{saurabh, cmurthy}@iisc.ac.in

Abstract—The columnwise Khatri-Rao product of two matrices is an important matrix type, reprising its role as a structured sensing matrix in many fundamental linear inverse problems. Robust signal recovery in such inverse problems is often contingent on proving the restricted isometry property (RIP) of a certain system matrix expressible as a Khatri-Rao product of two matrices. In this work, we analyze the RIP of a generic columnwise Khatri-Rao product matrix by deriving two upper bounds for its $k^{th}$ order Restricted Isometry Constant ($k$-RIC) for different values of $k$. The first RIC bound is computed in terms of the individual RICs of the input matrices participating in the Khatri-Rao product. The second RIC bound is probabilistic, and is specified in terms of the input matrix dimensions. We show that the Khatri-Rao product of a pair of $m \times n$ sized random matrices comprising independent and identically distributed subgaussian entries satisfies $k$-RIP with arbitrarily high probability, provided $m \propto (k \log n)$. Our RIC bounds confirm that the Khatri-Rao product exhibits stronger restricted isometry compared to its constituent matrices for the same RIP order. The proposed RIC bounds are potentially useful in the sample complexity analysis of several sparse recovery problems.

Index Terms—Khatri-Rao product, Kronecker product, compressive sensing, Restricted isometry property, covariance matrix estimation, multiple measurement vectors, PARAFAC, CANDECOMP, direction of arrival estimation.

I. INTRODUCTION

The Khatri-Rao product, denoted by the symbol $\odot$, is a columnwise Kronecker product, which was originally introduced by Khatri and Rao in [1]. For any two matrices $A = [a_1, a_2, \ldots, a_p]$ and $B = [b_1, b_2, \ldots, b_p]$ of sizes $m \times p$ and $n \times p$, respectively, the columnwise Khatri-Rao product $A \odot B$ is a matrix of dimension $mn \times p$ defined as

$$A \odot B = [a_1 \odot b_1, a_2 \odot b_2, \ldots, a_p \odot b_p],$$

where $a \odot b$ denotes the Kronecker product between vectors $a$ and $b$. That is, each column of $A \odot B$ is the Kronecker product between the respective columns of the two input matrices $A$ and $B$. In this article, we shall refer to the columnwise Khatri-Rao product as simply the Khatri-Rao product or the KR product. Since the Kronecker product $A \otimes B$ comprises all pairwise Kronecker product combinations of the columns of the input matrices, it can be shown that $A \otimes B = (A \odot B)J$, where $J$ is a $p^2 \times p$ selection matrix with columns as a subset of the standard basis in $\mathbb{R}^{p^2}$ [2].

Khatri-Rao product matrices are encountered in several linear inverse problems of fundamental importance. Recent examples include compressive sensing [3], covariance matrix estimation [4], [5], direction of arrival estimation [6] and tensor decomposition [7]. In these examples, the KR product $A \odot B$, for certain $m \times n$ sized system matrices $A$ and $B$, plays the role of the sensing matrix used to generate linear measurements $y$ of an unknown signal vector $x$ according to

$$y = (A \otimes B)x + w, \quad (2)$$

where $w$ represents the additive measurement noise. It is now well established in the sparse signal recovery literature [8]–[12] that, if the signal of interest, $x$, is a $k$-sparse vector in $\mathbb{R}^m$, it can be stably recovered from its noisy underdetermined linear observations $y \in \mathbb{R}^{m^2}(m^2 < n)$ in a computationally efficient manner provided that the sensing matrix (here, $A \odot B$) satisfies the restricted isometry property defined next.

A matrix $\Phi \in \mathbb{R}^{m \times n}$ is said to satisfy the Restricted Isometry Property (RIP) [3] of order $k$, if there exists a constant $\delta_k(\Phi) \in (0, 1)$ such that for all $k$-sparse vectors $z \in \mathbb{R}^n$,

$$(1 - \delta_k(\Phi))||z||^2_2 \leq ||\Phi z||^2_2 \leq (1 + \delta_k(\Phi))||z||^2_2. \quad (3)$$

The smallest constant $\delta_k(\Phi)$ for which (3) holds for all $k$-sparse $z$ is called the $k^{th}$ order restricted isometry constant or the $k$-RIC of $\Phi$. Matrices with small $k$-RICs are good encoders for storing/sketching high dimensional vectors with $k$ or fewer nonzero entries [14]. For example, $\delta_k(A \otimes B) < 0.307$ is a sufficient condition for a unique $k$-sparse solution to (3) in the noiseless case, and its perfect recovery via the $\ell_1$ minimization technique [15]. As pointed out earlier, in many structured signal recovery problems, the main sensing matrix can be expressed as a columnwise Khatri-Rao product between two matrices. Thus, from a practitioner’s viewpoint, it is pertinent to study the restricted isometry property of a columnwise Khatri-Rao product matrix, which is the focus of this work.

A. Applications involving Khatri-Rao matrices

We briefly discuss some examples where it is required to show the restricted isometry property of a KR product matrix.

1) Support recovery of joint sparse vector from underdetermined linear measurements: Suppose $x_1, x_2, \ldots, x_L$ are unknown joint sparse signals in $\mathbb{R}^n$ with a common $k$-sized support denoted by an index set $S$. A canonical problem in multi-sensor signal processing is concerned with the recovery of the common support $S$ of the unknown signals from their noisy underdetermined linear measurements $y_1, y_2, \ldots, y_L \in \mathbb{R}^m$ generated according to

$$y_j = Ax_j + w_j, \quad 1 \leq j \leq L, \quad (4)$$

$^1$A vector is said to be $k$-sparse if at most $k$ of its entries are nonzero.
where \( A \in \mathbb{R}^{m \times n} (m < n) \) is a known measurement matrix, and \( w_j \in \mathbb{R}^n \) models the noise in the measurements. This problem arises in many practical applications such as MIMO channel estimation, cooperative wideband spectrum sensing in cognitive radio networks, target localization, and direction of arrival estimation. In [16], the support set \( S \) is recovered as the support of \( \gamma \), the solution to the Co-LASSO problem:

\[
\text{Co-LASSO:} \quad \min_{\gamma \geq 0} \left\| \text{vec}(\mathbf{R}_{yy}) - (A \circ A)\gamma \right\|_2^2 + \lambda \|\gamma\|_1,
\]

where \( \mathbf{R}_{yy} \triangleq \frac{1}{L} \sum_{j=1}^L y_j y_j^T \). From compressive sensing theory [11], the RIP of \( A \circ A \) (also called the self Khatri-Rao product of \( A \)) determines the stability of the sparse solution in the Co-LASSO problem.

In M-SBL [17], a different support recovery algorithm, \( A \circ A \) satisfying 2k-RIP can guarantee exact recovery of \( S \) from multiple measurements [13].

2) Sparse sampling of stationary graph signals: Let \( x = [x_1, x_2, \ldots, x_L]^T \in \mathbb{C}^n \) be a stochastic, zero mean and second-order stationary graph signal defined on \( n \) vertices of a graph \( G \). This implies that the graph signal \( x \) can be modeled as \( x = H \mathbf{n} \), where \( H \) is any valid graph filter [19], and \( n \sim \mathcal{N}(0, I_n) \). The covariance matrix \( \mathbf{R}_{xx} = \mathbb{E}[xx^H] \) can then be expressed as

\[
\mathbf{R}_{xx} = HH^H = U\text{diag}(p)U^H,
\]

where the nonnegative vector \( p \) refers to the graph power spectral density of the stationary graph signal \( x \) and the columns of \( U \) serve as Fourier like orthonormal basis for the graph signal.

