GENERALIZED INFORMATION STRUCTURES AND THEIR COHOMOLOGY

JUAN PABLO VIGNEAUX

Abstract. D. Bennequin and P. Baudot introduced a cohomological construction adapted to information theory, called information cohomology, that characterizes Shannon entropy through a cocycle condition. This text develops the relation between information cohomology and topos theory. We also introduce several new constructions and results. First, we define generalized information structures, as categories of finite random variables related by a notion of extension or refinement; classical and quantum probability spaces appear as models (representations) for these general structures. Generalized information structures form a category with finite products and coproducts. We prove that information cohomology is invariant under isomorphisms of generalized structures. Secondly, we prove that the relatively-free bar construction gives a projective object for the computation of cohomology. Thirdly, we provide detailed computations of $H^1$ for classical probabilities and describe the degenerate cases. We establish the homological nature of Tsallis entropy, introducing new modules for the coefficients. Finally, we re-interpret Shannon’s axioms for a ‘measure of choice’ in the context of this theory.

Key words and phrases. Information cohomology, entropy, non-extensive statistics, information structures.

1

In his seminal paper on the mathematical foundations of communication, Claude Shannon [18] defined the information content of a random variable \( X : (\Omega, \mathcal{F}) \to E_X \), taking values in a finite set \( E_X \), by the formula

\[
S_1[X](P) := -\sum_{x \in E_X} P(X = x) \log P(X = x),
\]

where \( P \) denotes a probability measure on \( \Omega \). The function \( S_1 \) is called Shannon entropy, Gibbs entropy or simply entropy. It measures the uncertainty of a measurement: \( S_1[X] \) is a concave function that attains its maximal value when the probability is uniformly distributed on all possible outputs of \( X \), and that vanishes whenever the probability is completely concentrated on a particular output. The function \( S_1[X] \) only depends on the restriction of \( P \) to the events \( \{ X = x \} \); this is locality in our probabilistic context.

In the presence of a second variable \( Y : (\Omega, \mathcal{F}) \to E_Y \), such that \( |E_Y| < \infty \), one can establish the identity

\[
S_1[X,Y] = S_1[X] + S_1[Y|X],
\]

where \( S_1[X,Y] \) is the entropy of the joint variable \( (X,Y) \), and \( S_1[Y|X] \) is the conditional entropy, defined as

\[
S_1[Y|X] := \sum_{x \in E_X} P(X = x) S_1[Y](P|_{X=x}).
\]

There is a strong resemblance between (1.2) and a cocycle condition in group cohomology; this becomes more evident if we rewrite it as

\[
0 = X.S_1[Y] - S_1[XY] + S_1[X]
\]

where \( XY \) stands for the joint variable, and \( X.S_1(Y) \) indicates conditioning seen as an action of variables on functions.

Information theory and statistical mechanics make use of several generalizations of entropy. For example, in 1967 Jan Havrda and František Charvát [11] introduced the \( \alpha \)-entropy: for \( \alpha > 0, \alpha \neq 1 \), it is given by the formula

\[
S_\alpha[X](P) = c_\alpha \left( \sum_{x \in E_X} P(x)^\alpha - 1 \right),
\]

where \( c_\alpha \) is some constant, positive if \( 0 < \alpha < 1 \) and negative otherwise. Typical choices satisfy

\[
\lim_{\alpha \to 1} (1 - \alpha)c_\alpha = 1;
\]
in this case, $S_\alpha[X] \rightarrow S_1[X]$ when $\alpha \rightarrow 1$ (cf. [2]). In this work, we shall take $c_\alpha = \frac{1}{1-\alpha}$ following [21]. The use of $\alpha$-entropies in statistical mechanics has been popularized by Constantino Tsallis, and the most common name for $S_\alpha$ is Tsallis $\alpha$-entropy.

Other notions of entropy have been introduced in information theory and statistical mechanics. An important example is the so-called generalized entropy of degree $\alpha$, also known as Tsallis $\alpha$-entropy; it is defined for each $\alpha \neq 1$ by

\begin{equation}
S_\alpha[X](P) := c_\alpha \left( \sum_{k=1}^{n} P(X = x_k)^\alpha - 1 \right),
\end{equation}

where $c_\alpha$ is some constant that depends on $\alpha$, usually chosen in such a way that $S_\alpha[X] \rightarrow S_1[X]$ when $\alpha \rightarrow 1$ [2]. This entropy also satisfies the relation (1.4), for a modified action of the variables.

Baudot and Bennequin [1] formalized the cohomological nature of information, already suggested by [4]. The purpose of their work is to present a ‘theory of shape’ related to information theory. This is done recurring to topos theory, developed by Grothendieck, Verdier, Artin and their collaborators as a tool for algebraic geometry. The theory provides a setting to apply in the future other geometrical or topological methods. The following paragraphs summarize the main constructions.

Each variable $X$ defines a partition of $\Omega$ by sets $\{X = x_i\} := \{\omega \in \Omega \mid X(\omega) = x_i\}$. In this sense, $X$ allows certain discrimination between elementary outputs $\omega \in \Omega$. We consider as equivalent two variables associated to the same partition, and we use both terms as equivalent. Some variables give partitions that are refinements of another. Finite partitions of $\Omega$ form a category $\Theta(\Omega)$, where an arrow $\pi : X \rightarrow Y$ means that $X$ refines $Y$; in fact, $\pi$ can be implemented as a surjection, in such a way that each set $y \in Y$ is the union of sets in $\pi^{-1}(y) \subset X$. The joint of two variables $(X, Y) : \Omega \rightarrow E_X \times E_Y$, $\omega \mapsto (X(\omega), Y(\omega))$ gives a new partition finer than those of $X$ or $Y$. In fact, $XY := (X, Y)$ correspond to the categorical product of $X$ and $Y$ in $\Theta(\Omega)$.

An information structure $S$ is, by definition, a full subcategory of $\Theta(\Omega)$ that is supposed to have between its objects the trivial partition $1 := \{\Omega\}$ and the product $YZ$ for each couple of variables $Y$ and $Z$ that are refined by a third variable $X$. These categories play a fundamental role in the geometrical constructions that follow. The definition implies that each set $\delta_X$ of variables refined by $X$ is a monoid. Let $A_X$ be the algebra generated by $\delta_X$ over $\mathbb{R}$; since $\delta_Y \hookrightarrow \delta_X$ for $X \rightarrow Y$, the functor $X \mapsto A_X$ is a contra-variant functor. Such functors are known as presheaves in the geometric literature.

Probabilities come as a functor $Q : S \rightarrow Sets$ that associates to each partition $X$ a simplicial subcomplex $Q_X$ of the simplex

\begin{equation}
\Delta(X) = \left\{ p : X \rightarrow [0, 1] \mid \sum_{x \in X} p(x) = 1 \right\}.
\end{equation}

To each arrow of refinement $\pi : X \rightarrow Y$, there corresponds an operation called marginalization, $\pi_* : Q_X \rightarrow Q_Y$, given by

\begin{equation}
\forall y \in Y, \quad \pi_* p(y) = \sum_{x \in \pi^{-1}(y)} p(x).
\end{equation}
We denote by $F(Q_X)$ the vector space of measurable functions on $Q_X$. It accepts an action of $\mathcal{A}_X$, parameterized by $\alpha \geq 0$: for a variable $Y$ in $\delta_X$, with values in $E_Y$, and $f \in F(Q_X)$, the new function $Y.f$ is given by

$$ (Y.f)(P) = \sum_{y \in E_Y} P(Y = y)\alpha f(P|_{Y=y}). $$

This means that $F(Q_X)$ is a $\mathcal{A}_X$-module, denoted $F_\alpha(Q_X)$. In fact, under the terminology introduced in the next paragraph, $F_\alpha(Q)$ is a fixed sheaf of $\mathcal{A}$-modules. Grothendieck defined abelian categories and derived functors as a general ground for homological algebra. Essentially, an abelian category has an appropriate notion of kernel and cokernel, and it allows the introduction of homological algebra mimicking the case of modules. A presheaf of $\mathcal{A}$-modules is a functor $F$ from $S^{op}$ to the category of abelian groups, such that each $F(X)$ has the structure of an $\mathcal{A}_X$-module, functorially in $X$. These presheaves and the natural transformations between them form an abelian category, that we denote $\mathcal{M}od(\mathcal{A})$. Moreover, in this abelian category it is possible to define right derived functors for $\text{Hom}(\cdot, A)$ (where $A$ is a fixed sheaf of $\mathcal{A}$-modules); this derived functors are called $\text{Ext}^n(\cdot, A)$ and they are cohomological functors: for an exact sequence $0 \to X' \to X \to X'' \to 0$ of sheaves, they induce a long exact sequence

$$ 0 \to \text{Hom}(X', A) \to \text{Hom}(X, A) \to \text{Hom}(X'', A) \to \text{Ext}^1(X', A) \to \text{Ext}^1(X, A) \to ... $$

as in the basic cases of singular or cellular cohomology.

Given an information structure $S$, the associated "information topos" is the category of presheaves on the ringed site $(S, \mathcal{A})$. We are particularly interested in the abelian category of $\mathcal{A}$-modules, since information functions appear there as generators of cohomology classes, as we describe now. In Section 3.2 information cohomology with coefficients in $F$ is defined as

$$ H^n(S, F) := \text{Ext}^n(\mathbb{R}_S, F), $$

where $\mathbb{R}_S$ is the sheaf that associates to every $X \in \text{Ob}(S)$ the set $\mathbb{R}$ with trivial $\mathcal{A}_X$ action (i.e. for all $Y \in \delta_X$ and all $r \in \mathbb{R}$, $Y.r = r$). Using the bar resolution construction (see Section 3.3), this is reduced to compute the cohomology of a differential complex $\{C^n(F), \delta\}_{n \geq 0}$. When $F = F_\alpha(Q)$, each element $f \in C^n$ corresponds to a collection of measurable functions

$$ \{ f_X[X_1|...|X_n] : Q_X \to \mathbb{R} | X \in \text{Ob}(S) \} \subset \delta_X; $$

these functions are subject to a condition called joint locality:

$$ f_X[X_1|...|X_n](P_X) = f_{X_1...X_n}[X_1|...|X_n)((X_1 \cdots X_n), P_X). $$

where $(X_1 \cdots X_n), P_X$ denotes the marginalization corresponding to the arrow $X \to X_1 \cdots X_n$. The map $\delta$ is given by

$$ \delta f[X_1|...|X_{n+1}] = X_1.f[X_2|...|X_{n+1}] + \sum_{k=1}^{n} (-1)^k f[X_1|...|X_kX_{k+1}|...|X_n] + (-1)^{n+1} f[X_1|...|X_n] $$

and it is known as Hochschild coboundary.
All the structures that we have described are already present in [1] (for α = 1), where it is claimed that, under some connectivity hypotheses, $H^1(\mathcal{S}, F_1(\mathcal{Q}))$ is one dimensional and generated by Shannon/Gibbs entropy. The first goal of our work is to fill some gaps in the proof of this statement; generalizing the conditioning action, with the introduction of α > 0, we are also able to find Tsallis entropy in cohomology.

We review the standard construction of the relative bar resolution and prove (Proposition 3.5) that, in fact, it gives a projective resolution in $\text{Mod}(\mathcal{A})$; this depends on the conditional existence of products in the definition of an information structure. Therefore, the cohomology of $\{C^n(F, \delta)\}_{n \geq 0}$ coincides with $\text{Ext}^n(\mathcal{R}, \mathcal{S}, \mathcal{F})$. Proposition 4.10 establishes the minimal hypothesis under which the cocycle equations have a unique solution. We also make explicit the notion of connectivity introduced in [1, p. 3273], defining an appropriate notion of non-degenerate product between two variables (see Section 4.5).

In general, $H^1(\mathcal{S}, F_\alpha(\mathcal{Q}))$ depends on the minimal objects of $\mathcal{S}$: those partitions not refined by others. If each of these partitions can be written as non-degenerate products, then Proposition 4.13 establishes that

\begin{equation}
H^1(\mathcal{S}, F_1(\mathcal{Q})) = \prod_{c \in \pi_0(\mathcal{S}^*)} \mathbb{R} \cdot S_1^{(c)}
\end{equation}

\begin{equation}
H^1(\mathcal{S}, F_\alpha(\mathcal{Q})) = \left( \prod_{c \in \pi_0(\mathcal{S}^*)} \mathbb{R} \cdot S_\alpha^{(c)} \right) / \mathbb{R} \cdot S_\alpha \quad \text{(when } \alpha \neq 1)\end{equation}

where $c$ represents a connected component of $\mathcal{S}^*$ — the category $\mathcal{S}$ without its terminal object — and

\begin{equation}
S_\alpha^{(c)}[X] = \begin{cases} S_\alpha[X] & \text{if } X \in \text{Ob}(c) \\ 0 & \text{if } X \notin \text{Ob}(c) \end{cases}
\end{equation}

On the other hand, if some of the minimal objects of $\mathcal{S}$ is irreducible (it cannot be written as a non-trivial product), the group $H^1(\mathcal{S}, F_\alpha(\mathcal{Q}))$ has infinite dimension; Proposition 4.15 makes this precise.

All the constructions (and consequently all the proofs) are local, in the sense that, over each partition $X$ in $\text{Ob}(\mathcal{S})$, we just consider laws on the quotient $\Omega/X$ and functions of them. This suggest that $\Omega$ is not essential and we could replace a concrete information structure $\mathcal{S} \hookrightarrow \mathcal{O}(\Omega)$ by an abstract information structure: a category whose objects are finite sets (that represent possible outputs of a variable, or the quotients $\Omega/X$) and whose morphisms are surjections (supposed non-injective), as a natural analog to refinements. For example, this point of view is adopted by Gromov at the beginning of [8], where the probability space is seen as an emergent object. We pursue this idea in Section 2.2 laying the appropriate axiomatization for such abstract information structures in Definition 2.6; the axioms recover the multiplicative structure of partitions, absent in [8]. An abstract structure can have different concrete incarnations as partitions of some set $\Omega$, that we call ‘model’. Information cohomology just depends on the abstract structure (see Corollary 4.4). In the category of abstract information structures, finite products and coproducts exists, and their have models whenever their factors have too, as shown in Proposition 2.15.
In Section 5.1 we make some remarks about Shannon’s axiomatic characterization of entropy. In fact, interpreted as a general expression for the third axiom proposed by Shannon (recurrence formula), along with the supposed measurability of information, turn out to be sufficient to characterize entropy. We do not need additional symmetry hypotheses or recurrence properties. The definition of information cohomology gives an interpretation of entropy in the context of extensions of algebras.

In [23], we have shown that the multiplicative relations between the multinomial coefficients, considered asymptotically, imply that $S_1$ is a 1-cocycle, which gives a combinatorial interpretation for the cocycle condition. Even if the argument is simple and based on the insights of type theory, we are not aware of other text where this link is made explicit. These results also make sense for $\alpha = 2$, if the usual multinomials are replaced by their $q$-deformation.

Finally, Section 6 extend the notion of model to the quantum setting, and explains how the general constructions of Sections 2 and 3 are compatible with the computations in [1], where it is proved that Von Neumann’s entropy

$$S(\rho) = \text{Tr} (-\rho \log_2 \rho).$$

is a 0-cocycle, whose coboundary is Shannon’s entropy.

2. Information structures

2.1. Random variables and probabilities. Let $\Omega$ be a set representing the collection of all possible ‘elementary outcomes’ of a given experience. For us, a random variable is a function on $\Omega$ taking values in a measurable space $(E_X, \mathcal{E}_X)$; in applications, this is usually $(\mathbb{R}^n, \mathcal{B}(\mathbb{R}^n))$ or a finite set $E$ with the $\sigma$-algebra $\mathcal{P}(E)$. Random variables are also called observables, and they represent things that we can measure. Throughout this work, we suppose that each random variable takes a finite number of different values, $E_X = \{x_1, \ldots, x_n\}$; to emphasize this we talk sometimes about finite random variables. Accordingly, we set $(E_X, \mathcal{P}(E_X))$ as codomain of $X$, and we drop $\mathcal{P}(E_X)$ from the notation. The collection of subsets $\{\omega \in \Omega | X(\omega) = x\} \subset \Omega$, for $x \in E_X$, form a partition of the space $\Omega$. Conversely, to any finite partition $\{\Omega_1, \ldots, \Omega_n\}$ of $\Omega$, one can associate a random variable $\sum_{i=1}^n a_i \chi_{\Omega_i}$, where $\chi_{\Omega_i}$ denotes the indicator function and the numbers $\{a_1, \ldots, a_n\} \subset \mathbb{R}$ (or any ring) are all different. Two such random variables can differ in the values they take, but both are equally good to “discriminate” between elementary outcomes. Two random variables will be equivalent for us if they define the same partition of $\Omega$; random variable and partition will be interchangeable terms.

\[\text{1}\]It is common to fix a $\sigma$-algebra $\mathcal{F}$ over $\Omega$ and define a random variable as a function $X : (\Omega, \mathcal{F}) \to (E_X, \mathcal{E})$ that is $\mathcal{F}/\mathcal{E}$-measurable, i.e. for all $S \in \mathcal{E}$, $X^{-1}(S) \in \mathcal{F}$. Here, we take a different point of view: an arbitrary function $X$ to a measurable space defines a $\sigma$-algebra $\sigma(X)$ on $\Omega$.

\[\text{2}\]In the sequel, $\{\omega \in \Omega | X(\omega) = x\}$ is simply written $\{X = x\}$. 

Every finite random variable $X$ defines an algebra of sets over $\Omega$ whose atoms are the elements of the finite partition defined by $X$. This is usually called the algebra induced by $X$, we shall denote it $\sigma(X)$. When $\sigma(Y) \subset \sigma(X)$, we say that $\sigma(Y)$ is coarser than $\sigma(X)$, or even that $Y$ is coarser than $X$; alternatively, $\sigma(X)$ is finer than $\sigma(Y)$ or refines $\sigma(Y)$.

We define now a category $\mathcal{O}(\Omega)$ of finite observables, whose objects are all the finite partitions of $\Omega$. There is an arrow between two objects $X$ and $Y$, given by a surjection $\pi: X \to Y$, each time that $Y$ is a refinement of $X$ (this means, $\sigma(Y) \subset \sigma(X)$); each subset $B \in Y$ equals $\cup_{A \in \pi^{-1}(B)} A$. In this case, $X$ discriminates better between elementary outcomes. The category $\mathcal{O}(\Omega)$ has a terminal element: the trivial partition $1 := \{ \Omega \}$. When $\Omega$ is finite, it also has an initial element: the partition by points, that we denote by $0$. The categorical product $X \times Y$ of two partitions $X$ and $Y$ is the coarsest partition that refines both.

Given two random variables $X: \Omega \to (E_X, \mathcal{E}_X)$ and $Y: \Omega \to (E_Y, \mathcal{E}_Y)$, we can form the joint variable $(X, Y): \Omega \to (E_X \times E_Y, \mathcal{E}_X \otimes \mathcal{E}_Y)$. The algebra
\begin{equation}
\mathcal{E}_X \otimes \mathcal{E}_Y := \sigma(\{ A \times B \mid A \in \mathcal{E}_X \text{ and } B \in \mathcal{E}_Y \}),
\end{equation}
is called the product ($\sigma$-)algebra (cf. [1]). The partition generated by $(X, Y)$ is $X \times Y$. For convenience, we set $XY := (X, Y) = X \times Y$. This product is commutative and associative. Moreover, every element $X$ is idempotent ($XX = X$) and satisfies $0X = 0$, $1X = X$.

**Definition 2.1.** A (concrete) classical information structure $S$ is a full subcategory of $\mathcal{O}(\Omega)$ that satisfies the following properties:

1. The partition $1$ is in $\text{Ob}(S)$.
2. For every $X, Y, Z$ in $\text{Ob}(S)$, if $X \to Y$ and $X \to Z$, then $YZ$ belongs to $\delta$.

A big family of examples can be obtained as follows: let $\Omega$ be a set and $\Sigma = \{ S_i : \Omega \to E_i \mid 1 \leq i \leq n \}$ an arbitrary collection of finite variables. Any subset $I := \{i_1, ..., i_k\}$ of $\{1, ..., n\}$ defines a new partition by means of the product already described, $S_I := S_{i_1} \cdots S_{i_k}$; by convention, $S_\emptyset := 1$. Let $W(\Sigma)$ be the full subcategory $\mathcal{O}(\Omega)$ with objects $\{S_I \mid I \subset [n]\}$. Since $W(\Sigma)$ contains all the products by construction, it is an information structure. Algebraically, $W(\Sigma)$ has the structure of a commutative idempotent monoid, with identity $1$.

