LARGE DEVIATION PRINCIPLES AND FLUCTUATION THEOREMS
FOR CURRENTS IN SEMI–MARKOV PROCESSES

ALESSANDRA FAGGIONATO

ABSTRACT. In this short note we consider semi–Markov processes satisfying the condi-
tion of direction–time independence (Markov renewal processes). We derive large de-
viation principles and fluctuation theorems for the empirical current and the empirical
currents along cycles. Our derivation is based on the joint LDP for the empirical measure
and flow recently proved in [12].

Keywords: Semi–Markov process, Markov renewal process, Large deviation principle,
Empirical current, Gallavotti–Cohen type symmetry, Fluctuation theorem.

1. INTRODUCTION

Semi–Markov processes with direction–time independence are stochastic processes sim-
ilar to continuous time Markov chains with the exception that the holding times are
not necessarily exponential random variables (hence, these processes are in general non
Markovian). In the mathematical literature they are also known as Markov renewal pro-
cesses [3]. They find several applications, also in the study of molecular motors (cf. e.g.
[3, 2, 7, 8, 10, 11, 12, 15] and references therein).

For several Markov processes (as diffusions and Markov chains) in the last years much
attention has been devoted to the large deviations of the empirical current and the asso-
ciated fluctuation theorems (also called Gallavotti–Cohen symmetries). See e.g. [4, 5, 9]
and references therein.

Considering semi–Markov processes with direction–time independence, previous deriva-
tions of large deviation principles for the joint empirical measure and current as well for the
empirical current have been obtained (in a not completely rigorous way) in [2, 11]. Fluc-
tuation theorems have also been discussed in particular in [2], also for empirical currents
along cycles.

In this short note we show how the above LDPs and the fluctuation theorems can be
derived from the joint LDP for the empirical measure and flow recently proved in [12].
We also give some extension to generic semi–Markov processes (without direction–time
independence). Our derivation covers also the case of semi–Markov processes with holding
times having law with heavy tails or without a probability density (these cases indeed do
not fit well with the arguments presented in [2, 11]). In addition, our derivation is given
by simple mathematical proofs.

2. SEMI–MARKOV PROCESSES

2.1. Semi–Markov processes with direction–time independence (DTI). Given a
finite state space $V$, the DTI semi–Markov process $X := (X_t)_{t \geq 0}$ on $V$ is defined from
the following objects: a transition probability kernel $(p_{x,y})_{x,y \in V}$ that we assume to be
irreducible, a probability measure $\gamma$ on $V$ and a family of probability measures $\psi_x$
on $(0, +\infty)$ parametrized by $x \in V$. Having these objects, we introduce a discrete–time
Markov chain $(X_k, \tau_k)_{k \geq 0}$ on $V \times (0, +\infty)$ such that
(C1) \((X_k)_{k \geq 0}\) is a Markov chain on \(V\) with transition probabilities \(p_{x,y}\), \(x, y \in V\), and initial distribution \(\gamma\). By the above assumption, this Markov chain is irreducible;

(C2) \((\tau_k)_{k \geq 0}\) is a random sequence on \((0, +\infty)\) such that, conditionally to \((X_k)_{k \geq 0}\), \((\tau_k)_{k \geq 0}\) are i.i.d random variables and \(\tau_k\) has law \(\psi_{X_k}\), i.e.,

\[
\mathbb{P}_\gamma(\tau_i \in A \mid (X_k)_{k \geq 0}) = \psi_{X_i}(A) \quad i \geq 0, \ A \subset \mathbb{R} \text{ measurable.} \tag{1}
\]

Then the DTI semi–Markov process \(X = (X_t)_{t \geq 0}\) is obtained from \((X_k)_{k \geq 0}\) by the following random time–change: at time 0 the system starts at state \(X_0\) and it remains there for a holding time \(\tau_0\), at time \(\tau_0\) the system jumps to state \(X_1\) and it remains there for a holding time \(\tau_1\) and so on. We can formalize this definition as follows. We set

\[
S_0 := 0, \quad S_k := \sum_{i=0}^{k-1} \tau_i \quad \text{for } k \geq 1. \tag{2}
\]

Then, given \(t \geq 0\), we define \(N_t\) as the unique nonnegative integer \(k\) such that \(S_k \leq t < S_{k+1}\). Note that the above definition is well posed \(\mathbb{P}_\gamma\)-a.s. since, as one can easily prove, \(\mathbb{P}_\gamma\)-a.s. it holds \(\lim_{k \to \infty} S_k = +\infty\). Then we define

\[
X_t := X_{N_t}. \tag{3}
\]

Note that \(X_t = X_0\) for \(t \in [0, \tau_0) = [S_0, S_1)\), \(X_t = X_1\) for \(t \in [\tau_0, \tau_0 + \tau_1) = [S_1, S_2)\),...

When \(\psi_x(dt)\) is of the form \(f(x,t)dt\) for some density function \(f(x,\cdot)\), then \(X_t\) corresponds to the process introduced in [11 Section 2.1] with \(Q(x,t) = f(x,t)\) there. Note that, when \(f(x,t) = \lambda_x e^{-\lambda_x t}\), then \(X_t\) is simply a continuous–time Markov chain on \(V\) with transition probability rates \(r_{x,y} = \lambda_x p_{x,y}\).

2.2. Generic semi–Markov processes. The condition of direction–time independence corresponds to the fact that the law of \(\tau_i\) is determined when \(X_i\) is known. In a generic semi–Markov process the law of \(\tau_i\) is determined when \(X_i, X_{i+1}\) are known, in particular the holding time at \(X_i\) can depend also from the new state \(X_{i+1}\) achieved after the transition.

