# Fractional iterated Ornstein-Uhlenbeck Processes 

Juan Kalemkerian<br>Universidad de la República, Facultad de Ciencias.

March 2, 2022

#### Abstract

In this work we present a Gaussian process that arise from the iteration of p fractional Ornstein-Uhlenbeck processes generated by the same fractional Brownian motion. This iteration results, when the values of lambdas are pairwise differents, in a particular linear combination of those processes. Although for $H>1 / 2$ each term of the linear combination is a long memory processes, we prove that it results in a short memory processes. We include applications to real data that show improvement in predictive performance compared with different ARMA models.

Keywords: fractional Brownian motion, fractional Ornstein-Uhlenbeck process, long memory processes. AMS: 62 M 10

## 1 Introduction

We begin with the following definition of fractional Brownian motion.
Definition 1. A fractional Brownian motion with Hurst parameter $H \in(0,1]$, is an almost surely continuous centered Gaussian process $\left\{B_{H}(t)\right\}_{t \in \mathbb{R}}$ with

$$
\mathbb{E}\left(B_{H}(t) B_{H}(s)\right)=\frac{1}{2}\left(|t|^{2 H}+|s|^{2 H}-|t-s|^{2 H}\right), \quad t, s \in \mathbb{R}
$$

When $H=1 / 2$, fractional Brownian motion become in a standard Brownian motion. An Ornstein-Uhlenbeck process is a Gaussian process defined by $X_{t}=\sigma \int_{-\infty}^{t} e^{-\lambda(t-s)} d B_{1 / 2}(t)$ for $t \in \mathbb{R}$, where $\sigma, \lambda>0$, are parameters (Ornstein \& Uhlenbeck, 1930). This process is the unique stationary solution of the Langevin equation (Langevin, 1908), defined by

$$
d X_{t}=-\lambda X_{t}+\sigma d B_{1 / 2}(t)
$$

If we consider the Langevin equation with a fractional Brownian motion, this is $d X_{t}=$ $-\lambda X_{t}+\sigma d B_{H}(t)$, then $X_{t}=\sigma \int_{-\infty}^{t} e^{-\lambda(t-s)} d B_{H}(t)$ for $t \in \mathbb{R}$ is the unique stationary solution (Cheridito et al, 2003). In this work, we use the notation $\left\{X_{t}\right\}_{t \in \mathbb{R}} \sim \operatorname{FOU}(\lambda, \sigma, H)$, for any process defined as $X_{t}=\sigma \int_{-\infty}^{t} e^{-\lambda(t-s)} d B_{H}(t)$, where $\sigma, \lambda>0, H \in(0,1]$.
If we change the process $\left\{B_{H}(t)\right\}_{t \in \mathbb{R}}$ by another $\{y(t)\}_{t \in \mathbb{R}}$ we can define the operators $T_{\lambda}(y)(t):=\int_{-\infty}^{t} e^{-\lambda(t-s)} d y(s)$ and for each $h=0,1,2, \ldots$

$$
\begin{equation*}
T_{\lambda}^{(h)}(y)(t):=\int_{-\infty}^{t} e^{-\lambda(t-s)} \frac{(-\lambda(t-s))^{h}}{h!} d y(s) \tag{1}
\end{equation*}
$$

These transformations are called, $O U$ operator with parameter $\lambda$ and $O U$ operator of degree $h$ and parameter $\lambda$ respectively (Arratia et al, 2016).

Observe that $T_{\lambda}^{(0)}=T_{\lambda}$.
Given $\left\{B_{H}(s)\right\}_{s \in \mathbb{R}}$ a fractional Brownian motion with parameter $H$, and $\lambda_{1} \neq \lambda_{2}$ are real positive numbers, we define the processes
$X_{t}^{(i)}:=T_{\lambda_{i}}\left(\sigma B_{H}\right)(t)=\sigma \int_{-\infty}^{t} e^{-\lambda_{i}(t-s)} d B_{H}(s)$ for $i=1,2$. This is $\left\{X_{t}^{(i)}\right\}_{t \in \mathbb{R}} \sim \operatorname{FOU}\left(\lambda_{i}, \sigma, H\right)$ for $i=1,2$ generated by the same fractional Brownian motion. It can be proved that the process defined as $X_{t}:=\left(T_{\lambda_{1}} \circ T_{\lambda_{2}}\right)\left(B_{H}\right)(t)$ is equal to $X_{t}=\frac{\lambda_{1}}{\lambda_{1}-\lambda_{2}} X_{t}^{(1)}+\frac{\lambda_{2}}{\lambda_{2}-\lambda_{1}} X_{t}^{(2)}$, this is a particular linear combination of process $\left\{X_{t}^{(1)}\right\}_{t \in \mathbb{R}}$ and $\left\{X_{t}^{(2)}\right\}_{t \in \mathbb{R}}$.

This implies that $\left(T_{\lambda_{1}} \circ T_{\lambda_{2}}\right)\left(B_{H}\right)=\left(T_{\lambda_{2}} \circ T_{\lambda_{1}}\right)\left(B_{H}\right)$.
In general, if we compose $p$ times the operator $T_{\lambda}$ result in the following equality: $T_{\lambda}^{p}=\sum_{j=0}^{p-1}\binom{p-1}{j} T_{\lambda}^{(j)}$. And if we compose $p_{1}$ times the operator $T_{\lambda_{1}}, p_{2}$ times $T_{\lambda_{2}}, \ldots$, and $p_{q}$ times the operator $T_{\lambda_{q}}$, for $\lambda_{i}$ pairwise different, we have

$$
\prod_{i=1}^{q} T_{\lambda_{i}}^{p_{i}}=\sum_{i=1}^{q} K_{i}(\lambda) T_{\lambda_{i}}^{p_{i}}=\sum_{i=1}^{q} K_{i}(\lambda) \sum_{j=0}^{p_{i}-1}\binom{p_{i}-1}{j} T_{\lambda_{i}}^{(j)}
$$

where $p=p_{1}+p_{2}+\ldots+p_{q}$ and

$$
\begin{equation*}
K_{i}(\lambda)=K_{i}\left(\lambda_{1}, \lambda_{2}, \ldots, \lambda_{q}\right)=\frac{1}{\prod_{j \neq i}\left(1-\lambda_{j} / \lambda_{i}\right)} \tag{2}
\end{equation*}
$$

(Arratia et al 2016).
It is known that for $H>1 / 2$ every $\operatorname{FOU}(\lambda, \sigma, H)$ is a long memory process (Cheridito et al, 2013), this is $\sum_{n=-\infty}^{+\infty}|\gamma(n)|=+\infty$ where $\gamma(n)=\mathbb{E}\left(X_{0} X_{n}\right)$. In this work we prove in section 2 that if we compose at least two operators of the form $T_{\lambda}$ evaluated in a fractional Brownian motion, with Hurst parameter $H>1 / 2$, we obtain a process $\left\{X_{t}\right\}_{t \in \mathbb{R}}$ such that $\sum_{n=-\infty}^{+\infty}\left|\mathbb{E}\left(X_{0} X_{n}\right)\right|<+\infty$. Furhter, the process obtained has short memory. In section 2, we define a $\operatorname{FOU}(p)$ processes, and summarize the results needed to obtain the auto-covariance function. We also obtain its spectral density and deduce that in the case in wich $p \geq 2$ it is a short memory process. In section 3 , we apply these models to real data sets and compare the performance of these models with ARMA models according to their predictive power. In section 4, we make the demonstration of the results established in section 2 . Our concluding remarks are in section 5 .

## 2 Definitions and properties

We start with the definition of the fractional iterated Ornstein-Uhlenbeck process.
Definition 2. If $\left\{\sigma B_{H}(s)\right\}_{s \in \mathbb{R}}$ is a fractional Brownian motion with Hurst parameter $H$, and escale parameter $\sigma$, and a pairwise different real positive numbers $\lambda_{1}, \lambda_{2}, \ldots, \lambda_{q}$ and $p_{1}, p_{2}, \ldots, p_{q} \in \mathbb{N}$ such that $p_{1}+p_{2}+\ldots+p_{q}=p$, we define $\left\{X_{t}\right\}_{t \in \mathbb{R}}$ by

$$
X_{t}:=\prod_{i=1}^{q} T_{\lambda_{i}}^{p_{i}}\left(\sigma B_{H}\right)(t)=\sum_{i=1}^{q} K_{i}(\lambda) \sum_{j=0}^{p_{i}-1}\binom{p_{i}-1}{j} T_{\lambda_{i}}^{(j)}\left(\sigma B_{H}\right)(t)
$$

where the numbers $K_{i}(\lambda)$ and the operators $T_{\lambda_{i}}^{(j)}$ were defined in (2) and (1) respectively.
Notation 1. $\left\{X_{t}\right\}_{t \in \mathbb{R}} \sim F O U\left(\lambda_{1}^{\left(p_{1}\right)}, \lambda_{2}^{\left(p_{2}\right)}, \ldots, \lambda_{q}^{\left(p_{q}\right)}, \sigma, H\right)$, or more simply $\left\{X_{t}\right\}_{t \in \mathbb{R}} \sim F O U(p)$.
Observe that the notation $\operatorname{FOU}\left(\lambda_{1}^{\left(p_{1}\right)}, \lambda_{2}^{\left(p_{2}\right)}, \ldots, \lambda_{q}^{\left(p_{q}\right)}, \sigma, H\right)$ implies that the $\lambda_{i}$ parameters are pairwise different.