Suppose now that $\Omega = \prod_{i \in [n]} E_i$, where $|E_i| \geq 2$ for all $i$, and $S_i : \Omega \to E_i$ is the $i$-th canonical projection ($i = 1, ..., n$). Under these assumptions, $S_I \neq S_J$, as partitions, whenever $I \neq J$, and $S_I \to S_J$ implies that $J \subset [n]$. In consequence, there is an injection $i : \Delta([n]) \to \text{Ob}(W(\Sigma))$, $I \mapsto S_I$, where $\Delta([n])$ denotes the abstract simplex of dimension $n-1$ (see Appendix A). Let $K$ be a simplicial subcomplex of $\Delta([n])$.

---

3An algebra of sets $\mathcal{T}$ over a set $\Omega$ is a collection of subsets of $\Omega$ such that:

1. $\emptyset$ and $\Omega$ are in $\mathcal{T}$;
2. $\mathcal{T}$ is closed complementation: if $A \in \mathcal{T}$, then $A^c := \Omega \setminus A \in \mathcal{T}$;
3. $\mathcal{T}$ is closed under finite unions: given any $A, B \in \mathcal{T}$, one has $A \cup B \in \mathcal{T}$.

When the algebra is finite, its elements are all the possible unions of its minimal sets— in the sense of inclusion—, called atoms; the atoms are said to generate the algebra.

4It would be simpler to take $\delta$ cartesian. But we already know that, in quantum mechanics, some measurements are incompatible. We would like to describe the classical and quantum cases with the same axioms; in the classical case, this just adds flexibility.

5Proof: for any $I \subset [n]$, 
\[ \sigma(S_I) = \{ S_I^{-1}(A) \mid A \in \bigotimes_{i \in I} \mathcal{E}_i \} \]
Figure 1. Identification of $\Delta([3])$ as the non-trivial part of $W(S_1,S_2,S_3)$. We have depicted also the barycentric subdivision, that has one point for each variable.

$\Delta([n])$: by $\iota$, it determines a full subcategory of $W(\Sigma)$, to which we adjoin $S_0$ as a terminal object, constructing this way a new category $\mathcal{S}(K)$, that is an information structure too. In fact, diagram $\begin{array}{ccc} S_I & \xleftarrow{S_J} & S_L \end{array}$ means that $J$ and $L$ are faces of $I$ (for this, we need $|E_i| \geq 2$; see Remark 2.3 bellow); therefore, $J \cup L$ is also a face of $I$, that belongs to $K$ by the simplicial condition; $I \cup J \in K$ implies that $S_I \cup S_J = S_I S_J \in Ob(\mathcal{S}(K))$.

Example 2.2. Take $\Omega = \{0,1\}^3$, and consider the projections $S_i : \Omega \to \{0,1\}$ such that $(x_1,x_2,x_3) \mapsto x_i$, for $i \in \{1,2,3\}$. Taking all the possible joint variables, we obtain the monoid depicted in Figure 2.1. However, if we forbid the maximal face $S_1S_2S_3$, we obtain a new information structure, which is not a monoid. This could be linked to physical constraints related to measurements.

Remark 2.3. Bennequin and Baudot \cite{1} define the structures $\mathcal{S}(K)$ for any collection of finite variables $\Sigma := \{ S_i : \Omega \to E_i \ | \ 1 \leq i \leq n \}$. However, these structures do not satisfy in general the axiom (2) above: for instance, let $\Omega = \{0,1\}^2$; $X_i$, the projection on the $i$-th component ($i = 1,2$), and $X_3 = \{(0,0),\{(0,0)\}^c\}$. Define $K$ as the simplicial subcomplex of $\Delta([3])$ with maximal faces $\{(1,2),\{3\}\}$. The product $X_1X_2$ is the atomic partition, that refines all the others, while some products (like $X_1X_3$) are not in $\mathcal{S}(K)$.

A probability law on $(\Omega,\mathcal{F})$, $\mathcal{F}$ finite, is a function $P : \mathcal{F} \to [0,1]$ such that:

1. $P(\Omega) = 1$.
2. Given a collection of disjoint sets $\{A_1,...,A_n\} \subset \mathcal{F}$,

\begin{equation}
P\left(\bigcup_{i=1}^{n} A_i\right) = \sum_{i=1}^{n} P(A_i).
\end{equation}

and every set $S_I^{-1}(A)$ has the form $\prod_{i \in I} F_i$ with $F_i = E_i$ whenever $i \notin I$. If $J \notin I$, say $j^* \in J \setminus I$, then in general $S_{j^*}(S_J^{-1}(A))$, with $A \in \bigotimes_{j \in J} E_i$, will differ from $E_i$, proving that $S_J^{-1}(A)$ is not in $\sigma(S_I)$. 

This property is called additivity.

We denote by \( \Delta(\mathcal{F}) \) the set of all possible laws on \( (\Omega, \mathcal{F}) \). Suppose \( \mathcal{F} \) has \( N \) atoms, say \( \{a_1, ..., a_N\} \); then, probability laws in \( (\Omega, \mathcal{F}) \) can be identified with functions \( p \) defined on the atoms, such that \( \sum_{i=1}^{N} p(a_i) = 1 \). In this sense, \( \Delta(\mathcal{F}) \) is a simplex embedded in \( \mathbb{R}^N \); as such, can be considered a measurable space in itself (this is important in Section 4.1). For convenience, we identify each vertex \( \delta \) of \( \Delta(\mathcal{F}) \) with the corresponding atom \( a_i \), such that \( \delta_i(a_i) = 1 \). The measure \( \delta_i \) is called the Dirac \((\delta)-\)measure on \( a_i \). More generally, we shall consider a simplicial subcomplex of \( \Delta(\mathcal{F}) \), denoted by \( Q\sigma \).

Classically, the law of a random variable \( X : (\Omega, \mathcal{F}, \mathbb{P}) \to (E_X, \mathcal{E}) \) is the image measure \( X[\mathbb{P}] = \mathbb{P} \circ X^{-1} : \mathcal{E} \to \mathcal{E} \). For a law is completely determined by the restriction of \( \mathbb{P} \) to \( \sigma(X) \), the set \( \Delta(\sigma(X)) \) contains all possible laws for \( X \). Given \( \pi : X \to Y \) in \( \Theta(\Omega) \), define the application \( \pi_* : \Delta(\sigma(X)) \to \Delta(\sigma(Y)) \) that associates to any law \( P \) on \( (\Omega, \sigma(Y)) \) a new law \( \pi_*P \) on \( (\Omega, \sigma(X)) \) given by

\[
\pi_*P(B_Y) = P(B_Y), \quad \text{for all } B_Y \in \sigma(Y) \subset \sigma(X).
\]

This is called marginalization by \( Y \). We write \( Y \) instead of \( \pi_* \) when \( \pi \) is clear from the context. Explicitly, for each \( y \in Y \),

\[
\pi_*P(y) = \sum_{x \in \pi^{-1}(y)} P(x).
\]

**Proposition 2.4.** Let \( X, Y \) be variables on \( \Omega, \pi : X \to Y \). If \( Q_X \) is a simplicial subcomplex of \( \Delta(\sigma(X)) \), then \( \pi_*Q_X \) is a simplicial subcomplex of \( \Delta(\sigma(Y)) \).

**Proof.** Remark that \( \pi_* \) sends the convex combination \( P = \sum_{x \in E_X} \lambda(x)\delta_x \) to the convex combination \( \pi_*P = \sum_{y \in Y} \left( \sum_{x \in \pi^{-1}(y)} \lambda(x) \right)\delta_y \). Let \( \sigma \) be a simplex of \( Q_X \), with vertices \( \{\delta_{x_1}, ..., \delta_{x_k}\} \). Each \( x_i \) refines the corresponding atom \( \pi(x_i) \in Y \); clearly, \( \pi_*\delta_{x_i} = \delta_{\pi(x_i)} \). Let \( \{y_1, ..., y_m\} \) be the set of images of \( \{x_1, ..., x_k\} \) under \( \pi \). The map \( \pi_* \) sends convex combinations of \( \{\delta_{x_1}, ..., \delta_{x_k}\} \) to convex combinations of \( \{\delta_{y_1}, ..., \delta_{y_m}\} \), and hence the simplex \( \sigma = [\delta_{x_1}, ..., \delta_{x_k}] \) to the simplex \( [\delta_{y_1}, ..., \delta_{y_m}] \).

Given a face \( \rho \) with vertices \( V \subset \{y_1, ..., y_m\} \), there is a corresponding face \( \sigma' \) of \( \sigma \) with vertices \( \pi^{-1}(V) \cap \{x_1, ..., x_k\} \), that is necessarily in \( Q_X \) by the definition of simplicial complex, and \( \pi_*\sigma' = \rho \), showing that \( \rho \) is in \( \pi_*Q_X \). \( \square \)

Given an information structure \( S \), a probability functor \( Q : S \to \text{Set} \) is a rule that assigns to each variable \( X \in \text{Ob}(S) \) a simplicial subcomplex of \( \Delta(\sigma(X)) \), denoted simply \( Q_X \), and to each arrow of refinement \( \pi : X \to Y \), the simplicial mapping \( Q(\pi) : Q_X \to Q_Y \) given by the marginalization \( P \mapsto \pi_*P \).

Proposition 2.4 shows that we can obtain examples in a standard way: given a measurable space \( (\Omega, \mathcal{F}) \) with \( \mathcal{F} \) finite, and a family of measurable functions on it (forming an information structure), fix initially a subcomplex \( Q_\mathcal{F} \) of \( \Delta(\mathcal{F}) \) and, for each variable \( X \), define \( Q_X : = X_\mathcal{F} Q_\mathcal{F} \subset \Delta(\sigma(X)) \).

Another fundamental operation is conditioning. Let \( X : (\Omega, \mathcal{F}) \to E_X \) be a random variable, \( P \) a law of \( \Delta(\mathcal{F}) \) and \( P(X = x) \neq 0 \) for certain \( x \in E_X \). Then, it is possible to define a new probability law \( P|_{X=x} \) on \( (\Omega, \mathcal{F}) \), called conditional law and given by

\[
P|_{X=x}(B) \equiv P(B|X = x) := \frac{P(B \cap \{X = x\})}{P(X = x)}.
\]
Proposition 2.5. With the previous notation, if $P$ belongs to a simplicial subcomplex $Q$ of $\Delta(\mathcal{F})$ and $P(X = x) > 0$, the law $P|_{X=x}$ also belongs to $Q$.

Proof. Suppose that the minimal face $\sigma$ that contains $P$ has vertices $V = \{\delta_{a_1}, \ldots, \delta_{a_k}\}$ (maybe just one): this means that $P(a) > 0$ for all $a \in V$ and $P(a') = 0$ for all other atom $a'$. The set $V' := \{a \text{ atom of } \mathcal{F} \mid P(a \cap \{X = x\}) > 0\}$ is contained in $V$, because $P(a \cap \{X = x\}) \leq P(a)$. The minimal face that contains $P|_{X=x}$ is that of vertices $V'$, which is a face of $\sigma$, and therefore contained in $Q$. \hfill \Box

A probability family $Q$ and an information structure $\mathcal{S}$ are mutually adapted, if the conditioning of any law in $Q$ by an element of $\mathcal{S}$ belongs to $Q$. In particular, simplicial families are adapted: if $X$ is any variable coarser than $Y$ and $Q_Y$ is simplicial complex, Proposition 2.5 (applied to $\mathcal{F} = \sigma(Y)$ and $Q = Q_Y$) implies that $P|_{X=x}$ belongs to $Q_Y$ (when it is well defined).

2.2. Category of information structures. To some extent, the determination of a probability space $\Omega$ on which random variables can be defined seems arbitrary. For example, suppose that we want to study the tossing of a die. As we know in advance that there are six possible outcomes, it seems natural to choose $\Omega = \{1, 2, 3, 4, 5, 6\}$ with the algebra of sets generated by $\{\{j, j+1\} : j = 1, \ldots, 6\}$ and associate each interval $[j, j+1)$ with the result “observe $j$ dots”. This example is discussed by Doob [5], who adds: “The natural objection that the model is needless complicated, is easily refuted. In fact, ‘needlessly complicated’ models cannot be excluded, even in practical studies. How a model is setup depends on what parameters are taken as basic. [...] If, however, the die is thought as a cube to be tossed into the air and let fall, the position of the cube in the space is determined by six parameters, and the most natural $\Omega$ might well be considered to be the twelve dimensional space of initial positions and velocities.”

In practice, random variables (also called “observables”) correspond to measurements. Empiricism postulates that knowledge is given by all the possible physical measurements. What we know are possible outcomes of experiments — already constrained by the limitations of our experimental devices — and possible probabilities of each outcome. A particular law can be interpreted as the current state of knowledge (bayesianism), but this state is susceptible to vary within a given set defined by physical and logical constraints. Given a family of commuting observables, we can pick a measurable set $\Omega$ as a model that allow us to treat observables as concrete measurable functions on $\Omega$\footnote{When observables do not commute, this is not possible. In this case, the underlying space $H$ is defined as a Hilbert space and observable values appear as the spectrum of hermitian operators on $H$.}. The existence of such a space can be linked to the common belief in reality, a unified underlying structure that accounts for all our observations. However, the probabilistic properties of the observables should not depend on the particular model that has been chosen. As Terence Tao [20] says: “sample [probability] spaces (and their attendant structures) will be used to model probabilistic concepts, rather than to actually be the concepts themselves.”\footnote{Terence Tao defines an extension of a probability space $(\Omega, \mathcal{B}, P)$ by $(\Omega', \mathcal{B}', P')$ as a surjective map $\pi : \Omega' \to \Omega$ which is measurable and probability preserving ($P'(\pi^{-1}(E)) = P(E)$ for every $E \in \mathcal{B}$). Then he proposes the following principle: probability theory studies concepts and}
Doob’s example can be rephrased as follows: there is a variable $X$ taking six possible values \{∅, ⊤, ⊥, ◦, ◦, ◦\}, and this variable can be implemented as a category of partitions for multiple sets $Ω$. In any case, the corresponding concrete information structure will give the surjection of partitions

\[(\mathbb{S}, \mathbb{E}) \rightarrow \{\ast\}.\]

More generally, given two finite observables $X$ and $Y$, a surjection $π : E_X \rightarrow E_Y$ between their possible outcomes says that the event of observing $y \in E_Y$ (usually denoted \{\(Y = y\)\}) is compatible with the events \(\{X = x\}\) for $x \in π^{-1}(y)$, and only with them. In other words, \(Y = y\) if and only if $\bigvee_{x \in π^{-1}(y)} \{X = x\}$.

As Gromov in [8], we want to approach measurements from a categorical point of view and consider the underlying space $Ω$ as an emerging object. While he simply considers surjections between finite sets, we are forced to introduced axiomatically the additional structure concerning products. These generalized structures have several advantages: on one hand, they provide common basis for classical and quantum information; on the other, they form a category with well defined products and coproducts (see Proposition 2.8).

**Definition 2.6.** A (generalized) information structure is a couple \((S, E)\), where $S$ (‘the variables’) is a small category and $E : S \rightarrow \text{Sets}$ (‘the values’) is a functor, such that

1. $S$ has a terminal object, denoted \(1\);
2. $S$ is a partially ordered set (poset);
3. The nerve of $S$ has finite dimension;
4. for objects $X, Y, Z \in \text{Ob}(S)$, if $Z \rightarrow X$ and $Z \rightarrow Y$, then the categorical product $X \wedge Y$ exists;
5. $E(1) \cong \{\ast\}$;
6. for every arrow $π : X \rightarrow Y$ such that $X \neq Y$, the map $π_* := E(π) : E(X) \rightarrow E(Y)$ is a strict surjection ($|E(X)| > |E(Y)|$);
7. for every diagram $X \xrightarrow{π} X \wedge Y \xrightarrow{σ} Y$ in $S$, there is an injection $E(X \wedge Y) \rightarrow E(X) \times E(Y)$, $z \mapsto (x(z), y(z))$, such that, for all $z \in E(X \wedge Y)$, $π_*(z(x(z))) \cap σ_*(y(z)) = \{z\}$;
8. for all $X \in \text{Ob}(S)$ and for all $x \in E(X)$, there exists an element $s(x) \in \lim E$ such that $π_{E(X)}(s(x)) = x$.

To make sense of the last axiom, recall that

\[(\text{2.7}) \quad \lim S := \text{Hom}_{(S, \text{Sets})}(\ast, E),\]

performs operations which are invariant under extension of the underlying sample space. The arrows of information categories correspond to an enlarged notion of extension, where probabilities are allowed to vary.

\[\text{If } A \text{ and } B \text{ are events, } A \lor B \text{ means “the event that } A \text{ holds or } B \text{ holds”. We prefer to avoid set-theoretic notation. See Tao [20].}\]

\[\text{If } A \text{ and } B \text{ are different objects, } \text{Hom}(A, B) \text{ has at most one element; if } A \neq B \text{ and } A \rightarrow B, \text{ then } B \not\rightarrow A.\]

\[\text{In this work, we are interested in the information theory of finite random variables and finite dimensional quantum systems.}\]

\[\text{Equivalently, for every } (x, y) \in E(X) \times E(Y), |π_*^{-1}(x) \cap σ_*^{-1}(y)| \leq 1.\]
where $[\mathcal{S}, \text{Sets}]$ is the category of functors from $\mathcal{S}$ to sets and $*$ is the functor that associates to each object a one-point set. It is well known that

\begin{equation}
\lim \mathcal{S} \cong \left\{ (s_Z)_{Z \in \text{Ob}(\mathcal{S})} \in \prod_{Z \in \text{Ob}(\mathcal{S})} E(Z) \mid E(\pi_{YX})(s_X) = s_Y \text{ for all } \pi_{YX} : X \to Y \right\},
\end{equation}

The requirements imposed on $(s_Z)_{Z \in \text{Ob}(\mathcal{S})}$ in Equation (2.8) are referred hereafter as ‘compatibility conditions’. We denote the restriction of each projection $\pi_{E(X)} : \prod_{Z \in \text{Ob}(\mathcal{S})} E(Z) \to E(X)$ to lim $E$ by the same symbol. We interpret the limit as all possible combinations of compatible measurements. Therefore, the last axiom asks for certain minimality of the model: just consider the values that are actually part of a family of compatible measurements.

All concrete classical information structures $\mathcal{S}$, as defined in Section 2.1, are examples of generalized information structures (forget the inclusion in $\Theta(\Omega)$, and take the identity functor for $E$). In the general case, we still call $X \in \text{Ob}(\mathcal{S})$ a partition (also: variable, observable) and the elements in $E(X)$—sometimes written $E_X$ to simplify the notation—are interpreted as the elements of this partition (or the possible values of the variable). In general, we can transfer to general information structures all the notations and notions from the previous sections. For example, the set-notation $\{X = x\}$ simply means “the element $x$ contained in $E(X)$” and $\{X = x, Y = y\}$ should be interpreted as the element $z$ of $E(X \land Y)$ mapped to $x$ by $E(X \land Y) \to E(X)$ and to $y$ by $E(X \land Y) \to E(Y)$ (if such $z$ does not exist, write $\{X = x, Y = y\} = \emptyset$); the uniqueness of $z$ is guaranteed by axiom (7). As before, we write $XY := X \land Y$ and refer to this as the product of observables.

The definition of $W(\Sigma)$ introduced in Section 2.1 is more natural in this context. Let $I$ be a finite set, and $\Delta(I)$ be the category of subsets of $I$, with arrows $I \to J$ whenever $J \subseteq I$. Set $\mathcal{S} = \Delta(I)$. Let $E(I) = E_i$ be arbitrary sets such that $|E_i| \geq 2$, and associate to $I = \bigwedge_{i \in I} E_i$ the product $\prod_{i \in I} E_i$; the surjections $E(\pi) : E(I) \to E(J)$, for $\pi : I \to J$ are the canonical projectors. There is no need to consider all the abstract simplicial complex $\Delta(I)$, $\mathcal{S}$ could be a simplicial subcomplex $K$ of $\Delta(I)$: we obtain this way the corresponding structure $\mathcal{S}(K)$.

Let us introduce the functor $\Delta : \mathcal{S} \to \text{Sets}$, that associates to each $X \in \text{Ob}(\mathcal{S})$ the set

\begin{equation}
\Delta(X) := \{ p : E_X \to [0,1] \mid \sum_{x \in E_X} p(x) = 1 \},
\end{equation}

of probability laws for $X$, and to each arrow $\pi : X \to Y$ the natural collapsing map

\begin{equation}
\forall P \in Q_X, \forall y \in E_Y \quad \Delta(\pi)(P)(y) = \sum_{x \in \pi^{-1}(y)} P(x).
\end{equation}

More generally, a probability functor $Q$ on an information structure $(\mathcal{S}, E)$ is a functor $Q : \mathcal{S} \to \text{Sets}$ such that, for every $X \in \text{Ob}(\mathcal{S})$, the set $Q_X$ is a subcomplex of $\Delta(X)$ and each arrow $\pi : X \to Y$ is sent to $Q(\pi) = \Delta(\pi)|_{Q_X}$, written simply $\pi_*$ or even $Y_*$ to simplify the notation.