As a consequence, instead of working with the family \(\{\psi_x\}_{x \in V}\), we have a family of probability measures \(\psi_{x,y}\) on \((0, +\infty)\) parameterized by \((x, y) \in V \times V\). Then one again consider the discrete–time process \((X_k, \tau_k)_{k \geq 0}\) (which is not anymore Markov) satisfying conditions (C1) and (C2*), where the new condition (C2*) reads as follows:

(C2*) \((\tau_k)_{k \geq 0}\) is a random sequence on \((0, +\infty)\) such that, conditionally to \((X_k)_{k \geq 0}\), \((\tau_k)_{k \geq 0}\) are i.i.d random variables and \(\tau_k\) has law \(\psi_{X_k,X_{k+1}}\), i.e.,

\[
\mathbb{P}_\gamma(\tau_i \in A \mid (X_k)_{k \geq 0}) = \psi_{X_i, X_{i+1}}(A) \quad \forall i \geq 0, \ A \subset \mathbb{R} \text{ measurable.} \tag{4}
\]

Then the semi–Markov process \(X_t\) is again defined by (2) and (3).

For the above definition it is simple to check that

\[
\mathbb{P}_\gamma(\tau_k \in A, X_{k+1} = y \mid X_0, X_1, \ldots, X_k, \tau_0, \tau_1, \ldots, \tau_{k-1}) = p(X_k, y)\psi_{X_k,y}(A). \tag{5}
\]

In particular, the above defined semi–Markov process corresponds to the one introduced in [11 Appendix A.1] by setting there \(A(x,y; t) := p_{x,y}\psi_{x,y}(t, +\infty)\). When \(\psi_{x,y}\) is absolutely continuous w.r.t. the Lebesgue measure on \((0, +\infty)\), i.e. \(\psi_{x,y}(dt) = f_{x,y}(dt)\), we then obtain that the function \(Q(x, y; t)\) in [11 Appendix A.1] equals \(p_{x,y}f_{x,y}(t)\).

We recall that any generic semi–Markov process on \(V\) with irreducible transition kernel can be formulated in terms of a DTI semi–Markov process on \(E := \{(x, y) \in V \times V : p(x, y) > 0\}\) with irreducible transition kernel. To this aim, consider the discrete–time Markov chain \((Y_k)_{k \geq 0}\) on \(E\), with irreducible transition kernel given by \(p(y,z) := \delta_{y,v}p_{y,v}\)
and initial distribution given by the distribution of \((X_0, X_1)\) under \(P_\gamma\). We write \((Y_t)_{t \geq 0}\) for the associated semi–Markov process with direction–time independence such that \(\psi_{x,y}\) is the holding time distribution at state \((x, y)\) \(\in E\). Then the semi–Markov process \((X_t)_{t \geq 0}\) can be realized simply by defining \(X_t\) as the first coordinate of \(Y_t\).

2.3. Empirical measure and flow. Given \(t > 0\), the empirical measure \(\mu_t\) is defined as the random probability measure

\[
\mu_t := \frac{1}{t} \int_0^t \delta(x_{N_s}, \tau_{N_s}) \, ds = \frac{1}{t} \int_0^t \delta(x_s, \tau_{N_s}) \, ds .
\]

In other words, the expectation \(\mu_t(f)\) of a function \(f\) is given by

\[
\mu_t(f) = \frac{1}{t} \int_0^t f(x_s, \tau_{N_s}) \, ds = \sum_{k=0}^{N_t-1} \frac{\tau_k}{t} f(X_k, \tau_k) + \frac{t - S_{N_t}}{t} f(X_{N_t}, \tau_{N_t}) .
\]

The empirical measure \(\mu_t\) is a probability on \(V \times (0, +\infty)\) and, by trivial extension, can be thought of as an element of \(\mathcal{P}(V \times (0, +\infty))\), the space of probabilities on \(V \times (0, +\infty)\).

The empirical flow is defined as the random element of \(\mathbb{R}_+^{V \times V}\) given by

\[
Q_t(x, y) := \frac{1}{t} \sum_{k=0}^{N_t-1} 1(x = x, X_{k+1} = y) .
\]

We recall that \(\mathbb{R}_+ := [0, +\infty)\). Note that, for \(x \neq y\), we have \(Q_t(x, y) = \frac{1}{t} \sum_{s \in [0, t]} 1(x_s = x, X_s = y)\). If one allows \(p_{x,x}\) to be positive, then \(Q_t(x, x)\) can be positive.

Due to the above definitions, the joint empirical measure and flow \((\mu_t, Q_t)\) is a random element of the product space

\[
\Lambda := \mathcal{P}(V \times (0, +\infty)) \times \mathbb{R}_+^{V \times V} .
\]

3. LDP for the joint empirical measure and flow for DTI semi–Markov processes \([12]\)

In this section we restrict to DTI semi–Markov processes and we recall the joint large deviation principle for the empirical measure and flow recently obtained by Mariani and Zambotti \([12]\). We point out that our notation is slightly different from the one in \([12]\) since they call \(\tau_{k+1}\) our random variable \(\tau_k\).

We write \(\mathcal{P}(V \times (0, +\infty))\) for the space of probability measures on \(V \times (0, +\infty)\) \((V\) has the discrete topology, and \((0, +\infty)\) is a metric space by the identification \(0 < \tau \rightarrow 1/\tau \in (0, 1])\). The space \(\mathcal{P}(V \times (0, +\infty))\) is endowed with the weak topology. We also consider the euclidean space \(\mathbb{R}_+^{V \times V}\) of functions \(V \times V \ni (x, y) \mapsto Q(x, y) \in \mathbb{R}_+\).

