proposition 3.6 are also valid in the equivariant setting when $X$ is a variety with a $G$-action, and $Z \subset X$ is a closed $G$-invariant subvariety. Even more generally, we can replace $X$ (resp., $Z$) with a Deligne-Mumford stack $\mathcal{X}$ (resp., closed substack of $\mathcal{Z}$).
3.2. The Grothendieck ring of geometric dg categories. A pretriangulated dg category is called geometric, if it is a dg enhancement of a semiorthogonal summand in \( D(X) \) for some smooth projective variety \( X \). Let \( S_0(\text{gdg-cat}) \) (resp. \( K_0(\text{gdg-cat}) \)) be the Grothendieck semigroup (resp. group) of geometric dg categories with relations coming from semiorthogonal decompositions \([10, \text{Section 4} \]) . Namely, \( S_0(\text{gdg-cat}) \) (resp. \( K_0(\text{gdg-cat}) \)) is the free abelian semigroup (resp., group) generated by quasi-equivalence classes of geometric pretriangulated dg categories \( \mathcal{V} \).

The Grothendieck ring of geometric dg categories, \( K_0(\text{gdg-cat}) \), has the following properties:

\[
\mathcal{V} = [\mathcal{A}] + [\mathcal{B}],
\]

where

1. \( \mathcal{A} \) and \( \mathcal{B} \) are dg subcategories of \( \mathcal{V} \);
2. \( H^0(\mathcal{A}) \) and \( H^0(\mathcal{B}) \) are admissible subcategories of \( \mathcal{V} \);
3. \( H^0(\mathcal{V}) = \langle H^0(\mathcal{A}), H^0(\mathcal{B}) \rangle \) is a semiorthogonal decomposition.

The (completed) tensor product makes \( S_0(\text{gdg-cat}) \) (resp. \( K_0(\text{gdg-cat}) \)) into an associative and commutative semiring (resp. ring) (see Example \([2,6] \)).

**Theorem 3.8.** \([10, \text{Section 7}] \) There exists a ring homomorphism

\[
\mu : K_0(\text{Var}) \to K_0(\text{gdg-cat}).
\]

The homomorphism \( \mu \) associates to the class of a smooth projective variety \( X \) the class of the category \( I(X) \).

The proof of this theorem is based on the following two facts.

1. By the results of \([25, 5] \) there is a presentation of \( K_0(\text{Var}) \) as follows. It is generated by the isomorphism classes of smooth projective varieties with the defining set of relations

\[
[Y] + [Z] = [X] + [E],
\]

where \( Y \) is the blowup of \( X \) along \( Z \) with exceptional divisor \( E \).

2. In \( K_0(\text{gdg-cat}) \) exactly the same type of relation is satisfied:

\[
[I(Y)] + [I(Z)] = [I(X)] + [I(E)].
\]

Let \( K_0(\text{DM}) \) be the Grothendieck group of Deligne-Mumford stacks. \( K_0(\text{DM}) \) is the group freely generated by equivalence classes \( [\mathcal{X}] \) of (generically tame) Deligne-Mumford stacks \( \mathcal{X} \) subject to the scissor relations

\[
[\mathcal{X}] = [\mathcal{X} \setminus Z] + [Z],
\]

where \( Z \subset \mathcal{X} \) is a closed substack. \( K_0(\text{DM}) \) can be equipped with a product induces by the product of stacks. It follows from the scissor relations that when \( Y \) is a variety with a \( G \)-action, and \( W \subset Y \) is a closed \( G \)-invariant subvariety, then in \( K_0(\text{DM}) \)

\[
[[Y/G]] = [[[Y \setminus W]/G]] + [[W/G]].
\]

A DM stack is called projective if it admits a closed embedding to a smooth DM stack which is proper over \( \text{Spec}(k) \) and has a projective coarse moduli space. Smooth projective stacks play a similar role in \( K_0(\text{DM}) \) as smooth projective varieties in \( K_0(\text{Var}) \).

**Theorem 3.9.** There exists a ring homomorphism

\[
\mu' : K_0(\text{DM}) \to K_0(\text{gdg-cat}).
\]

The homomorphism \( \mu' \) associates to the class of a smooth projective Deligne-Mumford stack \( \mathcal{X} \) the class of the category \( I(\mathcal{X}) \). In particular, for a smooth projective variety \( X \) with the action of a group \( G \)

\[
\mu'([X/G]) = I_G(X).
\]

We postpone the proof of this theorem until Section \([4,2] \). By an abuse of notation we will also write \( \mu \) instead of \( \mu' \), but it will be always clear from the context which homomorphism \( \mu \) is used out of the two possibilities.
4. Power structures

4.1. Power structure over \( K_0(\text{Var}) \).

Definition 4.1. A power structure \([17]\) over a (semi)ring \( R \) is a map

\[
(1 + tR[[t]]) \times R \rightarrow 1 + tR[[t]] : (A(t), m) \mapsto (A(t))^m
\]
such that:

1. \((A(t))^0 = 1;\)
2. \((A(t))^1 = A(t);\)
3. \((A(t) \cdot B(t))^m = (A(t))^m \cdot (B(t))^m;\)
4. \((A(t))^{m+n} = (A(t))^m \cdot (A(t))^n;\)
5. \((A(t))^{mn} = ((A(t))^m)^n;\)
6. \((1 + t)^m = 1 + mt + \text{terms of higher degree};\)
7. \((A(t^k))^m = (A(t))^m|_{t \mapsto t^k}.\)

A power structure over the ring \( K_0(\text{Var}) \) was defined in \([17]\) by the following formula:

\[
(A(t))^{[M]} = 1 + \sum_{k=1}^{\infty} \left\{ \sum_{\sum k_i = k} \left[ \left( \prod_i M^{k_i} \setminus \Delta \right) \times \prod_i A_i^{k_i} \right] / \prod_i S_{k_i} \right\} \cdot t^k.
\]

Here \( A(t) = 1 + [A_1]t + [A_2]t^2 + \ldots. \) The coefficients \( A_i, i = 1, 2, \ldots \) and the exponent \( M \) are quasiprojective varieties. The index \( k \) is taken from the set \( \{k_i : i \in \mathbb{Z}_{>0}, k_i \in \mathbb{Z}_{\geq 0}\}. \) \( \Delta \) is the large diagonal in \( M^{\sum k_i} \) which consists of \( \sum k_i \)-tuples of points of \( M \) with at least two coinciding one, and the permutation group \( S_{k_i} \) acts by permuting the corresponding \( k_i \) factors of \( \prod_i M^{k_i} \setminus \Delta \subset \prod_i M^{k_i} \) and the spaces \( A_i \) simultaneously.