Remark 1. When $p_{1}=p_{2}=\ldots=p_{q}=1$ the process is equal to

$$
X_{t}=\prod_{i=1}^{q} T_{\lambda_{i}}\left(\sigma B_{H}\right)(t)=\sum_{i=1}^{q} K_{i}(\lambda) T_{\lambda_{i}}\left(\sigma B_{H}\right)(t)
$$

and we call $\left\{X_{t}\right\}_{t \in \mathbb{R}} \sim \operatorname{FOU}\left(\lambda_{1}, \lambda_{2}, \ldots, \lambda_{q}, \sigma, H\right)$.

Remark 2. When $p=1$, we obtain a fractional Ornstein-Uhlenbeck process $(F O U(\lambda, \sigma, H))$.
Remark 3. Any $\operatorname{FOU}\left(\lambda_{1}^{\left(p_{1}\right)}, \lambda_{2}^{\left(p_{2}\right)}, \ldots, \lambda_{q}^{\left(p_{q}\right)}, \sigma, H\right)$, is Gaussian, centered and almost surely continuous process.

Now, we compute the auto-covariance function of any $\operatorname{FOU}(p)$ process. For this we need the following formula, whose proof can be seen in (Pipiras \& Taqqu, 2000): if $H \in(1 / 2,1)$ and

$$
f, g \in\left\{f: \mathbb{R} \rightarrow \mathbb{R}: \iint_{\mathbb{R}^{2}}|f(u) f(v)||u-v|^{2 H-2} d u d v<+\infty\right\}
$$

then

$$
\begin{gather*}
\mathbb{E}\left(\int_{-\infty}^{+\infty} f(u) d B_{H}(u) \int_{-\infty}^{+\infty} g(v) d B_{H}(v)\right)=  \tag{3}\\
H(2 H-1) \int_{-\infty}^{+\infty} f(u) d u \int_{-\infty}^{+\infty} g(v)|u-v|^{2 H-2} d v
\end{gather*}
$$

We start with $\gamma(t)=\mathbb{E}\left(X_{t} X_{0}\right)=$

$$
\begin{aligned}
\mathbb{E} & \sum_{h=1}^{q} K_{h}(\lambda) \sum_{j=0}^{p_{h}-1}\binom{p_{h}-1}{j} T_{\lambda_{h}}^{(j)}\left(\sigma B_{H}\right)(t) \sum_{h^{\prime}=1}^{q} K_{h^{\prime}}(\lambda) \sum_{j^{\prime}=0}^{p_{h^{\prime}-1}}\binom{p_{h^{\prime}}-1}{j^{\prime}} T_{\lambda_{h^{\prime}}}^{\left(j^{\prime}\right)}\left(\sigma B_{H}\right)(0)= \\
& \sum_{i=1}^{q} \sum_{i^{\prime}=1}^{q} \sum_{j=0}^{p_{i}-1} \sum_{j^{\prime}=0}^{p_{i^{\prime}}-1} K_{i}(\lambda)\binom{p_{i}-1}{j} K_{i^{\prime}}(\lambda)\binom{p_{i^{\prime}}-1}{j^{\prime}} \mathbb{E} T_{\lambda_{i}}^{(j)}\left(\sigma B_{H}\right)(t) T_{\lambda_{i^{\prime}}}^{\left(j^{\prime}\right)}\left(\sigma B_{H}\right)(0) .
\end{aligned}
$$

Define $\gamma_{\lambda, \lambda^{\prime}}^{\left(j, j^{\prime}\right)}(t):=\mathbb{E} T_{\lambda}^{(j)}\left(\sigma B_{H}\right)(t) T_{\lambda^{\prime}}^{\left(j^{\prime}\right)}\left(\sigma B_{H}\right)(0)$, then

$$
\begin{equation*}
\gamma(t)=\sum_{i, i^{\prime}=1}^{q} K_{i}(\lambda) K_{i^{\prime}}(\lambda) \sum_{j=0}^{p_{i}-1} \sum_{j^{\prime}=0}^{p_{i^{\prime}}-1}\binom{p_{i}-1}{j}\binom{p_{i^{\prime}}-1}{j^{\prime}} \gamma_{\lambda_{i}, \lambda_{i^{\prime}}}^{\left(j, j^{\prime}\right)}(t) . \tag{4}
\end{equation*}
$$

Now, we compute $\gamma_{\lambda, \lambda^{\prime}}^{\left(j, j^{\prime}\right)}(t)$.

$$
\begin{gather*}
\gamma_{\lambda, \lambda^{\prime}}^{\left(j, j^{\prime}\right)}(t)=\mathbb{E} T_{\lambda}^{(j)}\left(\sigma B_{H}\right)(t) T_{\lambda^{\prime}}^{\left(j^{\prime}\right)}\left(\sigma B_{H}\right)(0)= \\
\sigma^{2} \mathbb{E} \int_{-\infty}^{t} e^{-\lambda(t-u)} \frac{(-\lambda(t-u))^{j}}{j!} d B_{H}(u) \int_{-\infty}^{0} e^{\lambda^{\prime} v} \frac{\lambda^{\prime j^{\prime} v^{j^{\prime}}}}{j^{\prime}!} d B_{H}(v) \tag{5}
\end{gather*}
$$

Using (3), we obtain that (5) is equal to

$$
\begin{gather*}
\sigma^{2} H(2 H-1) \int_{-\infty}^{t} e^{-\lambda(t-u)} \frac{(-\lambda(t-u))^{j}}{j!} d u \int_{-\infty}^{0} e^{\lambda^{\prime} v} \frac{\lambda^{\prime j^{\prime}} v^{j^{\prime}}}{j^{\prime}!}|u-v|^{2 H-2} d v= \\
\frac{\sigma^{2} H(2 H-1) \lambda^{j} \lambda^{\prime} j^{\prime}}{j!j^{\prime}!} \int_{-\infty}^{t} e^{-\lambda(t-u)}(u-t)^{j} d u \int_{-\infty}^{0} e^{\lambda^{\prime} v} v^{j^{\prime}}|u-v|^{2 H-2} d v \stackrel{w=u-t}{=} \\
\frac{\sigma^{2} H(2 H-1) \lambda^{j} \lambda^{\prime j^{\prime}}}{j!j^{\prime}!} \int_{-\infty}^{0} e^{\lambda w} w^{j} d w \int_{-\infty}^{0} e^{\lambda^{\prime} v} v^{j^{\prime}}|w+t-v|^{2 H-2} d v= \\
\frac{\sigma^{2} H(2 H-1) \lambda^{j} \lambda^{\prime j^{\prime}}(-1)^{j+j^{\prime}}}{j!j^{\prime}!} \int_{0}^{+\infty} e^{-\lambda w} w^{j} d w \int_{0}^{+\infty} e^{-\lambda^{\prime} v} v^{j^{\prime}}|v+t-w|^{2 H-2} d v . \tag{6}
\end{gather*}
$$

To obtain the results in this work, we need to define the following functions:

$$
\begin{align*}
f_{H}^{(1)}(x) & :=e^{-x}\left(\Gamma(2 H)-\int_{0}^{x} e^{s} s^{2 H-1} d s\right),  \tag{7}\\
f_{H}^{(2)}(x) & :=e^{x}\left(\Gamma(2 H)-\int_{0}^{x} e^{-s} s^{2 H-1} d s\right),  \tag{8}\\
f_{H}(x) & :=f_{H}^{(1)}(x)+f_{H}^{(2)}(x)
\end{align*}
$$

Then,

$$
\begin{equation*}
f_{H}(x):=e^{-x}\left(\Gamma(2 H)-\int_{0}^{x} e^{s} s^{2 H-1} d s\right)+e^{x}\left(\Gamma(2 H)-\int_{0}^{x} e^{-s} s^{2 H-1} d s\right) . \tag{9}
\end{equation*}
$$

Remark 4. For $H>1 / 2$, is verified that $f_{H}^{(1)}(x) \rightarrow+\infty$ and $f_{H}^{(2)}(x) \rightarrow-\infty$ when $x \rightarrow+\infty$.

As $H$ increases, the functions $f_{H}$ increases as can be seen in Figure 1 Then, when $x \rightarrow+\infty$, it is verified that as $H$ increases the functions $f_{H}$ goes to zero more slowly. The following proposition includes properties of $f_{H}$ that will be used later. We denote $f \sim g$ for $x \rightarrow a$, when $f(x) / g(x) \rightarrow 1$ for $x \rightarrow a$.