As motivated in [19], in many applications, we are interested in reconstructing the sparse graph power spectral density \( p \) by observing a small subset of the graph vertices. Let \( y_1, y_2, \ldots, y_L \) denote the \( L \) independent observations of the subsampled graph signal \( x \), i.e.,

\[
y_j = \Phi x_j, \quad 1 \leq j \leq L,
\]

where \( \Phi \in \{0,1\}^{m \times n} \) is referred to as a binary subsampling matrix with \( ml(n \ll n) \) rows, each row containing exactly one nonzero unity element. To recover the graph power spectral density \( p \) from the subsampled observations, we note that

\[
\frac{1}{L} \sum_{j=1}^L y_j y_j^H \approx \Phi \mathbf{R}_{xx} \Phi^T = \Phi U\text{diag}(p)U^H \Phi^T
\]

or,

\[
\text{vec} \left( \frac{1}{L} \sum_{j=1}^L y_j y_j^T \right) \approx (\Phi^* \circ \Phi^T)p,
\]

the superscript \( * \) denoting conjugation without transpose. Here again, the Khatri-Rao product \( \Phi^* \circ \Phi^T \) satisfying RIP of order \( 2r \) guarantees a unique \( r \)-sparse solution for \( p \) in [18].

3) PARAFAC model for low-rank three-way arrays: Consider an \( I \times J \times K \) tensor \( X \) of rank \( r \). We can express \( X \) as the sum of \( r \) rank-one three way arrays as \( X = \sum_{z=1}^r a_z \circ b_z \circ c_z \), where \( a_z, b_z, c_z \) are loading vectors of dimension \( I, J, K \), respectively, and \( \circ \) denotes the vector outer product. The tensor \( X \) itself can be arranged into a matrix as \( X = [\text{vec}(X_1), \text{vec}(X_2), \ldots, \text{vec}(X_K)] \). In the parallel factor analysis (PARAFAC) model [20], the matrix \( X \) can be approximated as

\[
X \approx (A \circ B)C^T,
\]

where \( A, B \) and \( C \) are the loading matrices with columns as the loading vectors \( a_z, b_z, c_z \), respectively. In many problems such as direction of arrival estimation using a 2D-antenna array, the loading matrix \( C \) turns out to be row-sparse matrix [21]. In such cases, the uniqueness of the PARAFAC model shown in [9] depends on the restricted isometry property of the Khatri-Rao product \( A \circ B \).

Finding the exact \( k \)-th order RIC of a given matrix \( X \) entails computation of extreme singular values of all possible \( k \)-column submatrices of \( X \), which is an NP hard task [22]. In this work, we follow an alternative approach to analyzing the RIP of a KR product matrix. We seek to derive tight upper bounds for its restricted isometry constants.

B. Related Work

Perhaps the most direct approach for analyzing the RICs of the KR product matrix is to use the eigenvalue interlacing theorem [23], which relates the singular values of any \( k \)-column submatrix of the KR product between two matrices to the singular values of their Kronecker product. This is possible because any \( k \) columns of the KR product can together be interpreted as a submatrix of the Kronecker product. However, barring the maximum and minimum singular values of the Kronecker product, there is no available explicit characterization of its non-extremal singular values that can be used to obtain tight bounds for the \( k \)-RIC of the KR product. Bounding the RIC using the extreme singular values of the Kronecker product matrix turns out to be too loose to be useful. In this context, it is noteworthy to mention that an upper bound for the \( k \)-RIC of the Kronecker product is derived in terms of the \( k \)-RICs of the input matrices in [4], [24]. However, the \( k \)-RIC of the Khatri-Rao product is yet to be analyzed.

Recently, [25], [26] gave probabilistic lower bounds for the minimum singular value of the columnwise KR product between two or more matrices. These bounds are limited to randomly constructed input matrices, and are polynomial in the matrix size. In [27], it is shown that for any two matrices \( A \) and \( B \), the Kruskal-rank [9] of \( A \circ B \) has a lower bound in terms of K-rank(\( A \)) and K-rank(\( B \)). In fact, K-rank(\( A \circ B \)) is at least as high as \( \min \{ \text{K-rank}(A), \text{K-rank}(B) \} \), thereby suggesting that \( A \circ B \) exhibits a stronger restricted isometry property than both \( A \) and \( B \).

A closely related yet weaker notion of restricted isometry constant is the \( \tau \)-robust K-rank, denoted by K-rank\(_\tau \). For a given matrix \( \Phi \), the K-rank\(_\tau \) is defined as the largest \( k \) for which every \( n \times k \) submatrix of \( \Phi \) has its smallest singular value larger than \( 1/\tau \). In [25], it is shown that the \( \tau \)-robust K-rank is super-additive, implying that the K-rank\(_\tau \) of the Khatri-Rao product is strictly larger than individual K-rank\(_\tau \)'s of the input matrices.

The Kruskal rank or K-rank of any matrix \( A \) is the largest integer \( r \) such that any \( r \) columns of \( A \) are linearly independent.
In [7], the isometry property of the Kronecker product $A \otimes B$ is analyzed in the $\ell_1$-norm sense for the restricted class of input vectors expressible as vectorized $\delta$-distributed sparse matrices, wherein, $A$ and $B$ are the adjacency matrices of two independent uniformly random $\delta$-left regular bipartite graphs. In this paper, we instead analyze the restricted isometry of the columnwise Khatri-Rao product $A \odot B$, which is equivalent to the RIP of the Kronecker product $A \otimes B$ with respect to vectorized sparse diagonal matrices. In our work, we assume that input matrices $A$ and $B$ are random with independent subgaussian elements.

C. Main Contributions

We derive two kinds of upper bound on the $k$-RIC of the columnwise Khatri-Rao product of $m \times n$ sized matrices $A$ and $B$. The bounds are briefly described below.

1) A deterministic upper bound for the $k$-RIC of $A \otimes B$ in terms of the $k$-RICs of the input matrices $A$ and $B$. The bound is valid for $k \leq m$, and for input matrices with unit $\ell_2$-norm columns.

2a) A probabilistic upper bound for the $k$-RIC of $A \otimes B$ in terms of $m, n$ and $k$, for real valued random matrices $A, B$ containing i.i.d. subgaussian elements. The probabilistic bound is polynomially tight with respect to the input matrix dimension $n$.

2b) A probabilistic upper bound for the $k$-RIC of the self KR product $A \odot A$ in terms of $m, n$, and $k$, where $A$ is a real valued matrix containing i.i.d. subgaussian elements.

A key idea used in our RIC analysis is the fact (stated formally as Proposition [12]) that given any two matrices $A$ and $B$, the Gram matrix of their Khatri-Rao product $(A \odot B)^H (A \odot B)$ can be interpreted as the Hadamard product (element wise multiplication) between Gram matrices $A^H A$ and $B^H B$. The Hadamard product form turns out to be more analytically tractable than columnwise Kronecker product form of the KR matrix.

In light of this, our proposed RIC bounds are quite timely, and pave the way towards obtaining order-wise sample complexity bounds in several fundamental learning problems.