Geometrically this means that the coefficient of the monomial \( t^k \) in the series \( (A(t))^{[M]} \) is represented by the set whose element is a finite subset \( K \) of points of the variety \( M \) with positive multiplicities such that the total number of points of the set \( K \) counted with multiplicities is equal to \( k \), and the set \( K \) is endowed with a map \( \varphi : K \rightarrow \prod_{i=0}^{\infty} A_i \) such that a point with multiplicity \( j \) goes to the component \( A_j \).

When each \( A_i = 1 = (pt), \) then

\[
\bigcup_{\sum k_i = k} \left( \prod_i M^{k_i} \setminus \Delta \right) / \prod_i S_{k_i} = \bigcup_{\sum k_i = k} S^k_{\Delta} M = S^k M.
\]

Here \( S^k_{\Delta} M \) is the stratum of \( S^k M \) where for each \( i \) there are exactly \( k_i \) points of multiplicity \( i. \) It follows from \((1)\) and \((2)\) that

\[
\left( \frac{1}{1-t} \right)^{[M]} = \sum_{n=0}^{\infty} \left[ \text{Sym}^n(M) \right] t^n.
\]

For sequence of integer \( k \) such that \( \sum ik_i = k \), let us denote \( M^k_{\Delta} = p_k^{-1}(S^k_{\Delta} M) \) where \( p_k : M^k \rightarrow S^k M \) is the natural projection. For example, \( M^k_{(k,0,\ldots,0)} = M^k \setminus \Delta. \)

4.2. Destackification. Let \( \mathcal{X} \) be an algebraic stack in the sense of Deligne-Mumford. We will need two basic operations, which can be performed on \( \mathcal{X}. \) First, one can take a blow-up along a smooth center. Second, one can form root stacks over it, i.e. a root constructions along smooth divisors. These two operations are called smooth stacky blow-ups.

We will restrict our attention to the case of global quotients \( \mathcal{X} = [M/G]. \) Since \( G \) is finite, there is a canonical map \( \mathcal{X} \rightarrow \mathcal{X}_s = M/G \) to the coarse moduli space. In general, the quotient \( \mathcal{X}_s = M/G \) is not smooth. As a remedy, the concept of destackifications was developed in \([1]\). The following results are valid in the much more general setting of tame algebraic stacks with diagonalizable stabilizers, but, for simplicity, we specialize to the case of DM stacks.
Definition 4.2. A destackification of $\mathcal{X}$ is a map $f: \mathcal{Y} \to \mathcal{X}$ of algebraic stacks which is a composition of smooth stacky blowups such that

1. the coarse space $\mathcal{Y}_{cs}$ of $\mathcal{Y}$ is smooth;
2. the canonical map $\mathcal{Y} \to \mathcal{Y}_{cs}$ is a (sequence/fiber product of) root stack(s along distinct divisors);
3. the components of the branch divisor in $\mathcal{Y}_{cs}$ are smooth, and they only have simple normal crossings.

A particular case of [1], Corollary 1.4] is

Theorem 4.3. If $\mathcal{X} = [M/G]$ is a global quotient where $G$ is a finite group, then there exists a destackifications $f: \mathcal{Y} \to \mathcal{X}$ of $\mathcal{X}$.

For further calculations it is important to investigate how the derived category of a stack behaves under the two stacky blow-up operations.

Let $\mathcal{X}$ be a DM stack and $\mathcal{Z} \subset \mathcal{X}$ an effective divisor. Fix a positive integer $n$ and let $f: \mathcal{Y} \to \mathcal{X}$ be the $n$-th root construction of $\mathcal{X}$ along $\mathcal{Z}$. Let $V_k$ be the $k$-th irreducible representation of the cyclic group $\mathbb{Z}_n$. For a triangulated category $\mathcal{T}$, let $\mathcal{T}^{Z_n}$ be the category of equivariant objects with respect to the trivial $\mathbb{Z}_n$-action, and let

$$i_k: \mathcal{T} \to \mathcal{T}^{Z_n}, \quad F \mapsto F \otimes V_k.$$ 

The preimage $\mathcal{E}$ of $\mathcal{Z}$ in $\mathcal{Y}$ as a stack is equivalent to $[\mathcal{Z}/\mathbb{Z}_n]$, i.e. $\mathcal{Z}$ equipped with a trivial action of $\mathbb{Z}_n$. Denote by $i: \mathcal{E} \hookrightarrow \mathcal{Y}$ the embedding of $\mathcal{E}$ as the ramification divisor. Let $\mathcal{U} = \mathcal{Y} \setminus \mathcal{E}$ and and let $j: \mathcal{U} \hookrightarrow \mathcal{Y}$ be the embedding morphism. We have the induced functors

$$f_k^*: D(\mathcal{X}) \to D(\mathcal{Y}), \quad i_k^*: D(\mathcal{Z}) \to D(\mathcal{Y}).$$

Proposition 4.4 ([19], Theorem 1.6][24, Theorem 4.1], [4, Theorem 4.7]). For each $k \in \{0, \ldots, n-1\}$ the functors $f_k^*$ are fully faithful and admit left and right adjoints. Moreover, for $k, l \in \{0, \ldots, n-1\}$

- $(i_k^* D(\mathcal{Z}), i_k^* D(\mathcal{Z}))$ is semiorthogonal if $k \neq l, l+1$;
- $(i_k^* D(\mathcal{Z}), f_k^* D(\mathcal{Y}))$ is semiorthogonal if $k \neq l$;
- $(f_k^* D(\mathcal{Z}), i_k^* D(\mathcal{Z}))$ is semiorthogonal if $k \neq l - 1$.

Proposition 4.5. The functor $j^*: D(\mathcal{Y}) \to D(\mathcal{U})$ has a right adjoint $j_*: D(\mathcal{U}) \to D(\mathcal{Y})$. Moreover, there is a semiorthogonal decomposition

$$D(\mathcal{Y}) = \langle j_* D(\mathcal{U}), i_0^* D(\mathcal{Z}), \ldots, i_{n-1}^* D(\mathcal{Z}) \rangle.$$

Proof. The group $\mathbb{Z}_n$ acts on $\mathcal{Z}$ trivially. By Proposition 3.3 there is a semiorthogonal decomposition

$$D(\mathcal{E}) = D([\mathcal{Z}/\mathbb{Z}_n]) = \langle i_0 D(\mathcal{Z}), \ldots, i_{n-1} D(\mathcal{Z}) \rangle.$$ 