We adopt the probabilistic notation, in the following sense: if $X, Y \in \text{Ob}(\mathcal{S})$, $\pi_{YX} : X \to Y$ in $\mathcal{S}$, $P_X \in Q_X$, and for $y \in E(y)$, the notation $P_X(Y = y)$ means $P(\pi_{YX}^{-1}(y)) = \pi_{YX}^*P(y)$; similarly, if $Y \xrightarrow{\pi_{YX}} X \xrightarrow{\pi_{XY}} Z$ is a diagram in $\mathcal{S}$,
the notation $P_X(Y = y, Z = z) \equiv P_X(\{Y = y\} \cap \{Z = z\})$ means $P_X(\pi_{Y,X}^{-1}(y) \cap \pi_{Z,X}^{-1}(z))$, which equals $P_X((\pi_{Y,X}, \pi_{Z,X})^{-1}(w(y, z)))$ for the unique $w(y, z)$ sent to $(y, z)$ by the injection in Definition 2.7. Conditioning is carried out as before.

We say that the functor $Q$ is adapted if it is stable by conditioning.

Even if the axiom (4) in the previous definition is the obvious analogue of the conditional existence of products imposed in Section 2.1 only (7) allows us to recover the good properties of the product of partitions. See the proof of Proposition 4.1.

Information structures form a category.

**Definition 2.7.** Given two structures $(S, E), (S', E')$, a morphism $\phi = (\phi_0, \phi^\#) : (S, E) \to (S', E')$ between them is a functor $\phi_0 : S \to S'$ and a natural transformation $\phi^\# : E \Rightarrow E' \circ \phi_0$, such that

1. $\phi_0(1) = 1$;
2. if $X \cap Y$ exists, then $\phi_0(X \cap Y) = \phi_0(X) \cap \phi_0(Y)$;
3. for each $X \in \text{Ob}(S)$, the component $\phi^\#_X : E(X) \to E(\phi_0(X))$ is a surjection.

Given $\phi : (S, E) \to (S', E')$ and $\psi : (S'', E'') \to (S', E')$, their composition $\psi \circ \phi$ is defined as $(\psi_0 \circ \phi_0, \psi^\# \circ \phi^\#) : E \Rightarrow E'' \circ \psi_0 \circ \phi_0$ (it is easy to verify that $\psi \circ \phi$ is also a morphism). If there is no risk of ambiguity, we write $\phi$ instead of $\phi_0$.

We denote by $\text{InfoStr}$ the category of information structures and its morphisms in the sense just defined.

Note that, if $X \cap Y$ exists, then $\phi_0(X \cap Y) \to \phi_0(X)$ and $\phi_0(X \cap Y) \to \phi_0(Y)$, and thus the product $\phi_0(X) \cap \phi_0(Y)$ exists too, in virtue of Definition 2.6 (4).

The definition of products and coproducts of information structures is one of the main motivations for the generalized setting. It allows a natural formulation of Proposition 4.1.

**Proposition 2.8.** The category $\text{InfoStr}$ has finite products and coproducts.

**Proof.** **Products:** Given information structures $(S_1, E_1)$ and $(S_2, E_2)$, we define a new category $\delta$ whose objects all the couples $(X_1, X_2)$ with $X_i \in \text{Ob}(S_i)$ $(i = 1, 2)$; we include an arrow $(\pi_1, \pi_2) : (X_1, X_2) \to (Y_1, Y_2)$ whenever $\pi_i : X_i \to Y_i$ in $S_i$ $(i = 1, 2)$. Introduce also a functor $E : \delta \to \text{Sets}$, such that $E((X_1, X_2)) = E_1(X_1) \times E_2(X_2)$, and $E((\pi_1, \pi_2)) = E_1(\pi_1) \times E_2(\pi_2)$. The couple $(\delta, E)$ is an information structure:

- $\delta$ is a small category, with terminal object $(1_{S_1}, 1_{S_2})$;
- if the dimension of Nerve($S_i$) is $N_i$ $(i = 1, 2)$, the dimension of Nerve($\delta$) is $N_1N_2$;
- $\delta$ is a poset: for $(X_1, X_2) \neq (Y_1, Y_2)$,

$$\text{Hom}((X_1, X_2), (Y_1, Y_2)) \neq 0 \Leftrightarrow X_1 \to Y_1 \text{ and } X_2 \to Y_2$$

$$\Leftrightarrow Y_1 \not\to X_1 \text{ or } Y_2 \not\to X_2$$

The last equivalence, because both arrows cannot be identities. Therefore,

$$\text{Hom}((Y_1, Y_2), (X_1, X_2)) = 0$$

- Given $(X_1, X_2), (Y_1, Y_2)$ and $(Z_1, Z_2)$ such that $(X_1, X_2) \to (Y_1, Y_2)$ and $(X_1, X_2) \to (Z_1, Z_2)$, then $Y_1 \xleftarrow{\pi_{Y_1}} X_1 \xrightarrow{\pi_{Z_1}} Z_1$ in $\delta_i$ $(i = 1, 2)$. By
the conditional existence of products in $\mathcal{S}_i$, $Y_i \times Z_i$ exists ($i = 1, 2$) and evidently $\langle Y_1 \times Z_1, Y_2 \times Z_2 \rangle$ is the infimum of $\langle Y_1, Y_2 \rangle$ and $\langle Z_1, Z_2 \rangle$ in $\mathcal{S}$,

$$\langle Y_1, Y_2 \rangle \land \langle Z_1, Z_2 \rangle = \langle Y_1 \land Z_1, Y_2 \land Z_2 \rangle.$$ 

- $E(\langle 1_{s_1}, 1_{s_2} \rangle) = \{ (\ast, \ast) \}$;
- The argument above gives the following diagram in $\mathcal{S}$:

$$\begin{array}{ccc}
\langle Y_1, Y_2 \rangle & \xleftarrow{\langle \pi_{Y_1}, \pi_{Y_2} \rangle} & \langle Y_1 \land Z_1, Y_2 \land Z_2 \rangle \\
\xrightarrow{\langle \pi_{Z_1}, \pi_{Z_2} \rangle} & \quad \quad \quad \downarrow & \xrightarrow{\langle \pi_{Z_1}, \pi_{Z_2} \rangle} \\
\langle Z_1, Z_2 \rangle,
\end{array}$$

where $Y_i \xleftarrow{\pi_{Y_i}} Y_i \land Z_i \xrightarrow{\pi_{Z_i}} Z_i$ is the diagram of the product in $\mathcal{S}_i$ ($i = 1, 2$). Given $(y_1, y_2) \in E(\langle Y_1, Y_2 \rangle)$ and $(z_1, z_2) \in E(\langle Z_1, Z_2 \rangle)$,

$$\langle \pi_{Y_1}, \pi_{Y_2} \rangle^{-1}(y_1, y_2) \cap \langle \pi_{Z_1}, \pi_{Z_2} \rangle^{-1}(z_1, z_2)$$

$$= \{ \pi_{Y_1}^{-1}(y_1) \times \pi_{Y_2}^{-1}(y_2) \} \cap \{ \pi_{Z_1}^{-1}(z_1) \times \pi_{Z_2}^{-1}(z_2) \}$$

$$= \{ \pi_{Y_1}^{-1}(y_1) \cap \pi_{Z_1}^{-1}(z_1) \} \times \{ \pi_{Y_2}^{-1}(y_2) \cap \pi_{Z_2}^{-1}(z_2) \}. $$

Thus $|\langle \pi_{Y_1}, \pi_{Y_2} \rangle^{-1}(y_1, y_2) \cap \langle \pi_{Z_1}, \pi_{Z_2} \rangle^{-1}(z_1, z_2)| \leq 1$, which allows us to build the desired injection.

- Consider a point $(x_1, x_2) \in E(\langle X_1, X_2 \rangle)$. There exist sections $s^i(x_i) = (s_{2}^i(x_i))_{Z \in \text{Ob}(\mathcal{S})} \in \lim E_i \subset \prod_{Z \in \text{Ob}(\mathcal{S})} E(Z)$, such that $\pi_{E_i(x_i)}(s(x_i)) = x_i$ (for $i = 1, 2$). Note that the vector $s(x_1, x_2) := (s^1_{Z_1}(x_1), s^2_{Z_2}(x_2))_{(Z_1, Z_2) \in \text{Ob}(\mathcal{S})} \in \prod_{Z_1 \land Z_2 \in \text{Ob}(\mathcal{S})} E(\langle Z_1 \land Z_2 \rangle)$ satisfies all the compatibility conditions and is therefore in $\lim \mathcal{S}$. By definition, $\pi_{E_i((x_1, x_2))}(s(x_1, x_2)) = (x_1, x_2)$.

For each $i \in \{1, 2\}$, we define functors $\pi_{s_i} : \langle \mathcal{S}, E \rangle \to \langle \mathcal{S}_i, E_i \rangle$ such that $\pi_{s_i,0}$ maps each $(X_1, X_2)$ to $X_i$, and each morphism $(f_1, f_2)$ to $f_i$. At the level of $E$, let $\pi_{s_i}^E : E_1(X_1) \times E_2(X_2) \to E_i(X_i)$ be the canonical projection. The reader can verify that these formulae define morphisms of information structures. We claim that $\mathcal{S}$, with the projections

$$\begin{array}{ccc}
\langle S_1, E_1 \rangle & \xleftarrow{\pi_{s_1}} & \langle S, E \rangle \\
\xrightarrow{\pi_{s_2}} & \quad \quad \quad \downarrow & \xrightarrow{\pi_{s_2}} \\
\langle S_2, E_2 \rangle,
\end{array}$$

is the product of $\langle S_1, E_1 \rangle$ and $\langle S_2, E_2 \rangle$ in $\text{InfStr}$, written $\langle S_1, E_1 \rangle \times \langle S_2, E_2 \rangle$, unique up to unique isomorphism. In fact, given $\langle S_1, E_1 \rangle \xleftarrow{f_1} \langle R, F \rangle \xrightarrow{f_2} \langle S_2, E_2 \rangle$, define a morphism $\langle f_1, f_2 \rangle : \langle R, F \rangle \to \langle S, E \rangle$, such that

$$\langle f_1, f_2 \rangle_0 : R \to S$$

$$R \mapsto \langle f_1(R), f_2(R) \rangle$$

where $R$ is an object or a morphism; given an variable $X \in \mathcal{R}$, the surjection $\phi_X^# : F(X) \to E(\langle f_1(X), f_2(X) \rangle) = E_1(f_1(X)) \times E_2(f_2(X))$ is the product $f_{1}^# \times f_{2}^#$ of the surjections $f_{i}^# : F(X) \to E_i(f_i(X))$. Evidently, $\pi_{s_i} \circ \langle f_1, f_2 \rangle = f_i$ for $i = 1, 2$.

**Co products:** Given information structures $\mathcal{S}_1$ and $\mathcal{S}_2$, we define a category $\mathcal{S}$ such that $\text{Ob}(\mathcal{S}) = \text{Ob}(\mathcal{S}_1) \cup \text{Ob}(\mathcal{S}_2)/1_{\mathcal{S}_1} \sim 1_{\mathcal{S}_2}$ and $A \to B$ in $\mathcal{S}$ if and only if $A \to B$ in $\mathcal{S}_1$ or in $\mathcal{S}_2$ (this means: put both posets side by side and identify the terminal objects). Define a functor $E : \mathcal{S} \to \text{Sets}$ such that $E(X) = E_i(X)$ if $X \in \text{Ob}(\mathcal{S}_i)$. The pair $(\mathcal{S}, E)$ is an information structure: axioms [2], [4], and [7] in Definition 2.6 are verified locally in $\mathcal{S}_1$ or $\mathcal{S}_2$; if the dimension of $\text{Nerve}(\mathcal{S}_i)$ is bounded by $N_i$ ($i = 1, 2$), the dimension of $\text{Nerve}(\mathcal{S})$ is bounded by $\max\{N_1, N_2\}$. We just give some hints to prove [8]: given $X \in \mathcal{S}_i$, $x \in E(X)$, there exists
s_1(x) = (s_Z(x))_{Z \in \text{Ob}(S_1)} \in \lim E_1 \text{ satisfying } \pi_{E(X)}(s_1(x)) = x, \text{ and similarly for } E_2; \text{ we can build a new vector } (s_Z(x))_{Z \in \text{Ob}(S_1) \cup \text{Ob}(S_2)} \text{ such that } s_Z = s'_Z \text{ if } Z \in \text{Ob}(S_1); \text{ luckily, for } 1 \text{ there is no choice. Injections } \iota_i : S_i \to S \text{ are defined in the obvious way: } \iota_i(A) = A \text{ for } A \in \text{Ob}(S_i) \text{ or } A \in \text{Hom}(S_i); \text{ the corresponding maps } \iota_i^# \text{ are identities. If } (S_1, E_1) \xrightarrow{f_1} (R, F) \leftarrow (S_2, E_2), \text{ define }
\langle f_1, f_2 \rangle_0 : S \to R \\
A \mapsto \begin{cases} f_1(A) & \text{if } A \in \text{Ob}(S_1) \text{ or } A \in \text{Hom}(S_1) \\ f_2(A) & \text{otherwise} \end{cases}.
\text{and, if } X \in \text{Ob}(S_i), \text{ set } \langle f_1, f_2 \rangle_X^# = f_i^#_X. \text{ By construction, } \langle f_1, f_2 \rangle \circ \iota_i = f_i. \text{ Therefore, } S \text{ is the coproduct of } (S_1, E_1) \text{ and } (S_2, E_2) \text{ in InfStr, denoted } (S_1, E_1) \coprod (S_2, E_2), \text{ which is unique up to unique isomorphism.} \quad \Box

\end{array}
\\
\text{Let } Q_i \text{ be a probability functor on } (S_i, E_i) \ (i = 1, 2). \text{ We define:}
\\
(1) \ Q_1 \times Q_2 : S_1 \times S_2 \to \text{Set} \text{ as a functor that associates to each object } (X_1, X_2) \in \text{Ob}(S_1 \times S_2) \text{ the set of laws: }
\\
(2.11) \ Q_1 \times Q_2((X_1, X_2)) := \{ P : E_1(X_1) \times E(X_2) \to [0, 1] \mid \exists P_1 \in Q_1(X_1), \exists P_2 \in Q_2(X_2) \text{ such that } P(x_1, x_2) = P_1(x_1)P_2(x_2) \}.
\\
\text{If two couples } (P_1, P_2), \text{ and } (P'_1, P'_2) \text{ correspond to the same law } P : E_1(X_1) \times E(X_2) \to [0, 1], \text{ we can marginalize one of the components under the arrow } \pi_1 : X_1 \to 1_{S_1} \text{ to conclude that } P_2 = P'_2; \text{ analogously, } P_1 = P'_1. \text{ Therefore, what we call } Q_1 \times Q_2((X_1, X_2)) \text{ is in bijection with the usual product of sets } Q_1(X_1) \times Q_2(X_2); \text{ we write } P = (P_1, P_2).
For each morphism \( \langle X_1, X_2 \rangle \) the induced map \( Q_1 \times Q_2(\langle X_1, X_2 \rangle) \) is compatible with marginalizations: for every \((y_1, y_2) \in E(\langle Y_1, Y_2 \rangle)\),

\[
\begin{align*}
[Q(\langle \pi_1, \pi_2 \rangle)(P_1, P_2)](y_1, y_2) & \overset{\text{(def)}}{=} \sum_{(x_1, x_2) \in \langle \pi_1, \pi_2 \rangle^{-1}(y_1, y_2)} (P_1, P_2)(x_1, x_2) \\
& = \sum_{x_1 \in \pi_1^{-1}(y_1)} P_1(x_1) \sum_{x_2 \in \pi_2^{-1}(y_2)} P_2(x_2) \\
& = [Q(\pi_1)(P_1)](x_1) [Q(\pi_2)(P_2)](x_2).
\end{align*}
\]

We summarize this with the formula

\[
Q(\langle \pi_1, \pi_2 \rangle)(P_1, P_2) = (Q(\pi_1)(P_1), Q(\pi_2)(P_2)).
\]

\begin{equation}
(2.12)
\end{equation}

(2) \( Q_1 \coprod Q_2 : \mathcal{S}_1 \coprod \mathcal{S}_2 \to \text{Sets} \), a functor that coincides with \( Q_1 \) on the \( \mathcal{S}_1 \) and with \( Q_2 \) on the \( \mathcal{S}_2 \).

**Example 2.10.** Let \( X : \Omega \to E_X \) be a finite random variable; it defines a concrete structure \( \mathcal{S} \) given by \( X \to 1 \). Let \( Q_X \) be the collection of probability laws on \( X \). The product \( S^{\times n} := S \times \ldots \times S \) \( (n \text{ times}) \) represents \( n \) independent trials, not necessarily identically distributed. In fact, an element \( P \in Q_X^{\times n} \) is a probability law \( P : E_X^n \to [0,1] \) which can be factored as \( P_1 P_2 \cdots P_n \), where each \( P_i \in Q_X \).

### 2.3. Classical models.

In this section, we formalize the relation between information structures and usual probability spaces.

**Definition 2.11.** A classical model of an information structure \((\mathcal{S}, E)\) is a couple \((\Omega, \rho)\), where \( \Omega \) is a set and \( \rho : \mathcal{S} \to \Theta(\Omega) \) is a functor, such that:

1. \( \rho \) is injective on objects;
2. For each \( X \in \text{Ob}(\mathcal{S}) \), there is a bijection of sets \( E(X) \cong \rho(X) \);
3. If \( X \wedge Y \) exists, \( \rho(X \wedge Y) = \rho(X) \rho(Y) \).

If \((\Omega, \rho)\) is a classical model of \( \mathcal{S} \), each observable \( X \in \mathcal{S} \) can be associated (not uniquely) to a function \( \tilde{X} \) on \( \Omega \), in such a way that \( \rho(X) \) is the partition induced by \( \tilde{X} \). Under this representation as functions, all observables commute. It is also possible to introduce quantum models, which respect the non-commutativity of quantum observables; see Section 6. All the cohomological computations in this paper (Section 4) are restricted to the case of classical probabilities, but the general constructions in Section 3 only depend on the abstract structure and are equally valid in the quantum setting.

A concrete information structure, as defined in Section 2.1, can be seen as a classical model of an underlying generalized information structure. We now show that, in certain cases, \( \lim E \) provides a model for a structure \((\mathcal{S}, E)\). In general, if we begin with a concrete structure \( \mathcal{S} \subset \Theta(\Omega) \) and forget \( \Omega \) to obtain a generalized structure \((\mathcal{C} \mathcal{S}, E = \text{id})\), the set \( \lim E \) is different from \( \Omega \). See Example 2.13.

Given a structure \((\mathcal{S}, E)\), define \( \tilde{\rho} : \mathcal{S} \to \lim E \) as follows: associate to \( X \in \text{Ob}(\mathcal{S}) \) the collection \( \tilde{\rho}(X) := \{ \pi^{-1}_E \langle x \rangle \}_{x \in E(X)} \), which is a partition of \( \lim E \) in virtue of [\( \mathcal{S} \)] in Definition 2.8. Given \( \pi_{YX} : X \to Y \), there is a corresponding arrow \( \tilde{\rho}(X) \to \tilde{\rho}(Y) \) in \( \Theta(\Omega) \), which is equivalent to \( \tilde{\rho}(Y) \subset \tilde{\rho}(X) \). The existence of such
The “only if” part is immediate. We simply prove sufficiency.

Proposition 2.12. Let $\langle S, E \rangle$ be an information structure.

1. The couple $(\lim E, \tilde{\rho})$ is a classical model of $(S, E)$ if, and only if, for every couple of variables $X, Y$ such that $X \land Y$ does not exist, $\tilde{\rho}(X) \neq \tilde{\rho}(Y)$.

2. If $\langle S, E \rangle$ has a model $(\Omega, \rho)$, then $(\lim E, \tilde{\rho})$ is also a model (maybe the same).

Proof. (1) The “only if” part is immediate. We simply prove sufficiency.