Let us write \(\nu\) for the unique invariant distribution of the Markov chain \((X_k)_{k \geq 0}\). As discussed in \([12]\) Section 4, as \(t \to \infty\) the empirical measure \(\mu_t\) satisfies the following LLN for any initial distribution \(\gamma\):

\[
\mu_t(x, d\tau) \to \frac{\nu_x}{\sum_z \nu_z \int \tau \psi_z(d\tau)} \tau \psi_x(d\tau) , \quad P_\gamma\text{-a.s.}
\]

Again, in \([12]\) Section 4, it is proved that as \(t \to \infty\) the empirical flow \(Q_t\) satisfies the following LLN for any initial distribution \(\gamma\):

\[
Q_t(x, y) \to \frac{\nu_x p_{x,y}}{\sum_z \nu_z \int \tau \psi_z(d\tau)} , \quad P_\gamma\text{-a.s.}
\]

To describe the large deviations from the above LLN’s we need some notation.
Definition 3.1. We define $\Lambda_0$ as the subspace of $\Lambda$ given by the pairs $(\mu, Q)$ such that, for any $x \in V$, the following holds:

- the measure $\mu(x, d\tau)$ restricted to $(0, +\infty)$ is absolutely continuous w.r.t. $\psi_x$,
- $Z_x := \int_{(0, +\infty)} \mu(x, d\tau) \frac{1}{\tau} = \sum_{y \in V} Q(x, y) = \sum_{y \in V} Q(y, x)$.

Given $(\mu, Q) \in \Lambda_0$, we define

$$p^Q_{x,y} := \frac{Q(x, y)}{Z_x}, \quad \tilde{\mu}(x, d\tau) = \frac{1}{Z_x} \mu(x, d\tau),$$

with the convention that $\tilde{\mu}(x, \{+\infty\}) = 0$.

Note that $p^Q_{x,y}$ is a probability kernel on $V$ and that $\tilde{\mu}$ is a probability measure on $V \times (0, +\infty)$. We also point out that if $(\mu, Q) \in \Lambda_0$ then $\text{div} Q \equiv 0$. We recall that, given an element $f \in \mathbb{R}^{V \times V}$, the divergence $\text{div} f : V \to \mathbb{R}$ is defined as

$$\text{div} f(x) := \sum_{y \in V} f(x, y) - \sum_{y \in V} f(y, x).$$

In the case of a flow $Q$, the divergence $\text{div} Q(x)$ is simply the difference between the flow exiting from $x$ and the flow entering into $x$.

In what follows, given two probability measures $P, P'$, we denote by $H(P|P')$ the entropy of $P$ w.r.t. $P'$.

Fact 3.1. (Joint LDP for $(\mu_t, Q_t)$ by Mariani & Zambotti [12])

Under $P_\gamma$, the random pair $(\mu_t, Q_t)$ satisfies a large deviation principle as $t \to \infty$, with speed $t$ and explicit rate function $I$ given by

$$I(\mu, Q) := \begin{cases} \sum_{x \in V} Z_x \left[ H(p^Q_{x,x} | p_{x,x}) + H(\tilde{\mu}(x, \cdot) | \psi_x) + \xi_x \mu(x, \{+\infty\}) \right] & \text{if } (\mu, Q) \in \Lambda_0, \\ +\infty & \text{otherwise}, \end{cases}$$

where

$$\xi_x := \sup\{c \geq 0 : \int \psi_x(d\tau)e^{c\tau} < \infty\}, \quad x \in V.$$ \hspace{1cm} (12)

Moreover, the rate function $I$ is good, i.e. the level set $\{(\mu, Q) : I(\mu, Q) \leq \alpha\}$ is compact for any $\alpha \in [0, +\infty)$.

Note that if e.g. $\psi_x$ is an exponential distribution with parameter $\lambda_x$, then $\xi(x) = \lambda_x$.

4. Fluctuation theorem for the empirical current of DTI semi–Markov processes

We denote by $\mathbb{R}^{V \times V}_{\text{antis}}$ the space of antisymmetric functions $J : V \times V \to \mathbb{R}$ (equivalently, antisymmetric real square matrixes with indexes in $V$). The empirical current is defined as the random element of $\mathbb{R}^{V \times V}_{\text{antis}}$ given by

$$J_t(x, y) := Q_t(x, y) - Q_t(y, x), \quad (x, y) \in V \times V, \hspace{1cm} (13)$$

i.e., for $x \neq y$, $J_t(x, y)$ is given by the number of transitions per unit time from $x$ to $y$ minus the number of transitions per unit time from $y$ to $x$ performed by the semi–Markov process $(X_s)_{s \in [0,t]}$. Trivially, $J_t(x, x) = 0$.

Given $Q \in \mathbb{R}^{V \times V}_+$ we define $J^Q \in \mathbb{R}^{V \times V}_{\text{antis}}$ as

$$J^Q(x, y) = Q(x, y) - Q(y, x), \quad (x, y) \in V \times V.$$ \hspace{1cm} (14)

1We use the convention that $\xi_x \mu(x, \{+\infty\}) = 0$ if $\xi_x = \infty$ and $\mu(x, \{+\infty\}) = 0$. 

By applying the contraction principle to Fact 3.1 we get:

**Proposition 4.1.** [LDP for \((\mu_t, J_t)\) and LDP for \(J_t\)] Under \(\mathbb{P}_\gamma\), the random pair \((\mu_t, J_t)\) satisfies a large deviation principle as \(t \to \infty\), with speed \(t\) and good rate function \(\tilde{I}\) given by

\[
\tilde{I}(\mu, J) = \inf \{ I(\mu, Q) : Q \in \mathbb{R}_+^{V \times V}, J^Q = J \}.
\]

Similarly, under \(\mathbb{P}_\gamma\), the empirical current \(J_t\) satisfies a large deviation principle as \(t \to \infty\), with speed \(t\) and good rate function \(\mathcal{I}\) given by

\[
\mathcal{I}(J) = \inf \{ I(\mu, Q) : (\mu, Q) \in \Lambda, J^Q = J \}.
\]

We now move to the fluctuation theorem. To this aim, as usual, we restrict to the case \(p_{x,y} > 0\) if and only if \(p_{y,x} > 0\).