Suppose that $F \in D_{\mathcal{E}}(\mathcal{Y})$. That is, each cohomology sheaf of $F$ is supported set-theoretically on the space underlying $\mathcal{Z}$. Then it admits a filtration by sheaves supported on the space underlying $\mathcal{Z}$ scheme-theoretically. This filtration can also be chosen $\mathbb{Z}_n$-equivariantly. By [4] any $\mathbb{Z}_n$-equivariant sheaf scheme-theoretically supported on the space underlying $\mathcal{Z}$ can be written as the direct sum of sheaves contained in the categories $i_l^* D(\mathcal{Z})$. Therefore

$$D_{\mathcal{E}}(\mathcal{Y}) = \langle i_0^* D(\mathcal{Z}), \ldots, i_{n-1}^* D(\mathcal{Z}) \rangle.$$

Due to Proposition 4.4 the subcategory $D_{\mathcal{E}}(\mathcal{Y})$ is admissible in $D(\mathcal{Y})$. The statement then follows from Proposition 3.6 and the remark after it. □
Corollary 4.6. In the setting of Proposition 4.3
\[ \mu(U) = \mu(X) - \mu(Z) = \mu(Y) - \mu(E). \]

To compute the derived category of the destackification of an orbifold one has to consider also the derived category of an iterated root construction. The details of this are developed in [4]. Here we give a brief summary. Suppose that \( X \) is a DM stack and \( Z = (Z_i)_{i \in I} \) is a snc divisor on \( X \) for some index set \( I \). This means that for each subset \( J \subset I \) and each element \( i \in J \) the morphism
\[ \cap_{j \in J} Z_j \to \cap_{j \in J \setminus \{i\}} Z_j \]
is the inclusion of a smooth, effective Cartier divisor. The divisors \( Z_i \) are the components of \( Z \).

Let \( \underline{n} = (n_i)_{i \in I} \) be a multi-index with positive integer entries. Let \( X_i \to X \) be the root stack over \( X \) of degree \( n_i \) and branch divisor \( Z_i \). The \( \underline{n} \)-th root stack over \( X \) with branch divisor \( Z \) is defined as the fiber product
\[ Y = \prod_{i \in I} X_i \to X. \]

Let \( Z_{\underline{n}} = \prod_{i} Z_{n_i} \). For any multi-index \( \underline{k} \) satisfying \( \underline{n} > \underline{k} \geq 0 \), let \( V_{\underline{k}} = \otimes_i V_{n_i}^{k_i} \), where \( V_{n_i}^{k_i} \) is the \( k_i \)-th irreducible representation of \( Z_{n_i} \). Let moreover \( I_{\underline{k}} \) be the support of \( \underline{k} \). \( Z(I_{\underline{k}}) = \cap_{i \in I_{\underline{k}}} Z_i \), and \( E(I_{\underline{k}}) \) be the preimage of \( Z(I_{\underline{k}}) \) in \( Y \). For any triangulated category \( T \) let
\[ i_{\underline{k}}: T \to T_{Z_{\underline{n}}}, \quad F \mapsto F \otimes V_{\underline{k}}. \]

Again, let
\[ f^*_{\underline{k}}: D(X) \to D(Y), \quad i^*_{\underline{k}}: D(Z(I_{\underline{k}})) \to D(Y), \quad i_{\underline{k}}: Z(I_{\underline{k}}) \to Y. \]

Proposition 4.7 ([3, Theorem 4.9]). For each \( \underline{n} > \underline{k} \geq 0 \) the functors
\[ f^*_{\underline{k}}: D(X) \to D(Y), \quad i^*_{\underline{k}}: D(Z(I_{\underline{k}})) \to D(Y) \]
are fully faithful and admit left and right adjoints. Moreover, for \( \underline{n} > \underline{k} \geq 0 \)
- \( (i^*_{\underline{k}} D(Z(I_{\underline{k}})), i^*_{\underline{k}} D(Z(I_{\underline{k}}))) \) is semithogonal if \( \underline{k} \neq \underline{l} + (0, \ldots, 0, 1, \ldots, 1) \);
- \( (i^*_{\underline{k}} D(Z(I_{\underline{k}})), f^*_\underline{l} D(X)) \) is semithogonal if \( \underline{k} \neq \underline{l} \).

Here \( 1_i \) denotes the vector which is 1 at position \( i \), and zero everywhere else.

Let again \( U = Y \setminus E \) and and let \( j: U \to Y \) be the embedding morphism.

Proposition 4.8. The functor \( j^*: D(Y) \to D(U) \) has a right adjoint \( j_*: D(U) \to D(Y) \). Moreover, there is a semithogonal decomposition
\[ D(Y) = (j_*, D(U), i_{k_s}^* D(I_{k_s}^{n_s})), \ldots, i_{k_m}^* D(I_{k_m}^{n_m}) \]
where the multi-indices \( \underline{k} \) with \( \underline{n} > \underline{k} \geq 0 \) are arranged into any sequence \( \underline{k}_1, \ldots, \underline{k}_m \) such that \( \underline{k}_s \geq \underline{k}_t \) implies \( s \geq t \) for all \( s, t \in \{1, \ldots, m\} \) where \( m = \prod_{i \in I} n_i \).

The statement of the following lemma is encoded in the proof of [3, Theorem 4.9], but it can also be obtained with an induction argument.

Lemma 4.9. With the notations of Proposition 4.3
\[ D(E) = (i_{k_s}^* D(I_{k_s}^{n_s})), \ldots, i_{k_m}^* D(I_{k_m}^{n_m}) \]

Proof of Proposition 4.8. Replace indices everywhere with multi-indices in the proof of Proposition 4.5 and use Proposition 4.7 (resp. Lemma 4.9) instead of Proposition 4.4 (resp. equation 4). \( \square \)
Corollary 4.10. In the setting of Proposition 4.8
\[ \mu(U) = \mu(X) - \mu(Z) = \mu(Y) - \mu(E). \]

The other stacky blowup operation is the blowup along a smooth center. In this case the open part away from the center does not appear in general as a semiorthogonal summand. But a weaker result is still true in this case.

Proposition 4.11. Let \( X \) be a smooth projective DM stack and \( f: Y \to X \) be its blowup along a smooth closed substack \( Z \subset X \) of codimension \( n \). Let \( E \subset Y \) be the exceptional divisor. Then, there is a semiorthogonal decomposition
\[ D(Y) = \langle f^*D(X), i_1^*D(Z), \ldots, i_{(n-1)}^*D(Z) \rangle \]
where \( i_k^*: D(Z) \to D(Y) \) are certain functors.

Proof. For schemes this result was proved in [27]. In the case of a quotient stack \( X = [M/G] \) with \( G \) an affine algebraic group the statement follows from [13, Theorem 10.2]. By [21, Theorem 4.4], every (generically tame) smooth projective DM stack is a quotient stack by an affine algebraic group, so the statement is true for all smooth projective DM stack.