The rest of this article is organized as follows. In Secs. II and III we present our main results: deterministic and probabilistic RIC bounds, respectively, for a generic columnwise KR product matrix. Sec. II also discusses about the RIP of the self Khatri-Rao product of a matrix with itself, an important matrix type encountered in the sparse diagonal covariance matrix estimation problem. In Secs. IV and V we present some background concepts required for proving the proposed RIC bounds. Secs. IV and VII provide the detailed proofs of the deterministic and probabilistic RIC bounds, respectively. Final conclusions are presented in Sec. VIII.

Notation: In this work, bold lowercase letters are used for representing both scalar random variables as well as vectors. Bold uppercase letters are reserved for matrices. The $\ell_2$-norm of a vector $x$ is denoted by $\|x\|_2$. For an $m \times n$ matrix $A$, $\|A\|$ denotes its operator norm, $\|A\| \equiv \sup_{x \in \mathbb{R}^n, x \neq 0} \frac{|Ax|_2}{\|x\|_2}$. The Hilbert-Schmidt (or Frobenius) norm of $A$ is defined as $\|A\|_{HS} = \sum_{i=1}^m \sum_{j=1}^n |A_{ij}|^2$. The symbol $[n]$ denotes the index set $\{1, 2, \ldots, n\}$. For any index set $S \subseteq [n]$, $A_S$ denotes the submatrix comprising the columns of $A$ indexed by $S$. The matrices $A \otimes B$, $A \odot B$ and $A \odot B$ denote the Kronecker product, Hadamard product and columnwise Khatri-Rao product of $A$ and $B$, respectively. $A \leq B$ implies that $B - A$ is a positive semidefinite matrix. $A^T$, $A^H$, $A^{-1}$, and $A^\odot$ denote the transpose, conjugate-transpose, inverse and generalized matrix inverse operations of $A$, respectively. $\mathbb{E}(x)$ denotes the expectation of the random variable $x$. $\mathbb{P}(E)$ denotes the probability of event $E$. $\mathbb{P}(E|E')$ denotes the conditional probability of event $E$ given event $E'$ has occurred.

II. DETERMINISTIC $k$-RIC BOUND

In this section, we present our first upper bound on the $k$-RIC of a generic columnwise KR product $A \odot B$, for any two same-sized matrices $A$ and $B$ with normalized columns. The bound is given in terms of the $k$-RICs of $A$ and $B$.

Theorem 1. Let $A$ and $B$ be $m \times n$ sized real-valued matrices with unit $\ell_2$-norm columns and satisfying the $k^\text{th}$ order restricted isometry property with constants $\delta_A^k$ and $\delta_B^k$, respectively. Then, their columnwise Khatri-Rao product $A \odot B$ satisfies the restricted isometry property with $k$-RIC at most $\delta^k$, where $\delta^k \geq (\delta_A^k \delta_B^k)$, i.e.,

\[
(1 - \delta^2)\|z\|_2^2 \leq \|(|A \odot B)z\|_2^2 \leq (1 + \delta^2)\|z\|_2^2
\]

holds for all $k$-sparse vectors $z \in \mathbb{R}^n$.

Proof. The proof is provided in Section VII. \hfill $\Box$

Remark 1: The RIC bound for $A \odot B$ in Theorem 1 is relevant only when $\delta_A^k (A)$ and $\delta_B^k (B)$ lie in $(0, 1)$, which is true only for $k \leq m$. In other words, the above $k$-RIC characterization for $A \odot B$ requires the input matrices $A$ and $B$ to be $k$-RIP compliant.

Remark 2: Since the input matrices $A$ and $B$ satisfy $k$-RIP with $\delta_A^k (A), \delta_B^k (B)$ in $(0, 1)$, it follows from Theorem 1 that $\delta_k (A \odot B)$ is strictly smaller than $\max(\delta_k (A), \delta_k (B))$. If $B = A$, the special case of self Khatri-Rao product $A \odot A$ arises, for which

\[
\delta_k (A \odot A) < \delta_k^2 (A) \tag{11}
\]

Above implies that the self Khatri-Rao product $A \odot A$ is a better restricted isometry compared to $A$ itself. This observation is in alignment with the expanding Kruskal rank and shrinking mutual coherence of the self Khatri-Rao product reported in [16]. In fact, for $k = 2$, the 2-RIC bound [11] exactly matches the mutual coherence bound shown in [16].

For $k \in (m, m^2]$, using (28), Theorem 1), one can show that $\delta_k (A \odot B) \leq \left(\sqrt{k} + 1\right) \delta_k \sqrt{\kappa}$, where $\delta_k \sqrt{\kappa} = \max \left(\delta_k (A), \delta_k (B)\right)$. This bound, however, loses its tightness and quickly becomes unattractive for larger values of $k$. Finding a tighter $k$-RIC upper bound for the $k > m$ case remains an open problem.
normalized sensing matrices is commonplace in compressive sensing, we are often interested in showing the restricted isometry of the Khatri-Rao product of randomly constructed input matrices with columns being normalized only in the average sense. This concern is addressed by our second RIC bound which is of probabilistic type and is applicable to the columnwise KR product of random input matrices containing i.i.d. subgaussian entries. Below, we define a subgaussian random variable and state some of its properties.

Definition 1. (Subgaussian Random Variable): A zero mean random variable $\mathbf{x}$ is called subgaussian, if its tail probability is dominated by that of a Gaussian random variable. In other words, there exist constants $C, K > 0$ such that $P(|\mathbf{x}| \geq t) \leq Ce^{-t^2/K^2}$ for $t > 0$.

Gaussian, Bernoulli and all bounded random variables are subgaussian random variables. For a subgaussian random variable, its $p^{th}$ order moment grows no faster than $O(p^{p/2})$ [50]. In other words, there exists $K_1 > 0$ such that

$$
\left( \mathbb{E} |\mathbf{x}|^p \right)^{\frac{1}{p}} \leq K_1 \sqrt{p}, \quad p \geq 1.
$$

The minimum such $K_1$ is called the subgaussian or $\psi_2$ norm of the random variable $\mathbf{x}$, i.e.,

$$
||\mathbf{x}||_{\psi_2} = \sup_{p \geq 1} p^{-1/2} \left( \mathbb{E} |\mathbf{x}|^p \right)^{\frac{1}{p}}.
$$

Given a pair of random input matrices with i.i.d. subgaussian entries, Theorem 2 presents an upper bound on the $k$-RIC of their columnwise KR product.

Theorem 2. Suppose $\mathbf{A}$ and $\mathbf{B}$ are $m \times n$ random matrices with real i.i.d. subgaussian entries, such that $\mathbb{E} \mathbf{A}_{ij} = 0$, $\mathbb{E} \mathbf{A}_{ij}^2 = 1$, and $||\mathbf{A}_{ij}||_{\psi_2} \leq \kappa$, and similarly for $\mathbf{B}$. Then, the $k^{th}$ order restricted isometry constant of $\frac{\mathbf{A}}{\sqrt{m}} \odot \frac{\mathbf{B}}{\sqrt{m}}$, denoted by $\delta_k$, satisfies $\delta_k \leq \delta$ with probability at least $1 - 10m^{-2(\gamma - 1)}$ for any $\gamma > 1$, provided that

$$
m \geq 4c\gamma \kappa_\alpha^4 \left( \frac{k \log n}{\delta} \right),
$$

where $\kappa_\alpha = \max(\kappa, 1)$ and $c$ a universal positive constant.