Proposition 1. If $H>1 / 2, \alpha, \beta>0$, then

1. $\alpha^{1-2 H} f_{H}^{(1)}(\alpha x)+\beta^{1-2 H} f_{H}^{(2)}(\beta x) \rightarrow 0$ when $x \rightarrow+\infty$.
2. $\alpha^{1-2 H} f_{H}^{(1)}(\alpha x)+\beta^{1-2 H} f_{H}^{(2)}(\beta x) \sim \frac{\alpha+\beta}{\alpha \beta}(2 H-1) x^{2 H-2}$ when $x \rightarrow+\infty$.
3. $f_{H}(x) \sim 2(2 H-1) x^{2 H-2}$ when $x \rightarrow+\infty$.
4. $f_{H}(x)-f_{H}(0)=f_{H}(x)-2 \Gamma(2 H)=-\frac{x^{2 H}}{H}+o\left(x^{2 H}\right)$ when $x \rightarrow 0$.
5. $f_{H}(x)=\frac{\Gamma(2 H+1) \sin (H \pi)}{2 \pi} \int_{-\infty}^{+\infty} \frac{e^{i v}|v|^{1-2 H}}{v^{2}+x^{2}} d v$.

Figure 1: $f_{H}$ functions for $H=0.5,0.6,0.7,0.8$ and, 0.9 values. The lowest curve corresponds to $H=0.5$ while the highest curve corresponds to $H=0.9$.

Property 1 show us that when $H>1 / 2, f_{H}(x) \rightarrow 0$ as $x \rightarrow+\infty$, also will be used to prove property 3 . Property 3 show us that when $H>1 / 2$, then $\sum_{n=1}^{+\infty} f_{H}(n)=+\infty$. In Figure 1 it is perceived the slow decrease to zero of function $f_{H}$ as $H$ increases. We will prove later in (11) that the auto-covariance function of any $\operatorname{FOU}(\lambda, \sigma, H)$ can be expressed as a multiple of $f_{H}(\lambda t)$, therefore, any $\operatorname{FOU}(\lambda, \sigma, H)$ is a long memory process for $H>1 / 2$. Property 5 will be used to obtain the spectral density of any $\operatorname{FOU}(p)$ process.

The following proposition, is the key that will allows us to express the autocovariance function of any $\operatorname{FOU}\left(\lambda_{1}, \lambda_{2}, \ldots, \lambda_{p}, \sigma, H\right)$ as a linear combination of $f_{H}\left(\lambda_{i} t\right)$. The proof it is based on (3).
Proposition 2. Let $\left\{X_{t}^{(1)}\right\}_{t \in \mathbb{R}} \sim F O U\left(\lambda_{1}, \sigma, H\right)$ and $\left\{X_{t}^{(2)}\right\}_{t \in \mathbb{R}} \sim F O U\left(\lambda_{2}, \sigma, H\right)$ are generated by the same fractional Brownian motion $\left\{\sigma B_{H}(t)\right\}_{t \in \mathbb{R}}$. Then, for all $t$ and $H>1 / 2$ it is verified that

$$
\begin{equation*}
\mathbb{E}\left(X_{0}^{(1)} X_{t}^{(2)}\right)=\frac{\sigma^{2} H}{\lambda_{1}+\lambda_{2}}\left(\lambda_{1}^{1-2 H} f_{H}^{(1)}\left(\lambda_{1}|t|\right)+\lambda_{2}^{1-2 H} f_{H}^{(2)}\left(\lambda_{2}|t|\right)\right) \tag{10}
\end{equation*}
$$

In particular when $t=0$, we get

$$
\mathbb{E}\left(X_{0}^{(1)} X_{0}^{(2)}\right)=\frac{\sigma^{2} H \Gamma(2 H)}{\lambda_{1}+\lambda_{2}}\left(\lambda_{2}^{1-2 H}+\lambda_{1}^{1-2 H}\right)=\frac{\sigma^{2} \Gamma(2 H+1)}{2\left(\lambda_{1}+\lambda_{2}\right)}\left(\lambda_{1}^{1-2 H}+\lambda_{2}^{1-2 H}\right)
$$

If we put $\lambda_{1}=\lambda_{2}=\lambda$ in 10 we obtain the auto-covariance function of any $\operatorname{FOU}(\lambda, \sigma, H):$

Corollary 1. For any $\left\{X_{t}\right\}_{t \in \mathbb{R}} \sim F O U(\lambda, \sigma, H)$ where $H>1 / 2$ we get

$$
\begin{equation*}
\mathbb{E}\left(X_{0} X_{t}\right)=\frac{\sigma^{2} H f_{H}(\lambda t)}{2 \lambda^{2 H}} \tag{11}
\end{equation*}
$$

Observe that property 3 of propositon 8 and 11 , show that any $\operatorname{FOU}(\lambda, \sigma, H)$ is a long memory process.

Remark 5. Observe that $f_{H}(0)=2 \Gamma(2 H)$, and put $t=0$ in (11), to obtain the known formula for the variance of any $\operatorname{FOU}(\lambda, \sigma, H)$ :

$$
\mathbb{V}\left(X_{t}\right)=\frac{\sigma^{2} \Gamma(2 H+1)}{2 \lambda^{2 H}}
$$

In section 4 we prove the following proposition that shows us that the auto-covariance function of any $\operatorname{FOU}(p)$ where $\lambda_{1}, \lambda_{2}, \ldots, \lambda_{p}$ are pairwise different, is a linear combination of the functions $f_{H}\left(\lambda_{i} t\right)$.

Proposition 3. If $\left\{X_{t}\right\} \sim F O U\left(\lambda_{1}, \lambda_{2}, \ldots, \lambda_{p}, \sigma, H\right)$ and $p \geq 2$, then

$$
\begin{equation*}
\mathbb{E}\left(X_{0} X_{t}\right)=\frac{\sigma^{2} H}{2} \sum_{i=1}^{p} \frac{\lambda_{i}^{2 p-2 H-2}}{\prod_{j \neq i}\left(\lambda_{i}^{2}-\lambda_{j}^{2}\right)} f_{H}\left(\lambda_{i} t\right) \tag{12}
\end{equation*}
$$

Remark 6. If $p=1$, we can consider that (12) it is equal to (11).

Using (12), and property 5 of the function $f_{H}$ (in Proposition 1) and a little more work, we obtain Theorem 2, which gives a formula for the spectral density of the process, that shows that if $p \geq 2$, then any $\operatorname{FOU}(p)$ is a short memory process.

Observe that when $p=2$, then $\sqrt{12}$ ) says that

$$
\begin{equation*}
\mathbb{E}\left(X_{0} X_{t}\right)=\frac{\sigma^{2} H}{2\left(\lambda_{1}^{2}-\lambda_{2}^{2}\right)}\left(\lambda_{1}^{2-2 H} f_{H}\left(\lambda_{1} t\right)-\lambda_{2}^{2-2 H} f_{H}\left(\lambda_{2} t\right)\right) \tag{13}
\end{equation*}
$$

Now, if we put $\lambda_{1}=\lambda$ and $\lambda_{2} \rightarrow 0$ in (13) we obtain 11). This is $\operatorname{FOU}\left(\lambda_{1}, \lambda_{2}, \sigma, H\right) \rightarrow$ $\operatorname{FOU}(\lambda, \sigma, H)$. Therefore, for small values of $\lambda_{2}$, the $\operatorname{FOU}\left(\lambda_{1}, \lambda_{2}, \sigma, H\right)$ process can be used to model both short and long memory processes.

Theorem 2. If $X=\left\{X_{t}\right\}_{t \in \mathbb{R}} \sim \operatorname{FOU}\left(\lambda_{1}^{\left(p_{1}\right)}, \lambda_{2}^{\left(p_{2}\right)}, \ldots, \lambda_{q}^{\left(p_{q}\right)}, \sigma, H\right)$ where $p_{1}+p_{2}+\ldots+p_{q}=p$, then the spectral density of the process is

$$
\begin{equation*}
f^{(X)}(x)=\frac{\sigma^{2} H \Gamma(2 H+1) \sin (H \pi)|x|^{2 p-1-2 H}}{2 \pi \prod_{i=1}^{q}\left(\lambda_{i}^{2}+x^{2}\right)^{p_{i}}} \tag{14}
\end{equation*}
$$

In particular, if $\left\{X_{t}\right\}_{t \in \mathbb{R}} \sim F O U\left(\lambda_{1}, \lambda_{2}, \ldots, \lambda_{p}, \sigma, H\right)$ then

$$
\begin{equation*}
f^{(X)}(x)=\frac{\sigma^{2} H \Gamma(2 H+1) \sin (H \pi)|x|^{2 p-1-2 H}}{2 \pi \prod_{i=1}^{p}\left(\lambda_{i}^{2}+x^{2}\right)} \tag{15}
\end{equation*}
$$

Remark 7. For $H \in(1 / 2,1)$, if $p=1$, then 0 is a singularity of the spectral density of the process, then we have a long memory process, and if $p \geq 2$, then 0 is not a singularity of the spectral density of the process, then we are under a short memory process.