Many properties of models are always verified by $(\lim E, \tilde{\rho})$. The axiom [8] in Definition 2.6 implies that each $\pi^{-1}(x) \neq \emptyset$; we obtain in this way the desired bijection $E(x) \simeq \rho(X)$. To prove property [3] in Definition 6.1 take a diagram $X \leftarrow X \land Y \rightarrow Y$, and an arbitrary partition $W$ of $\lim E$ that refines $\tilde{\rho}(X)$ and $\tilde{\rho}(Y)$. We have to show that $W$ also refines $\rho(X \land Y)$. If $W$ refines $\tilde{\rho}(X)$, each $w \in W$ ($w$ is a subset of $\lim E$) is mapped to certain $x_w$ by $\pi_{E(X)}$; analogously, $\pi_{E(Y)}(w) = \{y_w\}$. This means that $\pi_{E(X \land Y)}(w) = \{z_w\}$, where $z_w$ is the only point of $E(X \land Y)$ that satisfies $E(\pi_{E(X \land Y)})(z_w) = x_w = E(\pi_{E(X \land Y)})(z_w) = y_w$, which means that $w \subset \pi_{E(X \land Y)}(z_w)$. Thus, $W$ refines $\tilde{\rho}(X \land Y)$.

To prove the property [1] in Definition 6.1 consider to variables $X, Y$ such that $X \neq Y$. If their infimum exists, $X \leftarrow X \land Y \rightarrow Y$ in $S$, then $\tilde{\rho}(X) \neq \tilde{\rho}(Y)$: we prove it by contradiction. Each point in $E(X \land Y)$ is indexed by a couple $(x, y) \in E(X) \times E(Y)$; a point $w \in E(\pi_{X \land Y})^{-1}(x, y) \subseteq \lim E$ goes to $x$ under $\pi_{E(X)}$ and to $y$ under $\pi_{E(Y)}$. If $\tilde{\rho}(Y) = \tilde{\rho}(Y)$, there is a bijection $y : E(X) \rightarrow E(Y)$, $x \mapsto y(x)$ in such a way that $\pi_{E(X)}(x) = \pi_{E(Y)}(y(x))$. Therefore, the points of $X \land Y$ would be indexed by $(x, y(x))$, with $x \in X$, in contradiction with $\pi_{X \land Y}$ being a strict surjection. If moreover we suppose that for each couple of variables such that $X \land Y$ does not exist $\tilde{\rho}(X) \neq \tilde{\rho}(Y)$, then $\tilde{\rho}$ is injective on objects.

(2) Here, we denote $\{X = x\}$ the image of $x \in E(X)$ under the bijection $E(X) \xrightarrow{\sim} \rho(X)$ given by property [2] in Definition 6.1. Each element $\omega \in \Omega$ defines a section $s(\omega) = (s(\omega))_{X \in \Ob(S)} \in \lim E$, such that $s(\omega) = x$ if $\omega \in \{X = x\}$. It is clear that several $\omega$ could give the same section. Suppose now that $\tilde{\rho}(X) = \tilde{\rho}(Y)$. If $\omega \in \{X = x\} \subset \Omega$, then $s(\omega) \in \pi^{-1}(x) = \pi^{-1}(y(x))$. We conclude that $\omega \in \{Y = y(x)\}$, and therefore $\rho(X)$ and $\rho(Y)$ are the same partition, only with different labels. For $\rho$ is injective on objects, $X = Y$. Use the first part to conclude.

Example 2.13. Let $\Omega = \{1, 2, 3, 4\}$. Define the partitions $X_i = \{\{i\}, \Omega \setminus \{i\}\}$, for $i = 1, \ldots, 4$, and $S$ as let $S$ be the concrete information structure that includes
only the partitions $X_1$, $X_2$, $X_3$, $X_1X_2$, and $X_2X_3$. The corresponding general information structure has as variables the free category $\square S$ generated by the graph

\[
\begin{array}{ccc}
X_1 & \rightarrow & X_2 \\
\uparrow & & \uparrow \\
X_1X_2 & \rightarrow & X_2X_3
\end{array}
\]

and the corresponding functor $E$ can be represented by the diagram

\[
\begin{array}{ccc}
{x_1, x_2, x_3, x_4} & \rightarrow & \{x_{1,2,3,4}\} \\
\uparrow & & \uparrow \\
\{x_1, x_2, x_3\} & \rightarrow & \{x_{1,2,3}\} \\
\uparrow & & \uparrow \\
\{x_1, x_2\} & \rightarrow & \{x_{1,2}\} \\
\uparrow & & \uparrow \\
\{x_1\} & \rightarrow & \{x_1\}
\end{array}
\]

Each arrow corresponds to a surjection of finite sets, that sends $x_I$ to $x_J$ when $I \subset J$. These are just the surjections of partitions in the original $S$. In this case, $\lim E \subset \{\ast\} \times E(X_1) \times E(X_2) \times E(X_3) \times E(X_1X_2) \times E(X_2X_3)$ corresponds to the set

\[
\lim E = \{(x_{1,2,3,4}, x_{1,1,3,4,}, x_{1,3,}, x_{1,1,}, x_{1,3,}), (x_{1,2,3,4}, x_{1,1,3,4,}, x_{1,1,}, x_{1,3,}), (x_{1,2,3,4}, x_{1,1,3,4,}, x_{1,1,}, x_{1,3,}, x_{1,1,}, x_{1,3,}), (x_{1,2,3,4}, x_{1,1,3,4,}, x_{1,1,}, x_{1,3,}, x_{1,1,}, x_{1,3,}), x_{1,2,3,4}, x_{1,1,3,4}, x_{1,1,}, x_{1,3,}, x_{1,1,}, x_{1,3,}\}\}
\]

The difference between $\Omega$ and $\lim E$ is explained by the presence of $\{x_{1,2,3,4}, x_{1,1,3,4,}, x_{1,3,}, x_{1,1,}, x_{1,3,}\}$;

this measurement (where $X_1 = x_{1,1,}$, $X_3 = x_{1,3,}$) is impossible in the concrete structure $S \subset \Theta(\Omega)$, but the observables in $\square S, E$ cannot distinguish between the points 1 and 3, a sort of non-separability. In fact, if we also include $X_1X_3$ at the beginning, we obtain $\Omega \cong \lim E$.

**Example 2.14.** Consider the information structure given by

\[
\begin{array}{ccc}
\{x_{00,01}, x_{10,11}\} & \rightarrow & \{x_{00,10}, x_{01,11}\} \\
\uparrow & & \uparrow \\
\{x_{00}, x_{10}, x_{1,0}, x_{1,1}\} & \rightarrow & \{x_{00}, x_{10}, x_{1,0}, x_{1,1}\}
\end{array}
\]

where we suppose again that $x_I \rightarrow x_J$ when $I \subset J$. Such structure cannot be modeled by its inverse limit, since the two minimal variables induce the same partition.

The inverse limit construction associates the sample space $\{\square \Omega, \square \Omega, \square \Omega, \square \Omega, \square \Omega\}$ to the information category represented in [2.6]. This is the model of minimal cardinality. In the presence of other observables (corresponding to position and momentum, for example) and non-trivial relations between them (given by arrows in our categorical approach), we would obtain something rather different.
Finally, we study the category of information structures.

Let $\Omega_1$ and $\Omega_2$ be sets. Given collections $\mathcal{A} = \{A_i\}_i$ of subsets of $\Omega_1$ and $\mathcal{B} = \{B_j\}_j$ of subsets of $\Omega_2$, denote by $\mathcal{A} \times \mathcal{B}$ the collection $\{A_i \times B_j | A_i \in \mathcal{A} \text{ and } B_j \in \mathcal{B}\}$ of subsets of $\Omega_1 \times \Omega_2$. If $\mathcal{A}$ and $\mathcal{B}$ are partitions, then $\mathcal{A} \times \mathcal{B}$ is a partition too.

Let $(\Omega_i, \rho_i)$ be a model of $(S_i, E_i)$, for $i = 1, 2$. Associate to each variable $\langle X_1, X_2 \rangle \in \text{Ob}(S_1 \times S_2)$ the partition of $\Omega_1 \times \Omega_2$ given by

$$\rho_X(\langle X_1, X_2 \rangle) = \rho_1(X_1) \times \rho_2(X_2).$$

(2.14)

Analogously, for each $X \neq 1$ in $\text{Ob}(\Omega_1 \sqcup \Omega_2)$, let us define the partition of $\Omega_1 \times \Omega_2$ given by

$$\rho_{\Omega}(X) = \begin{cases} \rho_1(X) \times \{\Omega_2\} & \text{if } X \in \text{Ob}(\Omega_1), \\ \{\Omega_1\} \times \rho_2(X) & \text{if } X \in \text{Ob}(\Omega_2). \end{cases}$$

(2.15)

By convention, $\rho_{\Omega}(1) = \{\Omega_1 \times \Omega_2\}$. 

**Proposition 2.15.** Let $(\Omega_i, \rho_i)$ be a classical model of $(S_i, E_i)$, for $i = 1, 2$. Then

(1) $(\Omega_1 \times \Omega_2, \rho_X)$ is a classical model of $(S_1, E_1) \times (S_2, E_2)$;

(2) $(\Omega_1 \times \Omega_2, \rho_{\Omega})$ is a classical model of $(S_1, E_1) \sqcup (S_2, E_2)$.

It depends on the following lemma.

**Lemma 2.16.**

(1) If $\mathcal{A} = \{A_i\}_i$ and $\mathcal{A}' = \{A'_i\}_j$ are finite partitions of a set $\Omega$, then $\sigma(\mathcal{A}, \mathcal{A}') = \sigma(\{A_i \cap A'_j\}_{i,j})$, and $\{A_i \cap A'_j\}_{i,j}$ are the atoms of $\sigma(\mathcal{A}, \mathcal{A}')$.

(2) If $\mathcal{A} = \{A_i\}_i$, $\mathcal{A}' = \{A'_i\}_j$ are two finite partitions of $\Omega_1$ and $\mathcal{B} = \{B_i\}_i$, $\mathcal{B}' = \{B'_m\}_m$ two finite partitions of $\Omega_2$, then $(\mathcal{A} \times \mathcal{B})(\mathcal{A}' \times \mathcal{B}') = \mathcal{A} \mathcal{A}' \times \mathcal{B} \mathcal{B}'$, where juxtaposition of partitions denotes their product in $\mathcal{O}(\Omega)$, as introduced in Section 2.1.

**Proof.**

(1) On one hand, note that each set $A_i \cap A'_j$ is contained in $\sigma(\mathcal{A}, \mathcal{A}')$, therefore $\sigma(\{A_i \cap A'_j\}_{i,j}) \subset \sigma(\mathcal{A}, \mathcal{A}')$. On the other, each generator $A_i \in \mathcal{A}$ of $\sigma(\mathcal{A}, \mathcal{A}')$ can be written as

$$A_i = A_i \cap \Omega = A_i \cap \left( \bigcup_j A'_j \right) = \bigcup_j (A_i \cap A'_j),$$

and similarly for the generators $A'_j \in \mathcal{A}'$, which implies that $\sigma(\mathcal{A}, \mathcal{A}') \subset \sigma(\{A_i \cap A'_j\}_{i,j})$. The reader can verify that $\{A_i \cap A'_j\}_{i,j}$ are atoms.

(2) The previous result can be read as $\mathcal{A} \mathcal{A}' = \{A_i \cap A'_j\}_{i,j}$. The set-theoretical identity

$$\bigcap_i A_i \cap B_i \cap A'_j \cap B'_j = (A_i \cap A'_j) \cap (B_i \cap B'_j)$$

implies that the atoms of $(\mathcal{A} \times \mathcal{B})(\mathcal{A}' \times \mathcal{B}')$ and $\mathcal{A} \mathcal{A}' \times \mathcal{B} \mathcal{B}'$ coincide. \hfill \Box
Proof of Proposition 2.15. Most verifications are trivial and left to the reader. To prove that \( \rho_x((X_1, X_2) \land (Y_1, Y_2)) = \rho_x((X_1, X_2)) \rho_x((Y_1, Y_2)) \), note that
\[
\rho_x((X_1, X_2) \land (Y_1, Y_2)) = \rho_x((X_1 \land Y_1, X_2 \land Y_2)) = \rho_1(X_1 \land Y_1) \times \rho_2(X_2 \land Y_2) = \rho_1(X_1) \rho_1(Y_1) \times \rho_2(X_2) \rho_2(Y_2) = (\rho_1(X_1) \times \rho_2(X_2)) (\rho_1(Y_1) \times \rho_2(Y_2)) = \rho_x((X_1, X_2)) \rho_x((Y_1, Y_2)).
\]
The first equality comes from the construction of \( \delta_1 \times \delta_2 \); the second, from the definition of \( \rho_x \); the third, from the fact that \( \rho_1 \) and \( \rho_2 \) are models; the fourth equality is just a consequence of Lemma 2.16 and the fifth is just a rewriting of the previous one. \( \square \)

The partitions of \( \Omega_1 \times \Omega_2 \) in the image of \( \rho_\Pi \) are also in the image of \( \rho_x \). This is consistent with the existence of a morphism of structures \( \phi : (\delta_1, E_1) \coprod (\delta_2, E_2) \rightarrow (\delta_1, E_1) \times (\delta_2, E_2) \), with \( \phi_0 \) given at the level of objects by the injection
\[
(2.17) \quad X \mapsto \begin{cases} 1_{\delta_1 \times \delta_2} & \text{if } X = 1_{\delta_1 \coprod \delta_2} \\ (X, 1_{\delta_2}) & \text{if } X \in \text{Ob}(\delta_1) \\ (1_{\delta_1}, X) & \text{if } X \in \text{Ob}(\delta_2) \end{cases}
\]
and the corresponding components \( \phi_X^\# \) being the obvious bijections: \( E_1(X) \rightarrow E_1(X) \times \{\ast\} \) when \( X \in \text{Ob}(\delta_1) \) or \( E_2(X) \rightarrow \{\ast\} \times E_2(X) \) when \( X \in \text{Ob}(\delta_2) \). The model \( (\Omega_1 \times \Omega_2, \rho_x) \) on \( (\delta_1, E_1) \times (\delta_2, E_2) \) restricts then to a model \( (\Omega_1 \times \Omega_2, \rho_x \circ \phi_0) \) on \( (\delta_1, E_1) \coprod (\delta_2, E_2) \), that coincides with \( (\Omega_1 \times \Omega_2, \rho_\Pi) \). This is clearly a particular example of a more general procedure to restrict models, valid for any morphism of structures \( \phi = (\phi_0, \phi^\#) \) such that \( \phi_0 \) is injective on objects and each \( \phi_X^\# \) is a bijection; therefore, it makes sense to call these morphisms embeddings.

3. Topoi and information cohomology

In this section, we suppose that the reader is familiar with abelian categories and derived functors. We use the definitions and notations of [24, Ch. 1 & 2].

3.1. Sheaves of modules. We summarize here the principal facts about sheaves of modules, a particular abelian category used throughout this work.

Let \( C \) be a category. A presheaf of sets is any contra-variant functor \( F \) from \( C \) to \( \text{Sets} \), the category of sets. A morphism of presheaves \( \phi : F \rightarrow G \) is a natural transformation of functors. Presheaves of sets and their morphisms form a new category, denoted by \( \mathcal{P}sh(C) \). By definition, we say the \( \phi \) is injective (resp. surjective) if for every \( X \in \text{Ob}(C) \), the map \( \phi(X) : F(X) \rightarrow G(X) \) is injective (resp. surjective).

Proposition 3.1. The injective morphisms defined above are exactly the monomorphisms of \( \mathcal{P}sh(C) \). The surjective morphisms are exactly the epimorphisms of \( \mathcal{P}sh(C) \).

It is possible to define a topology on a category, obtaining a site. Presheaves that are ‘well-behaved’ for this topology are called sheaves. Moreover, every category admits a trivial topology, such that every presheaf is a sheaf [7, Ch. 0]. If \( C \) is a
site, we can consider the full subcategory of $\mathcal{PSh}(\mathcal{C})$, whose objects are the sheaves; this category is denoted by $\mathcal{Sh}(\mathcal{C})$.

Abelian presheaves are presheaves that take values in abelian groups. They form an abelian category (for a proof, see [15, Ch. 9, Prop. 3.1]). A morphism of abelian presheaves $\phi : F \to G$ is a natural transformation between $F$ and $G$ that induces a homomorphism of abelian groups $\phi(X) : F(X) \to G(X)$ on every $X \in \text{Ob}(\mathcal{C})$. Given a morphism $\phi : F \to G$, the kernel of $\phi$ is the abelian presheaf $X \mapsto \ker\{\phi : F(X) \to G(X)\}$ and its cokernel is $X \mapsto \text{coker}\{\phi : F(X) \to G(X)\}$. One has $\text{cok}(\phi) = \text{im}(\phi)$, because it holds over each $X \in \text{Ob}(\mathcal{C})$. Moreover, a sequence of presheaves $F_1 \to F_2 \to F_3$ is exact if $F_1(X) \to F_2(X) \to F_3(X)$ is exact as a sequence of groups over every $X \in \text{Ob}(\mathcal{C})$. Given a site $\mathcal{C}$, the category of abelian sheaves (denoted by $\mathcal{A}b(\mathcal{C})$) is the full subcategory of $\mathcal{PSh}(\mathcal{C})$ of those abelian presheaves whose underlying presheaves of sets are sheaves.

If $\mathcal{C}$ is a site and $O$ is a sheaf of rings on $\mathcal{C}$, the couple $(\mathcal{C}, O)$ is called a ringed site and $O$, the structure ring. The couple $(\mathcal{Sh}(\mathcal{C}), O)$ is called a ringed topos. There exist appropriate notions of morphisms between ringed sites or ringed topos, cf. [19, Modules on sites, Secs. 6, 7].

Given a ringed site $(\mathcal{C}, O)$, a sheaf of $O$-modules is given by an abelian sheaf $F$ together with a map of presheaves of sets $O \times F \to F$, such that for every $X \in \text{Ob}(\mathcal{C})$, the map $O(X) \times F(X) \to F(X)$ defined a structure of $O(X)$-module on the abelian group $F(X)$. A morphism $\phi : F \to G$ between sheaves of $O$-modules is a morphism of abelian presheaves $\phi : F \to G$ such that

$$O \times F \xrightarrow{1 \times \phi} F \xrightarrow{\phi} O \times G \xrightarrow{\phi} G$$

The set of $O$-module morphisms from $F$ to $G$ is denoted by $\text{Hom}_O(F, G)$. Sheaves of $O$-modules and its morphisms form the category $\text{Mod}(O)$. We quote a important result in the context of our work.

**Proposition 3.2.** Let $(\mathcal{Sh}(\mathcal{C}), O)$ be a ringed topos. The category $\text{Mod}(O)$ is abelian. Moreover, it has enough injective objects.

**Proof.** For the first assertion, see [19, Ch. 18, Lem. 4.1]. For the second, [19, Ch. 19, Lem. 5.1]. □

This result is due to Grothendieck [9]. Gabriel proves in [6] that there is a minimal injective object containing a given object, called its injective envelope.

Finally, given a (trivial) ringed site $(\mathcal{C}, O)$ and $E$ in $\mathcal{PSh}(\mathcal{C})$, it is possible to define a presheaf of $O$-modules —denoted by $O[E]$— that associates to each $X \in \text{Ob}(\mathcal{C})$ the free $O(X)$-module on generators $E(X)$. There is an adjunction

$$\text{Mor}_{\text{Mod}(O)}(O\{E\}, F) \cong \text{Mor}_{\mathcal{PSh}(\mathcal{C})}(E, \square F).$$

Here, $\square$ denotes the forgetful functor and will be omitted in the sequel.

### 3.2. Information cohomology.

Let $\delta$ be the poset of variables of an information structure $(\delta, \mathcal{E})$. We view it as a site with the trivial topology, such that every presheaf is a sheaf. For each $X \in \text{Ob}(\delta)$, set $\delta_X := \{Y \in \text{Ob}(\delta) \mid X \to Y\}$, with the monoid structure given by the product of observables in $\delta$: $(Z, Y) \to ZY = Z \wedge Y$. Let $\mathcal{A}_X := \mathbb{R}[\delta_X]$ be the corresponding monoid algebra. The contra-variant
functor \( X \mapsto \mathcal{A}_X \) is a sheaf of rings; we denote it by \( \mathcal{A} \). The couple \((\delta, \mathcal{A})\) is a
ringed site.

For a fixed object \( A \) of \( \text{Mod}(\mathcal{A}) \), the covariant functor \( \text{Hom}(A, -) \) is always
additive and left exact. As \( \text{Mod}(\mathcal{A}) \) has enough injective objects, it is possible
to define the right derived functors associated to any left exact additive covariant
functor. In the case of \( \text{Hom}(A, -) \), the associated right derived functors are called
\( \text{Ext}^n(A, -) \), for \( n \geq 0 \).

Let \( \mathbb{R}_S(X) \) be the \( \mathcal{A}_X \)-module defined by the trivial action of \( \mathcal{A}_X \) on the abelian
group \((\mathbb{R}, +)\) (for \( s \in \delta_X \) and \( r \in \mathbb{R} \), take \( s \cdot r = r \)). The presheaf that associates to
each \( X \in \text{Ob}(\delta) \) the module \( \mathbb{R}_S(X) \), and to each arrow the identity map is denoted \( \mathbb{R}_S \).