Proof. The proof is provided in Section VII. $\square$

The normalization constant $\sqrt{m}$ used while computing the KR product $\frac{\mathbf{A}}{\sqrt{m}} \odot \frac{\mathbf{B}}{\sqrt{m}}$ ensures that the columns of the input matrices $\frac{\mathbf{A}}{\sqrt{m}}$ and $\frac{\mathbf{B}}{\sqrt{m}}$ have unit average energy, i.e. $\mathbb{E} ||\mathbf{a}_i/\sqrt{m}||_2^2 = \mathbb{E} ||\mathbf{b}_i/\sqrt{m}||_2^2 = 1$ for $1 \leq i \leq n$. Column normalization is a key assumption towards correct modelling of the isotropic, norm-preserving nature of the effective sensing matrix $\frac{\mathbf{A}}{\sqrt{m}} \odot \frac{\mathbf{B}}{\sqrt{m}}$, an attribute desired in most sensing matrices employed in practice.

Theorem 2 implies that

$$
\delta_k \left( \frac{\mathbf{A}}{\sqrt{m}} \odot \frac{\mathbf{B}}{\sqrt{m}} \right) \leq O \left( \frac{k \log n}{m} \right)
$$

(14)

with arbitrarily high probability. Thus, the above $k$-RIC bound decreases as $m$ increases, which is intuitively appealing. Interestingly, for fixed $k$ and $n$, the above $k$-RIC upper bound for $\frac{\mathbf{A}}{\sqrt{m}} \odot \frac{\mathbf{B}}{\sqrt{m}}$ decays as $O(\frac{1}{\sqrt{m}})$. This is a significant increment.
improvement over the $O\left(\frac{1}{\sqrt{m}}\right)$ decay rate [11], already known for the individual $k$-RICs of the input subgaussian matrices $A/\sqrt{m}$ and $B/\sqrt{m}$. Thus, for any $m$, the Khatri-Rao product exhibits stronger restricted isometry property, with significantly smaller $k$-RICs compared to the $k$-RICs for the input matrices.

In some applications, the effective sensing matrix is expressible as the self-Khatri-Rao product $XX'$ of a certain system matrix $X$ with itself [15]. In Theorem 3 below, we present a $k$-RIC bound for self-Khatri-Rao matrix products.

**Theorem 3.** Let $A$ be an $m \times n$ random matrix with real i.i.d. subgaussian entries, such that $E A_{ij} = 0$, $E A_{ij}^2 = 1$, and $\| A_{ij} \|_{\psi_2} \leq \kappa$. Then, the $k$th order restricted isometry constant of the column normalized self Khatri-Rao product $A/\sqrt{m} \otimes A/\sqrt{m}$ satisfies $\delta_k \leq \delta$ with probability at least $1 - 5n^{-2(\gamma - 1)}$ for any $\gamma \geq 1$, provided

$$m \geq 4c' \gamma \kappa_o^4 \left( \frac{k \log n}{\delta} \right).$$

Here, $\kappa_o = \max(\kappa, 1)$ and $c' > 0$ is a universal constant.

**Proof.** See Appendix B.

Theorem 3 implies that $\delta_k \left( A/\sqrt{m} \otimes A/\sqrt{m} \right) \leq O\left( \frac{k \log n}{m} \right)$ (15) with arbitrarily high probability. The above $k$-RIC bound for the self Khatri-Rao product scales with $m, n, k$ in a similar fashion as the asymmetric Khatri-Rao product.

**Remark 3:** From Theorem 3, the $k$-RIC of the columnwise Khatri-Rao product of two $m \times n$ sized subgaussian matrices can be guaranteed to be less than unity for $m = O\left(k \log n\right)$. We conjecture that the Khatri-Rao product continues to be $k$-RIP compliant even when $m < k$. However, proving such a result is beyond the scope of this work.

### IV. Preliminaries for Deterministic $k$-RIC Bound

In this section, we present some preliminary concepts and results which are necessary for the derivation of the deterministic $k$-RIC bound in Theorem 1. For the sake of brevity, we provide proofs only for claims that have not been explicitly shown in their cited sources.

**A. Properties of the Kronecker and Hadamard product**

For any two matrices $A$ and $B$ of dimensions $m \times n$ and $p \times q$, the kronecker product $A \otimes B$ is the $mp \times nq$ matrix

$$A \otimes B = \begin{pmatrix} a_{11} B & a_{12} B & \cdots & a_{1n} B \\ a_{21} B & a_{22} B & \cdots & a_{2n} B \\ \vdots & \vdots & \ddots & \vdots \\ a_{m1} B & a_{m2} B & \cdots & a_{mn} B \end{pmatrix}. \quad (16)$$

The following Proposition relates the spectral properties of the Kronecker product and its constituent matrices.

**Proposition 4 (7.1.10 in [2]).** Let $A \in \mathbb{R}^{n \times n}$ and $B \in \mathbb{R}^{p \times p}$ admit eigenvalue decompositions $U_A A U_A^T$ and $U_B B U_B^T$, respectively. Then,

$$(U_A \otimes U_B)(A \otimes B)(U_A \otimes U_B)^T$$

yields the eigenvalue decomposition for $A \otimes B$.

For any two matrices of matching dimensions, say $m \times n$, their Hadamard product $A \circ B$ is obtained by elementwise multiplication of the entries of the input matrices, i.e.,

$$[A \circ B]_{i,j} = a_{i,j} b_{i,j} \quad \text{for } i \in [m], j \in [n]. \quad (17)$$

The Hadamard product $A \circ B$ is a principal submatrix of the Kronecker product $A \otimes B$ [3], [31]. For $n \times n$ sized square matrices $A$ and $B$, one can write,

$$A \circ B = J^T (A \otimes B) J, \quad (18)$$

where $J$ is an $n^2 \times n^2$ sized selection matrix constructed entirely from 0's and 1's which satisfies $J^T J = I_n$.

In Proposition 5, we present an upper bound on the spectral radius of a generic Hadamard product.

**Proposition 5.** For every $A, B \in \mathbb{R}^{m \times n}$, we have

$$\sigma_{\max}(A \circ B) \leq \max(\sigma_{\max}(A), c_{\max}(B))$$

where $\sigma_{\max}(\cdot)$, $\max(\cdot)$ and $c_{\max}(\cdot)$ are the largest singular value, the largest row $\ell_2$-norm and the largest column $\ell_2$-norm of the input matrix, respectively.

**Proof.** See Theorem 5.5.3 in [32].

We now state an important result about the Hadamard product of two positive semidefinite matrices.

**Proposition 6 (Mond and Pečarić [33]).** Let $A$ and $B$ be positive semidefinite $n \times n$ Hermitian matrices and let $r$ and $s$ be two nonzero integers such that $s > r$. Then,

$$(A^s \circ B^r)^{1/s} \geq (A^{r} \circ B^{s})^{1/r}. \quad (20)$$

In Propositions 7 and 8 we state some spectral properties of correlation matrices and their Hadamard products. Correlation matrices are symmetric positive semidefinite matrices with diagonal entries equal to one. Later on, we will exploit the fact that the singular values of the columnwise KR product are related to the singular values of the Hadamard product of certain correlation matrices.