Corollary 4.12. In the setting of Proposition 4.11 with \( U = Y \setminus E \approx X \setminus Z \),
\[ \mu(U) = \mu(X) - \mu(Z) = \mu(Y) - \mu(E). \]

We are now ready to give the

Proof of Theorem 3.9. In analogy with Theorem 3.8, the proof follows from the following two statements.

1. By [2, Theorem 1.1] there is a presentation of \( K_0(DM) \) as follows. It is generated by the isomorphism classes of smooth projective DM stacks with the defining set of relations
\[ [\mathcal{Y}] + [Z] = [X] + [E], \]
where \( \mathcal{Y} \to X \) is a stacky blowup along a smooth center \( Z \) with exceptional divisor \( E \).

2. By Propositions 4.5 and 4.11 the relation
\[ [I(\mathcal{Y})] + [I(Z)] = [I(X)] + [I(E)] \]
is satisfied for stacky blowups of smooth projective DM stacks along a smooth centers in \( K_0(gdg-cat) \).
Proof. Part (1):

Let $D_k$ be a connected component of $M_k^k$. $D_k$ can also be described as the fixed point set of an element of $S_k$ of conjugacy type described by $k$, which are not fixed by any other element in the same conjugacy class. Each point in $D_k$ has stabilizer $H = \prod_i (S_i)^{k_i}$. Let $X_k = [D_k/H]$. $X_k$ is a smooth quasi-projective stack which is equivalent to $[M_k^k/S_k]$. Let $\overline{X_k} = [\overline{D_k}/H]$ be its closure in $[M^k/H]$. $\overline{X_k}$ is a smooth projective DM stack and $X_k \subset \overline{X_k}$ is an open substack. Let $f_k : Y_k \to \overline{X_k}$ be the destackification of $\overline{X_k}$. Then the coarse space $\mathcal{V}_k$ is a (iterated) root stack and the coarse map $Y_k \to \mathcal{V}_k$ is a root stack (possibly precomposed with a gerbe). $Y_k$ being obtained from $\overline{X_k}$ with stacky blowups is itself a smooth projective Deligne-Mumford stack. Thus, $\mu(Y_k) = I(Y_k)$.

The coarse space $(\overline{X}_k)_{cs} = \overline{D_k}/H$ has smooth locus $(X_k)_{cs} = D_k/H = D_k$. Therefore, each center of the stacky blowups in the composite mapping $f_k$ avoids the preimage of $X_k$. Moreover, the substack $E_k = f_k^{-1}(\overline{X_k} \setminus X_k) \subset Y_k$ is also the preimage of $\mathcal{V}_k$ away from the branch divisor under the coarse map $Y_k \to \mathcal{V}_k$.

Let $U_k = Y_k \setminus E_k$. Again, since the destackification algorithm removes the stackiness only from $\overline{X_k}$, the gerbe part of the coarse map $Y_k \to \mathcal{V}_k$ is trivial over $U_k$. By Proposition 4.13, there is a semiorthogonal decomposition

$$D(Y_k) = \langle D(U_k), D(E_k(Y_k)) \rangle$$

It follows that $I(U_k)$ is geometric and $\mu(U_k) = I(U_k)$. On the other hand, by Corollaries 4.10 and 4.12

$$\mu(U_k) = \mu(Y_k) - \mu(E_k) = \mu(\overline{X_k} \setminus X_k) = \mu(X_k).$$

The morphism $f_k|_{U_k} : U_k \to X_k$ is a (composition of) regular covering(s) without branch locus. Thus,

$$I(U_k) = I(X_k) = I([M_k^k/S_k]).$$

In particular, $I([M_k^k/S_k])$ is geometric.

Part (2):

We continue to use the notations from the proof of Part (1).

Step 1: Assume first that $k = (k, 0, \ldots, 0)$. Then, by the definition of a destackification, the coarse map $Y_k \to \mathcal{V}_k$ is an (iterated) root stack and has no gerbe part. It follows that we have the diagram

$$U_k \overset{\cong}{\leftarrow} Y_k \overset{\cong}{\leftarrow} [V_k/A] \leftarrow [W_k/A],$$

where $A$ is the finite abelian covering group of the root stack, and $W_k$ is the underlying variety of the root stack, and $V_k$ is the part of $W_k$ away from the ramification divisor. Applying Theorem 3.4, we obtain that

$$D(U_k)^{A'} = D(V_k) \quad \text{and} \quad D(Y_k)^{A'} = D(W_k).$$

$Y_k$ was obtained from $\overline{X_k}$ with stacky blowup operations, so $Y_k$ is itself a smooth projective DM stack. Let us investigate the stacky blowup sequence $f_k : Y_k \to \overline{X_k}$. $V_k$ is obtained from the quasi-projective variety $D_k$ with the stacky blowup operations. It follows that $f_k$ induces a regular covering map $V_k \to D_k$ with covering group a finite Abelian group acting freely on $V_k$. So we get that $D_k = V_k/A'$, and

$$D(D_k) = D([V_k/A']) = D(V_k)^{A'}.$$ 

Therefore, $D(D_k) = D(V_k)^{A'}$. 

Proof complete.
The action of $A'$ on $\mathcal{Y}_k$ also preserves the substacks $U_k$ and $E_k$. Theorem 3.5 combined with (5), (6) and (7) gives
\[
D([W_k/A']) = D(W_k)^{A'} = (D(\mathcal{Y}_k)^{A'})^{A'} = (D(U_k)^{A'})^{A'} = (D(E_k)^{A'})^{A'} = (D(D_k), (D_E(\mathcal{Y}_k)^{A'})^{A'}).
\]

$[W_k/A']$ is a smooth projective Deligne-Mumford stack. It follows from [4, Theorem 6.6] that $I([W_k/A']) = I(W_k)^{A'}$ is geometric, and therefore $I(D_k)$ is also geometric. $M_k$ is a disjoint union of a finite number of connected components, each of which is isomorphic $D_k$. We obtain that $I(M_k)$ is also geometric.

Step 2: In general, $M_k$ is isomorphic to $D_k^{\sum_i k_i}$, where $\sum_i k_i = k$. Again, because $M_k$ is a disjoint union of a finite number of connected components, each of which is isomorphic $D_k$, this implies that $I(M_k)$ is geometric. 

Let $\mathcal{M}$ be an arbitrary geometric dg category. Then, $H^0(\mathcal{M}) \subset D(M)$ is a semiorthogonal summand for some smooth projective variety $M$. Let

\[
\mathcal{M}_k = \left\{ F \in I(M_k) \mid F = G|_{M_k} \text{ for some } G \in M_k \in I(M_k) \right\}.
\]

**Proposition 4.14.** For every integer sequence $k$ such that $\sum_i ik_i = k$, the dg category $\mathcal{M}_k$ is geometric.