It is convenient to introduce the set \(E\) of pairs \((x, y)\) such that both the transition from \(x\) to \(y\) and the transition from \(y\) to \(x\) are possible:

\[
E := \{(x, y) \in V \times V : p_{x,y} > 0, p_{y,x} > 0\}.
\]

As we will show, the fluctuation theorem follows from the following key symmetry of the rate functional \(I(\mu, Q)\):

**Theorem 4.2.** For any \((\mu, Q) \in \Lambda\) it holds

\[
I(\mu, Q) = I(\mu, Q^T) - \frac{1}{2} \sum_{(x,y) \in E} J^Q(x, y) \ln \frac{p_{x,y}}{p_{y,x}},
\]

where \(Q^T(x, y) := Q(y, x)\) and \(J^Q\) is given by (14).

Since the rate function \(I\) has value in \((-\infty, +\infty]\) while \(\sum_{(x,y) \in E} J^Q(x, y) \ln \frac{p_{x,y}}{p_{y,x}}\) is finite, the above identity is well defined in \((-\infty, +\infty]\).

**Proof.** To simplify notation we write \(J\) instead of \(J^Q\). Trivially, \((\mu, Q) \in \Lambda_0\) if and only if \((\mu, Q^T) \in \Lambda_0\) (cf. Definition 3.1). If \((\mu, Q) \notin \Lambda_0, (\mu, Q^T) \notin \Lambda_0\), then (19) reads \(+\infty = +\infty\), which is trivially true. Hence we can restrict to the case \((\mu, Q) \in \Lambda_0\). Due to (14), to prove (19) it is enough to show that

\[
\sum_{x \in V} Z_x H \left( p_{x,x}^Q : |p_x| \right) = \sum_{x \in V} Z_x H \left( p_{x,x}^{Q^T} : |p_x| \right) - \frac{1}{2} \sum_{(x,y) \in E} J(x,y) \ln \frac{p_{x,y}}{p_{y,x}}.
\]

We point out that \(Z_x > 0\) for any \(x\). Hence, the l.h.s. of (20) is infinite if and only if the following condition \(C\) is satisfied: there exists a pair \((x, y)\) with \(p_{x,y} = 0\) and \(Q(x, y) > 0\). On the other hand, the l.h.s. of (20) is infinite if and only if for some \(x\) the probability \(p_{x,x}^Q\) is not absolutely continuous w.r.t. \(p_x\), i.e. if and only if there exists a pair \((x, y)\) with \(p_{x,y} = 0\) and \(Q(x, y) > 0\). Due to (17) \(p_{x,y} = 0\) if and only if \(p_{y,x} = 0\). Hence, we can restate condition \(C\) as follows: there exists a pair \((y, x)\) such that \(p_{y,x} = 0\) and \(Q^T(y, x) = 0\). This property is equivalent to the fact that \(\sum_{x \in V} Z_x H \left( p_{x,x}^{Q^T} : |p_x| \right) = \sum_{y \in V} Z_y H \left( p_{y,y}^{Q^T} : |p_y| \right)\) is infinite. Hence, under condition \(C\) (20), reduces to the identity \(+\infty = +\infty\) and therefore it is true.

Let us suppose that condition \(C\) is not fulfilled. Then, by the above observations, the three sums in (20) have finite value. Moreover, if \(p(x, y) = 0\) then \(p(y, x) = 0\), \(Q(x, y) = 0\)
and $Q^T(x, y) = 0$. Hence, using the convention that $0 \ln 0 = 0$, we can write

$$
\sum_{x \in V} Z_x H(p^Q_{x'}, |p_{x'}|) = \sum_{(x, y) \in E} Q(x, y) \ln \frac{Q(x, y)}{Z_x p_{x,y}}
$$

$$
= \frac{1}{2} \sum_{(x, y) \in E} \left[ Q(x, y) \ln \frac{Q(x, y)}{Z_x p_{x,y}} + Q(y, x) \ln \frac{Q(y, x)}{Z_y p_{y,x}} \right]
$$

$$
= \frac{1}{2} \sum_{(x, y) \in E} \left[ Q(x, y) \ln Q(x, y) + Q^T(x, y) \ln Q^T(x, y) \right]
$$

$$
- \frac{1}{2} \sum_{(x, y) \in E} \left[ Q(x, y) \ln(Z_x p_{x,y}) + Q^T(x, y) \ln(Z_y p_{y,x}) \right].
$$

(21)

Since $(Q^T)^T = Q$ a similar expression holds:

$$
\sum_{x \in V} Z_x H(p^{Q^T}_{x'}, |p_{x'}|) = \frac{1}{2} \sum_{(x, y) \in E} \left[ Q^T(x, y) \ln Q^T(x, y) + Q(y, x) \ln Q(x, y) \right]
$$

$$
- \frac{1}{2} \sum_{(x, y) \in E} \left[ Q^T(x, y) \ln(Z_x p_{x,y}) + Q(x, y) \ln(Z_y p_{y,x}) \right].
$$

(22)

By subtracting (22) from (21) and using that $J = Q - Q^T$, we get

$$
\sum_{x \in V} Z_x H(p^Q_{x'}, |p_{x'}|) - \sum_{x \in V} Z_x H(p^{Q^T}_{x'}, |p_{x'}|)
$$

$$
= -\frac{1}{2} \sum_{(x, y) \in E} \left[ J(x, y) \ln(Z_x p_{x,y}) - J(x, y) \ln(Z_y p_{y,x}) \right]
$$

$$
= -\frac{1}{2} \sum_{(x, y) \in E} J(x, y) \ln \frac{p_{x,y}}{p_{y,x}} - \frac{1}{2} \sum_{(x, y) \in E} J(x, y)[\ln(Z_x) - \ln(Z_y)].
$$