**Proposition 7.** If $A$ is an $n \times n$ correlation matrix, then $A^{1/2} \circ A^{1/2}$ is a doubly stochastic matrix.

**Proof.** See Appendix A.

**Proposition 8 (Werner [34]).** For any correlation matrices $A$ and $B$ of the same size, we have $A^{1/2} \circ B^{1/2} \preceq I$, where $A^{1/2}$ and $B^{1/2}$ are the positive square roots of $A$ and $B$, respectively.

**Proof.** Since $A$ is a correlation matrix, from Proposition 7 it follows that $A^{1/2} \circ A^{1/2}$ is doubly stochastic. Since the rows and columns of $A^{1/2} \circ A^{1/2}$ sum to unity, we have $r_{\max}(A^{1/2}) = c_{\max}(A^{1/2}) = 1$. Similarly, $r_{\max}(B^{1/2}) = c_{\max}(B^{1/2}) = 1$. Then, from Proposition 5 it follows that the largest eigenvalue of $A^{1/2} \circ B^{1/2}$ is at most unity. \(\square\)
B. Matrix Kantorovitch Inequalities

Matrix Kantorovitch inequalities relate positive definite matrices by inequalities in the sense of the Löwner partial order.\footnote{The L"owner partial order here refers to the relation “≤”. For positive definite matrices $A$ and $B$, $A \preceq B$ if and only if $B - A$ is a positive semi-definite matrix.} These inequalities can be used to extend the Löwner partial order to the Hadamard product of positive definite matrices. Our proposed RIC bound relies on the tightness of these Kantorovitch inequalities and their extensions.

A matrix version of the Kantorovitch inequality was first proposed by Marshall and Olkin in \cite{35}. It is stated below as Proposition \ref{Proposition9}.

**Proposition 9** (Marshall and Olkin \cite{35}). Let $A$ be an $n \times n$ positive definite matrix. Let $A$ admit the Schur decomposition $A = U A U^T$ with unitary $U$ and $\Lambda = \text{diag}(\lambda_1, \lambda_2, \ldots, \lambda_n)$ such that $\lambda_i \in [m, M]$. Then, we have
\[
A^2 \preceq (M + m)A - mM I_n. \tag{21}
\]
The above inequality (21) is the starting point for obtaining a variety of forward and reverse Kantorovitch-type matrix inequalities for positive definite matrices. In Propositions \ref{Proposition10} and \ref{Proposition11}, we state specific forward and reverse inequalities, respectively, which are relevant to us.

**Proposition 10** (Liu and Neudecker \cite{36}). Let $A$ be an $n \times n$ positive definite Hermitian matrix, with eigenvalues in $[m, M]$. Let $V$ be an $n \times n$ matrix such that $V^T V = I_n$. Then,
\[
V^T A^2 V - (V^T A V)^2 \leq \frac{1}{4} (M - m)^2 I_n. \tag{22}
\]

**Proposition 11** (Liu and Neudecker \cite{37}). Let $A$ and $B$ be $n \times n$ positive definite matrices. Let $m$ and $M$ be the minimum and maximum eigenvalues of $B^{1/2} A^{-1/2} B^{1/2}$. Let $X$ be an $n \times p$ matrix. Then, we have
\[
(X^T B X) (X^T A X)^\dagger (X^T B X) \geq \frac{4mM}{(M + m)^2} X^T B A^{-1} X. \tag{23}
\]

Proposition \ref{Proposition10} can be proved using (21) by pre- and post-multiplying by $V^T$ and $V$, respectively, followed by completion of squares for the right hand side terms. The proof of Proposition \ref{Proposition11} is given in \cite{37}.

C. Kantorovitch Matrix Inequalities for the Hadamard Products of Positive Definite Matrices

Lemmas \ref{Lemma1} and \ref{Lemma2} stated below extend the Kantorovitch inequalities from the previous subsection to Hadamard products.

**Lemma 1** (Liu and Neudecker \cite{36}). Let $A$ and $B$ be $n \times n$ positive definite matrices, with $m$ and $M$ denoting the minimum and maximum eigenvalues of $A \circ B$. Then, we have
\[
A^2 \circ B^2 \preceq (A \circ B)^2 + \frac{1}{4} (M - m)^2 I_n. \tag{24}
\]

*Proof.* Let $J$ be the selection matrix such that $J^T J = I_n$ and $A \circ B = J^T (A \otimes B) J$. Then, by applying Proposition \ref{Proposition10} with $A$ replaced with $A \circ B$, and $V$ replaced with $J$, we obtain
\[
J^T (A \otimes B)^2 J - (J^T (A \otimes B) J)^2 \leq \frac{1}{4} (M - m)^2 I_n.
\]

Using Fact 8.21.29 in \cite{4}, i.e., $(A \otimes B)^2 = A^2 \otimes B^2$, we get
\[
J^T (A^2 \otimes B^2) J - (A \circ B)^2 \leq \frac{1}{4} (M - m)^2 I_n,
\]
Finally, by observing that $J^T (A^2 \otimes B^2) J = A^2 \circ B^2$, we obtain the desired result. \qed

**Lemma 2** (Liu \cite{38}). Let $A, B$ be $n \times n$ positive definite correlation matrices. Then,
\[
A^{1/2} \circ B^{1/2} \preceq \frac{2\sqrt{mM}}{m + M} I_n \tag{25}
\]
where the eigenvalues of $A$ and $B$ lie inside $[m, M]$.

Lemma 2 follows from Proposition \ref{Proposition11} by replacing $A$ with $I_n \otimes B$, $B$ with $A^{1/2} \otimes B^{1/2}$, and $X$ with $J$, where $J$ is the $n^2 \times n$ binary selection matrix such that $J^T J = I$ and $A \circ B = J^T (A \otimes B) J$. \qed

V. \textsc{Proof of the Deterministic k-RIC Bound (Theorem 1)}

The key idea used in bounding the $k$-RIC of the columnwise KR product $A \circ B$ is the observation that the Gram matrix of $A \circ B$ can be interpreted as a Hadamard product between the two correlation matrices $A^T A$ and $B^T B$, as mentioned in the following Proposition.

**Proposition 12** (Rao and Rao \cite{39}). For $A, B \in \mathbb{R}^{m \times n}$,
\[
(A \circ B)^T (A \circ B) = (A^T A) \circ (B^T B) \tag{26}
\]

*Proof.* See Proposition 6.4.2 in \cite{39}. \qed

Then, by using the forward and reverse Kantorovitch matrix inequalities, we obtain the proposed upper bound for $k$-RIC of $A \circ B$ in Theorem 1 as explained in the following arguments.

Without loss of generality, let $S \subseteq \{1, \ldots, n\}$ be an arbitrary index set representing the nonzero support of $z$ in (10), with $|S| \leq k$. Let $A^S$ denote the $m \times |S|$ submatrix of $A$, constituting $|S|$ columns of $A$ indexed by the set $S$. Let $B^S$ be constructed similarly. Since $\delta_S(A)$, $\delta_S(B) < 1$, both $A^S$, $B^S$ have full column rank, and consequently the associated Gram matrices $A^S_T A^S$, $B^S_T B^S$ are positive definite. Further, since $A$ and $B$ have unit norm columns, both $A^S_T A^S$ and $B^S_T B^S$ are correlation matrices with unit diagonal entries.