**Proof.** For simplicity, we prove the statement first for the sequence $k = (k, 0, \ldots, 0)$. In this case $M_k = M^k$. Since $\mathcal{M}$ is geometric, $H^0(\mathcal{M}) \subset D(M)$ is a semiorthogonal summand for some smooth projective variety $M$. Applying the mutation functors of [5] on a semiorthogonal sequence of $D(M)$ containing $H^0(\mathcal{M})$ we can assume that there is a semiorthogonal decomposition

\[
D(M) = \langle A, \phi(H^0(\mathcal{M})), \rangle,
\]

where $\phi(H^0(\mathcal{M}))$ is equivalent to $H^0(\mathcal{M})$. By Lemma 3.2, $\phi(H^0(\mathcal{M}))$ is right admissible in $D(M)$. For ease, we replace $\mathcal{M}$ with $\phi(\mathcal{M})$ and assume that $H^0(\mathcal{M})$ is right admissible in $D(M)$. It is easy to see that in this case $H^0(\mathcal{M}_k)$ is also right admissible in $D(M_k)$. By [4, Theorem 4.2] there is a right admissible subcategory $H^0(\mathcal{M}) \subset D_q(\mathcal{M}_k)$, which restricts to $H^0(\mathcal{M}_k)$ in $D(M_k)$. This means that the functor $i : H^0(\mathcal{M}_k) \hookrightarrow D_q(\mathcal{M}_k)$ has a right adjoint $i^* : D_q(\mathcal{M}_k) \rightarrow H^0(\mathcal{M}_k)$. On the level of quasi-coherent sheaves the restriction functor $j^* : D_q(\mathcal{M}_k) \rightarrow D_q(M_k)$ has a right adjoint $j_* : D_q(\mathcal{M}_k) \rightarrow D_q(\mathcal{M}_k)$, which restricts to $H^0(\mathcal{M}_k)$ in $D(M_k)$. Let’s denote by $H^0(\mathcal{M}_k) \cap D(M_k) = H^0(\mathcal{M}_k)$ under $j_* : D_q(\mathcal{M}_k) \rightarrow D_q(M_k)$. Since everything in the construction is functorial, $H^0(\mathcal{M}_k) \cap D(M_k) = H^0(\mathcal{M}_k)$. Since $j_* \circ j_*$ is the identity, the composition

\[
D_q(M_k) \xrightarrow{j_*} D_q(M_k) \xrightarrow{i^*} H^0(\mathcal{M}_k) \xrightarrow{j_*} H^0(\mathcal{M}_k)
\]

is right adjoint to the embedding $H^0(\mathcal{M}_k) \hookrightarrow D_q(M_k)$. This means that $H^0(\mathcal{M}_k) \subset D_q(M_k)$ is right admissible. Moreover, the above composition maps perfect complexes to perfect complexes. So it restricts to a functor $D(M_k) \rightarrow H^0(\mathcal{M}_k)$, which is right adjoint to the embedding $H^0(\mathcal{M}_k) \hookrightarrow D(M_k)$. 

\[\]
Hence, \( H^0(\mathcal{M}^k_{(k,0,\ldots,0)}) \) is a semiorthogonal summand in \( D(\mathcal{M}^k_{(k,0,\ldots,0)}) \) whose enhancement is geometric by Theorem 4.13 (2).

The proof of the statement for an arbitrary sequence \( k \) is the same except that \( M^k \) has to be replaced by the smooth projective variety \( \mathcal{M}^k_\Delta \).

It is not true in general that \( H^0(\mathcal{M}^k_\Delta) \subset H^0(\mathcal{M}^k) \) are semiorthogonal summands since it is not true even for \( I(M) \). But we have

**Proposition 4.15.** For any \( [\mathcal{M}] \in K_0(\text{gdg-cat}) \), the class of \( \mathcal{M}^k \) decomposes as

\[
[\mathcal{M}^k] = \sum_{k \sum ik_i = k} [\mathcal{M}^k_\Delta].
\]

**Proof.** For any variety \( M \) there is a decomposition \( M^k = \bigcup_{k \sum ik_i = k} M^k_\Delta \). By Theorem 4.18 for \( \mathcal{M} = I(M) \) this induces the required decomposition

\[
[I(M^k)] = \sum_{k \sum ik_i = k} [I(M^k_\Delta)].
\]

In general, for a geometric dg category \( \mathcal{M} \subset I(M) \) each \( H^0(\mathcal{M}^k_\Delta) \) (resp., \( H^0(\mathcal{M}^k) \)) is a semiorthogonal summand in the corresponding \( D(\mathcal{M}^k_\Delta) \) (resp., \( D(\mathcal{M}^k) \)). Applying the restriction functor \( I(M) \to \mathcal{M} \) on each component on the above sum we obtain the required decomposition of \([\mathcal{M}^k] \). \( \square \)

### 4.4. Power structure over \( K_0(\text{gdg-cat}) \)

Let \( \mathcal{A}(t) = 1 + [\mathcal{A}_1]t + [\mathcal{A}_2]t^2 + \ldots \), where the coefficients are (represented by) dg categories \( \mathcal{A}_i \), \( i = 1, 2, \ldots \). Let further \( \mathcal{M} \) be a pretriangulated category. We want to define \( (\mathcal{A}(t))^{[\mathcal{M}]} \) in analogy with the formula (1). For a general pretriangulated category \( \mathcal{M} \) the difficulty is that for the tensor power \( \mathcal{M}^k \) there is no obvious diagonal component, i.e. a semiorthogonal summand in \( \mathcal{M}^k \) representing tensors with “coinciding components”. However, for geometric dg categories we can induce such a summand from the decomposition of the underlying space.

From now on we will use the convention that a single number \( k \), when appears in the subscript of a category or a space, means the sequence \( k = (k, 0, \ldots, 0) \). For example, \( M^k = M_{(k,0,\ldots,0)} = M^k \setminus \Delta \).