**Definition 3.3.** The **information cohomology** associated to the structure \( \delta \),
with coefficients in \( M \in \text{Mod}(\mathcal{A}) \) is

\[
H^*(\delta, M) := \text{Ext}^*(\mathbb{R}_S, M).
\]

The definition of information cohomology is formally analogous to that of group
cohomology. In this case, one begins with a multiplicative group \( G \) and constructs
the free abelian group \( \mathbb{Z}[G] \), whose elements are finite sums \( \sum m_g g \), with \( g \in G \)
and \( m_g \in \mathbb{Z} \). The product of \( G \) induces a product between two such elements,
and makes \( \mathbb{Z}[G] \) a ring, called the integral group ring of \( G \). The category of \( \mathbb{Z}[G] \)
modules is abelian and has enough injective objects. The cohomology groups of \( G \)
with coefficients in a \( \mathbb{Z}[G] \)-module \( A \) are defined by

\[
H^n(G, A) = \text{Ext}^n(\mathbb{Z}, A),
\]

where \( \mathbb{Z} \) is the trivial module. When \( G \) is the Galois group of a field extension,
this construction is called Galois cohomology; this tool has been successfully used
in class field theory.

Finally, we make some observations concerning the computation of cohomology.
Let \( C \) be an abelian category with enough injectives, just like \( \text{Mod}(\mathcal{A}) \), and suppose
that we are interested in computing the groups \{\( \text{Ext}^n(A, B) \)\}_{n \geq 0} for certain fixed
objects \( A \) and \( B \). In addition, we assume that \( A \) has a projective resolution \( 0 \leftarrow A \leftarrow P_0 \leftarrow P_1 \leftarrow \ldots \). Then, Theorem 4.6.10 in [10] implies that, for all \( n \geq 0 \),

\[
(\text{Hom}^C(A, -))(B) \simeq (\text{Hom}^C(-, B))(A).
\]

We denote \((\text{Hom}^C(-, B))(A)\) by \( \text{Ext}^n(A, B) \). They are given by the formulas:

\[
\text{Ext}^0(A, B) = \ker(\text{Hom}(P_0, B) \rightarrow \text{Hom}(P_1, B)),
\]

\[
\text{Ext}^i(A, B) = \frac{\ker(\text{Hom}(P_i, B) \rightarrow \text{Hom}(P_{i+1}, B))}{\text{im}(\text{Hom}(P_{i-1}, B) \rightarrow \text{Hom}(P_i, B))}, \quad \text{for } i \geq 1.
\]

### 3.3. Non-homogeneous bar resolution.

In this section, we introduce a projective resolution of the sheaf of \( \mathcal{A} \)-modules \( \mathbb{R}_S \): a long right exact sequence

\[
0 \leftarrow \mathbb{R}_S \leftarrow B_0 \overset{\partial_1}{\leftarrow} B_1 \overset{\partial_2}{\leftarrow} B_2 \leftarrow \ldots
\]

that will allow us to compute the information cohomology.

Remember that \( \mathcal{A}_X \) is the algebra over \( \mathbb{R} \) generated by the monoid \( \delta_X \). Let
\( B_0(X) \) be the free \( \mathcal{A}_X \)-module generated by the symbols \([X_1][X_2] \ldots [X_n] \), where \( \{X_1, \ldots, X_n\} \subset \delta_X \). Remark that \( B_0(X) \) is the free module on one generator \([ ] \), in consequence isomorphic to \( \mathcal{A}_X \).
We introduce now $\mathcal{A}_X$-module morphisms $\epsilon_X : B_0(X) \to \mathbb{R}_S(X)$, from $B_0(X)$ to the trivial $\mathcal{A}_X$-module $\mathbb{R}_S(X)$, given by the equation $\epsilon([]) = 1$, and boundary morphisms $\partial : B_n(X) \to B_{n-1}(X)$, given by
\begin{equation}
\partial([X_1|...|X_n]) = X_1[X_2|...|X_n] + \sum_{k=1}^{n-1} (-1)^k [X_1|...|X_kX_{k+1}|...|X_n] + (-1)^n [X_1|...|X_{n-1}].
\end{equation}

These morphisms are natural in $X$.

**Proposition 3.4.** The complex $(3.7)$ is a resolution of the sheaf $\mathbb{R}_S$.

**Proof.** This corresponds to the example developed at the end of Section 2.3 for the case $R = \mathcal{A}$ and $S = \mathbb{R}$ (the constant sheaf). Taking $C = \mathbb{R}_S$, the construction simplifies, because $C(X)$ is generated by 1 as an $\mathcal{A}_X$-module (and also as a vector space over $\mathbb{R}$). Therefore, $B_0C$ is generated over $\mathcal{A}_X$ by the symbol $[1]$, written simply as $[1]$. In general, $B_nC(X)$ is generated over $\mathcal{A}_X$ by the symbols $[X_1|...|X_n|1]$, or simply $[X_1|...|X_n]$ if we omit the 1.

Thus far we have a resolution with relatively free objects, that in general need not be projective. However, the special properties of $\delta$ allow us to improve the result.

**Proposition 3.5.** For each $n \geq 0$, the sheaf $B_n$ is a projective object in $\text{Mod}(\mathcal{A})$.

**Proof.** Let $F$ be the presheaf of sets defined by $F(X) = \{[X_1|...|X_n]| X_i \in \delta_X\}$, for $X \in \text{Ob}(\delta)$. Following the notations of Section 3.1, $B_n = \mathcal{A}[F]$.

Consider an epimorphism $\sigma : M \to N$ and a morphism $\epsilon : \mathcal{A}[F] \to N$, both in $\text{Mod}(\mathcal{A})$. By the adjunction,
\begin{equation}
\text{Mor}_{\text{Mod}(\mathcal{A})}(\mathcal{A}[F], G) \cong \text{Mor}_{\mathcal{PSh}(\delta)}(F, G),
\end{equation}
\(\epsilon\) determines a unique morphism $\tilde{\epsilon} : F \to N$ in $\mathcal{PSh}(\delta)$. We want to find a lift of $\tilde{\epsilon}$, this is, a morphism $\tilde{\epsilon}' : F \to M$ such that $\tilde{\epsilon} = \sigma\tilde{\epsilon}'$. This lift extends to a morphism of $\mathcal{A}$-modules that solves our problem.

To define $\tilde{\epsilon}'$, one has to determine the image of every symbol $[X_1|...|X_n]$ (with $\{X_1,...,X_n\} \subset \delta$), each time it appears in a set $F(X)$. Note that $[X_1|...|X_n] \in F(X) \iff (\forall i)(X \to X_i) \iff X \to X_1 \cdots X_n =: \Pi X_i$.

The last equivalence is true due to the definition of $\delta$. Therefore, the symbol $[X_1|...|X_n]$ just appears in the sets $F(X)$ where $X \to \Pi X_i$; we will denote the full subcategory of $\delta$ determined by these objects $X$ by $\delta/\Pi X_i$. This category $\delta/\Pi X_i$ has a terminal object, $\Pi X_i$ itself.

This means that, to solve the lift problem, it is enough to pick $m \in \sigma^{-1}_{\Pi X_i}(\tilde{\epsilon}([X_1|...|X_n]))$, and define $\tilde{\epsilon}'_{\Pi X_i}([X_1|...|X_n]) := m$. This choice gives, by functoriality, a well defined value $\tilde{\epsilon}_X([X_1|...|X_n]) = M(\pi)(m)$ over each $X$ such that $\pi : X \to \Pi X_i$ in $\delta$.

The existence of this projective resolution just depends on the definition of an abstract information structure (Definition 2.6). It appears in the computation of classical and quantum information cohomology: the difference between these cases lies in the coefficients.
4. INFORMATION COHOMOLOGY FOR CLASSICAL PROBABILITIES

4.1. Functional module. Let \((S, E)\) be an information structure, and \(Q\) an adapted probability functor. Information theory uses some functions defined on each set \(Q_X\) to measure the amount of information associated to the variable \(X\). For example, given a variable \(X\) and a probability \(P \in Q_X\), the Shannon-Gibbs entropy

\[
S_1[X](P) := -\sum_{x \in E_X} P(x) \log P(x)
\]

was proposed by Shannon [18] as a measure of the uncertainty associated to the random variable. This uncertainty is the information ‘produced’ in the process of communication of a message with the same a priori probability distribution than \(X\). Other example is given by the structural \(\alpha\)-entropy, defined as

\[
S_{\alpha}[X](P) = \frac{1}{1 - \alpha} \left( \sum_{x \in E_X} P(x)^\alpha - 1 \right),
\]

for \(\alpha > 0, \alpha \neq 1\).

In view of these considerations, let us introduce, for each \(X \in \text{Ob}(S)\), the real vector space \(F(Q_X)\) of measurable functions on \(Q_X\); we call it functional space. For each arrow \(\pi : X \to Y\) in \(S\), there is a morphism \(\pi^* : F(Q_Y) \to F(Q_X)\) defined by

\[
\pi^* f(P_X) = f(\pi_* P_X).
\]

Therefore, \(F\) is a contra-variant functor from \(S\) to the category of real vector spaces. Whenever \(Q\) is adapted to \(S\), the functional space \(F(Q_X)\) admits an action of the monoid \(S_X\) (parameterized by \(\alpha > 0\): for \(Y \in \text{Ob}(S_X)\), and \(f \in F(Q_X)\), the new function \(Y.f\) is given by

\[
(Y.f)(P_X) = \sum_{y \in E_Y} P_X(Y = y_i)^\alpha f(P_X|Y=y_i).
\]

By convention, a summand is simply 0 if \(P_X(Y = y_i) = 0\). Remark that \(P_X(Y = y_i) = Y_\ast P_X(Y = y_i)\); these coefficients just depend on the “localization” of \(P_X\) on \(Y\). By Proposition 4.1, there is a morphism of monoids \(S_X \to \text{End}(F(Q_X))\), given by Equation (4.3), that extends by linearity to a morphism of rings

\[
\Lambda_\alpha(X) : \mathcal{A}_X \to \text{End}(F(Q_X))
\]

This means that, for each \(\alpha > 0\), \(F(Q_X)\) has the structure of a \(\mathcal{A}_X\)-module, denoted \(F_\alpha(Q_X)\).

Proposition 4.1. Given any \(X \in \text{Ob}(S)\), observables \(Y\) and \(Z\) in \(S_X\), and \(f \in F(Q_X)\):

\[
(ZY).f = Z.(Y.f).
\]

Proof. The universal property of products gives the commutative diagram:

\[
\begin{array}{ccc}
X & \xrightarrow{\rho_Y} & Y \\
\downarrow{\rho_Y} & & \downarrow{\rho_Z} \\
Y & \xleftarrow{\pi_Y} & Y \land Z \\
\end{array}
\]

\[\text{As } \mathcal{A}_X \text{ is a } \mathbb{R}\)-algebra, it comes with an inclusion } f_X : \mathbb{R} \to \mathcal{A}_X, r \mapsto r1_\mathcal{A}. \text{ The composite } \Lambda_\alpha(X) \circ f_X \text{ gives an action of } \mathbb{R} \text{ over } F(Q_X), \text{ that coincides with the usual multiplication of functions by scalars, since } 1_\mathcal{A} \text{ acts trivially.}
For $P \in Q_X$, 
\[
Z(Y,f)(P) = \sum_{z \in E_Z} P(Z = z)^a \sum_{y \in E_Y} \left( P|_{Z=z}(y) \right)^a f((P|_{Z=z})|_{Y=y})
\]
\[
= \sum_{z \in E_Z} \sum_{y \in E_Y} P\{Y = y\} \cap \{Z = z\}^a f((P|_{Z=z})|_{Y=y})
\]

The equality $P(Z = z)P|_{Z=z}(Y = y) = P\{\{Y = y\} \cap \{Z = z\}\} \neq 0$, and in particular $P(Y = y)$ and $P(Z = z)$ are different from zero; in this case, the equality $\left( P|_{Z=z}\right)|_{Y=y}(A) = \frac{P|_{Z=z}(A \cap \{Y=y\})}{P|_{Z=z}(Y=y)} = \frac{P(A \cap \{Y=y\} \cap \{Z=z\})}{P\{\{Y = y\} \cap \{Z = z\}\}} = P|_{Z=z,X=x}(A)$ holds for every $A \subset X$. By (7), the non-empty sets $\{Y = y\} \cap \{Z = z\} = \rho_Y^{-1}(y) \cap \rho_Z^{-1}(z) \subset E_X$ are the preimage by $(\rho_Y, \rho_Z)_*$ of a unique element $w(y, z) \in E(Y \land Z)$; moreover, for every element $w \in E(Y \land Z)$ we find such set. Remark that $P\{\{Y = y\} \cap \{Z = z\}\} = P(\rho_Y^{-1}(y) \cap \rho_Z^{-1}(z)) = P((\rho_Y, \rho_Z)_*^{-1}(w, y, z))$. Therefore,
\[
Z(Y,f)(P) = \sum_{w(y,z) \in E_Y \land Z} P\{\{Y = x\} \cap \{Z = z\}\}^a f((P|_{Z=z,X=x}) = (ZY), f(P).
\]

This action is compatible with the morphisms between functional modules. Hence, the sheaf $F_\alpha(Q)$ belongs to $\text{Mod}(\mathcal{A})$, and can be used as coefficients in information cohomology.

**Proposition 4.2.** Given $\pi_{YX} : X \to Y$ and $\pi_{ZY} : Y \to Z$, the action of $Z$ makes the following diagram commute

\[
\begin{array}{ccc}
F(Q_Y) & \xymatrix{ \ar[r]^-Z & \ar[d]^-{\pi_{YX}} F(Q_Y) } & \ar[d]^-{\pi_{YX}} F(Q_X) \\
F(Q_X) & \xymatrix{ \ar[r]^-Z & \ar[d]^-{\pi_{ZY}} F(Q_X) } & \ar[d]^-{\pi_{ZY}} F(Q_Z)
\end{array}
\]

The proof is straightforward and left to the reader.

### 4.2. Description of cocycles

We have shown the existence of a projective resolution of $\mathbb{R}_S$ in $\text{Mod}(\mathcal{A})$,

\[
0 \leftarrow \mathbb{R}_S \leftarrow B_0 \leftarrow B_1 \leftarrow B_2 \leftarrow ...
\]

Recall the functional module introduced in Section 4.1. We can compute then the information cohomology $H^\bullet(\mathbb{R}_S, F_\alpha(Q))$ as $\text{Ext}^n(\mathbb{R}_S, F_\alpha(Q))$, defined in formulas (3.5) and (3.6). This means that:

\[
H^0(\mathbb{R}_S, F_\alpha(Q)) = \ker\{\delta : \text{Hom}_{\mathcal{A}}(B_0, F_\alpha(Q)) \to \text{Hom}_{\mathcal{A}}(B_1, F_\alpha(Q))\},
\]

\[
H^i(\mathbb{R}_S, F_\alpha(Q)) = \ker\{\delta : \text{Hom}_{\mathcal{A}}(B_i, F_\alpha(Q)) \to \text{Hom}_{\mathcal{A}}(B_{i+1}, F_\alpha(Q))\} \cap \text{im}\{\delta : \text{Hom}_{\mathcal{A}}(B_{i-1}, F_\alpha(Q)) \to \text{Hom}_{\mathcal{A}}(B_i, F_\alpha(Q))\}, \text{ for } i \geq 1
\]

In consequence, we shall study the differential complex $\{C^n(S, F_\alpha(Q)), \delta\}$, where $C^n(S, F_\alpha(Q)) := \text{Hom}_{\mathcal{A}}(B_n(\mathbb{R}_S), F_\alpha(Q))_{n \geq 0}$ and $\delta$ is given by (4.7). A morphism $f$ in $C^n(S, F_\alpha(Q))$ is called $n$-cochain (of type $\alpha$) in this context. Following the
description in Section 3.1, a \( n \)-cochain \( f \) consist of a collection of morphism \( f_X \in \text{Hom}_A(B_n(X), F_\alpha(Q_X)) \) that satisfy the following conditions:

(1) \( f \) is a natural transformation: given \( X \to Y \), the diagram

\[
\begin{array}{ccc}
B_n(Y) & \xrightarrow{f_Y} & F_\alpha(Q_Y) \\
\downarrow & & \downarrow \\
B_n(X) & \xrightarrow{f_X} & F_\alpha(Q_X)
\end{array}
\]

commutes. This means that \( f \) is a functor of (pre)sheaves.

(2) \( f \) is compatible with the action of \( \mathcal{A} \): given \( X \to Y \), the diagram

\[
\begin{array}{ccc}
\mathcal{A}_X \times B_n(X) & \xrightarrow{1 \times f_X} & B_n(X) \\
\downarrow & & \downarrow \\
\mathcal{A}_X \times F_\alpha(Q_X) & \xrightarrow{f_X} & F_\alpha(Q_X)
\end{array}
\]

commutes. This means that \( f_X \) is equivariant, \( f_X(Y[Z]) = Y.f_X[Z] \). Since \( B_n(X) \) is a free module, \( f_X \) is simply determined by the values on the generators \([X_1|...|X_n]\). Just to simplify notation, we shall write \( f_X([X_1|...|X_n]) \) as \( f_X[X_1|...|X_n] \). Note that \( f_X[X_1|...|X_n] \) is itself a function on \( Q_X \).

The coboundary of \( f \in C^n(F_\alpha(Q)) \) is the \((n + 1)\)-cochain \( \delta f = f \partial : B^{n+1} \to F_\alpha(Q) \). More explicitly,

\[
(4.7) \quad \delta f[X_1|...|X_{n+1}] = X_1.f[X_2|...|X_{n+1}] + \sum_{k=1}^{n} (-1)^k f[X_1|...|X_k X_{k+1}|...|X_n] + (-1)^{n+1} f[X_1|...|X_n]
\]

If \( f \in C^n(\mathcal{S}, F_\alpha(Q)) \) and \( \delta f = 0 \), we call \( f \) an \( n \)-cocycle; the submodule of all \( n \)-cocycles is denoted by \( Z^n(\mathcal{S}, F_\alpha(Q)) \). The image under \( \delta \) of \( C^{n-1} \) forms another submodule of \( C^n(\mathcal{S}, F_\alpha(Q)) \), denoted \( \delta C^{n-1}(\mathcal{S}, F_\alpha(Q)) \); its elements are called \( n \)-coboundaries. By definition, \( \delta C^{-1}(\mathcal{S}, F_\alpha(Q)) = \{0\} \), the trivial module. It is easy to verify that \( \delta^2 = 0 \). With this notation, \( H^n(\mathcal{S}, F_\alpha(Q)) = Z^n(\mathcal{S}, F_\alpha(Q))/\delta C^{n-1}(\mathcal{S}, F_\alpha(Q)) \), for every \( n \geq 0 \).

Requirement (1) is equivalent to the following condition, called joint locality: given an arrow \( \pi_{Y,X} : X \to Y \) in \( \mathcal{S} \) and a set of observables \( \{X_1,...,X_n\} \) in \( \mathcal{S}_Y \), a morphism \( f \in \text{Hom}_A(B_n(\mathbb{R}_\mathcal{S}), F_\alpha(Q)) \) must satisfy

\[
(4.8) \quad f_X[X_1|...|X_n](P_X) = f_Y[X_1|...|X_n](Y,P_X).
\]

Recall that \( Y_* = Q(\pi_{Y,X}) \). Since \( (X_1|...|X_n) \) is the coarsest variable \( Y \) such that \( \{X_1,...,X_n\} \) in \( \mathcal{S}_Y \), joint locality implies that, for any \( X \) such that \([X_1|...|X_n] \in B_n(X)\),

\[
(4.9) \quad f_X[X_1|...|X_n](P_X) = f_{X_1|...|X_n}[X_1|...|X_n](Y(P_X)) = f_{X_1|...|X_n}(Y,P_X) = (X_1|...|X_n), P_X \text{ for any sequence } X \to Y \to X_1 \cdots X_n \text{ and therefore constitute an equivalent characterization.}
\]
4.3. **Functoriality.** Let $\phi : (\mathcal{S}, E) \to (\mathcal{S}', E')$ be a morphism of information structures; let $Q$ be a probability functor on $\mathcal{S}$ and $Q'$, a probability functor on $\mathcal{S}'$. Given a $X \in \text{Ob}(\mathcal{S})$ and a law $P \in Q_X$, define a law $m_X(P)$ on $E'_{\phi(X)}$ by the equation

\begin{equation}
\forall x' \in E_{\phi(X)}, \quad (m_X(P))(x') = \sum_{x \in \phi_X^{-1}(x')} P(x).
\end{equation}

We suppose that, for all $X \in \text{Ob}(\mathcal{S})$ and all $P \in Q_X$, the law $m_X(P)$ belongs to $Q'_{\phi(X)}$. Then $m_{\bullet} : Q \to Q' \circ \phi$ is a natural transformation. In fact, for every arrow $\pi : X \to Y$ and $y' \in E_{\phi(Y)}$,

\begin{equation}
(Q'(\pi)(m_X(P)))(y') = \sum_{x' \in E'(\phi(\pi))^{-1}(y')} \sum_{x \in \phi_X^{-1}(x')} P(x) = \sum_{x \in (E(\phi(\pi)) \circ \phi_X)^{-1}(y')} P(x) = \sum_{y \in \phi_Y^{-1}(y')} \sum_{x \in E(\pi)^{-1}(y)} P(x).
\end{equation}

The forth equality comes from the naturality of $\phi_{\#}$, as stated in Definition 2.7.