Using Proposition \ref{Proposition12} we can write
\[
(A^S \circ B^S)^T (A^S \circ B^S) = A^S_T A^S \circ B^S_T B^S. \tag{27}
\]

Next, for $k \leq m$, by applying Lemma \ref{Lemma1} to the positive definite matrices $(A^S_T A^S)^{1/2}$ and $(B^S_T B^S)^{1/2}$, we get
\[
A^S_T A^S \circ B^S_T B^S \preceq \left( (A^S_T A^S)^{1/2} \circ (B^S_T B^S)^{1/2} \right)^2 + \frac{1}{4} (M - m)^2 I_k \leq I_k + \frac{1}{4} (M - m)^2 I_k, \tag{28}
\]
where the second inequality is a consequence of the unity bound on the spectral radius of the Hadamard product between correlation matrices, shown in Proposition 8 in \cite{38}. $M$ and $m$ are upper and lower bounds for the maximum and minimum eigenvalues of $(A^S_T A^S)^{1/2} \circ (B^S_T B^S)^{1/2}$, respectively. From the restricted isometry of $A$ and $B$, and by application of
Proposition 4, the minimum and maximum eigenvalues of $(A_S^T A_S)^{1/2} \odot (B_S^T B_S)^{1/2}$ are lower and upper bounded by $(1 - \delta^2)\delta_1^2$ and $(1 + \delta^2)(1 + \delta_1^2)$, respectively. By introducing $\delta \triangleq \max(\delta_1^1, \delta_1^2)$, it is easy to check that the eigenvalues of $(A_S^T A_S)^{1/2} \odot (B_S^T B_S)^{1/2}$ also lie inside the interval $[1 - \delta, 1 + \delta]$. Plugging $m = 1 - \delta$ and $M = 1 + \delta$ in (28), and by using (27), we get

$$(A_S \odot B_S)^T (A_S \odot B_S) \leq (1 + \delta^2)I_k.$$  

(29)

Similarly, by applying Lemma 2 to $A_S^T A_S$ and $B_S^T B_S$ with $m = 1 - \delta$ and $M = 1 + \delta$, we obtain

$$(A_S^T A_S)^{1/2} \odot (B_S^T B_S)^{1/2} \geq (\sqrt{1 - \delta^2})I_k.$$  

From Proposition 6 we have $A_S^T A_S \odot B_S^T B_S \geq ((A_S^T A_S)^{1/2} \odot (B_S^T B_S)^{1/2})^2$. Therefore, we can write

$$A_S^T A_S \odot B_S^T B_S \geq (1 - \delta^2)I_k.$$  

Further, using (27), we get

$$(A_S \odot B_S)^T (A_S \odot B_S) \geq (1 - \delta^2)I_k.$$  

(30)

Finally, Theorem 1 is statement follows from (29) and (30).

VI. PRELIMINARIES FOR PROBABILISTIC K-RIC BOUND

In this section, we briefly discuss some concentration results for functions of subgaussian random variables which will appear in the proofs of Theorems 2 and 3.

A. Tail Probability for Subgaussian Vectors

The theorem below presents the Hanson-Wright inequality [40, 41], a tail probability for a quadratic form constructed using independent subgaussian random variables.

Theorem 13 (Rudelson and Vershynin [41]). Let $x = (x_1, x_2, \ldots, x_n) \in \mathbb{R}^n$ be a random vector with independent components $x_i$, satisfying $\mathbb{E} x_i = 0$ and $|x_i|_{\psi_2} \leq K$. Let $A$ be an $n \times n$ matrix. Then, for every $t \geq 0$,

$$\mathbb{P}\{\|x^T Ax - \mathbb{E} x^T Ax\| > t\} \leq 2 \exp \left[ -c \min \left( \frac{t^2}{K^2 \|A^T\|_{HS}^2}, \frac{t^2}{K^2 \|A\|_2^2}\right) \right]$$

where $c$ is a universal positive constant.

The following corollary of Hanson-Wright inequality discusses the concentration of weighted inner products between two subgaussian vectors.

Corollary 1. Let $u = (u_1, u_2, \ldots, u_n) \in \mathbb{R}^n$ and $v = (v_1, v_2, \ldots, v_n) \in \mathbb{R}^n$ be independent random vectors with independent subgaussian components satisfying $\mathbb{E} u_i = \mathbb{E} v_i = 0$ and $\|u_i\|_{\psi_2} \leq K, \|v_i\|_{\psi_2} \leq K$. Let $D$ be an $n \times n$ matrix. Then, for every $t \geq 0$,

$$\mathbb{P}\{|u^T D v| > t\} \leq 2 \exp \left[ -c \min \left( \frac{t^2}{K^2 \|D^T\|_{HS}^2}, \frac{t^2}{K^2 \|D\|_2^2}\right) \right]$$

where $c$ is a universal positive constant.

Proof. The desired tail bound is obtained by using the Hanson-Wright inequality in Theorem 13 with $x = [u^T v^T]^T$ and $A = [0_{n \times n} \mid D; 0_{n \times n} \mid 0_{n \times n}]$.

VII. PROOF OF THE PROBABILISTIC K-RIC BOUND (THEOREM 2)

The proof of Theorem 2 starts with a variational definition of the k-RIC, $\delta_k \triangleq \left(\frac{A_m}{\sqrt{m}} \odot \frac{B_m}{\sqrt{m}}\right)$, given below.

$$\delta_k \left(\frac{A_m}{\sqrt{m}} \odot \frac{B_m}{\sqrt{m}}\right) = \sup_{\|z\|_2 = 1, \|z\|_0 \leq k} \left\|\left(\frac{A_m}{\sqrt{m}} \odot \frac{B_m}{\sqrt{m}}\right) z\right\|_2.$$  

(31)

In order to find a probabilistic upper bound for $\delta_k$, we intend to find a constant $\delta \in (0, 1)$ such that $\mathbb{P}(\delta_k \left(\frac{A_m}{\sqrt{m}} \odot \frac{B_m}{\sqrt{m}}\right) \geq \delta)$ is arbitrarily close to zero. We therefore consider the tail event

$$\mathcal{E} \triangleq \left\{ \sup_{\|z\|_2 = 1, \|z\|_0 \leq k} \left\|\left(\frac{A_m}{\sqrt{m}} \odot \frac{B_m}{\sqrt{m}}\right) z\right\|_2 \geq \delta \right\},$$

(32)

and show that for $m$ sufficiently large, $\mathbb{P}(\mathcal{E})$ can be driven arbitrarily close to zero. In other words, the constant $\delta$ serves as a probabilistic upper bound for $\delta_k \left(\frac{A_m}{\sqrt{m}} \odot \frac{B_m}{\sqrt{m}}\right)$. Let $U_k$ denote the set of all $k$ or less sparse unit norm vectors in $\mathbb{R}^n$. Then, using Proposition 12 the tail event in (32) can be rewritten as

$$\mathbb{P}(\mathcal{E}) = \mathbb{P}\left(\sup_{z \in U_k} \left\|z^T (A \odot B)^T (A \odot B) z - m^2\right\| \geq \delta m^2\right)$$

$$= \mathbb{P}\left(\sup_{z \in U_k} \left\|z^T (A^T A \odot B^T B)^{1/2} z^2 - m^2\right\| \geq \delta m^2\right)$$

$$= \mathbb{P}\left(\sup_{z \in U_k} \sum_{i=1}^n \sum_{j=1}^n \sum_{i=1}^n z_i z_j (a_i a_j^T b_i b_j^T) - m^2 \geq \delta m^2\right)$$

(33)

where $a_i$ and $b_j$ denote the $i$th column of $A$ and $B$, respectively. Further, by applying the triangle inequality and the union bound, the above tail probability splits as

$$\mathbb{P}(\mathcal{E}) \leq \mathbb{P}\left(\sup_{z \in U_k} \sum_{i=1}^n \sum_{j=1}^n z_i z_j (a_i a_j^T b_i b_j^T) - m^2 \geq \alpha \delta m^2\right)$$

$$+ \mathbb{P}\left(\sup_{z \in U_k} \sum_{i=1}^n \sum_{j=1}^n z_i z_j (a_i a_j^T b_i b_j^T) - m^2 \leq (1 - \alpha) \delta m^2\right).$$

(34)

In the above, $\alpha \in (0, 1)$ is a variational union bound parameter which can be optimized at a later stage. We now proceed to find separate upper bounds for each of the two probability terms in (34).