(23)

To get (20) we have only to show that $\sum_{(x, y) \in E} J(x, y)[\ln(Z_x) - \ln(Z_y)]$. Recall that we are assuming that $(\mu, Q) \in \Lambda_0$ and that condition C is not fulfilled. As already observed, the latter implies that $J(x, y) = 0$ if $(x, y) \in (V \times V) \setminus E$, hence

$$
\sum_{(x, y) \in E} J(x, y)[\ln(Z_x) - \ln(Z_y)] = \sum_{(x, y) \in V \times V} J(x, y)[\ln(Z_x) - \ln(Z_y)].
$$

(24)

Since $(\mu, Q) \in \Lambda_0$, as already observed before (10), $\text{div} \, Q \equiv 0$. Hence, using also the antisymmetry of $J$, we get

$$
0 = \text{div} \, Q(x) = \sum_{y \in V} Q(x, y) - \sum_{y \in V} Q(y, x) = \sum_{y \in V} J(x, y)
$$

$$
= \frac{1}{2} \sum_{y \in V} (J(x, y) - J(y, x)) = \frac{1}{2} \text{div} \, J(x),
$$

(25)
thus proving that $\text{div } J \equiv 0$. Since $J$ is divergenceless, the scalar product of $J$ with a gradient function is zero. In our case, this reads

$$
\sum_{(x,y) \in V \times V} J(x, y)[\ln(Z_x) - \ln(Z_y)] = \sum_{x \in V} \ln(Z_x)[\sum_{y \in V} J(x, y) - \sum_{y \in V} J(y, x)]
= \sum_{x \in V} \ln(Z_x) \text{div } J(x) = 0.
$$

(26)

As a byproduct of (23), (24) and (26), we get (20) and therefore (19).

$\square$

**Remark 4.3.** Recall the rate function $\tilde{I}(\mu, Q)$ of Prop. 4.1. As derived in the proof of Theorem 4.2, if $I(\mu, J) < +\infty$ then $\text{div } J = 0$ and $J(x, y) = 0$ for any pair $(x, y) \in V \times V$ such that $p_{x,y} = 0$. Moreover, if $I(\mu, Q) < +\infty$, then $\text{div } Q = 0$ and $Q(x, y) = 0$ for any pair $(x, y) \in V \times V$ such that $p_{x,y} = 0$

We observe that, given $J \in \mathbb{R}^{V \times V}_{\text{antis.}}$, the map

$$
\{Q \in \mathbb{R}^{V \times V}_+ : J^Q = J\} \ni Q \rightarrow Q^T \in \{Q \in \mathbb{R}^{V \times V}_+ : J^Q = -J\}
$$

is bijective. The above observation, Proposition 4.1 and Theorem 4.2 imply immediately the following fact:

**Theorem 4.4.** (Fluctuation theorems for $\tilde{I}$ and for $I$)

The joint LD rate function $\tilde{I}$ for $(\mu_t, J_t)$ satisfies

$$
\tilde{I}(\mu, J) = \tilde{I}(\mu, -J) - \frac{1}{2} \sum_{(x,y) \in E} J(x, y) \ln \frac{p_{x,y}}{p_{y,x}},
$$

(27)

for any $\mu \in \mathcal{P}(V \times (0, +\infty])$ and $J \in \mathbb{R}^{V \times V}_+.$

Similarly, the LD rate function $I$ for $J_t$ satisfies

$$
I(J) = I(-J) - \frac{1}{2} \sum_{(x,y) \in E} J(x, y) \ln \frac{p_{x,y}}{p_{y,x}},
$$

(28)

for any $J \in \mathbb{R}^{V \times V}_+.$

We recall that the identities (27) and (28) have to be thought in $(-\infty, +\infty]$.

5. **Fluctuation theorem for the empirical current along chords**

Considering e.g. applications to biochemical processes (see e.g. [1] [2] [7] [8] [14] [15] and references therein), it is relevant to extend the above analysis to generalized empirical currents along cycles (or equivalently, chords).

Again we assume condition (17). Recall (18). We consider the unoriented graph $G$ with vertex set $V$ and edges

$$
E = \{(x, y) : x \neq y, (x, y) \in E\} = \{(x, y) : x \neq y, p_{x,y} > 0, p_{y,x} > 0\}.
$$

Due to our irreducibility assumption on the transition kernel $p_{x,y}$, the graph $G$ is connected.

An oriented cycle $C$ in $G$ is given by a sequence $(z_1, \ldots, z_s)$ of vertexes in $V$ such that $(z_i, z_{i+1}) \in E$, with the convention that $z_{s+1} := z_1$. To the oriented cycle $C$ we associate the affinity $A(C)$ defined as

$$
A(C) = \sum_{i=1}^s \ln \frac{p_{z_i, z_{i+1}}}{p_{z_{i+1}, z_i}}.
$$

(29)
Fix once and for all an unoriented spanning tree $T$ in $G$, i.e. a subgraph of the unoriented graph $G$ without loops and such that any $x \in V$ is also a vertex of $T$. We recall that the edges of $G$ that do not belong to $T$ are called chords. For each chord choose once and for all an orientation, and denote by $c_1, \ldots, c_m$ the oriented chords of $G$. It is known that for each $k = 1, \ldots, m$ there is a unique self-avoiding oriented cycle $C_k$ starting with the oriented edge $c_k$ and lying inside the graph obtained from $T$ by adding the edge $c_k$. More precisely, there is a unique cycle $C_k = (z_1, \ldots, z_s)$ such that $z_1, \ldots, z_s$ are all distinct vertexes of $V$, $(z_1, z_2) = c_k$ and $(z_i, z_{i+1})$ is an edge of $T$ when disregarding the orientation for all $i = 2, \ldots, s$ (with the convention that $z_{s+1} := z_1$).