## 3 Applications to real data

In this section we analize three real data set. In each one of them, we adjusted different $\mathrm{FOU}(p)$ models for $p=2,3,4$, and ARMA models. To fit the $\operatorname{FOU}(p)$ model, we supose that the real data set, are indexed in the interval $[0, T]$ for $T=20$. We also asume in all of cases that the observations are equally spaced in time, this is: $X_{T / n}, X_{2 T / n}, \ldots, X_{T}$. A change in the value of $T$ results in a change of estimated values of the parameters $\lambda_{i}$ and $\sigma$ but it does not change the substantial conclusions. That is why we choose arbitrarily $T=20$.

To estimate the parameters of each $\operatorname{FOU}(p)$, we will apply a naive method. We call $\lambda=\left(\lambda_{1}, \lambda_{2}, \ldots, \lambda_{q}\right)$ and $\widehat{\gamma}$ for the empirical auto-covariance function, and use

$$
(\widehat{\lambda}, \widehat{\sigma}, \widehat{H})=\arg \min \frac{1}{h} \sum_{i=1}^{h}(\gamma(i T / n)-\widehat{\gamma}(i T / n))^{2}
$$

This is, we choose the values of $(\lambda, \sigma, H)$ that minimize the difference in quadratic mean between the empirical and theoric auto-covariances in the first $h$ points. The value of $h$ was choosen arbitrarily. In this section, we show the results for $h=10$ terms. Similar results were obtained for other values of $h$. The arg min was taken over the set $\{(\lambda, \sigma, H): \quad \lambda>0, \quad \sigma>0, \quad H \geq 1 / 2\}$.

In each case, we also fit different ARMA models, and we compare the performance between these ARMA models and FOU models, through four measures on the quality of predictions: the root mean square error of prediction for the last $m$ observations, this is

$$
R M S E=\sqrt{\frac{1}{m} \sum_{i=1}^{m}\left(X_{n-m+i}-\widehat{X}_{n-m+i}\right)^{2}}
$$

the mean absolute error of prediction for last $m$ observations and their respectives predictions, this is

$$
M A E=\frac{1}{m} \sum_{i=1}^{m}\left|X_{n-m+i}-\widehat{X}_{n-m+i}\right|
$$

the Willmott index (Willmott, 1982) defined by

$$
d=1-\frac{\sum_{i=1}^{m}\left(X_{n-m+i}-\widehat{X}_{n-m+i}\right)^{2}}{\sum_{i=1}^{m}\left(\left|\widehat{X}_{n-m+i}-\bar{X}(m)\right|+\left|\widehat{X}_{n-m+i}-\bar{X}(m)\right|\right)^{2}}
$$

and Wilmott $L^{1}$ index defined by

$$
d_{1}=1-\frac{\sum_{i=1}^{m}\left|X_{n-m+i}-\widehat{X}_{n-m+i}\right|}{\sum_{i=1}^{m}\left(\left|\widehat{X}_{n-m+i}-\bar{X}(m)\right|+\left|\widehat{X}_{n-m+i}-\bar{X}(m)\right|\right)}
$$

where $\bar{X}(m):=\frac{1}{m} \sum_{i=1}^{m} X_{n-m+i}$, and $X_{1}, X_{2}, \ldots, X_{n}\left(\right.$ or $X_{T / n}, X_{2 T / n}, \ldots, X_{T}$ ) are the real observations, being $\widehat{X}_{i}$ are the predictions given by the model for the value $X_{i}$. All the predictions considered are one step. We will also compare in the three cases the graphs of empirical auto-covariance function with those of some fitted models.

### 3.1 Oxygen saturation in blood

The oxygen saturation in blood of a newborn child has been monitored during seventeen hours, and measures taking every two seconds. We asume that a series $X_{1}, X_{2}, \ldots, X_{304}$ of measures taken at intervals of 200 seconds. We adjusted an $\operatorname{AR}(1)$ and ARMA $(3,3)$ to compare with some FOU models. The AR(1) model was choosen because it maximize Willmott index among all the $\operatorname{ARMA}(p, q)$ models with $p, q \leq 4$. The ARMA $(3,3)$ model was choosen because it was where the maximum AIC value was obtained between all the $\operatorname{ARMA}(p, q)$ models with $p, q \leq 4$. Figure 2 shows the empirical auto-covariances of the series and the auto-covariances of the adjusted ARMA and FOU models. In Figure 3 we show the last 20 observations and their corresponding predictions according to each model. We observe that the shape of the predictions for the $\operatorname{FOU}(2)$ model with $\lambda_{1} \neq \lambda_{2}$ is more similar to the observed values than the other models considered. In Figure 5 we show the boxplots of $M A E$ for $m=1,2,3, \ldots, 20$ predictions for four models adjusted.

In Table 1, we show the values of $d, R M S E, d_{1}$ and $M A E$, for the last 20 predictions, for different $\operatorname{FOU}(p)$ for $p=2,3,4$. We see that $\operatorname{FOU}\left(\lambda_{1}, \lambda_{2}, \sigma, H\right)$ model achieves a $14 \%$ improvement over the $\mathrm{AR}(1)$ model in Willmott $d$ index, $17 \%$ in Willmott $d_{1}$ index, 6,5 $\%$ in $M A E$, and $0.6 \%$ in RMSE. We also observe the good behavior of FOU $\left(\lambda^{(3)}, \sigma, H\right)$. Is the best in $R M S E$ and $M A E$ and it is very close to the best in $d$ and $d_{1}$. We also see a similar performance of $\mathrm{FOU}(2), \mathrm{FOU}(3)$ and $\mathrm{FOU}(4)$ for pairwise different values of $\lambda_{i}$.

Figure 2: Empirical auto-covariances vs fitted auto-covariances according to the adjusted model.

Figure 3: Last 20 observed values (o) and your corresponding predictions $(\triangle)$ according to te model.

In Figure 4 we show the graph of Willmott index for $m=1,2,3, \ldots, 20$ predictions and the graph of the $M A E$. We observe that for values of $m$ between 6 to 20 , the mean absolute predictions error of $\operatorname{FOU}(2)$ with $\lambda_{1} \neq \lambda_{2}$ values are less than the $\mathrm{AR}(1)$ and ARMA(3, 3) models.

Figure 4: $\operatorname{FOU}\left(\lambda_{1}, \lambda_{2}\right)(\circ), \operatorname{FOU}\left(\lambda^{(2)}\right)(\triangle), \operatorname{ARMA}(3,3)(+), \operatorname{AR}(1)(\times)$. MAE for the last $m=1,2,3, \ldots, 20$ observations for the four models, and Willmott values.

Figure 5: Absolute differences between observed and predicted values according to the model.

Table 1. Values of $d, R M S E, d_{1}$ and $M A E$ for different models.

| Model | $d$ | $R M S E$ | $d_{1}$ | $M A E$ |
| :---: | :---: | :---: | :---: | :---: |
| AR $(1)$ | 0.4972 | 1.3051 | 0.3866 | 1.0617 |
| ARMA $(3,3)$ | 0.4259 | 1.3148 | 0.2868 | 1.1257 |
| $\operatorname{FOU}\left(\lambda_{1}, \lambda_{2}, \sigma, H\right)$ | 0.5663 | 1.2967 | 0.4513 | 0.9967 |
| $\operatorname{FOU}\left(\lambda_{1}, \lambda_{2}, \lambda_{3}, \sigma, H\right)$ | 0.5653 | 1.2803 | 0.4482 | 0.9894 |
| $\operatorname{FOU}\left(\lambda_{1}, \lambda_{2}, \lambda_{3}, \lambda_{4}, \sigma, H\right)$ | 0.5643 | 1.2783 | 0.4476 | 0.9882 |
| $\operatorname{FOU}\left(\lambda^{(2)}, \sigma, H\right)$ | 0.4754 | 1.3565 | 0.3303 | 1.1554 |
| $\operatorname{FOU}\left(\lambda^{(3)}, \sigma, H\right)$ | 0.5652 | 1.2750 | 0.4479 | 0.9858 |
| $\operatorname{FOU}\left(\lambda^{(4)}, \sigma, H\right)$ | 0.5607 | 1.2980 | 0.4474 | 1.0015 |

### 3.2 Box, Jenkins and Reinsel "series A"

The Series A is a record of 197 chemical process concentration readings, taken every two hours. This series was introduced by Box et al (Box et al, 1994, Ch. 4), also suggest an ARMA $(1,1)$ to this data set. An $\operatorname{AR}(7)$ are proposed in (Cleveland, 1971) and (McLeod \& Zang, 2006). In Figure 6 we observe that auto-covariances of AR(7) and ARMA(1, 1) adjusted models, goes to zero very quickly and their auto-covariance structure does not resemble that observed.