The first probability term in (34) admits the following sequence of relaxations.

$$\mathbb{P}\left(\sup_{z \in U_k} \sum_{i=1}^n \sum_{j=1}^n z_i^2 \|a_i a_j^T b_i b_j^T - m^2\| \geq \alpha \delta m^2\right)$$

$$\leq \mathbb{P}\left(\sup_{z \in U_k} \sum_{i=1}^n \sum_{j=1}^n z_i^2 \|a_i a_j^T b_i b_j^T - m^2\| \geq \alpha \delta m^2\right).$$

(35)
In the above, step (a) follows from the triangle inequality combined with the fact that \( z_i^T \)'s sum to one. The inequality in step (b) is a consequence of the fact that any nonnegative convex combination of \( n \) arbitrary numbers is at most the maximum among the \( n \) numbers. Step (c) is obtained by simply rewriting the tail event for the maximum of \( n \) random variables as the union of tail events for the individual random variables. Step (d) is the application of the union bound over values of index \( i \in [n] \) and exploiting the i.i.d. nature of the columns of \( \mathbf{A} \) and \( \mathbf{B} \). Step (e) is the union bound combined with the fact that for any two vectors \( \mathbf{a}, \mathbf{b} \in \mathbb{R}^m \), the following triangle inequality holds:

\[
||\mathbf{a}||_2^2 - ||\mathbf{b}||_2^2 - m^2 \leq (||\mathbf{a}||_2 - m)(||\mathbf{b}||_2 - m) + m(||\mathbf{a}||_2 - m) + m(||\mathbf{b}||_2^2 - m).
\]

In step (e), \( \beta \in (0, 1) \) is a variational union bound parameter. Step (f) is once again the tail bound which exploits the fact that the columns \( \mathbf{a}_1 \) and \( \mathbf{b}_1 \) are identically distributed. Step (g) is obtained by setting \( \beta = \alpha \delta / 4 \). Lastly, step (h) is the Hanson-Wright inequality (Theorem [13]) applied to the subgaussian vector \( \mathbf{a}_1 \).

Next, we turn our attention to the second tail probability term in (34). We note that

\[
\begin{align*}
&\underset{\mathbf{z} \in \mathcal{U}_k}{\sup} \sum_{i=1}^{n} \sum_{j=1, j \neq i}^{n} |z_i z_j| \left| \mathbf{a}_i^T \mathbf{a}_j \right| \left| \mathbf{b}_i^T \mathbf{b}_j \right|
\leq \underset{\mathbf{z} \in \mathcal{U}_k}{\sup} \sum_{i=1}^{n} \sum_{j=1, j \neq i}^{n} |z_i z_j| \max_{i, j \in \text{supp}(u), i \neq j} \left| \mathbf{a}_i^T \mathbf{a}_j \right| \left| \mathbf{b}_i^T \mathbf{b}_j \right|
\leq k \left( \max_{i, j \in [n], i \neq j} \left| \mathbf{a}_i^T \mathbf{a}_j \right| \left| \mathbf{b}_i^T \mathbf{b}_j \right| \right),
\end{align*}
\]

where the second step is the application of the Hölder's inequality. The last step uses the fact that \( ||\mathbf{z}||_1 \leq \sqrt{k} \) for \( \mathbf{z} \in \mathcal{U}_k \). Using (36), and by applying the union bound over \( \binom{n}{2} \) possible distinct \((i, j)\) pairs, the second probability term in (34) can be bounded as

\[
\begin{align*}
&\mathbb{P} \left( \sup_{\mathbf{z} \in \mathcal{U}_k} \sum_{i=1}^{n} \sum_{j=1, j \neq i}^{n} z_i z_j \mathbf{a}_i^T \mathbf{a}_j \mathbf{b}_i^T \mathbf{b}_j \geq (1 - \alpha)\delta m^2 \right)
\leq n^2 \mathbb{P} \left( \mathbf{a}_1^T \mathbf{a}_2 \mathbf{b}_1^T \mathbf{b}_2 \geq (1 - \alpha)\delta m^2 \right)
\leq n^2 \mathbb{P} \left( \mathbf{a}_1^T \mathbf{a}_2 \geq \frac{\sqrt{(1 - \alpha)\delta m}}{\sqrt{k}} \right)
\leq 2n^2 e^{-\frac{c(1 - \alpha)\delta m}{\alpha \delta k \log n} - 2}.
\end{align*}
\]

The last inequality in the above is obtained by using the tail bound for \( \mathbf{a}_1^T \mathbf{a}_2 \) from Corollary [1]. Finally, by combining (34), (35) and (37), and setting \( \alpha = 1/2 \), we obtain the following simplified tail bound,

\[
\mathbb{P}(\mathcal{E}) \leq 8n \left( \frac{c n \delta^2 (1 - \delta/2) \gamma^2}{\alpha \delta \kappa \log n} - 1 \right) + 2n \left( \frac{c n \delta^2 (1 - \delta/2) \gamma^2}{\alpha \delta \kappa \log n} - 2 \right).
\]

From (38), for \( m > \max \left( \frac{4 \gamma^5 \kappa \log n}{c \delta} - \frac{32 \gamma^5 \kappa \log n}{c \delta^2 (1 - \delta/8)^2} \right) \) and any \( \gamma > 1 \), we have \( \mathbb{P}(\mathcal{E}) < 10n^{-2(\gamma - 1)} \). Note that, in terms of \( k \) and \( n \), the first term in the inequality for \( m \) scales as \( k \log n \); it dominates the second term, which scales as \( \log n \). This ends our proof.

VIII. CONCLUSIONS

In this work, we have analyzed the restricted isometry property of the columnwise Khatri-Rao product matrix in terms of its restricted isometry constants. We gave two upper bounds for the \( k \)-RIC of a generic columnwise Khatri-Rao product matrix. The first \( k \)-RIC bound, a deterministic bound, is valid for the Khatri-Rao product of an arbitrary pair of input matrices of the same size with normalized columns. It is conveniently computed in terms of the \( k \)-RICs of the input matrices. We also gave a probabilistic RIC bound for the columnwise KR product of a pair of random matrices with i.i.d. subgaussian entries. The probabilistic RIC bound is one of the key components needed for computing sample complexity bounds for several machine learning algorithms.