Let us define a power structure over the Grothendieck semiring of geometric dg categories \( S_0(\text{gdg-cat}) \) by the following formula:

\[
(\mathcal{A}(t))^{[\mathcal{M}]} = 1 + \sum_{k=1}^{\infty} \left\{ \sum_{k \sum ik_i = k} \left[ \left( \mathcal{M}^{\sum ik_i} \otimes \prod_i \mathcal{A}^{k_i}_i \right) \Pi_i S_{k_i} \right] \right\} \cdot t^k.
\]

**Lemma 4.16.** Suppose that, for each integer \( i \), \( H^0(\mathcal{A}_i) \) is a semiorthogonal summand in \( D(\mathcal{A}_i) \), where \( \mathcal{A}_i \) is a smooth projective variety. Then, the coefficient of the monomial \( t^k \) in the series \( (\mathcal{A}(t))^{[\mathcal{M}]} \) is represented by the (prefect hull of the) category with objects (injective complexes of perfect) sheaves \( F = F_{k_1} \otimes \ldots \) satisfying any of the following equivalent descriptions:

**I** (a) \( F \) is an \( (\prod_i S_{k_i}) \)-equivariant sheaf on \( (M^{\sum i k_i} \setminus \Delta) \times A^{k_i}_i \);

(b) \( F_{k_i} = p_{k_i}^* (G_{k_i}) \), where \( G_{k_i} \) is an \( S_{k_i} \)-equivariant object of \( \mathcal{M}^{k_i} \otimes \mathcal{A}^{k_i}_i \), i.e. an \( S_{k_i} \)-equivariant sheaf on \( (M^{k_i} \setminus \Delta) \times A^{k_i}_i \).

**II** (a) \( F \) is a sheaf on the space of \( (\prod_i S_{k_i}) \)-equivariant maps \( (M^{\sum i k_i} \setminus \Delta) \to A^{k_i}_i \);

(b) \( F_{k_i} = p_{k_i}^* (G_{k_i}) \), where \( G_{k_i} \) is an \( S_{k_i} \)-equivariant object of \( \mathcal{M}^{k_i} \otimes \mathcal{A}^{k_i}_i \), i.e. a sheaf on the space of \( S_{k_i} \)-equivariant maps \( (M^{k_i} \setminus \Delta) \times A^{k_i}_i \).

**III** (a) \( F \) is a sheaf on \( ((M^{\sum i k_i} \setminus \Delta) \times A^{k_i}_i) / \prod_i S_{k_i} \);
(b) \( F_{k_{i_{j}}} = p_{k_{i_{j}}}^*(G_{k_{i_{j}}}) \), where \( G_{k_{i_{j}}} \) is an \( S_{k_{i_{j}}} \)-equivariant object of \( \mathcal{M}_{k_{i_{j}}} \otimes A_{k_{i_{j}}^i} \), i.e. a sheaf on \( ((M_{k_{i_{j}}}^i \setminus \Delta) \times A_{k_{i_{j}}^i})/S_{k_{i_{j}}} \).

In the first two descriptions \( p_{k_{i_{j}}} \) is the composition

\[
\prod_i M_{k_{i_{j}}}^i \setminus \Delta \rightarrow \prod_i M_{k_{i_{j}}}^i \rightarrow M_{k_{i_{j}}},
\]

whereas in the third description \( p_{k_{i_{j}}} \) is the induced map on the quotients.

**Proof.** Description (I) follows directly from the definition \([\text{II}]\). The group \( S_{k_{i_{j}}} \) acts freely on \( (M_{k_{i_{j}}}^i \setminus \Delta) \times A_{k_{i_{j}}^i} \). This gives us description (III). Description (II) follows from description (III) taking into account the description of \( ((M_{\sum_i k_{i_{j}}^i} \setminus \Delta) \times A_{\sum_i k_{i_{j}}^i})/\prod S_{k_{i_{j}}} \) as distinct points of \( M \) with multiplicities and maps from the points to the appropriate space \( A_i \).

**Theorem 4.17.** The equation \([\text{II}]\) defines a power structure over the Grothendieck semiring \( \mathcal{S}_0(\text{gdg-cat}) \) of geometric dg categories.

**Proof.** Properties 1, 2, 6 and 7 from the definition of a power structure are obvious. Properties 3, 4 and 5 follow straightly from the corresponding properties for the power structure on \( K_0(\text{Var}) \) by analyzing the spaces on which the sheaves under consideration are defined.

Proof of Property 3. Let \( B(t) = \sum_{i=0}^{\infty} B_i t^i \) be another series with coefficients from the same semiring, such that, for each integer \( i \), \( H^0(B_i) \) is a semiorthogonal summand in \( D(B_i) \), where \( B_i \) is a smooth projective variety. Let \( C_j = \sum_{i=0}[A_i][B_j-i] = \sum_{i=0}[A_i \otimes B_j-i] \) be the coefficient of \( t^k \) in the product \( A(t) \cdot B(t) \). Then \( H^0(C_i) \) is a semiorthogonal summand in \( D(C_i) = D(\prod_{i=0} A_i \times B_i-j_i) \).

The coefficient of the monomial \( t^k \) on the left hand side (LHS) of equation (3) is represented by a category whose objects are sheaves on

\[
\bigsqcup_{k \sum ik_i = k} \left( \prod_i M_{k_i}^i \setminus \Delta \right) \times \prod_i C_i^k_i / \prod_i S_{k_i}.
\]

Each such sheaf can be written as \( F = F_{k_{i_{j}}} \otimes \ldots \), where \( F_{k_{i_{j}}} = p_{k_{i_{j}}}^*(G_{k_{i_{j}}}) \) for some sheaf \( G_{k_{i_{j}}} \) on \( (M_{k_{i_{j}}}^i \setminus \Delta)/S_{k_{i_{j}}} \) with values in \( C_j = \sum_{i=0}[A_i \otimes B_j-i] \).

The coefficient of the monomial \( t^k \) on the right hand side (RHS) of equation (3) is represented by a category whose objects are sheaves on

\[
\bigsqcup_{k_{i_{j}}, k_{i_{j}} = k} \left( \prod_i M_{k_{i_{j}}}^i \setminus \Delta \right) \times \prod_i A_{k_{i_{j}}}^i / \prod_i S_{k_{i_{j}}} \times \left( \prod_i M_{k_{i_{j}}}^i \setminus \Delta \right) \times \prod_i B_{k_{i_{j}}}^i / \prod_i S_{k_{i_{j}}}.
\]

Here the sheaves are of the form \( F = F_{k_{i_{j}}} \otimes \cdots \otimes F_{k_{i_{j}}}, \) where \( F_{k_{i_{j}}} = p_{k_{i_{j}}}^*(G_{k_{i_{j}}}) \) for some sheaf \( G_{k_{i_{j}}} \) on \( (X_{k_{i_{j}}} \setminus \Delta)/S_{k_{i_{j}}} \) with values in \( A_i \), and \( F_{k_{i_{j}}} = p_{k_{i_{j}}}^*(G_{k_{i_{j}}}) \) for some sheaf \( G_{k_{i_{j}}} \) on \( (X_{k_{i_{j}}} \setminus \Delta)/S_{k_{i_{j}}} \) with values in \( B_i \).