We construct now a functor between cohomology groups.

**Proposition 4.3.** Let $\phi : (\mathcal{S}, E) \to (\mathcal{S}', E')$ be a morphism of information structures; let $Q$ (resp. $Q'$) be an adapted probability functor on $\mathcal{S}$ (resp. $\mathcal{S}'$). Suppose that

1. for all $X \in \text{Ob}(\mathcal{S})$, the map $\phi_{\#}^X$ is a bijection, and
2. for all $X \in \text{Ob}(\mathcal{S})$ and all $P \in Q_X$, the law $m_X(P)$ belongs to $Q'_{\phi(X)}$.

Then, there exist a cochain map

\begin{equation}
\phi_{\#} : (C^\bullet(F_\alpha(Q'), \delta) \to (C^\bullet(F_\alpha(Q), \delta),
\end{equation}

given by the formula

\begin{equation}
(\phi_{\#}^*f)_Y[X_1, \ldots, X_n](P) := f_{\phi(Y)}[\phi(X_1), \ldots, \phi(X_n)](m_Y(P)).
\end{equation}

The chain map induces a morphism of graded vector spaces in cohomology

\begin{equation}
\phi_{\#}^* : H^\bullet(\mathcal{S}', F_\alpha(Q')) \to H^\bullet(\mathcal{S}, F_\alpha(Q)).
\end{equation}

**Proof.** First, we prove that $\phi^*f$ is jointly local. For $f$ is jointly local,

\begin{equation}
f_{\phi(Y)}[\phi(X_1), \ldots, \phi(X_n)](m_Y(P))
\end{equation}

only depends on

\begin{equation}
(\phi(X_1), \ldots, \phi(X_n))_* m_Y(P) = (\phi(X_1 \cdots X_n))_* m_Y(P).
\end{equation}
Let \( \pi : Y \to X_1 \cdots X_n \) be the corresponding refinement. Since \( m_\bullet \) is a natural transformation, \( m_{X_1 \cdots X_n} \circ Q(\pi) = Q'(\phi(\pi)) \circ m_Y \); this means that

\[
(4.14) \quad (\phi(X_1 \cdots X_n))_* m_Y(P) = m_{X_1 \cdots X_n}(Q(\pi)(P)) = m_{X_1 \cdots X_n}((X_1 \cdots X_n)_*P).
\]

We conclude that \( \phi^* f \) depends only on \( (X_1 \cdots X_n)_*P \) and its therefore a cocycle.

We show now that \( \phi^* \) commutes with \( \delta \). For simplicity, we write the formulas for \( n = 2 \); the argument works in general. Note that

\[
(4.15) \quad (\phi^*(\delta f))_Y[X_1][X_2] = \delta f_{\phi(Y)}[\phi(X_1)]\phi(X_2)]
\]

\[
(4.16) \quad = \phi(X_1)_* f_{\phi(Y)}[\phi(X_2)] - f_{\phi(Y)}[\phi(X_1)\phi(X_2)] + f_{\phi(Y)}[\phi(X_1)].
\]

By definition, \( f_{\phi(Y)}[\phi(X_1)] = \phi^* f_Y[X_1] \) and similarly \( f_{\phi(Y)}[\phi(X_1)\phi(X_2)] = \phi^* f_Y[X_1X_2] \), since \( \phi(X_1)\phi(X_2) = \phi(X_1X_2) \). The remaining term gives:

\[
(4.17) \quad (\phi(X_1)_* f_{\phi(Y)})(\phi(X_2))(m_Y(P)) = \\
\sum_{x'_1 \in E(\phi(X_1))} \{(\phi(\pi_1)_* m_Y(P))(x'_1) f_{\phi(Y)}[\phi(X_2)](m_Y(P))\}_\phi(X_1) = x'_1,
\]

where \( \pi_1 : Y \to X_1 \). We write \( \phi(\pi_1)_* \) instead of \( Q'(\phi(\pi_1)) \) and \( \pi_1* \) instead of \( Q(\pi_1) \). Set \( x_1 = \phi_{X_1}^{-1}(x'_1) \). The naturality of \( m_\bullet \) implies that

\[
(4.18) \quad (m_Y(P))(x'_1) = (m_{X_1} \circ \pi_1)(P)(x'_1) = \sum_{x \in \phi_{X_1}^{-1}(x'_1)} \pi_1 P(x) = \pi_1 P(x_1).
\]

Finally, for every \( y' \in \phi(Y) \),

\[
(m_Y(P))(\phi(X_1) = x'_1)(y') = \frac{m_Y(P)(\{y'\} \cap \{\phi(X_1) = x'_1\})}{m_Y(P)(\phi(X_1) = x'_1)}
\]

\[
= \frac{\sum_{z \in \phi_Y^{-1}(\{y'\}) \cap \phi_Y^{-1}(\{\phi(X_1) = x'_1\})} P(z)}{\sum_{z \in \phi_Y^{-1}(\{\phi(X_1) = x'_1\})} P(z)}
\]

\[
= \frac{\sum_{z \in \phi_Y^{-1}(\{y'\})} P(z \cap \{X_1 = x_1\})}{P(X = x_1)}
\]

\[
= m_Y(P|_{X=x_1}).
\]

The first equality comes from the definition of conditioning and the second from that of \( m_Y \). The third is a consequence of \( \phi_Y^{-1}(\{\phi(X_1) = x'_1\}) = \{ z \in Y | \phi(\pi) \circ \phi_Y(z) = x'_1 \} \)

\[
= \{ z \in Y | \phi_{X_1} \circ \pi(z) = x'_1 \} = \{ z \in Y | \pi(z) = x_1 \}.
\]

that depends on \( \phi_{X_1}^{-1} \), being a bijection. Therefore,

\[
(4.19) \quad f_{\phi(Y)}(\phi(X_2))(m_Y(P))(\phi(X_1) = x'_1) = f_{\phi(Y)}(\phi(X_2))(m_Y(P|_{X=x_1}))(x'_1)
\]

\[
= (\phi^* f_Y)(X_1)(x'_1) = (\phi_X^* f_Y)(P).
\]

In consequence, \( \delta \) commutes with \( \phi^* \), as we wanted to prove.

\[\Box\]

**Corollary 4.4.** If \( \phi : S \to S' \) is an isomorphism of information structures, and \( Q'(\phi(X)) = m_X(Q_X) \) for every \( X \in \text{Ob}(S) \), then \( \phi^* : H^\bullet(S', F_\alpha(Q')) \to H^\bullet(S, F_\alpha(Q)) \) is an isomorphism too.
Proof. Let \( \psi : S' \to S \) be the inverse of \( \phi \). It is easy to deduce that \( \phi_0 \) and \( \psi_0 \) are bijective on objects. Moreover, for every \( X \in \text{Ob}(S) \), we have \( \psi_{\phi(X)} \circ \phi_X^\# = \text{id}_X \), and similarly for \( \phi(X) \); this implies that \( \phi_X^\# \) and \( \psi_{\phi(X)}^\# \) are bijections. Proposition 4.3 ensures the existence of \( \psi \); let \( \psi^\# \) be the functor defined on \( S \). We also recover from Proposition 4.3 two functorial properties for concrete information structures stated in (1).

\[
\text{Proposition 4.5. Consider concrete information structures } S, S' \text{ associated to a measurable spaces } (\Omega, \mathcal{B}) \text{ and } (\Omega', \mathcal{B}'), \text{ respectively. Let } Q \text{ (resp. } Q' \text{) be a probability functor defined on } S \text{ (resp. } S' \text{). Let } \sigma : (\Omega, \mathcal{B}) \to (\Omega', \mathcal{B}') \text{ be a surjective measurable function, such that}
\]

1. for all \( X \in \text{Ob}(S) \), there exists \( \phi(X) \in \text{Ob}(S') \) such that \( \sigma \) descends to a bijection \( \sigma_X : \Omega/X \to \Omega'/\phi(X) \);
2. for every \( X \in \text{Ob}(S) \) and \( P \in Q_X \), the marginalization \( \sigma_X \cdot P \) is in \( Q'_\phi(X) \);

Then, there exists a natural morphism of graded vector spaces

\[
(4.20) \quad \sigma^* : H^*(S', F_\alpha(Q')) \to H^*(S, F_\alpha(Q)),
\]

defined at the level of cochains by

\[
(4.21) \quad (\sigma^* f)_Y[X_1|...|X_n](P) = f_{\phi(Y)}[\phi(X_1)|...|\phi(X_n)](\sigma^* P),
\]

where \( X_j = X'_j \circ \phi \), for each index \( i \).

Proof. The correspondence \( X \mapsto \phi(X) \) defines a functor from \( \phi_0 : S \to S' \); in fact, if \( \pi : X \to Y \) is a measurable function, \( \sigma_Y \circ \pi \circ \sigma_X^{-1} : \Omega'/\phi(X) \to \Omega'/\phi(Y) \) is also a surjection, that gives a morphism \( \phi(X) \to \phi(Y) \) in \( S' \). We take as \( \phi_X^\# : X \to \phi(X) \) the bijection of partitions induced by \( \phi_X \) (recall that, for concrete structures, the functor of values is the identity). The condition \( \sigma_X \) implies that \( m_\phi : Q \to Q' \circ \phi \) is a natural transformation. Proposition 4.3 entails the existence of \( \phi^* = : \sigma^* \).

\[
\text{Proposition 4.6. Consider concrete information structures } S, S' \text{ associated to a measurable spaces } (\Omega, \mathcal{B}) \text{ and } (\Omega', \mathcal{B}'), \text{ respectively. Let } \eta : (\Omega, \mathcal{B}) \to (\Omega', \mathcal{B}') \text{ be a measurable function, such that}
\]

1. for all \( X' \in \text{Ob}(S') \), there exists \( \phi(X') \in \text{Ob}(S) \) such that \( \eta \) descends to a bijection \( \eta_X : \Omega/\phi(X') \to \Omega/X' \);
2. for all \( X' \in \text{Ob}(S') \) and \( P' \in Q'_{X'} \), there exists \( P \in \text{Ob}(\phi(X')) \) with \( P' = \eta_{X'} \cdot P \);

Then, there exists a natural morphism of graded vector spaces

\[
(4.22) \quad \eta_* : H^m(S, F_\alpha(Q)) \to H^m(S', F_\alpha(Q')),
\]

defined at the level of cochains by

\[
(4.23) \quad (\sigma_* f)_Y[X'_1|...|X'_n](P) = f_{\phi(Y)}[\phi(X'_1)|...|\phi(X'_n)](P),
\]

where \( P' = \eta_{X'} \cdot P \).
We compute now Example 4.8. Proposition 4.7. This means that $f$ is constant. Given an arrow $X \to Y$, and a 0-cochain $f$ such that $f_X(P) = K$,

$$\langle \delta f \rangle_P = Y.f_X(P) - f_X(P) = \sum_{y \in E_Y} P(Y = y)^\alpha - 1 = 0.$$ 

This means that $Z^0(S, F_1(Q)) = C^0(S, F_1(Q)) \cong \mathbb{R}$ and $Z^0(S, F_\alpha(Q)) = (0)$ when $\alpha \neq 1$ (as long as some $Q_Y$ contains a non-atomic probability). Equivalently, $H^0(S, F_1(Q)) \cong \mathbb{R}$, and $H^0(S, F_\alpha(Q)) \cong (0)$ when $\alpha \neq 1$.

4.4. Determination of $H^0$. Each 0-cochain $f[\cdot] \equiv f$ corresponds to a collection of functions $f_X(P_X) \in F_\alpha(Q_X)$, for each $X \in \text{Ob}(S)$, that satisfy $f_X(Y, P_X) = f_X(P_X)$ for any arrow $X \to Y$ in $S$. As we assume that $1 \in \text{Ob}(S)$, this means that $f$ is constant. Given an arrow $X \to Y$, and a 0-cochain $f$ such that $f_X(P) = K$,

$$\langle \delta f \rangle_P = Y.f_X(P) - f_X(P) = \sum_{y \in E_Y} P(Y = y)^\alpha - 1 = 0.$$ 

4.5. Local structure of 1-cocycles. Now we turn to $C^1(S, F_\alpha(Q))$. The 1-cochains are families $\{f_X \mid X \in \text{Ob}(S)\}$ such that for all $Z \to X \to Y$, the equality $f_Y(Y, X, P) = f_Z(Y, P, Z)$ holds. This means that it is sufficient to know $f_Y(Y, Y, P)$ to recover $f_X(Y, P)$, for any $X \to Y$; in this sense, we usually omit the subindex and just write $f[Y]$. The computation above implies that $\delta C^0(S, F_1(Q)) = (0)$. On the other hand, $\delta C^0(S, F_\alpha(Q)) \cong \mathbb{R}$, and correspond to multiples of the section of $F_\alpha(Q)$ given by $X \mapsto S_\alpha[X]$; we write

$$\delta C^0(S, F_\alpha(Q)) \cong \mathbb{R} \cdot S_\alpha.$$ 

By equation (4.7) and commutativity of the product, every 1-cycle ($\delta f = 0$) must satisfy the following symmetric relation:

The following proposition reflects that certain events do not give information.

Proposition 4.7. Let $f$ be a 1-cocycle. Then

1. $f[1] = 0$
2. For any $X \in \text{Ob}(S)$, any $x \in E_X$, one has $f[X](\delta_x) = 0$.

Proof. Statement (1) is a particular case of (2); we prove the later. From $f[XX] = f[X] + X.f[X]$, we conclude that

$$X.f[X] = \sum_{x \in E_X} P(X = x)^\alpha f[X](P|_{X=x}) = 0.$$ 

For $P = \delta_x$, one obtains $f[X](\delta_x) = 0$.

Example 4.8. We compute now $H^1(S, F_\alpha(\Delta))$, taking $S$ equal to $0 \to 1$, and $E(0) = \{a, b\}$. Proposition Proposition 4.7 implies that $f[0](1, 0) = f[0](0, 1) = 0$, as a consequence of $f[0] = f[0] + 0.f[0]$. All the other relations derived from the
cyclic condition \((4.25)\) become tautological. Therefore, 1-cocycles are in correspondence with measurable functions \(f\) on arguments \((p_a, p_b)\) such that \(f(0, 1) = 0\). We conclude that \(H^1(S, F_{\alpha}(Q))\) has infinite dimension. For a more general statement, see Proposition 4.15.

The functions \(S_{\alpha}[X]\) introduced in (4.1) and (4.2) are local, since they only depend on \(X, P\). The following proposition establishes that they correspond to a 1-cocycles.

**Proposition 4.9.** Let \((S, E)\) be an information structure, \(Q\) an adapted probability functor, \(X\) an element of \(\text{Ob}(S)\), and \(Y, Z \in \text{Ob}(S)\) two variables refined by \(X\). Then, for all \(\alpha > 0\), the section \(S_{\alpha}\) of \(F_{\alpha}(Q)\) satisfy the relation

\[
(S_{\alpha})_X[YZ] = (S_{\alpha})_X[Y] + (S_{\alpha})_X[Z].
\]

This means that \(S_{\alpha}\) belongs to \(Z^1(S, F_{\alpha}(Q))\).

**Proof.** Let \(P\) be a probability in \(Q_X\). We further simplify the notation, writing \(P(y)\) instead of \(P(Y = y)\), and \(P(z|y)\) in place of \(P(Z = z|Y = y)\). We label the points in \(E(YZ)\) by their image under the injection \(\iota : E(YZ) \to E(Y) \times E(Z)\), writing \(w(y, z) \in E(YZ)\).

1. Case \(\alpha = 1\): by definition

\[
-S_1[YZ](P) = \sum_{w(y, z) \in E(YZ)} P(y, z) \log P(y, z)
\]

and in fact we can extend this to a sum over the whole set \(E(Y) \times E(Y)\), since \(P(y, z) = 0\) whenever \((y, z) \notin \text{im} \iota\). We rewrite the previous expression using the conditional probabilities

\[
-S_1[YZ](P) = \sum_{z \in E_Z} \sum_{y \in E_Y} P(z|y) P(y) \log P(y) + \log P(z|y)
\]

This gives the result, because \(\sum_{z \in E_Z} P(z|y) = 1, \text{ and } \sum_{z \in E_Z} P(z|y) \log P(z|y) = S_1[Z](P|Y=y).\) Cf. [13].

2. Case \(\alpha \neq 1\): The result is a consequence of \(\delta^2 = 0\), but can be proved by a direct computation.

\[
(1 - \alpha)(S[Y] + X.S[Y]) = \left( \sum_{y \in E_Y} P(y)^{\alpha - 1} \right) + \sum_{y \in E_Y} P(y)^{\alpha} \left( \sum_{z \in E_Z} P(z|y)^{\alpha - 1} \right)
= \sum_{y \in Y} \sum_{z \in Z} P(z|y)^{\alpha} P(y)^{\alpha - 1}
= (1 - \alpha)S[Y].
\]

The last equality comes from \(P(z|y)P(y) = P(z, y)\), and the fact that we can restrict the sum to \(E(YZ)\), neglecting terms that vanish.

□

We shall see that any non-trivial 1-cocycle of type \(\alpha\) is locally a multiple of \(S_{\alpha}\); we still have to formalize this notion of locality. Proposition 4.10 presents the solution to a functional equation that comes from the cocycle condition. Then, Proposition
4.12 determine the local form of a cocycle. Finally, Proposition 4.13 determine $H^1$ under appropriate non-degeneracy hypotheses on the information structure $S$ and the probability functor $Q$.

For convenience, we introduce the notation

\begin{align}
(4.27) \quad s_1(p) &:= -p\log p - (1 - p)\log(1 - p); \\
(4.28) \quad s_\alpha(p) &:= \frac{1}{1 - \alpha} (p^\alpha + (1 - p)^\alpha - 1) \quad \text{(for } \alpha \neq 1),
\end{align}

both defined for $p \in [0, 1]$.

**Proposition 4.10.** Let $f_1, f_2 : \Delta^2 \to \mathbb{R}$ be two unknown measurable functions satisfying

1. $f_i(0, 1) = f_i(1, 0) = 0$ for $i = 1, 2$, 
2. for all $(p_0, p_1, p_2) \in \Delta^2$,

\begin{align}
(1 - p_2)^\alpha f_1 \left( \frac{p_0}{1 - p_2}, \frac{p_1}{1 - p_2} \right) - f_1(1 - p_1, p_1) &= (1 - p_1)^\alpha f_2 \left( \frac{p_0}{1 - p_1}, \frac{p_2}{1 - p_1} \right) - f_2(1 - p_2, p_2).
\end{align}

Then, $f_1 = f_2$ and there exists $\lambda \in \mathbb{R}$ such that $f_1(p) = \lambda s_\alpha(p)$.