The analysis of the RIP of Khatri-Rao product matrices in this article can be extended in multiple ways. The current RIC bounds can be extended to the Khatri-Rao product of three or more matrices. More importantly, in order to relate the RICs to the dimensions of the input matrices, we had to resort to the randomness in their entries. Removing this randomness aspect of our results could be an interesting direction for future work.
APPENDIX

A. Proof of Proposition \[7\]

Proof. Since \(A\) is a correlation matrix, it admits the Schur decomposition, \(A = UΛU^T\), with unitary \(U\) and eigenvalue matrix \(Λ = \text{diag}(λ_1,λ_2,\ldots,λ_n)\). Since \(A\) is positive semidefinite, its nonnegative square-root exists and is given by \(A^{1/2} = UΛ^{1/2}U^T\). Consider
\[
A^{1/2} \circ A^{1/2} = \sum_{i=1}^{n} λ_i^{1/2} u_i u_i^T \circ \sum_{j=1}^{n} λ_j^{1/2} u_j u_j^T = \sum_{i=1}^{n} \sum_{j=1}^{n} λ_i^{1/2} λ_j^{1/2} (u_i u_i^T) \circ (u_j u_j^T) = \sum_{i=1}^{n} \sum_{j=1}^{n} λ_i^{1/2} λ_j^{1/2} (u_i \circ u_j) (u_i \circ u_j)^T. \tag{39}
\]
The second equality above follows from the distributive property of the Hadamard product and the last step follows from Fact 7.6.2 in [2]. Using (39), we can show that the rows and columns of \(A^{1/2} \circ A^{1/2}\) sum to one, as follows:
\[
(A^{1/2} \circ A^{1/2})1 = \sum_{i=1}^{n} \sum_{j=1}^{n} λ_i^{1/2} λ_j^{1/2} (u_i \circ u_j) (u_i \circ 1)^T = \sum_{i=1}^{n} \sum_{j=1}^{n} λ_i^{1/2} λ_j^{1/2} (u_i \circ u_j) (u_i \circ 1) u_j = \sum_{i=1}^{n} λ_i (u_i \circ u_i) = d \text{ (say)}.
\]
The above arguments follow from the orthonormality of the columns of \(U\), and repeated application of Fact 7.6.1 in [2]. Note that for \(k \in [n]\), \(d(k) = \sum_{i=1}^{n} λ_i (u_i(k))^2 = |Λ_{kk}| = 1\). Thus, we have shown that \((A^{1/2} \circ A^{1/2})1 = 1\). Likewise, it can be shown that \(1^T (A^{1/2} \circ A^{1/2}) = 1^T\). Thus, \(A^{1/2} \circ A^{1/2}\) is doubly stochastic. \(\square\)

B. Proof of Theorem \[3\]

Proof. The proof of Theorem \[3\] follows along similar lines as that of Theorem \[2\]. We consider the tail event
\[
\mathcal{E}_1 \triangleq \left\{ \sup_{z \in \mathcal{U}_k} \left\| \left( \frac{A}{\sqrt{m}} \odot \frac{A}{\sqrt{m}} \right) z \right\|^2_2 - 1 \geq \delta \right\}, \tag{40}
\]
and show that for sufficiently large \(m\), \(P(\mathcal{E}_1)\) can be driven arbitrarily close to zero, thereby implying that \(\delta\) is a probabilistic upper bound for \(δ_2 \left( A/\sqrt{m} \odot A/\sqrt{m} \right)\). Once again, \(\mathcal{U}_k\) denotes the set of all \(k\) or less sparse unit norm vectors in \(\mathbb{R}^m\). We note that \(P(\mathcal{E}_1)\) admits the following union bound:
\[
P(\mathcal{E}_1) = P \left( \sup_{z \in \mathcal{U}_k} \left\| z^T \left( A \odot A^T \right) z - m^2 \right\|_2 \geq \delta m^2 \right) = P \left( \sup_{z \in \mathcal{U}_k} \left\| z^T \left( A^T A \right) A \odot A^T A \right\|_2 \geq \delta m^2 \right) = P \left( \sup_{z \in \mathcal{U}_k} \left\| z^T A^T A \right\|_2 \geq \delta m^2 \right) \leq P \left( \sup_{z \in \mathcal{U}_k} \left\| z^T A^T A \right\|_2 \geq (1 - 1/\sqrt{n}) m^2 \right),
\]
In the above, the second identity follows from Proposition \[12\]. The last inequality uses the triangle inequality followed by the union bound, with \(\alpha \in (0, 1)\) being a variational parameter to be optimized later. Similar to the proof of Theorem \[2\], we now derive separate upper bounds for each of the two probability terms in (41).

The first term in (41) admits the following series of relaxations.
\[
P \left( \sup_{z \in \mathcal{U}_k} \left\| z^T A^T A \right\|_2 \geq \delta m^2 \right) \leq P \left( \sup_{z \in \mathcal{U}_k} \sum_{i=1}^{n} \sum_{j=1}^{n} z_i z_j (a_i^T a_j)^2 \geq (1 - \alpha) \delta m^2 \right), \tag{41}
\]
Finally, step (f) is obtained by choosing the union bound parameter \(\beta = \alpha \delta/4\). Finally, step (g) is the Hanson-Wright inequality (Theorem \[13\]) applied to the subgaussian vector \(a_1\).

Next, we derive an upper bound for the second tail probability term in (43). We observe that
\[
\sup_{z \in \mathcal{U}_k} \sum_{i=1}^{n} \sum_{j=1}^{n} z_i z_j (a_i^T a_j)^2 \leq \left( \frac{m \alpha \delta (1 - \alpha \delta/4)^2}{4m \log n} \right)
\]
where the second step is the application of the Hölder’s inequality. The last step uses the fact that $|z|_i \leq \sqrt{k}$ for $z \in U_k$. Using (43), and by applying the union bound over $\binom{n}{2}$ possible distinct $(i, j)$ pairs, the second probability term in (34) can be bounded as

$$P\left( \sup_{z \in U_k} \left| \sum_{i,j=1}^{n} z_i z_j (a_i^T a_j)^2 \right| \geq (1 - \alpha) \delta m^2 \right) \leq \frac{n^2}{2} P\left[ \left| a_i^T a_j \right|^2 \geq \frac{(1 - \alpha) \delta m^2}{k} \right] \leq \frac{n^2}{2} \left[ \left| a_i^T a_j \right|^2 \geq \frac{(1 - \alpha) \delta m^2}{\sqrt{k}} \right] \leq n^2 e^{-\frac{(1 - \alpha) \delta m}{n^2 k \log n}}. \quad (44)$$

The last inequality in the above is obtained by using the tail bound for $|a_i^T a_j|$ from Corollary 1. Finally, by combining (41), (42) and (44), and setting $\alpha = 1/2$, we obtain the following tail bound.

$$P(E) \leq 4n^2 e^{-\frac{(1 - \alpha) \delta m}{n^2 k \log n}}. \quad (45)$$

From (45), we can conclude that for $m > \max\left( \frac{4e^2(1-\delta)^2}{2\gamma c \log n}, \frac{32\gamma^2 c \log n}{c^2(1-\delta)^2} \right)$ and any $\gamma > 1$, we have $P(E) < 5n^{-2(\gamma - 1)}$. Note that, in terms of $k$ and $n$, the first term in the inequality for $m$ scales as $k \log n$; it dominates the second term, which scales as $\log n$. \qed