The fact that the two underlying spaces of the categories on the LHS and on the RHS are canonically isomorphic follows from the proof of Property 3 for the power structure on \( K_0(\text{Var}) \) in \([\text{IV}]\) Theorem 1]. Then, the identity functor for the sheaves on one space to the other is an equivalence of categories between LHS and RHS.
Proof of Property 4. An object of the coefficient of the monomial $t^k$ on the LHS is sheaf on

$$
\bigcup_{k \sum ik_i = k} \left( \prod_i (M \sqcup N)^{k_i} \setminus \Delta \right) \times \prod_i A_i^{k_i} / \prod_i S_{k_i},
$$

where $k$ is a partition of $k$. An object of the coefficient of the monomial $t^k$ on the RHS is sheaf on

$$
\bigcup_{k_1 + k_2 = k} \left( \left( \prod_i M^{k_{1,i}} \setminus \Delta \right) \times \prod_i A_i^{k_{1,i}} \right) / \prod_i S_{k_{1,i}}
\times \left( \left( \prod_i N^{k_{2,i}} \setminus \Delta \right) \times \prod_i A_i^{k_{2,i}} \right) / \prod_i S_{k_{2,i}}.
$$

Again, the canonical isomorphism of the underlying spaces of the categories on the LHS and on the RHS follows from the proof of Property 4 for the power structure on $K_0(Var)$ in [17, Theorem 1].

Proof of Property 5. Again, an object of the coefficient of the monomial $t^k$ on the LHS is sheaf on

$$
\bigcup_{k \sum ik_i = k} \left( \prod_i (M \times N)^{k_i} \setminus \Delta \right) \times \prod_i A_i^{k_i} / \prod_i S_{k_i}
$$

for some partition $k$ of $k$. An object of the coefficient of the monomial $t^k$ on the RHS is sheaf on

$$
\bigcup_{k \sum ik_i = k} \left( \left( \prod_i N^{k_{1,i}} \setminus \Delta \right) \times \prod_i A_i^{k_{1,i}} \right) / \prod_i S_{k_{1,i}}
= \left( \bigcup_i \left( \prod_i (M \times N)^{k_{1,i}} \setminus \Delta \right) \times \prod_i A_i^{k_{1,i}} \right) / \prod_i S_{k_{1,i}}.
$$

As above, a canonical isomorphism of the underlying spaces of the categories on the LHS and on the RHS is given in the proof of Property 5 for the power structure on $K_0(Var)$ in [17, Theorem 1].

A more precise version of Theorem 1.1 is

**Theorem 4.18.** There exists a unique power structure over the Grothendieck ring $K_0(gdg\text{-}cat)$ which extends the one defined over the semiring $S_0(gdg\text{-}cat)$.

Taking into account Theorem 4.17 the proof of this theorem is the same as that of the analogous [17, Theorem 2] for the power structure on $K_0(Var)$ except for replacing varieties by categories. We do not reproduce it here.

5. THE CATEGORICAL ZETA FUNCTION

The categorical zeta-function of a geometric dg category $\mathcal{M}$ was defined in [15] as

$$
Z_{\text{cat}}(\mathcal{M}, t) = \sum_{n=0}^{\infty} \text{Sym}^n(\mathcal{M}) t^n \in 1 + tK_0(gdg\text{-}cat)[[t]].
$$

Let us recall Theorem 1.2 here.
Theorem 5.1.

\[ Z_{cat}(\mathcal{M}, t) = \prod_{n=1}^{\infty} \left( \frac{1}{1 - q^n} \right)^{[\mathcal{M}]} . \]

Proof. The expansion

\[ \prod_{n=1}^{\infty} \frac{1}{1 - q^n} = \sum_{k=0}^{\infty} p(k) \]

is well known. Here \( p(k) \) is the number of partitions of \( k \). Therefore, we need to show that

\[ (9) \quad [\text{Sym}^k(\mathcal{M})] = \sum_{k: \sum i k_i = k} \left[ \left( \mathcal{M}_{\sum i k_i}^{\sum k_i} \times \prod_i [p(i)]^{k_i} \right) \Pi_i S_{k_i} \right] \]

By Proposition 4.15 there is a decomposition \( [\mathcal{M}^k] = \sum_{k: \sum i k_i = k} [\mathcal{M}_{\sum i k_i}^k] \) of the classes in \( K_0(\text{gdg-cat}) \). This gives the decomposition

\[ [\text{Sym}^k(\mathcal{M})] = \sum_{k: \sum i k_i = k} [(\mathcal{M}_{\sum i k_i}^k)^{S_k}] \]

for the classes of the categories of \( S_n \)-equivariant objects. Hence, to prove (9) it is enough to prove the categorical equivalence

\[ \left( \mathcal{M}_{\sum i k_i}^{\sum k_i} \times \prod_i [p(i)]^{k_i} \right) \Pi_i S_{k_i} = (\mathcal{M}_{\sum i k_i}^k)^{S_k}. \]

For simplicity, first suppose that \( \mathcal{M} = I(\mathcal{M}) \). We want to show that

\[ \left( I \left( \mathcal{M}_{\sum i k_i}^{\sum k_i} \right) \times \prod_i [p(i)]^{k_i} \right) \Pi_i S_{k_i} = \mu \left( [\mathcal{M}_{\sum i k_i}^k/S_k] \right) \]

for every sequence \( k \) of \( k \). The stabilizer of each point in \( M_{\sum i k_i}^k \) is \( H = \prod_i (S_i)^{k_i} \). Therefore, the coarse map \([M_{\sum i k_i}^k/S_k] \rightarrow M_{\sum i k_i}^k/S_k\) is an \( H \)-gerbe, i.e. a Zariski locally trivial fibration whose fiber is \( BH \). The coarse spaces \( M_{\sum i k_i}^k/S_k \) and \( M_{\sum i k_i}^{\sum k_i}/\prod_i S_{k_i} \) are naturally isomorphic. But the stacks \([M_{\sum i k_i}^k/S_k]\) and \([M_{\sum i k_i}^{\sum k_i}/\prod_i S_{k_i}]\) are not equivalent, since the group in the latter case acts freely. To get a stack equivalent to \([M_{\sum i k_i}^k/S_k]\) we have to equip each configuration in \( M_{\sum i k_i}^{\sum k_i}/\prod_i S_{k_i} \) with a map to \( BH \) such that a point of multiplicity \( i \) in the configuration is mapped to \( B S_i \) (i.e. locally the map from the configuration is a product of maps from the points of the configuration). Points of multiplicity \( i \) in \( M_{\sum i k_i}^{\sum k_i}/\prod_i S_{k_i} \) are those which are in the image of the component \( M_{\sum i k_i}^{k_i} \). Equivalently, \([M_{\sum i k_i}^k/S_k]\) is isomorphic to the space of \((\prod_i S_{k_i})\)-equivariant maps \( M_{\sum i k_i}^{\sum k_i} \rightarrow BH \).
As a consequence,
\[
\mu([M^k_x/S_k]) = I([M^k_x/S_k]) \\
= I \left( \prod_i S_k \right) -\text{equivariant maps } M^{\sum_i k_i \cdot 0, \ldots 0} \to BH \\
= I \left( [M^{\sum_i k_i \cdot 0, \ldots 0} \times BH] / \prod_i S_k \right).
\]