**Proof.** The restriction $p_0 = 0$ (with $p_1 = x, p_2 = 1 - x$) implies $f_2(x, 1 - x) = f_1(1 - x, x)$. We eliminate $f_2$ in (4.29) and set $u(x) := f_1(x, 1 - x)$. When $p_1 = x$, $p_2 = y$ and $p_0 = 1 - x - y$, we obtain the functional equation

\begin{align}
(4.30) \quad u(1 - x) + (1 - x)^\alpha u \left( \frac{y}{1 - x} \right) = u(y) + (1 - y)^\alpha u \left( \frac{1 - x - y}{1 - y} \right).
\end{align}

This functional equation is related to the so-called “fundamental equation of information theory”, which first appeared in the work of Tverberg [22]. In [12], Kannappan and Ng show that every measurable solution of (4.30) with $\alpha = 1$ has the form $u(x) = \lambda s_1(x)$, with $\lambda \in \mathbb{R}$. Analogously, we show in Appendix C that the general solution in the case $\alpha \neq 1$ is $u(x) = \lambda s_\alpha(x)$, with $\lambda \in \mathbb{R}$. \hfill \Box

**Example 4.11.** Let $S$ be the poset represented by

\[
\begin{array}{ccc}
& \Omega & \\
X_1 & \searrow & \nearrow & \swarrow \quad X_2 \\
X_1X_2 & & & \\
& \searrow & \nearrow & \swarrow
\end{array}
\]

and $E$ be the functor defined at the level of objects by $E(X_1) = \{x_{(1)}, x_{(0,2)}\}$, $E(X_2) = \{x_{(2)}, x_{(0,1)}\}$, and $E(X_1X_2) = \{x_{(1)}, x_{(2)}, x_{(1)}\}$; for each arrow $\pi : X \to Y$, the map $\pi_* : E(X) \to E(Y)$ sends $x_I \mapsto x_J$ iff $I \subset J$. The couple $(S, E)$ is an information structure (in fact, it comes from a concrete one). Consider $f \in Z^1(F_\alpha(\Delta))$: the cocycle condition means that, as functions on $\Delta(X_1X_2)$,

\begin{align}
(4.31) \quad f[X_1X_2] &= X_1.f[X_2] + f[X_1], \\
(4.32) \quad f[X_1X_2] &= X_2.f[X_1] + f[X_2].
\end{align}
Write $f[X_1] = f_1$ and $f[X_2] = f_2$. Clearly, the determination of $f_1$ and $f_2$ such that $X_1, f_2 + f_1 = X_2, f_1 + f_2$ fix $f$ completely. In terms of a probability $(p_0, p_1, p_2)$ in $\Delta(X_1X_2)$ this equation is exactly \([4.29]\). We conclude that every cocycle is a multiple of the corresponding $\alpha$-entropy: there exists a unique constant $\lambda \in \mathbb{R}$ such that, for every variable $Z \in \mathbb{Ob}(S)$ and every probability law $P \in \Delta(X_1X_2)$,
\[
f[Z](P) = \lambda S_\alpha[Z](P).
\]
This establishes that $Z^1(S, F_\alpha(\Delta)) \cong \mathbb{R}$. Together with the coboundary computations at the beginning of this section, this implies that $H^1(S, F_1(\Delta)) \cong \mathbb{R}$, and $H^1(S, F_\alpha(\Delta)) \cong \{0\}$. The hypotheses are minimal: on one hand, if we remove $X_1$ or $X_2$, Proposition \([4.15]\) shows that $\dim H^1 = \infty$; on the other, if $Q_{X_1X_2}$ does not contain the interior of $\Delta^2$, the cocycle equations accept an infinite number of solutions, because \([4.29]\) is absent.

We would like to extend this result to a general information structure $(S, E)$, with a sufficiently good functor $Q$. The strategy is to reduce the problem locally to Proposition \([4.10]\) as we did in the previous example. However, the general situation is more involved and it is convenient to introduce some new terminology.

Given two partitions $X$ and $Y$, such that $|E_X| = k$ and $|E_Y| = l$, we can always number the parts of $X$ and $Y$, and represent the product $XY$ as a rectangular array $A_{XY} = (a_{ij})_{1 \leq i \leq k, 1 \leq j \leq l}$, where the component $a_{ij}$ is the element $\{X = x_i, Y = y_j\} \in E(XY)$ or the symbol $\emptyset$ if such element does not exist. We define an elementary block as a submatrix of $A_{XY}$, of dimension $2 \times 2$, such that three of its components (write $b_1, b_2$ and $b_3$) satisfy:
\[
\{(P(b_1), P(b_2), P(b_3)): P \in Q_{XY}\} \cong \Delta^2.
\]
We call the product $XY$ non-degenerate if, for some order of the parts of $X$ and $Y$, there exist elementary blocks $B_1, ..., B_n$ such that

(1) $a_{11} \in B_1$ and $a_{12} \in B_n$,

(2) two consecutive blocks $B_i, B_{i+1}$ have exactly two elements in common.

Note that the product of a variable $X$ with itself is always degenerate, because it only accepts non-trivial probabilities on the diagonal of $A_{X^2}$.

**Proposition 4.12.** Let $(S, E)$ be an information structure, $Q$ an adapted probability functor, and $X, Y$ two different variables in $\mathbb{Ob}(S)$ such that $XY \in \mathbb{Ob}(S)$. Let $f$ be a 1-cocycle of type $\alpha$, i.e. an element of $Z^1(S, F_\alpha(Q))$. If $XY$ is non-degenerate, there exists $\lambda \in \mathbb{R}$ such that
\[
f[X] = \lambda S_\alpha[X], \quad f[Y] = \lambda S_\alpha[Y], \quad f[XY] = \lambda S_\alpha[XY].
\]

**Proof.** As $f$ is a 1-cocycle, it satisfies the two equations derived from \([4.7]\)
\[
\begin{align*}
Y.f[X] &= f[XY] - f[Y], \\
X.f[Y] &= f[XY] - f[X].
\end{align*}
\]
and therefore the symmetric equation
\[
\]
We write
\[
f[X] \left( \begin{array}{cccc}
  s & t & u & \ldots \\
  p & q & r & \ldots \\
\end{array} \right)
\]
if $P(s) = p$, $P(t) = q$, $P(u) = r$, etc. and the probabilities of the unwritten parts are zero.
Fix an order \((x_1, \ldots, x_k)\) and \((y_1, \ldots, y_l)\) that satisfy the definition of non-degenerate product. The proof goes by recursion on the elementary blocks \(B_1, \ldots, B_n\). Let
\[
\begin{bmatrix}
  a_{r,c} & a_{r,c+1} \\
  a_{r+1,c} & a_{r+1,c+1}
\end{bmatrix}
\]
be the current block \(B_i\). Let \(P_\mu\) be a probability given by \(p_{r,c+1} = \mu_r\), \(p_{r+1,c} = \mu_{r+1}\), \(p_{r+2,c} = \mu_{r+2}\), \(\ldots\), \(p_{k,c} = \mu_k\), and zero otherwise. Here we have assumed that \(a_{r,c+1}\) and \(a_{r+1,c}\) are between the \(b_i\) of \((4.33)\). For this law, knowledge of \(X\) implies knowledge of \(Y\) with certainty, therefore \(X.f[Y](P_\mu) = 0\); by equation \((4.35)\), \(f[XY](P_\mu) = f[X](P_\mu)\). Equation \((4.34)\) reads
\[
(1-\mu)^\alpha f[X] \left( \frac{x_{r+1}}{\mu_{r+1}/(1-\mu_r)} \ldots \frac{x_k}{\mu_k/(1-\mu_r)} \right) = f[X] \left( \frac{x_r}{\mu_r} \ldots \frac{x_k}{\mu_k} \right) \cdot f[Y] \left( \frac{y_c}{1-\mu_r} \frac{y_{c+1}}{\mu_r} \right).
\]
Moreover, if \(\mu_{r+1} = 1-\mu_r\) and \(\mu_{r+2} = \ldots = \mu_k = 0\) (here we use again \((4.33)\)),
\[
f[X] \left( \frac{x_r}{\mu_r} \frac{x_{r+1}}{1-\mu_r} \right) = f[Y] \left( \frac{y_c}{1-\mu_r} \frac{y_{c+1}}{\mu_r} \right).
\]
We obtain the recurrence formula:
\[(4.37)\]
f[X] \left( \frac{x_r}{\mu_r} \ldots \frac{x_k}{\mu_k} \right) = (1-\mu)^\alpha f[X] \left( \frac{x_{r+1}}{\mu_{r+1}/(1-\mu_r)} \ldots \frac{x_k}{\mu_k/(1-\mu_r)} \right) + f[X] \left( \frac{x_r}{\mu_r} \frac{x_{r+1}}{1-\mu_r} \right).

If the law \(P_\mu\) does not belong to \(Q_{XY}\), we could attain the same conclusion working with the family of laws \(P_{\mu'}\) given by \(p_{r,c} = \mu'_r\), \(p_{i,c+1} = \mu'_i\), for \(i \geq r + 1\) and zero otherwise, and such that \(\langle \mu'_r, \mu'_r+1 \rangle\) can take any value in \(\Delta^1\). Either \(P_\mu\) or \(P_{\mu'}\) are in \(Q_{XY}\) by the definition of non-degenerate product.

Analogously:
\[(4.38)\]
f[Y] \left( \frac{y_c}{\nu_c} \ldots \frac{y_l}{\nu_l} \right) = (1-\nu)^\alpha f[Y] \left( \frac{y_{c+1}}{\nu_{c+1}/(1-\nu_c)} \ldots \frac{y_l}{\nu_l/(1-\nu_c)} \right) + f[Y] \left( \frac{y_c}{1-\nu_c} \frac{y_{c+1}}{\nu_c} \right).

We proceed to the determination of
\[
\phi_r(z) := f[X] \left( \frac{x_r}{z} \frac{x_{r+1}}{1-z} \right) \quad \text{and} \quad \psi_c(z) := f[Y] \left( \frac{y_c}{z} \frac{y_{c+1}}{1-z} \right), \quad \text{for} \ z \in [0,1].
\]
Let \(b_1, b_2, b_3\) be the three components of \(B_i\) given by the hypothesis \((4.33)\). Take \(\langle \mu_0, \mu_X, \mu_Y \rangle \in \Delta^3\) arbitrary. Set \(P_{(b_j)} := \mu_X\), where \(b_j\) is the component that differ from the others on the column-coordinate. Similarly, set \(P_{(b_j)} := \mu_X\), where \(b_j\) is the component that differ from the others on the row-coordinate. With this assignment, the equation \((4.36)\) gives:
\[(1 - \mu_X)^\alpha f[Y] \left( \begin{array}{c}
\sigma(y_0/(1-\mu_X)) \\
\sigma(y_{0+1}/(1-\mu_X))
\end{array} \right) \cdot f[X] \left( \begin{array}{c}
y_0 \\
y_{0+1}
\end{array} \right) = (1 - \mu_Y)^\alpha f[X] \left( \begin{array}{c}
\tau(x_0/(1-\mu_Y)) \\
\tau(x_{0+1}/(1-\mu_Y))
\end{array} \right) \cdot f[Y] \left( \begin{array}{c}
x_0 \\
x_{0+1}
\end{array} \right)
\]
where \(\sigma, \tau\) are the identity or the permutation of both non-trivial arguments. In any case, this leads to the functional equation in Proposition \((4.10)\) which imply that \(\phi_r(z) = \psi_c(z) = \lambda \phi_{r+1} \psi_{c+1}\) for certain \(\lambda \in \mathbb{R}\).

In the next step, for \(B_{i+1}\), one finds the functions \(\phi_{r+1}\) and \(\psi_{c+1}\), or the functions \(\phi_{r+1}\) and \(\phi_{c+1}\), since two consecutive blocks \(B_i, B_{i+1}\) have exactly two elements in common. This ensures that the constant \(\lambda\) that appears in each step is the same.
As the number of blocks is finite, the process stops and we finally obtain

\[
(4.39) \quad f[X](\mu_1, \ldots, \mu_k) = \lambda \sum_{i=0}^{k-1} \left( 1 - \sum_{j=1}^{i} \mu_j \right)^{\alpha} s_{\alpha} \left( \frac{\mu_{i+1}}{1 - \sum_{j=1}^{i} \mu_j} \right).
\]

Set \( T_i := 1 - \sum_{j=1}^{i} \mu_j \). When \( \alpha = 1 \),

\[
(4.40) \quad \sum_{i=0}^{k-1} (1 - T_i) s_{\alpha} \left( \frac{\mu_{i+1}}{1 - T_i} \right) = \sum_{i=0}^{k-1} \left[ -\mu_{i+1} \log \mu_{i+1} + \mu_{i+1} \log(1 - T_i) \right] - (1 - T_{i+1}) \log(1 - T_i) + (1 - T_{i+1}) \log(1 - T_i)
\]

\[
(4.41) \quad = \sum_{i=1}^{k} \mu_i \log \mu_i + \sum_{i=0}^{k-1} \left[ (1 - T_i) \log(1 - T_i) - (1 - T_{i+1}) \log(1 - T_i) \right]
\]

\[
(4.42) \quad = \sum_{i=1}^{k} \mu_i \log \mu_i + (1 - T_0) \log(1 - T_0) - (1 - T_k) \log(1 - T_k)
\]

\[
(4.43) \quad = \sum_{i=1}^{k} \mu_i \log \mu_i.
\]

because \( 1 - T_k = 0 \) and \( 1 - T_0 = 1 \). When \( \alpha \neq 1 \),

\[
(4.45) \quad \sum_{i=0}^{k-1} (1 - T_i)^{\alpha} s_{\alpha} \left( \frac{\mu_{i+1}}{1 - T_i} \right) = \sum_{i=0}^{k-1} \left[ \mu_{i+1}^{\alpha} + (1 - T_{i+1})^{\alpha} - (1 - T_i)^{\alpha} \right]
\]

\[
(4.46) \quad = \sum_{i=1}^{k} \mu_i^{\alpha} + (1 - T_k)^{\alpha} - (1 - T_0)^{\alpha}
\]

\[
(4.47) \quad = \sum_{i=1}^{k} \mu_i^{\alpha} - 1.
\]

Therefore, for any \( \alpha > 0 \), we have \( f[X] = \lambda S_{\alpha}[X] \). Analogously, \( f[Y] = \lambda S_{\alpha}[Y] \). \( \square \)

4.6. **Determination of \( H^1 \).** In this section, we shall specify conditions on \( (\mathcal{S}, E, Q) \) that allows us to determine \( H^1(\mathcal{S}, F_{\alpha}(Q)) \).

We call a variable \( Z \) reducible if there exist \( X, Y \in \text{Ob}(\mathcal{S}) \setminus \{1, Z\} \) such that \( Z = XY \), and irreducible otherwise.

We denote by \( \text{min}(\mathcal{S}) \) the set of minimal objects in \( \mathcal{S} \); these are the \( Y \in \text{Ob}(\mathcal{S}) \) such that \( \nexists X \in \text{Ob}(\mathcal{S}) \) with \( X \to Y \).

Every information category \( \mathcal{S} \) can be seen as an abstract complex \( K(\mathcal{S}) \) (compare with Section 2.1, specially Figure 2.1), whose vertices are the irreducible variables (except 1), the 1-cells are products between two irreducible variables (when they exist), the 2-cells products between three irreducible variables (when they exist), etc. (caveat: the same variable could correspond to several faces, whose dimensions are not necessarily equal). The minimal objects \( \text{min}(\mathcal{S}) \) correspond to the maximal
faces of this simplicial complex. All minimal objects are reducible if and only if all the maximal faces of $K(S)$ have dimension $\geq 1$.

**Proposition 4.13.** Let $(S, E)$ be an information structure, and $Q$ an adapted probability functor. Denote by $S^*$ the full subcategory of $S$ generated by $\text{Ob}(S)\setminus \{1\}$. Suppose that every minimal object can be factored as a non-degenerate product. Then,

$$H^1(S, F_1(Q)) = \prod_{c \in \pi_0(S^*)} \mathbb{R} \cdot S^{(c)}_1$$

and, when $\alpha \neq 1$,

$$H^1(S, F_\alpha(Q)) = \left( \prod_{c \in \pi_0(S^*)} \mathbb{R} \cdot S^{(c)}_\alpha \right) / \mathbb{R} \cdot S_\alpha$$

In the formulae above, $c$ represents a connected component of $S^*$, and

$$S^{(c)}_\alpha[X] = \begin{cases} S_\alpha[X] & \text{if } X \in \text{Ob}(c) \\ 0 & \text{if } X \notin \text{Ob}(c) \end{cases}$$

**Proof.** Let $f$ be an element of $Z^1(S, F_\alpha(Q))$. If every $M \in \text{min}(S)$ can be factorized as a non-degenerate product, Proposition 4.12 implies that $f[M] = \lambda_M S_\alpha[M]$, where $\lambda_M$ is a constant that depends a priori on $M$. If $Z \in S_M$,

If $Z$ is refined by two variables $M, N \in \text{min}(S)$, we can apply the previous formula twice to conclude that $f[Z] = \lambda_M S_\alpha[Z] = \lambda_N S_\alpha[Z]$, and therefore $\lambda_M = \lambda_N$.

Let $M, N$ be two elements of $\text{min}(S)$. If they belong to the same connected component of $S^*$, there is a zig-zag diagram in $S^*$ of the form

$$M \to X_1 \leftarrow M_1 \to X_2 \leftarrow M_2 \to \cdots \leftarrow M_k \to X_{k+1} \leftarrow N$$

for certain $k \in \mathbb{N}$, where $M_i \in \text{min}(S)$ for all $i$. Geometrically, each minimal object represents a maximal face of $K(S)$, and each $X_i$ is a variable that lies in the intersection of two maximal faces. The repeated application of the argument in the previous paragraph implies that $\lambda_M = \lambda_{M_1} = \cdots = \lambda_N$.

On the other hand, if $c$ and $c'$ are different components of $S^*$, there is no cocycle equation that relates $f[X]$ and $f[Y]$, for any variables $X \in c$ and $Y \in c'$. In fact, such a cocycle equation only is possible if there is a third non-trivial variable $Z$ such that $X, Y \in S_Z$, and therefore $[X], [Y]$ appear as generators of $B_1(Z)$; but this would mean that $X \leftarrow Z \to Y$ in $S^*$.

The previous argument proves that $Z^1(S, F_\alpha(Q)) \cong \prod_{c \in \pi_0(S^*)} \mathbb{R} \cdot S^{(c)}_1$, and we saw in Section 4.5 that $\delta C^0(S, F_1(Q)) \cong \{0\}$ and $\delta C^0(S, F_\alpha(Q)) \cong \mathbb{R} \cdot S_\alpha$. \hfill \Box

The result accepts a geometrical interpretation: $\dim H^1(S, F_1(Q))$ equals the number of connected components of $K(S)$.

As a byproduct of the previous proof, we also obtain the following proposition.

**Proposition 4.14.** Let $\{(S_i, E_i, Q_i)\}_{i \in I}$ be a collection of triples that satisfy separately the hypotheses stated in Proposition 4.13. Then,

$$Z^1 \left( \prod_{i \in I} S_i, F(\prod_{i \in I} Q_i) \right) \cong \prod_{i \in I} Z^1(S_i, F(Q_i)).$$
Proof. The category \((\prod_{i=1}^{n} S_i)^*\) is the disjoint union of the categories \(S_i^*\), for \(i \in I\).

The cases uncovered by Proposition 4.13 can be classified in two families:

1. There is an irreducible minimal object;
2. All minimal objects are reducible, but some of them cannot be written as non-degenerate products.

In the latter case, all kinds of behaviours are possible, as the examples at the end this section show.

In the Example 4.8, we proved that \(H^1(S, F_\alpha(Q))\) has infinite dimension when \(S \cong \emptyset(\{0, 1\})\); in this case, there is only one non-trivial variable and it is obviously irreducible. Now we proceed to the generalization of this result.

**Proposition 4.15.** Let \((S, E)\) be an information structure and \(Q\) an adapted probability functor. Let \(M \in \min(S)\) be an irreducible minimal object, \(X_1, \ldots, X_n\) all the variables coarser than \(M\) and suppose that

\[ M \to X_1 \to \ldots \to X_n \to 1, \]

in \(S\). Moreover, suppose that there exists \(k \in \{1, \ldots, n\}\) such that, for some \(x \in E(X_k)\), the set \(Q^*_M := \{P_{X_i=x} \mid P \in Q_M\}\) contains at least one non-atomic law. \(^{14}\)

Then, \(\dim H^1(S, F_\alpha(Q)) = \infty\).

Proof. Let \(\tilde{k}\) be the smallest \(k\) that satisfies the stated hypothesis. Set \(f[X_i] = 0\) for \(i = \tilde{k}, \ldots, n\). We shall show that \(f[M]\) can be chosen arbitrarily.