Figure 6: Empirical auto-covariances vs fitted auto-covariances according to the adjusted model for series A data set.

In Figure 7 we show the last 20 observations and their corresponding predictions according to each model.

Figure 7: Last 20 observed values (o) and your corresponding predictions ( $\triangle$ ) according to te model for series A data set.

Figure 8: $\operatorname{FOU}\left(\lambda_{1}, \lambda_{2}\right)(\circ), \operatorname{FOU}\left(\lambda^{(2)}\right)(\times), \operatorname{ARMA}(1,1)(\triangle), \operatorname{AR}(7)(+)$. MAE for the last $m=1,2,3, \ldots, 20$ observations for the four models, and Willmott values in seriesA.

Again, like the oxygen saturation in blood data set, we see that the graph of predictions generated by $\operatorname{FOU}(2)$ with $\lambda_{1} \neq \lambda_{2}$ model, have a shape more similar to the observed curve than those generated by the other models. In Table 2, we show the values
of $d, R M S E, d_{1}$ and $M A E$ for $\operatorname{AR}(7), \operatorname{ARMA}(1,1)$ and different $\operatorname{FOU}(p)$ for $p=2,3,4$ models. We see that $\operatorname{FOU}\left(\lambda_{1}, \lambda_{2}, \sigma, H\right)$ model achieves a $23 \%$ improvement over the AR (7) model in Willmott $d$ index, $11 \%$ in Willmott $d_{1}$ index, but has a loss of $14 \%$ in $M A E$, and $8 \%$ in $R M S E$. We also observe the good behavior of $\operatorname{FOU}\left(\lambda^{(4)}, \sigma, H\right)$. The models $\mathrm{FOU}(2), \mathrm{FOU}(3)$ and $\mathrm{FOU}(4)$ for pairwise different values of $\lambda_{i}$, are performing worse as the number of parameters increases in terms of $M A E$ and RMSE.

Table 2. Values of $d, R M S E, d_{1}$ and $M A E$ for different models adjusted to Series A.

| Model | $d$ | $R M S E$ | $d_{1}$ | $M A E$ |
| :---: | :---: | :---: | :---: | :---: |
| $\operatorname{AR~}(7)$ | 0.5389 | 0.3482 | 0.4690 | 0.2403 |
| $\operatorname{ARMA}(1,1)$ | 0.5043 | 0.3615 | 0.4175 | 0.2773 |
| FOU $\left(\lambda_{1}, \lambda_{2}, \sigma, H\right)$ | 0.6665 | 0.3788 | 0.5215 | 0.2737 |
| FOU $\left(\lambda_{1}, \lambda_{2}, \lambda_{3}, \sigma, H\right)$ | 0.6452 | 0.4462 | 0.4940 | 0.3204 |
| FOU $\left(\lambda_{1}, \lambda_{2}, \lambda_{3}, \lambda_{4}, \sigma, H\right)$ | 0.6509 | 0.4763 | 0.4839 | 0.3439 |
| FOU $\left(\lambda^{(2)}, \sigma, H\right)$ | 0.5866 | 0.3574 | 0.4534 | 0.2774 |
| $\operatorname{FOU}\left(\lambda^{(3)}, \sigma, H\right)$ | 0.6401 | 0.4339 | 0.4895 | 0.3141 |
| $\operatorname{FOU}\left(\lambda^{(4)}, \sigma, H\right)$ | 0.6662 | 0.3796 | 0.5313 | 0.2743 |

### 3.3 Level in feet of Lake Huron

Level in feet of years 1875 to 1972, is a time series of 98 observations.

Figure 9: Empirical auto-covariances vs fitted auto-covariances according to the adjusted model for Lake Huron data set.

Figure 10: Last 20 observed values (o) and your corresponding predictions ( $\triangle$ ) according to te model for Lake Huron data set.

Figure 11: $\operatorname{FOU}\left(\lambda_{1}, \lambda_{2}\right)(\circ), \operatorname{FOU}\left(\lambda^{(2)}\right)(\times), \operatorname{ARMA}(1,1)(+), \operatorname{AR}(2)(\triangle) . \operatorname{MAE}$ for the last $m=1,2,3, \ldots, 20$ observations for the four models, and Willmott values for Lake Huron data set.

The series has a slight tendency that was removed before adjusting the models. In (Brockwell \& Davis, 2002), suggest an $\operatorname{AR}(2)$ and $\operatorname{ARMA}(1,1)$ to this series. In Fig-
ure 9 we observe the auto-covariances of $\operatorname{AR}(2), \operatorname{ARMA}(1,1)$ and two $\mathrm{FOU}(2)$ adjusted models. In this case there are no substantial differences between the different models adjusted. Nor are there significant differences between the observed curve and the predictions curve for the the different models in the last 20 observations (Figure 10 ).

Figure 12: MAE values according to the model.

In Table 3 , we show the values of $d, R M S E, d_{1}$ and $M A E$, for adjusted $\operatorname{AR}(2)$, $\operatorname{ARMA}(1,1)$ and different $\operatorname{FOU}(p)$ for $p=2,3,4$ models.

We see that the performance of all models considered are similar (except FOU $\left(\lambda^{(3)}, \sigma, H\right)$ and $\operatorname{FOU}\left(\lambda^{(2)}, \sigma, H\right)$ models). Anyway, we see that $\operatorname{FOU}\left(\lambda_{1}, \lambda_{2}, \lambda_{3}, \lambda_{4}, \sigma, H\right)$ model shows a slightly better results.

Table 3. Values of $d, R M S E, d_{1}$ and $M A E$ for different models, adjusted to the series
"level on feet, Lake Huron".

| Model | $d$ | $R M S E$ | $d_{1}$ | $M A E$ |
| :---: | :---: | :---: | :---: | :---: |
| AR $(2)$ | 0.8739 | 0.7891 | 0.6735 | 0.6331 |
| ARMA $(1,1)$ | 0.8700 | 0.7994 | 0.66655 | 0.6523 |
| $\operatorname{FOU}\left(\lambda_{1}, \lambda_{2}, \sigma, H\right)$ | 0.8841 | 0.7620 | 0.6833 | 0.6205 |
| $\operatorname{FOU}\left(\lambda_{1}, \lambda_{2}, \lambda_{3}, \sigma, H\right)$ | 0.8872 | 0.7998 | 0.7023 | 0.6169 |
| $\operatorname{FOU}\left(\lambda_{1}, \lambda_{2}, \lambda_{3}, \lambda_{4}, \sigma, H\right)$ | 0.8963 | 0.7837 | 0.7197 | 0.5938 |
| $\operatorname{FOU}\left(\lambda^{(2)}, \sigma, H\right)$ | 0.7755 | 0.9394 | 0.5538 | 0.8007 |
| $\operatorname{FOU}\left(\lambda^{(3)}, \sigma, H\right)$ | 0.5915 | 2.1090 | 0.5818 | 1.1678 |
| $\operatorname{FOU}\left(\lambda^{(4)}, \sigma, H\right)$ | 0.8752 | 0.7755 | 0.6731 | 0.6294 |

We see that $\operatorname{FOU}\left(\lambda_{1}, \lambda_{2}, \lambda_{3}, \lambda_{4}\right)$ achieves the best results in $d, d_{1}$ and $M A E$, but the
results for $\operatorname{FOU}\left(\lambda^{(4)}\right)$ are very similars and has fewer parameters. In $R S M E$ the best result is obtained in $\operatorname{FOU}\left(\lambda^{(4)}\right)$ model.