To each $C_k = (z_1, \ldots, z_s)$ we associate a special current $J_k \in \mathbb{R}^{V \times V}_{\text{antis.}}$ as follows:

\[
J_k(x, y) := \begin{cases} 
1 & \text{if } (x, y) = (z_i, z_{i+1}) \text{ for some } i = 1, \ldots, s, \\
-1 & \text{if } (y, x) = (z_i, z_{i+1}) \text{ for some } i = 1, \ldots, s, \\
0 & \text{otherwise}. 
\end{cases} 
\]  

(30)

Trivially, $\text{div} J_k = 0$ and $J_k(x, y) = 0$ if $p_{x, y} = 0$ (i.e. if $(x, y) \notin E$).

The following fact is a direct consequence of Lemma 9.3 in [3]:

**Proposition 5.1.** Let $J \in \mathbb{R}^{V \times V}_{\text{antis.}}$ be such that $\text{div} J = 0$ and $J(e) = 0$ for any $e \notin E$. Then $J = \sum_{k=1}^m J(c_k) J_k$.

As consequence only of (28) in Theorem 4.4 and the decomposition given in Proposition 5.1 we get:

**Theorem 5.2.** Under $\mathbb{P}_\gamma$ the random vector $(J_1(c_1), J_1(c_2), \ldots, J_1(c_m))$ satisfies a LDP with speed $t$ and good rate function $\tilde{I}$ satisfying

\[
\tilde{I}(\vartheta_1, \ldots, \vartheta_m) = \tilde{I}(-\vartheta_1, \ldots, -\vartheta_m) - \sum_{k=1}^m \vartheta_k A(C_k). 
\]  

(31)

**Remark 5.3.** Having Theorem 4.4 one can easily derived a fluctuation theorem for generalized algebraic currents as in [7], i.e. currents associated to a basis $c_1, \ldots, c_m$ of the cycle space where the cycles $C_1, \ldots, C_m$ are not necessarily built from a spanning tree as above. We refer to [11,1] [3,7] for an overview on cycle theory, currents along cycles and physical implications, that still hold for DTI semi-Markov processes due to Theorem 5.2.

**Proof of Theorem 5.2.** The map $\mathbb{R}^{V \times V}_{\text{antis.}} \ni J \mapsto (J(c_1), \ldots, J(c_m)) \in \mathbb{R}^m$ is continuous. As a consequence of the contraction principle and the LDP stated in Theorem 4.4 we have that, under $\mathbb{P}_\gamma$, the random vector $(J_1(c_1), J_1(c_2), \ldots, J_1(c_m))$ satisfies a LDP with speed $t$ and good rate function $\tilde{I}$ given by

\[
\tilde{I}(\vartheta_1, \ldots, \vartheta_m) = \inf \{ \mathcal{I}(J) : J \in W \},
\]

(32)

where

\[ W := \{ J \in \mathbb{R}^{V \times V}_{\text{antis.}} : J(c_k) = \vartheta_k \forall k = 1, \ldots, m \}. \]

Recall the definition of $J_k$ given in (30). We claim that the above infimum in (32) is indeed a minimum attained at $J_* = \sum_{k=1}^m \vartheta_k J_k$, i.e. $\tilde{I}(\vartheta_1, \ldots, \vartheta_m) = \tilde{I}(J_*)$. Since $J(c_k) = \delta_{k,i}$, it is simple to check that $J_*$ belongs to $W$. Take now a generic $J \in W$. Due to Remark 4.3 $\mathcal{I}(J) = +\infty$ if $\text{div} J \neq 0$ or if $J(e) \neq 0$ for some $e \notin E$. On the other hand, by Proposition 5.1 the only element $J \in W$ for which $\text{div} J = 0$ and $J(e) = 0$ for all $e \notin E$ is $J_*$, thus proving our claim.
By the previous observation we also have \( \hat{I}(-\vartheta_1, \ldots, -\vartheta_m) = \hat{I}(-J_\ast) \). Hence, as a consequence of [23], we have

\[
\hat{I}(\vartheta_1, \ldots, \vartheta_m) = \hat{I}(-\vartheta_1, \ldots, -\vartheta_m) - \frac{1}{2} \sum_{(x,y) \in E} J_\ast(x, y) \ln \frac{p_{x,y}}{p_{y,x}}.
\]

To conclude we observe that

\[
\frac{1}{2} \sum_{(x,y) \in E} J_\ast(x, y) \ln \frac{p_{x,y}}{p_{y,x}} = \frac{1}{2} \sum_{k=1}^m \vartheta_k \sum_{(x,y) \in E} J_k(x, y) \ln \frac{p_{x,y}}{p_{y,x}}
\]

and that, if \( C_k = (z_1, \ldots, z_s) \),

\[
\frac{1}{2} \sum_{(x,y) \in E} J_k(x, y) \ln \frac{p_{x,y}}{p_{y,x}} = \sum_{i=1}^s \frac{1}{2} \left[ J_k(z_i, z_{i+1}) \ln \frac{p_{z_i,z_{i+1}}}{p_{z_{i+1},z_i}} + J_k(z_{i+1}, z_i) \ln \frac{p_{z_{i+1},z_i}}{p_{z_i,z_{i+1}}} \right] = A(C_k).
\]

6. Extended fluctuation theorem for the empirical current of generic semi–Markov processes

We conclude by discussing some extension of the above analysis to generic semi–Markov processes. Again we assume (17), i.e.

\[
p_{x,y} > 0 \quad \text{if and only if} \quad p_{y,x} > 0,
\]

and we introduce the set \( E \) according to (18).