where the group $\prod_i S_k$ in the last term acts on the two components simultaneously. The stack $BH$ is equivalent to the quotient stack $[\{pt\}/H]$. Applying Proposition 6.3 for $H = \prod_i (S_k)^k$ we obtain that
\[
I \left( [M^{\sum_i k_i \cdot 0, \ldots 0} \times BH] / \prod_i S_k \right) = \left( I \left( M^{\sum_i k_i \cdot 0, \ldots 0} \right) \times I(BH) \right) \prod_i S_k,
\]
\[
= \left( I \left( M^{\sum_i k_i \cdot 0, \ldots 0} \right) \times \prod_i \mu(i)^{k_i} \right) \prod_i S_k.
\]

In general, exactly the same proof shows the statement for an arbitrary geometric dg category $\mathcal{M}$ if we replace $I(M^{\sum_i k_i \cdot 0, \ldots 0})$ (resp., $\mu([M^k_x/S_k])$) with $\mathcal{M}^{\sum_i k_i \cdot 0, \ldots 0}$ (resp., $(M^k_x)^{S_k}$).

By comparing Theorem 5.1 and (3) we get Corollary 1.3.

6. Corollaries

6.1. The class of the Hilbert scheme of points. Let $R_1$ and $R_2$ be rings with power structures over them. A ring homomorphism $\phi: R_1 \to R_2$ induces a natural homomorphism $R_1[[t]] \to R_2[[t]]$ (also denoted by $\phi$) by $\phi(\sum_n a_n t^n) = \sum_n \phi(a_n) t^n$.

Lemma 6.1 ([18, Proposition 1]). To define a power structure over a ring $R$ it is sufficient to define the series $(1 - t)^{-a} = 1 + at + \ldots$ for each $a \in R$, so that $(1 - t)^{-(a+b)} = (1 - t)^{-a}(1 - t)^{-b}$, $(1 - t)^{-1} = 1 + t + t^2 + \ldots$.

It follows that to specify a homomorphism between rings with power structures it is enough to specify the homomorphism on elements of the form $(1 - t)^{-a}$, $a \in R$. This and Theorem 5.1 give

Proposition 6.2. (1) If a ring homomorphism $\phi: R_1 \to R_2$ is such that $\phi((1 - t)^{-a}) = \prod_{n=1}^\infty (1 - t^n)^{-\phi(a)}$, then $\phi((A(t))^{n}) = \prod_{n=1}^\infty (\phi(A(t^n)))^{\phi(n)}$.

(2) In particular, for the ring homomorphism $\mu: K_0(Var) \to K_0(gdg - cat)$,
\[
\mu \left( (A(t))^M \right) = \prod_{n=1}^\infty (\mu(A(t^n)))^{\mu(M)}.
\]

Let $X$ be any quasi-projective variety. Consider the generating series of the motives of Hilbert scheme of points on $X$:
\[
H_X(t) = \sum_{n=0}^\infty [\text{Hilb}^n(X)] t^n \in 1 + tK_0(Var)[[t]].
\]

Here $\text{Hilb}^n(X)$ is the Hilbert scheme of $n$ points on $X$.

Proposition 6.3 ([18, Theorem 1]). For a smooth quasi-projective variety $X$ of dimension $d$,
\[
H_X(t) = (H_{X^{(d,0)}}(t))^{[X]},
\]
where $H_{\mathbb{A}^d,0}(t) = \sum_{n=0}^{\infty} \text{Hilb}^n(\mathbb{A}^d,0)[t^n]$ is the generating series of the motives of Hilbert scheme of $n$ points on $\mathbb{A}^d$ supported at the origin.

Propositions 6.2 (2) and 6.3 give Corollary 6.4.

**Corollary 6.4.** For a smooth projective variety $X$ of dimension $d$, 
\[
\sum_{n=0}^{\infty} [I(\text{Hilb}^n(X))]t^n = \mu(H_X(t)) = \prod_{n=1}^{\infty} \mu(H_{\mathbb{A}^d,0}(t^n))^{[I(X)]}.
\]

6.2. **Character formula of the categorified Heisenberg action.** Let $X$ be a smooth projective variety. The geometric dg category
\[
\mathbb{I} = \bigoplus_{n \geq 0} I([X^n/S_n])
\]
is an enhancement of
\[
\mathbb{D} = \bigoplus_{n \geq 0} D([X^n/S_n]).
\]
Following [22] we define the following functors. For $1 \leq n \leq N$ and $A \in D(X)$ let 
\[
P^{(n)}_{N,F}: I([X^{N-n}/S_{N-n}]) \to I([X^n/S_n]), \quad F \mapsto \text{Inf}_{S_n \times S_n}^{S_N} (A \otimes^n \otimes F),
\]
where
\[
\text{Inf}_{S_n \times S_n}^{S_N}: I([X^N/(S_n \times S_N-n)]) \to I([X^n/S_n])
\]
is the adjoint of the forgetful functor. Let moreover
\[
P^*_F(n) = \bigoplus_{N \geq n} P^m_{N,F}: \mathbb{I} \to \mathbb{I}, \quad \text{for } n \geq 1, \quad P^{(1)}_F := \text{Id}_{\mathbb{I}}.
\]
Finally, let $Q^{(n)}_F: \mathbb{I} \to \mathbb{I}$ be the right adjoint of $P^{(n)}_F$. These functors are the dg enhancements of the derived functors defined in [22] (see also [11]). In fact, the statement and the whole proof of [22, Theorem 1.4] copies word-by-word to the dg enhancements giving

**Theorem 6.5.** The functors $P^{(n)}_F$ and $Q^{(n)}_F$ make $\mathbb{I}$ a (categorified) representation of a (categorical) Heisenberg algebra.

Theorem 5.1 gives the class in $K_0(gdg\text{-}cat)$ of the categorified “character formula” for this representation. Comparing it to the character formula of the classical Fock space representation of the Heisenberg algebra one obtains

**Corollary 6.6.** $\mathbb{I}$ is a categorified irreducible highest weight representation of the Heisenberg algebra.

It is instructive to compare this result to [26, Corollary 8.16].