## 4 Proofs

Proof of Proposition 1. 1. It is enough to prove that

$$
\frac{-\alpha^{1-2 H} \int_{0}^{\alpha x} e^{s} s^{2 H-1} d s+\beta^{1-2 H} e^{(\alpha+\beta) x} \int_{\beta x}^{+\infty} e^{-s} s^{2 H-1} d s}{e^{\alpha x}} \rightarrow 0 .
$$

We apply L'Hôpital rule two times and we obtain that

$$
\begin{gathered}
\lim _{x \rightarrow+\infty} \frac{\alpha+\beta}{\alpha} \frac{-e^{-\beta x} x^{2 H-1}+\beta^{1-2 H} \int_{\beta x}^{+\infty} e^{-s} s^{2 H-1} d s}{e^{-\beta x}}= \\
\lim _{x \rightarrow+\infty} \frac{\alpha+\beta}{\alpha \beta}(2 H-1) x^{2 H-2} \rightarrow 0 .
\end{gathered}
$$

2. Due $\alpha^{1-2 H} f_{H}^{(1)}(\alpha x)+\beta^{1-2 H} f_{H}^{(2)}(\beta x) \rightarrow 0$ and observe that $e^{-x} / x^{2-2 H} \rightarrow 0$ as $x \rightarrow+\infty$, we apply L'Hôpital rule and get

$$
\begin{gathered}
\lim _{x \rightarrow+\infty} \frac{\alpha^{1-2 H} f_{H}^{(1)}(\alpha x)+\beta^{1-2 H} f_{H}^{(2)}(\beta x)}{x^{2 H-2}}= \\
\lim _{x \rightarrow+\infty} \frac{\beta^{1-2 H} e^{(\alpha+\beta) x} \int_{\beta x}^{+\infty} e^{-s} s^{2 H-1} d s-\alpha^{1-2 H} \int_{0}^{\alpha x} e^{s} s^{2 H-1} d s}{e^{\alpha x} x^{2 H-2}}= \\
\lim _{x \rightarrow+\infty} \frac{\alpha+\beta}{\alpha} \frac{-x^{2 H-1}+\beta^{1-2 H} e^{\beta x} \int_{\beta x}^{+\infty} e^{-s} s^{2 H-1} d s}{x^{2 H-2}}=\frac{\alpha+\beta}{\alpha \beta}(2 H-1)
\end{gathered}
$$

where in the last equality was applied again the L'Hôpital rule.
3. In property 2 , put $\alpha=\beta=\lambda$, and we get that

$$
f_{H}(\lambda x)=f_{H}^{(1)}(\lambda x)+f_{H}^{(2)}(\lambda x) \sim 2(2 H-1)(\lambda x)^{2 H-2}
$$

where $x \rightarrow+\infty$.
4.

$$
\begin{gathered}
f_{H}(x)-f_{H}(0)=f_{H}(x)-2 \Gamma(2 H)= \\
\Gamma(2 H)\left(e^{x}+e^{-x}-2\right)-e^{-x} \int_{0}^{x} e^{s} s^{2 H-1} d s-e^{x} \int_{0}^{x} e^{-s} s^{2 H-1} d s= \\
o\left(x^{2 H}\right)-e^{x} \sum_{n=0}^{+\infty} \frac{x^{n+2 H}}{n!(n+2 H)}-e^{-x} \sum_{n=0}^{+\infty} \frac{(-1)^{n} x^{n+2 H}}{n!(n+2 H)}=o\left(x^{2 H}\right)-\frac{x^{2 H}}{H} .
\end{gathered}
$$

5. (Pipiras \& Taqqu, 2000), shown that if $X_{t} \sim \operatorname{FOU}(\lambda, \sigma, H)$, then

$$
\rho(t)=\mathbb{E}\left(X_{0} X_{t}\right)=\frac{\sigma^{2} \Gamma(2 H+1) \sin (H \pi)}{2 \pi} \int_{-\infty}^{+\infty} \frac{e^{i t x}|x|^{1-2 H}}{\lambda^{2}+x^{2}} d x
$$

But, due to $11 \rho(t)=\frac{\sigma^{2} H f_{H}(\lambda t)}{2 \lambda^{2 H}}$, then we deduce that

$$
f_{H}(\lambda t)=\frac{2 \Gamma(2 H) \sin (H \pi) \lambda^{2 H}}{H \pi} \int_{-\infty}^{+\infty} \frac{e^{i t x}|x|^{1-2 H}}{\lambda^{2}+x^{2}} d x
$$

Finally, if we make the change of variable $x=\lambda v$ we obtain the result.

## Proof of Proposition 2.

$$
\mathbb{E}\left(X_{t}^{(1)} X_{s}^{(2)}\right)=\sigma^{2} E\left(\int_{-\infty}^{t} e^{-\lambda_{1}(t-u)} d B_{H}(u) \int_{-\infty}^{s} e^{-\lambda_{2}(s-v)} d B_{H}(v)\right)
$$

As $H>1 / 2$, we can apply (3), then

$$
\mathbb{E}\left(X_{t}^{(1)} X_{s}^{(2)}\right)=\sigma^{2} H(2 H-1) \int_{-\infty}^{t} e^{-\lambda_{1}(t-u)} d u \int_{-\infty}^{s} e^{-\lambda_{2}(s-v)}|u-v|^{2 H-2} d v
$$

now we make the change of variable: $w=t-u, z=s-v$ and we get that

$$
\mathbb{E}\left(X_{t}^{(1)} X_{s}^{(2)}\right)=\sigma^{2} H(2 H-1) \int_{0}^{+\infty} e^{-\lambda_{1} w} d w \int_{0}^{+\infty} e^{-\lambda_{2} z}|t-w+z-s|^{2 H-2} d z
$$

Then, $\mathbb{E}\left(X_{t}^{(1)} X_{s}^{(2)}\right)$ it depends on $t-s$, so we only need to find a formula for $\mathbb{E}\left(X_{0}^{(1)} X_{t}^{(2)}\right)$.

$$
\mathbb{E}\left(X_{0}^{(1)} X_{t}^{(2)}\right)=\sigma^{2} H(2 H-1) \int_{0}^{+\infty} d w \int_{0}^{+\infty} e^{-\lambda_{1} w-\lambda_{2} z}|z-w-t|^{2 H-2} d z
$$

that after doing the change of variable $h=\lambda_{1} w+\lambda_{2} z$ in the integral in $z$ is equal to

$$
\begin{gather*}
\frac{\sigma^{2} H(2 H-1)}{\lambda_{2}} \int_{0}^{+\infty} d w \int_{\lambda_{1} w}^{+\infty} e^{-h}\left|\frac{h-\lambda_{1} w}{\lambda_{2}}-w-t\right|^{2 H-2} d h= \\
\frac{\sigma^{2} H(2 H-1)}{\lambda_{2}^{2 H-1}} \int_{0}^{+\infty} d w \int_{\lambda_{1} w}^{+\infty} e^{-h}\left|h-\left(\lambda_{1}+\lambda_{2}\right) w-\lambda_{2} t\right|^{2 H-2} d h= \\
\frac{\sigma^{2} H(2 H-1)}{\lambda_{2}^{2 H-1}} \int_{0}^{+\infty} e^{-h} d h \int_{0}^{h / \lambda_{1}}\left|h-\left(\lambda_{1}+\lambda_{2}\right) w-\lambda_{2} t\right|^{2 H-2} d w \tag{16}
\end{gather*}
$$

Now, we continue the calculus in the case $t \geq 0$, and we separate in zones according to the absolute value that apears in the last integral. Then, we get that 16 is equal to

$$
\frac{\sigma^{2} H(2 H-1)}{\lambda_{2}^{2 H-1}} \int_{0}^{\lambda_{2} t} e^{-h} d h \int_{0}^{h / \lambda_{1}}\left(\left(\lambda_{1}+\lambda_{2}\right) w+\lambda_{2} t-h\right)^{2 H-2} d w+
$$

$$
\begin{aligned}
& \frac{\sigma^{2} H(2 H-1)}{\lambda_{2}^{2 H-1}} \int_{\lambda_{2} t}^{+\infty} e^{-h} d h \int_{0}^{\frac{h-\lambda_{2} t}{\lambda_{1}+\lambda_{2}}}\left(h-\left(\lambda_{1}+\lambda_{2}\right) w-\lambda_{2} t\right)^{2 H-2} d w+ \\
& \frac{\sigma^{2} H(2 H-1)}{\lambda_{2}^{2 H-1}} \int_{\lambda_{2} t}^{+\infty} e^{-h} d h \int_{\frac{h-\lambda_{2} t}{\lambda_{1}+\lambda_{2}}}^{h / \lambda_{1}}\left(\left(\lambda_{1}+\lambda_{2}\right) w+\lambda_{2} t-h\right)^{2 H-2} d w
\end{aligned}
$$

Now we make $s=\lambda_{2} t-h$ in the first summand and $s=h+\lambda_{1} t$ in second, and we get

$$
\begin{gathered}
\frac{\sigma^{2} H}{\lambda_{1}+\lambda_{2}}\left(e^{-\lambda_{2} t} \Gamma(2 H) \lambda_{2}^{1-2 H}-\lambda_{2}^{1-2 H} \int_{0}^{\lambda_{2} t} e^{-h}\left(\lambda_{2} t-h\right)^{2 H-1} d h\right)+ \\
\frac{\sigma^{2} H}{\lambda_{1}+\lambda_{2}} \lambda_{1}^{1-2 H} \int_{0}^{+\infty} e^{-h}\left(h+\lambda_{1} t\right)^{2 H-1} d h= \\
\frac{\sigma^{2} H}{\lambda_{1}+\lambda_{2}}\left(e^{-\lambda_{2} t} \Gamma(2 H) \lambda_{2}^{1-2 H}-\lambda_{2}^{1-2 H} e^{-\lambda_{2} t} \int_{0}^{\lambda_{2} t} e^{s} s^{2 H-1} d s\right)+ \\
\frac{\sigma^{2} H}{\lambda_{1}+\lambda_{2}} \lambda_{1}^{1-2 H} e^{\lambda_{1} t} \int_{\lambda_{1} t}^{+\infty} e^{-s} s^{2 H-1} d s= \\
\frac{\sigma^{2} H}{\lambda_{1}+\lambda_{2}}\left(\lambda_{2}^{1-2 H} f_{H}^{(2)}\left(\lambda_{2} t\right)+\lambda_{1}^{1-2 H}\left[e^{\lambda_{1} t} \Gamma(2 H)-e^{\lambda_{1} t} \int_{0}^{\lambda_{1} t} e^{-s} s^{2 H-1} d s\right]\right)= \\
\frac{\sigma^{2} H}{\lambda_{1}+\lambda_{2}}\left(\lambda_{2}^{1-2 H} f_{H}^{(2)}\left(\lambda_{2} t\right)+\lambda_{1}^{1-2 H} f_{H}^{(1)}\left(\lambda_{1} t\right)\right)
\end{gathered}
$$

In the case $t \leq 0$, we work similarly.