Recall the notation introduced in Subsection 2.2 and in particular the process \( \mathbb{Y} := (\mathbb{Y}_t)_{t \geq 0} \) which is a DTI semi–Markov process with state space \( E \). To \( \mathbb{Y} \) one can apply Fact 3.1. On the other hand, \( \mathbb{Y} \) does not belong to the range of application of Theorems 4.2 and 1.4 since, given states \( x, y, z \) in \( V \) with \( x \neq z \) and \( (x, y), (y, z) \in E \), we have that \( \hat{p}_{(x,y),(y,z)} > 0 \) but \( \hat{p}_{(y,z),(y,x)} = 0 \).

**Proposition 6.1.** Consider the LDP rate functional \( I(\mu, Q) \) of Fact 3.1 referred to the semi–Markov process \( \mathbb{Y} \) on \( E \) with dynamical parameters \( \psi_{x,y} \) and \( \hat{p}_\ast \). In particular, \( \mu \in \mathcal{P}(E \times (0, +\infty)) \) and \( Q \in \mathbb{R}^{E \times E}_+ \). Let \( I_\ast(\mu, Q) \) be the LDP rate functional of Fact 3.1 referred to the semi–Markov process \( \mathbb{Y}_\ast \) on \( E \) with dynamical parameters \( \psi_{x,y}^\ast := \psi_{y,x} \) and \( \hat{p}_\ast \). Then

\[
I(\mu, Q) = I_\ast(\mu_\ast, Q_\ast) - \frac{1}{2} \sum_{(x,y) \in E} [\mathcal{K}^Q(x, y) - \mathcal{K}^Q(y, x)] \ln \frac{p_{x,y}}{p_{y,x}}, \quad (33)
\]

where

\[
\mu_\ast((x, y), d\tau) := \mu((y, x), d\tau),
\]

\[
Q_\ast((x, y), (z, v)) := Q((v, z), (y, x)),
\]

\[
\mathcal{K}^Q(x, y) := \sum_{z \in V} Q((x, y), (y, z)).
\]

**Proof.** To simplify notation we write \( \mu(xy, d\tau) \) instead of \( \mu((x, y), d\tau) \), \( Q(xy, vz) \) instead of \( Q((x, y), (v, z)) \) and similarly for \( \mu_\ast \), \( Q_\ast \). In general, we will write often \( xy \) instead of \( (x, y) \).

Note that, given \( (x, y) \in E \) and \( (v, z) \in E \), it holds \( \hat{p}_{(x,y),(v,z)} > 0 \) if and only if \( y = v \). Assume now that \( Q(xy, vz) > 0 \) for some \( (x, y), (v, z) \in E \) with \( y \neq v \). As a first
Since assumption, we have \( I_x (\mu_*, Q_*) = +\infty \) by Remark 1.3. On the other hand, under the same assumption, we have \( Q_x (\hat{w}, yz) = Q(yz, yx) > 0 \) and \( (z, y) \in E, (y, x) \in E, y \neq v \), thus implying that \( I_x (\mu_*, Q_*) = +\infty \) by the same arguments used above. Hence, under the above assumption, (33) is trivially satisfied.

From now on we assume that \( Q(yz, yx) = 0 \) for any \((x, y), (v, z) \in E \) with \( y \neq v \), and similarly for \( Q_x \).

We first claim that \( (\mu, Q) \in A_0 \) if and only if \( (\mu, Q) \in \Lambda_0^* \) (\( \Lambda_0^* \) being the analogous of \( \Lambda_0 \) for the semi–Markov process \( Y_* \) on \( E \) with dynamical parameters \( \psi_{x,y} \) and \( \hat{\mu} \)). We prove the claim. Trivially \( \mu(yx, d\tau) \ll \psi_{x,y} (d\tau) \) for any \( (x, y) \in E \) if and only if \( \mu^*(xy, d\tau) \ll \psi_{x,y}^* (d\tau) \) for any \( (x, y) \in E \). Suppose that \( (\mu, Q) \in \Lambda_0 \). Then, by definition of \( \Lambda_0 \), for any \( (x, y) \in E \) it holds

\[
Z_{xy} := \int_{(0, +\infty)} \mu(x, y, d\tau) \frac{1}{\tau} = \sum_z Q(x, y, z) = \sum_z Q(z, x, y).
\]

(34)

Since \( Z_{xy}^* := \int_{(0, +\infty)} \mu_*(y, x, d\tau) \frac{1}{\tau} = \int_{(0, +\infty)} \mu(x, y, d\tau) \frac{1}{\tau} =: Z_{xy}, \) the above identity (34) can be rewritten as

\[
Z_{xy}^* = \int_{(0, +\infty)} \mu_*(y, x, d\tau) \frac{1}{\tau} = \sum z Q_*(y, x, z) = \sum z Q_*(x, y, z),
\]

(35)

thus completing the proof that \( (\mu_*, Q_*) \in \Lambda_0^* \). By the same arguments one gets that \( (\mu, Q) \in \Lambda_0 \) if \( (\mu_*, Q_*) \in \Lambda_0^* \), concluding the derivation of the claim.

Due to the above claim we can restrict to the case \( (\mu, Q) \in \Lambda_0 \) and \( (\mu_*, Q_*) \in \Lambda_0^* \) (otherwise, (33) reads \(+\infty = +\infty \) which is trivially true).