Lemma 1. If $\lambda_{1}, \lambda_{2}, \ldots, \lambda_{p}$ are positives reals numbers, pairwise different, then

$$
K_{i}+2 \lambda_{i} \sum_{j \neq i} \frac{K_{j}}{\lambda_{i}+\lambda_{j}}=\frac{\lambda_{i}^{p-1}}{\prod_{j \neq i}\left(\lambda_{i}+\lambda_{j}\right)} \text { for } i=1,2,3, \ldots, p
$$

Proof. To obtain the result, it is enough to show that

$$
\begin{equation*}
K_{1}+2 \lambda_{1} \sum_{j=2}^{p} \frac{K_{j}}{\lambda_{i}+\lambda_{j}}=\frac{\lambda_{1}^{p-1}}{\prod_{j=2}^{p}\left(\lambda_{1}+\lambda_{j}\right)} \tag{17}
\end{equation*}
$$

Because, $K_{i}=\frac{\lambda_{i}^{p-1}}{\prod_{j \neq i}^{p}\left(\lambda_{i}-\lambda_{j}\right)}$, then 17 is equal to

$$
\frac{\lambda_{1}^{p-1}}{\prod_{j=2}^{p}\left(\lambda_{1}-\lambda_{j}\right)}+2 \lambda_{1} \sum_{j=2}^{p} \frac{K_{j}}{\lambda_{1}+\lambda_{j}}=\frac{\lambda_{1}^{p-1}}{\prod_{j=2}^{p}\left(\lambda_{1}+\lambda_{j}\right)}
$$

wich is equivalent to prove that (if we call $x=\lambda_{1}$ )

$$
\begin{equation*}
\frac{x^{p-2}}{\prod_{j=2}^{p}\left(x-\lambda_{j}\right)}-\frac{x^{p-2}}{\prod_{j=2}^{p}\left(x+\lambda_{j}\right)}=-2 \sum_{j=2}^{p} \frac{K_{j}}{x+\lambda_{j}} \tag{18}
\end{equation*}
$$

In fact, we develop the quotient in simple fractions, and we obtain that 18 is equal to

$$
\begin{gathered}
\frac{x^{p-2}}{\prod_{j=2}^{p}\left(x-\lambda_{j}\right)}-\frac{x^{p-2}}{\prod_{j=2}^{p}\left(x+\lambda_{j}\right)}=\sum_{i=2}^{p}\left(\frac{A_{i}}{x-\lambda_{i}}-\frac{B_{i}}{x+\lambda_{i}}\right)= \\
\sum_{i=2}^{p}\left(\frac{\lambda_{i}^{p-2}}{\prod_{j \neq i}\left(\lambda_{i}-\lambda_{j}\right)} \frac{1}{x-\lambda_{i}}-\frac{\left(-\lambda_{i}\right)^{p-2}}{\prod_{j \neq i}\left(\lambda_{j}-\lambda_{i}\right)} \frac{1}{x+\lambda_{i}}\right)= \\
\sum_{i=2}^{p}\left(\frac{\lambda_{i}^{p-2} 2 \lambda_{i}}{\prod_{j \neq i}\left(\lambda_{i}-\lambda_{j}\right)} \frac{1}{\left(x-\lambda_{i}\right)\left(x+\lambda_{i}\right)}\right)= \\
-2 \sum_{i=2}^{p} \frac{\lambda_{i}^{p-1}}{\left(\lambda_{i}-x\right) \prod_{j \neq i}\left(\lambda_{i}-\lambda_{j}\right)} \frac{1}{\left(x+\lambda_{i}\right)}=-2 \sum_{j=2}^{p} \frac{K_{j}}{x+\lambda_{j}} .
\end{gathered}
$$

Lemma 2. If $\lambda_{1}, \lambda_{2}, \ldots, \lambda_{p}$ son positives real numbers, pairwise different, then

$$
\frac{x^{2 p-2}}{\prod_{i=1}^{p}\left(x^{2}-\lambda_{j}^{2}\right)}=\sum_{i=1}^{p} \frac{\lambda_{i}^{2 p-2}}{\prod_{j \neq i}\left(\lambda_{i}^{2}-\lambda_{j}^{2}\right)} \frac{1}{x^{2}-\lambda_{i}^{2}}
$$

Proof. We decompose in simple fractions, and we obtain

$$
\begin{gathered}
\frac{x^{2 p-2}}{\prod_{i=1}^{p}\left(x^{2}-\lambda_{j}^{2}\right)}=\frac{x^{2 p-2}}{\prod_{i=1}^{p}\left(x-\lambda_{j}\right)\left(x+\lambda_{j}\right)}=\sum_{i=1}^{p}\left(\frac{A_{i}}{x-\lambda_{i}}+\frac{B_{i}}{x+\lambda_{i}}\right)= \\
\sum_{i=1}^{p}\left(\frac{\lambda_{i}^{2 p-2}}{2 \lambda_{i} \prod_{j \neq i}\left(\lambda_{i}^{2}-\lambda_{j}^{2}\right)} \frac{1}{x-\lambda_{i}}-\frac{\lambda_{i}^{2 p-2}}{2 \lambda_{i} \prod_{j \neq i}\left(\lambda_{i}^{2}-\lambda_{j}^{2}\right)} \frac{1}{x+\lambda_{i}}\right)= \\
\sum_{i=1}^{p} \frac{\lambda_{i}^{2 p-2}}{2 \lambda_{i} \prod_{j \neq i}\left(\lambda_{i}^{2}-\lambda_{j}^{2}\right)}\left(\frac{1}{x-\lambda_{i}}-\frac{1}{x+\lambda_{i}}\right)=\sum_{i=1}^{p} \frac{\lambda_{i}^{2 p-2}}{\prod_{j \neq i}\left(\lambda_{i}^{2}-\lambda_{j}^{2}\right)}\left(\frac{1}{x^{2}-\lambda_{i}^{2}}\right) .
\end{gathered}
$$

Proof of Proposition 3. We start with (4) in the case $p_{1}=p_{2}=\ldots \ldots=p_{q}=1$,

$$
\gamma(t)=\mathbb{E}\left(X_{t} X_{0}\right)=\sum_{i, j=1}^{q} K_{i} K_{j} \gamma_{\lambda_{h}, \lambda_{h^{\prime}}}^{(0,0)}(t)
$$

and using (6)

$$
\begin{gathered}
\gamma(t)=\sigma^{2} H \sum_{i, j=1}^{q} K_{i} K_{j} \frac{\left(\lambda_{i}^{1-2 H} f_{H}^{(1)}\left(\lambda_{i} t\right)+\lambda_{j}^{1-2 H} f_{H}^{(2)}\left(\lambda_{j} t\right)\right)}{\lambda_{i}+\lambda_{j}}= \\
\sigma^{2} H\left(\sum_{i, j=1}^{p} \frac{K_{i}^{2}}{2 \lambda_{i}} \lambda_{i}^{1-2 H} f_{H}\left(\lambda_{i} t\right)+\sum_{i=1}^{p} K_{i} \lambda_{i}^{1-2 H} f_{H}^{(1)}\left(\lambda_{i} t\right) \sum_{j \neq i} \frac{K_{j}}{\lambda_{i}+\lambda_{j}}\right)+ \\
\sigma^{2} H \sum_{i=1}^{p} K_{i} \lambda_{i}^{1-2 H} f_{H}^{(2)}\left(\lambda_{i} t\right) \sum_{j \neq i} \frac{K_{j}}{\lambda_{i}+\lambda_{j}}= \\
\sigma^{2} H \sum_{i=1}^{p} K_{i} \lambda_{i}^{-2 H} f_{H}\left(\lambda_{i} t\right)\left(\frac{K_{i}}{2}+\lambda_{i} \sum_{j \neq i} \frac{K_{j}}{\lambda_{i}+\lambda_{j}}\right)
\end{gathered}
$$