Since \( Z_{xy}^* = Z_{yx} \), we have \( \hat{\mu}_*(xy, d\tau) = \hat{\mu}(yx, d\tau) \) (recall the notation in (9)). This implies that \( H(\hat{\mu}_*(xy, d\tau)|\psi_{x,y}^*) = H(\hat{\mu}(yx, d\tau)|\psi_{yx}) \), and therefore that

\[
\sum_{(x,y) \in E} Z_{xy}^* H(\hat{\mu}_*(xy, d\tau)|\psi_{xy}^*) = \sum_{(y,z) \in E} Z_{yz} H(\hat{\mu}(yx, d\tau)|\psi_{yx}).
\]

(36)

Since moreover \( \xi_{xy}^* = \xi_{yx} \) (recall (12)) we have

\[
\sum_{(x,y) \in E} Z_{xy}^* \xi_{xy}^* \mu_*(xy, \{+\infty\}) = \sum_{(x,y) \in E} Z_{yx} \xi_{yx} \mu(yx, \{+\infty\}).
\]

(37)

Due to (36), (37) and Fact 3.1 we conclude that

\[
I(\mu, Q) = I_x (\mu_*, Q_*) + \sum_{(x,y) \in E} Z_{xy} H(\hat{\mu}_*(xy, |\hat{\mu}_y), \mu_*) - \sum_{(x,y) \in E} Z_{xy} H(\hat{\mu}_y, |\hat{\mu}_y, \mu_*)
\]

\[
= I_x (\mu_*, Q_*) - \sum_{(x,y,z) \in F} Q(x, y, z) \ln(Z_{xy} p_{y,z}) + \sum_{(x,y,z) \in F} Q^*(x, y, z) \ln(Z_{xy} p_{y,z})
\]

(38)

where

\[
F = \{(x, y, z) : (x, y) \in E, (y, z) \in E\}.
\]

Note that \( (x, y, z) \in F \) if and only if \( (z, y, x) \in F \).
Recall (34) and (35). They imply
\[
\sum_{(x,y,z) \in F} Q(xy, yz) \ln Z_{xy} = \sum_{(x,y) \in E} Z_{xy} \ln Z_{xy},
\]
(39)
\[
\sum_{(x,y,z) \in F} Q(x, yz) \ln p_{yz} = \sum_{(y,z) \in E} Z_{yz} \ln p_{yz},
\]
(40)
\[
\sum_{(x,y,z) \in F} Q^*(x, yz) \ln Z_{xy}^* = \sum_{(y,x) \in E} Z_{yx} \ln Z_{yx},
\]
(41)
\[
\sum_{(x,y,z) \in F} Q^*(x, yz) \ln p_{yz} = \sum_{(y,z) \in E} Z_{yz} \ln p_{yz}.
\]
(42)

Coming back to (38) we get
\[
I(\mu, Q) = I_*(\mu_*, Q_*) - (39) - (40) - (41) + (42) = I_*(\mu_*, Q_*) - (40) + (42)
\]
\[
= I_*(\mu_*, Q_*) - \sum_{(y,z) \in E} (Z_{yz} - Z_{zy}) \ln p_{yz}.
\]

To conclude it is enough to observe that
\[
\sum_{(y,z) \in E} (Z_{yz} - Z_{zy}) \ln p_{yz} = \frac{1}{2} \sum_{(y,z) \in E} (Z_{yz} - Z_{zy}) \ln p_{yz} + \sum_{(y,z) \in E} (Z_{zy} - Z_{yz}) \ln p_{yz}
\]
\[
= \frac{1}{2} \sum_{(y,z) \in E} (Z_{yz} - Z_{zy}) \ln \frac{p_{yz}}{p_{zy}},
\]
and observe that \( K^Q(y, z) = Z_{yz}, K^Q(z, y) = Z_{zy} \) by (33).

**Theorem 6.2.** The empirical current \( J_t \) of the generic semi–Markov process \( X \) on \( V \) with dynamical parameters \( p_{x,y} \) and \( \psi_{x,y} \) satisfies a LDP with speed \( t \) and good rate function \( \mathcal{I}(J) \). Writing \( \mathcal{I}_*(J) \) for the rate function obtained when replacing \( \psi_{x,y} \) with \( \psi_{x,y}^* := \psi_{y,x} \), we have
\[
\mathcal{I}(J) = \mathcal{I}_*(-J) - \frac{1}{2} \sum_{(x,y) \in E} J(x, y) \ln \frac{p_{xy}}{p_{yx}}.
\]
(43)

**Proof.** Let us write \( Q^X_t \) for the empirical flow associated to \( (X_t)_{t \geq 0} \) and \( Q^Y_t \) for the empirical flow associated to \( (Y_t)_{t \geq 0} \). We have \( Q^X_t(x, y) = \sum_z Q^Z_t(xy, yz) + O(1/t) \). Hence, we get the LDP of \( Q^X_t \) with a good rate function from the LDP of \( Q^Y_t \) with a good rate function (the latter holds by contraction due to Fact 3.1 and since \( Y \) is a DTI semi–Markov process).

Since \( J_t(x, y) = Q^X_t(x, y) - Q^Y_t(x, y) \), by contraction we get that the LDP of \( J_t \) with a good rate function.

We observe now that
\[
J_t(x, y) = Q^X_t(x, y) - Q^X_t(y, x) = \sum_z Q^Y_t((x, y), (y, z)) - \sum_z Q^Y_t((z, y), (y, x)) + O(1/t).
\]
As a consequence of (33) and the above identity we get (43).

By combining Theorem 6.2 with (28) in Theorem 4.4 we have

**Corollary 6.3.** In the same context of Theorem 6.3, under the DTI condition (i.e. \( \psi_{x,y} = \psi_x \) for all \( x, y \)), we have
\[
\mathcal{I}(J) = \mathcal{I}_*(J).
\]