Now, using Lemma 1, we obtain that the last expression is equal to

$$
\begin{gathered}
\frac{\sigma^{2} H}{2} \sum_{i=1}^{p} K_{i} \lambda_{i}^{-2 H} f_{H}\left(\lambda_{i} t\right) \frac{\lambda_{i}^{p-1}}{\prod_{j \neq i}\left(\lambda_{i}+\lambda_{j}\right)}= \\
\frac{\sigma^{2} H}{2} \sum_{i=1}^{p} \frac{\lambda_{i}^{p-1}}{\prod_{j \neq i}\left(\lambda_{i}-\lambda_{j}\right)} \lambda_{i}^{-2 H} f_{H}\left(\lambda_{i} t\right) \frac{\lambda_{i}^{p-1}}{\prod_{j \neq i}\left(\lambda_{i}+\lambda_{j}\right)}= \\
\frac{\sigma^{2} H}{2} \sum_{i=1}^{p} \frac{\lambda_{i}^{2 p-2 H-2}}{\prod_{j \neq i}\left(\lambda_{i}^{2}-\lambda_{j}^{2}\right)} f_{H}\left(\lambda_{i} t\right)
\end{gathered}
$$

Lemma 3. If $\lambda_{1}, \lambda_{2}, \ldots, \lambda_{p}$ are positive reals numbers pairwise different, then

$$
\frac{x^{2 p-2}}{\prod_{i=1}^{p}\left(\lambda_{i}^{2}+x^{2}\right)}=\sum_{i=1}^{p} \frac{\lambda_{i}^{2 p-2}}{\prod_{j \neq i}\left(\lambda_{i}^{2}-\lambda_{j}^{2}\right)} \frac{1}{\lambda_{i}^{2}+x^{2}} .
$$

Proof. We will proceed by induction in $p$. For $p=1$, the equality is evident. Supose that the equality holds por $p$. Then, calculate

$$
\begin{equation*}
\frac{x^{2 p}}{\prod_{i=1}^{p+1}\left(\lambda_{i}^{2}+x^{2}\right)}=\frac{x^{2 p-2}}{\prod_{i=1}^{p}\left(\lambda_{i}^{2}+x^{2}\right)} \frac{x^{2}}{\lambda_{p+1}^{2}+x^{2}} \tag{19}
\end{equation*}
$$

applying the hypothesis of induction, we deduce that( (19) is equal to

$$
\begin{gather*}
\sum_{i=1}^{p} \frac{\lambda_{i}^{2 p-2}}{\prod_{j \neq i}\left(\lambda_{i}^{2}-\lambda_{j}^{2}\right)} \frac{1}{\lambda_{i}^{2}+x^{2}} \frac{x^{2}}{\lambda_{p+1}^{2}+x^{2}}= \\
\sum_{i=1}^{p} \frac{\lambda_{i}^{2 p-2}}{\left(\lambda_{i}^{2}-\lambda_{p+1}^{2}\right) \prod_{j \neq i}^{p}\left(\lambda_{i}^{2}-\lambda_{j}^{2}\right)}\left(\frac{\lambda_{i}^{2}}{\lambda_{i}^{2}+x^{2}}-\frac{\lambda_{p+1}^{2}}{\lambda_{p+1}^{2}+x^{2}}\right)= \\
\sum_{i=1}^{p} \frac{\lambda_{i}^{2 p-2}}{\left(\lambda_{i}^{2}-\lambda_{p+1}^{2}\right) \prod_{j \neq i}^{p}\left(\lambda_{i}^{2}-\lambda_{j}^{2}\right)}\left(\frac{\lambda_{i}^{2}}{\lambda_{i}^{2}+x^{2}}-\frac{\lambda_{p+1}^{2}}{\lambda_{p+1}^{2}+x^{2}}\right)= \\
\sum_{i=1}^{p} \frac{\lambda_{i}^{2 p}}{\prod_{j \neq i}^{p+1}\left(\lambda_{i}^{2}-\lambda_{j}^{2}\right)} \frac{1}{\lambda_{i}^{2}+x^{2}}-\sum_{i=1}^{p} \frac{\lambda_{p+1}^{2} \lambda_{i}^{2 p-2}}{\prod_{j \neq i}^{p+1}\left(\lambda_{i}^{2}-\lambda_{j}^{2}\right)} \frac{1}{\lambda_{p+1}^{2}+x^{2}} . \tag{20}
\end{gather*}
$$

Now, using Lemma 2 with $x=\lambda_{p+1}$, we obtain that

$$
\sum_{i=1}^{p} \frac{\lambda_{i}^{2 p-2}}{\prod_{j \neq i}^{p+1}\left(\lambda_{i}^{2}-\lambda_{j}^{2}\right)}=-\frac{\lambda_{p+1}^{2 p-2}}{\prod_{j=1}^{p}\left(\lambda_{p+1}^{2}-\lambda_{j}^{2}\right)}
$$

and then (20) is equal to

$$
\sum_{i=1}^{p+1} \frac{\lambda_{i}^{2 p}}{\prod_{j \neq i}^{p+1}\left(\lambda_{i}^{2}-\lambda_{j}^{2}\right)} \frac{1}{\lambda_{i}^{2}+x^{2}}
$$

Proof of Theorem 2. First, we will prove the result for the case in wich $\left\{X_{t}\right\}_{t \in \mathbb{R}} \sim$ $\operatorname{FOU}\left(\lambda_{1}, \lambda_{2}, \ldots, \lambda_{p}, \sigma, H\right)$. Using property (5) of $f_{H}$ in (12) and Lemma 3, we obtain that $\mathbb{E}\left(X_{0} X_{t}\right)=$

$$
\begin{gathered}
\frac{\sigma^{2} H \Gamma(2 H+1) \sin (H \pi)}{2 \pi} \int_{-\infty}^{+\infty} e^{i t x}|x|^{1-2 H} \sum_{i=1}^{p} \frac{\lambda_{i}^{2 p-2}}{\prod_{j \neq i}\left(\lambda_{i}^{2}-\lambda_{j}^{2}\right)} \frac{1}{\lambda_{i}^{2}+x^{2}} d x= \\
\frac{\sigma^{2} H \Gamma(2 H+1) \sin (H \pi)}{2 \pi} \int_{-\infty}^{+\infty} e^{i t x} \frac{|x|^{2 p-2 H-1}}{\prod_{i=1}^{p}\left(\lambda_{i}^{2}+x^{2}\right)} d x
\end{gathered}
$$

then (15) it holds.

Now, in the general case in wich $\left\{X_{t}\right\}_{t \in \mathbb{R}} \sim \operatorname{FOU}\left(\lambda_{1}^{\left(p_{1}\right)}, \lambda_{2}^{\left(p_{2}\right)}, \ldots, \lambda_{q}^{\left(p_{q}\right)}, \sigma, H\right)$ where $p_{1}+p_{2}+\ldots+p_{q}=p$, observe that the process $\left\{X_{t}\right\}_{t \in \mathbb{R}}$ is puntual limit of the processes of $\left\{X_{t}^{(n)}\right\}_{t \in \mathbb{R}} \sim \operatorname{FOU}(p)$ with parameters $\lambda_{1}, \lambda_{1}+1 / n, \ldots, \lambda_{1}+\left(p_{1}-1\right) / n, \ldots, \lambda_{q}, \lambda_{q}+$ $1 / n, \ldots, \lambda_{q}+\left(p_{q}-1\right) / n, \sigma, H$. Also, the spectral density of $\left\{X_{t}^{(n)}\right\}_{t \in \mathbb{R}}$ it is according to 15. Now, using that the processes are Gaussian, we deduce that $f^{\left(X^{(n)}\right)}(x) \rightarrow f^{(X)}(x)$ for all $x$, then (14) holds.

## 5 Conclusions

In this work we have presented a Gaussian processes that arises from the iteration of p fractional Ornstein-Uhlenbeck processes generated by the same fractional Brownian motion. When the values of $\lambda_{i}$ are pairwise different, this iteration results in a particular linear combination of each fractional Ornstein-Uhlenbeck process. We proved that when $H>1 / 2$ and $\lambda_{i}$ are pairwise different, the auto-covariance function of the process can be expressed as a linear combination of auto-covariance function of each $\operatorname{FOU}\left(\lambda_{i}, \sigma, H\right)$. We have obtained a explicit formula for the spectral density of the process that allows us to deduce that, although every fractional Ornstein-Uhlenebeck process with $H>1 / 2$ is a long memory process, for $p \geq 2$ the iteration results in a short memory process. We adjusted these processes to model three real time data sets, and compare their predictive performance with respect to ARMA models. In all three cases, similar or better performances were observed. They were observed even the good performance of $\operatorname{FOU}\left(\lambda^{(i)}, \sigma, H\right)$ for different values of $i$ in each case. To estimate the parameters of $\operatorname{FOU}(p)$ we use a naive method that consists in matching correlations in a certain number of points.

## 6 Acknowledgement

I want to thank Enrique Cabaña and Jorge Graneri for their generosity and contribution of ideas for this work.