The cocycle equations are

\[ 0 = X_i.f[M] - f[X_iM] + f[X_i], \quad i = 1, \ldots, n. \]

For \(i < \tilde{k}\), the term \(X_i.f[M] = 0\) since all conditioned laws \(P|_{X_i=x}\) give \(\delta\)-laws. This implies that \(f[X_i] = f[M]\). For \(i = \tilde{k}\), we obtain \(f[M] = X_{\tilde{k}}.f[M]\). Given this one, the others equations become redundant since

\[ X_j.f[M] = X_j.(X_{\tilde{k}}.f[M]) = (X_j.X_{\tilde{k}}).f[M] = X_{\tilde{k}}.f[M], \quad \text{for} \ j > \tilde{k}. \]

Let \(P \in Q_M\) and \(\tilde{P} = (X_{\tilde{k}})_*P \in Q_{E_{\tilde{k}}}\). The equation \(f[M] = X_{\tilde{k}}.f[M]\) reads

\[ f[M](P) = \sum_{x \in X_{\tilde{k}}} \tilde{P}(x) f[M](P|_{X_{\tilde{k}}=x}). \]

If \(P|_{X_{\tilde{k}}=x} = \delta_m\) for some \(m \in M\) (atomic law), then \(f[M](P|_{X_{\tilde{k}}=x}) = 0\); otherwise, no condition determines \(f[M](P|_{X_{\tilde{k}}=x})\). This means that, for each set \(Q^*_M\) that contains non-atomic laws, we can introduce an arbitrary function. \(\square\)

We illustrate the proof with an example. Consider \(\Omega = \{0, 1, 2\}\) and the concrete structure \(S\) given by

\[ M = \{\{0\}, \{1\}, \{2\}\} \to X_1 = \{\{0, 1\}, \{2\}\} \to 1_\Omega \]

In this case, there is an infinite family of cocycles given by \(f[X_1] \equiv 0\), \(f[1] \equiv 0\) and

\[ f[M](p_0, p_1, p_2) = (p_0 + p_1)f[M]\left(\frac{p_0}{p_0 + p_1}, \frac{p_1}{p_0 + p_1}, 0\right) = (p_0 + p_1)g\left(\frac{p_0}{p_0 + p_1}, \frac{p_1}{p_0 + p_1}\right), \]

where \(g\) is an arbitrary function of two variables satisfying \(g(1, 0) = g(0, 1) = 0\).

\(^{14}\)The law \(P \in Q_M\) is atomic if \(P = \delta_m\) for some \(m \in M\).
To close this section, we make some remarks about the case of reducible minimal objects that cannot be written as non-degenerate products. If the product is degenerate, multiple constants can appear or the dimension of \( H^1(S, F_\alpha(Q)) \) can explode to infinity, as the following examples show.

**Example 4.16.** Consider the information structure \((S, E)\) given by the poset \(S\) represented by

```
   1
  / \
X   Y
  \
   XY
```

and the assignment \(E(X) = \{x_1, x_2, x_3, x_4\}, \ E(Y) = \{y_1, y_2, y_3, y_4\}\), and \(E(XY) = E(X) \times E(Y)\); the surjections are the terminal maps and the canonical projectors.

Let

\[
Q_{XY} = \{ P \in \Delta(XY) \mid P(x_i, y_j) = 0 \text{ if } (i, j) \in (\{x_1, x_2\} \times \{y_1, y_2\})^c \} \\
\cup \{ P \in \Delta(XY) \mid P(x_i, y_j) = 0 \text{ if } (i, j) \in (\{x_3, x_4\} \times \{y_3, y_4\})^c \}.
\]

(4.51)

Therefore, we just need to determine

\[
\begin{align*}
f[X] \left( \begin{array}{cc}
x_1 & x_2 \\
p & 1-p
\end{array} \right), & \quad f[X] \left( \begin{array}{cc}
x_3 & x_4 \\
p & 1-p
\end{array} \right), \\
f[Y] \left( \begin{array}{cc}
y_1 & y_2 \\
p & 1-p
\end{array} \right), & \quad f[Y] \left( \begin{array}{cc}
y_3 & y_4 \\
p & 1-p
\end{array} \right),
\end{align*}
\]

for arbitrary \(p \in [0, 1]\). Proposition 4.10 allows us to conclude that

\[
(4.52)
\]

\[
f[X] \left( \begin{array}{cc}
x_1 & x_2 \\
p & 1-p
\end{array} \right) = \lambda_1s_\alpha(p), \quad f[Y] \left( \begin{array}{cc}
y_1 & y_2 \\
p & 1-p
\end{array} \right) = \lambda_1s_\alpha(p).
\]

We use this proposition a second time to show that

\[
(4.53)
\]

\[
f[X] \left( \begin{array}{cc}
x_3 & x_4 \\
p & 1-p
\end{array} \right) = \lambda_2s_\alpha(p), \quad f[Y] \left( \begin{array}{cc}
y_3 & y_4 \\
p & 1-p
\end{array} \right) = \lambda_2s_\alpha(p).
\]

(4.54)

However, from Equations (4.34) and (4.35) it is impossible to find a relation between \(\lambda_1\) and \(\lambda_2\) when \(P \in Q_{XY}\). We conclude that \(Z^1(F_\alpha(Q)) \cong \mathbb{R}^2\).

**Example 4.17.** Let \((S, E)\) be the information structure defined in the previous example and

\[
Q_{XY} = \{ P \in \Delta(XY) \mid P(x_i, y_j) = 0 \text{ if } (i, j) \in (\{x_1, x_2\} \times \{y_1, y_2\})^c \} \\
\cup \{ P \in \Delta(XY) \mid P(x_3, y_3) + P(x_4, y_4) = 1 \}.
\]

(4.55)

As before, we can conclude that

\[
(4.56)
\]

\[
f[X] \left( \begin{array}{cc}
x_1 & x_2 \\
p & 1-p
\end{array} \right) = \lambda_1s_\alpha(p), \quad f[Y] \left( \begin{array}{cc}
y_1 & y_2 \\
p & 1-p
\end{array} \right) = \lambda_1s_\alpha(p).
\]

Equations (4.34) and (4.35) imply that

\[
(4.57)
\]

\[
f[XY] \left( \begin{array}{cc}
(x_3, y_3) & (x_4, y_4) \\
p & 1-p
\end{array} \right) = f[X] \left( \begin{array}{cc}
x_3 & y_3 \\
p & 1-p
\end{array} \right) = f[Y] \left( \begin{array}{cc}
y_3 & y_4 \\
p & 1-p
\end{array} \right).
\]
and these are the only relations between these functions. Therefore, we can introduce an arbitrary function \( g(p, 1-p) \) that satisfy \( g(0, 1) = g(1, 0) = 0 \). This means that \( \dim Z^1(F_\alpha(Q)) = \infty \).

5. Remarks on the notion of entropy

5.1. Shannon’s axiomatization. In his seminal paper \[18\], Shannon proposed an axiomatic characterization for a ‘measure of choice’.

Suppose we have a set of possible events whose probabilities of occurrence are \( p_1, p_2, \cdots, p_n \). These probabilities are known but that is all we know concerning which event will occur. Can we find a measure of how much “choice” is involved in the selection of the event or of how uncertain we are of the outcome?

If there is such measure, say \( H(p_1, p_2, \cdots, p_n) \), it is reasonable to require of it the following properties: [...]

3. If a choice be broken down into two successive choices, the original \( H \) should be the weighted sum of the individual values of \( H \). The meaning of this is illustrated in Fig. 6 [see Figure 2].

At the left we have three possibilities each with probabilities \( \frac{2}{3}, \frac{1}{3}, \frac{1}{6} \). The final results have the same probabilities as before. We require, in this special case, that

\[
H(\frac{1}{2}, \frac{1}{3}, \frac{1}{6}) = H(\frac{1}{2}, \frac{1}{2}) + \frac{1}{2} H(\frac{2}{3}, \frac{1}{3})
\]

The coefficient \( \frac{1}{2} \) is because this second choice only occurs half the time.

In the general case, we interpret the third axiom of Shannon as follows: given a partition of the space by a finite variable \( XY \) (‘a set of possible events’, ‘a choice be broken down into two successive choices’) and a probability \( P \) in \( \Delta(XY) \), the identity

\[
(5.1) \quad H[XY](P) = H[Y](Y, P) + \sum_{y_i} P(Y = y_i)H[X](X, (P|Y = y_i))
\]

\[15\] Shannon included two other axioms: the continuity of \( H \) and a monotonicity property. Since then, these axioms have been weakened several times; in this text, they are implied by his axiom 3.
is satisfied. For example, if \( \Omega = [0,1] \), \( Y = \chi_{[0,1/2]} \), and \( X = \chi_{[0,1/6]} \), we can read the left tree in Figure 2 as the three possible results of a variable \( XY \), and the right tree as the iterated choices given by \( Y \) and \( X \). The variable \( Y \) is interpreted as a particular ‘grouping’ of the possible results of \( XY \), as usually said in the literature.

5.2. Functorial extensions of algebras. The cocycle equation (5.1) has a meaning in the context of extensions of algebras. We introduce first some general definitions and results from [24]; what is said there for algebras remains valid with pre sheaves of algebras.

Let \( \Lambda \) be a presheaf of \( \mathbb{R} \)-algebras on \( S \). An extension of \( \Lambda \) is an epimorphism \( \sigma : \Gamma \rightarrow \Lambda \). The extension is called singular (or square zero) if \( \ker(\sigma_X)^2 = 0 \) for all \( X \in \text{Ob}(S) \) (in this case, \( \ker(\sigma_X) \) can be regarded as a \( \Lambda_X \)-bimodule). It is called cleft if there exists a morphism \( \phi : \Lambda \rightarrow \Gamma \), morphism of algebras, such that \( \sigma \circ \phi = 1_{\Lambda} \). Given a \( \Lambda \)-bimodule \( M \), a singular extension of \( \Lambda \) by \( M \) is a short exact sequence

\[
0 \rightarrow M \xrightarrow{\xi} \Gamma \xrightarrow{\sigma} \Lambda \rightarrow 0
\]

where \( \xi \) is a morphism of \( \Gamma \)-bimodules (\( M \) is \( \Gamma \)-bimodule by \( \gamma.m = \sigma(\gamma).m \), etc.). Two extensions are called congruent if there is an algebra morphism \( \gamma : \Gamma \rightarrow \Gamma' \) making

\[
0 \rightarrow M \xrightarrow{\xi} \Gamma \xrightarrow{\sigma} \Lambda \rightarrow 0 \quad \xrightarrow{\gamma} \quad 0 \rightarrow M' \xrightarrow{\xi'} \Gamma' \xrightarrow{\sigma'} \Lambda' \rightarrow 0
\]

commute.

A particular singular cleft extension of \( \Lambda \) by \( M \) is given by the semidirect sum, defined to be the presheaf of vector spaces \( M \oplus \Lambda \) with product defined by \( (m_1, \lambda_1) \cdot (m_2, \lambda_2) = (m_1 m_2 + \lambda_1 m_2, \lambda_1 \lambda_2) \); with \( \xi(m) = (m,0) \) and \( \sigma(m,\lambda) = \lambda \). The following Proposition is a well known result.

**Proposition 5.1.** Any singular cleft extension is congruent to \( M \rtimes \Lambda \).

In our case, \( \Lambda = \mathcal{A} \) and \( M = F_\alpha(Q) \), turned into a presheaf of \( \mathcal{A} - \mathcal{A} \)-bimodules with trivial right action: this means that each variable acts as the identity endomorphism. If \( \Gamma \) is a singular cleft extension of \( \mathcal{A} \) by \( F_\alpha(Q) \), it is isomorphic to \( F_\alpha \rtimes \mathcal{A} \). What are the possible morphisms \( \phi : \mathcal{A} \rightarrow F_\alpha \rtimes \mathcal{A} \) that implement this splitting? Set \( \phi(X) = (d[X],X) \); since \( \phi_X \) is a morphism of algebras,

\[
(d[Y],Y) \cdot (d[X],X) = (d[YX],YX) = (d[Y] + Y.d[X],YX) = (d[YX],YX).
\]

Thus \( d \) must be a 1-cocycle (also called derivation in this context). In this chapter, we have proved that in general there is no choice, one must take the entropy. Therefore, we can say that the entropy is the unique derivation that transforms a multiplicative operation on partitions into an additive operation on functions, introducing an appropriate ‘twist’.

Note that the definition of \( F_\alpha(Q) \) guarantees that \( d[X](P) \) depends only on \( X_*P \). This turns out to be the appropriate notion of locality and justifies the introduction of presheaves.
The extensions that are singular and \(\mathbb{R}\)-split (instead of cleft) are classified by \(H^2(\mathcal{S}, F_R(Q))\): the morphism \(\phi_X : \mathcal{A}_X \rightarrow \Gamma_X\) gives a natural vector space decomposition \(\Gamma_X \simeq \mathcal{A}_X \oplus F_X\), with product given by \((X, f) \cdot (Y, g) = (XY, f + X.g + a(X, Y))\). The function \(a : \mathcal{A} \otimes_\mathbb{R} \mathcal{A} \rightarrow \mathbb{R}\) is called the factor set of the extension and the associativity of the product in \(\Gamma\) entails that \(a\) is a 2-cocycle.

6. QUANTUM PROBABILITY AND QUANTUM MODELS

Let \(E\) be a finite dimensional Hilbert space: a complex vector space with a positive definite hermitian form \(\langle \cdot, \cdot \rangle\). In the quantum setting, random variables are generalized by endomorphisms of \(E\) (operators). An operator \(H\) is called hermitian if for all \(u, v \in E\), one has \(\langle u, Hv \rangle = \langle H u, v \rangle\); if \(H\) is represented as a matrix \(M_H\), this means \(M_H^* = M_H\). Real valued observables correspond to hermitian operators, for the following reason: in quantum mechanics, the measurable quantities are assumed to be the eigenvalues of the operators, and every hermitian operator has real eigenvalues. Generally, in physics the term observable means hermitian operator, and we follow in this work the same convention.

A fundamental result of linear algebra, the Spectral Theorem [10, Sec. 79], says that each hermitian operator \(Z\) can be decomposed as weighted sum of positive hermitian projectors

\[
Z = \sum_{j=1}^{K} z_j E_j
\]

where \(z_1, \ldots, z_K\) are the (pairwise distinct) real eigenvalues of \(Z\). Each \(E_j\) is the projector on the eigenspace spanned by the eigenvectors of \(z_j\); the dimension of this subspace equals the multiplicity of \(z_j\) as eigenvalue. As hermitian projectors, they satisfy the equation \(E_j^2 = E_j\) and \(E_j^* = E_j\). They are also mutually orthogonal \((E_j E_k = 0\) for integers \(j, k\)) and their sum equals the identity \(\sum_{1 \leq j \leq K} E_j = I_d_E\). This decomposition of \(Z\) is not necessarily compatible with the preferred basis of \(E\) (that diagonalizes the hermitian product).

In analogy to the classical case, we consider as equivalent two hermitian operators that define the same direct sum decomposition \(\{E_j\}_j\) of \(E\) by means of the Spectral Theorem, ignoring the particular eigenvalues. For us, observable and direct sum decomposition (sometimes just ‘decomposition’, for brevity) are then interchangeable terms. In what follows, we denote by \(E_A\) both the subspace of \(E\) and the orthogonal projector on it. A decomposition \(\{E_{\alpha}\}_{\alpha \in A}\) is said to refine \(\{E'_\beta\}_{\beta \in B}\) if each \(E'_\beta\) can be expressed as sum of subspaces \(\{E_{\alpha}\}_{\alpha \in A_\beta}\), for certain \(A_\beta \subseteq A\). In that case we say also that \(\{E_\alpha\}_{\alpha \in A}\) divides \(\{E'_\beta\}_{\beta \in B}\), and we write \(\{E_\alpha\}_{\alpha \in A} \rightarrow \{E'_\beta\}_{\beta \in B}\). With this arrows, direct sums decompositions form a category called \(\mathcal{DS}D(E)\).

Definition 6.1. A quantum model of an information structure \(S\) is a couple \((E, \rho)\), where \(E\) is a finite dimensional Hilbert space and \(\rho : S \rightarrow \mathcal{DS}D(E)\) is a functor, such that:

1. \(\rho\) is injective on objects;
2. For each \(X \in \text{Ob}(S)\), there is a bijection of sets \(X \simeq \rho(X)\);
3. If \(X \land Y\) exists, \(\rho(X \land Y) = \rho(X) \times \rho(Y)\).

A quantum model gives rise to a quantum information structure as defined in [1]. As the projective resolution found in [3.3] just depends on the underlying abstract structure, it can also be used to compute quantum information cohomology. The
quantum part comes from the coefficients: the model is used to define a sheaf of
density matrices and then the corresponding functional module.

**APPENDIX A. ABSTRACT SIMPLICIAL COMPLEXES**

In this section, we recall the main definitions concerning abstract (or combinatorial) simplicial complexes, for the convenience of the reader. Most of them are taken verbatim from [14].

We define an (abstract) simplicial complex as a collection 
\[ K \] of non-empty finite subsets of a finite set \( S \), subject to the condition: if \( s \in K \), then every non-empty subset of \( s \) is in \( K \). A subcomplex \( K' \) of \( K \) is collection of subsets of \( S \) contained in \( K \) that also satisfies the condition above.

The finite sets that make up \( K \) are called abstract simplices. Given an abstract simplex \( s \in K \), its elements are called vertexes and its non-empty subsets are called faces. We say that \( K \) is a finite complex when \( K \) is a finite set, and locally finite if every vertex belong to a finite number of simplices. The dimension of an abstract simplex \( s \in K \) is \( |s| - 1 \). When the dimensions of the simplices of \( K \) are bounded above, the complex is finite dimensional and its dimension is the smallest upper bound.

The \( d \)-skeleton of \( K \) is the subcomplex of \( K \) consisting of all the simplices that have dimension at most \( d \).

The vertex set of a complex \( K \) is
\[
K_0 = \bigcup_{s \in K} s.
\]

A simplicial map \( f : K \to \mathcal{L} \) is given by a vertex map \( f_0 : K_0 \to \mathcal{L}_0 \) which must satisfy the property that \( f(s) := \{f_0(v_1), \ldots, f_0(v_k)\} \in \mathcal{L} \) whenever \( s = \{v_1, \ldots, v_k\} \in K \).

**Example A.1.** The abstract simplex \( \Delta([n]) \) is the simplicial complex \( \mathcal{P}([n]) \): its 0-dimensional simplices are the singletons, the 1-dimensional simplices are the sets of cardinality two, etc.

**APPENDIX B. RELATIVE HOMOLOGICAL ALGEBRA**

**B.1. General results.** In this section, we summarize some results from [15, Ch. IX]. The purpose is to find the analogous of a free resolution of modules, but in the general context of abelian categories. Capital Latin letters \( A, B, C \ldots \) denote objects and Greek letters \( \alpha, \beta \ldots \) morphisms.

A **relative abelian category** is a pair of abelian categories \( \mathcal{A} \) and \( \mathcal{M} \) and a covariant functor \( \Box : \mathcal{A} \to \mathcal{M} \) which is additive, exact and faithful (we write \( \Box(X) = X_\Box \), for objects and morphisms). Additivity implies that \( (A \oplus B)_\Box = A_\Box \oplus B_\Box \); by exactness, \( \Box \) carries exact sequences into exact sequences; as \( \Box \) is faithful, \( \alpha_\Box = 0 \) implies \( \alpha = 0 \), therefore \( A_\Box = 0 \) entail \( A = 0 \).

**Example B.1.** The simple example to have in mind are \( R \)-modules and \( S \)-modules, when \( S \) is a subring of \( R \) with the same unity (write \( \iota : S \to R \) for the injection). In this case, every \( R \)-module \( A \) can be seen as an \( S \)-module \( \tilde{A} \) by restriction of scalars: denote by \( \tilde{\mathcal{A}} \) the underlying abelian group and by \( \Lambda : R \to \text{End}(\tilde{\mathcal{A}}) \) the action of \( R \) over \( \tilde{\mathcal{A}} \), then define the action \( \Lambda' : S \to \text{End}(\tilde{\mathcal{A}}) \) as the ring morphism
that makes the following diagram commute:

\[
\begin{array}{c}
S \\
\downarrow \\
\text{End}(\bar{A})
\end{array}
\quad \xrightarrow{\iota} \quad
\begin{array}{c}
R \\
\downarrow \\
\text{End}(\bar{A})
\end{array}
\]

Every $R$-module morphism $\alpha : A \to B$ is also a $S$-module morphism $\iota \cdot A \to \iota \cdot B$. Therefore, $\square A := \iota \cdot A$ and $\square \alpha := \iota \cdot \alpha$ is a functor from the category $\mathcal{A}$ of left $R$-modules to the category $\mathcal{M}$ of left $S$-modules; it “forgets” or “neglects” part of the structure. This functor is exact, additive and faithful.

A short exact sequence $\chi \parallel \sigma$ in $\mathcal{A}$ is relatively split ($\square$-split) if $\chi \square \parallel \sigma \square$ splits in $\mathcal{M}$, this means that $\sigma \square$ has a right inverse $k$ or, equivalently, $\chi \square$ has a left inverse $t$. We obtain a direct sum diagram in $\mathcal{M}$,

\[
\begin{array}{c}
A \\
\xrightarrow{t} \\
\chi \square
\end{array}
\quad \xrightarrow{\sigma \square} \quad
\begin{array}{c}
B \\
\xleftarrow{k} \\
C
\end{array}
\]

This class of short exact sequences is also called $\square$-allowable, or simply allowable (see [15, Ch. IX, Sec. 4]). A monomorphism $\chi$ is called allowable if $\chi \parallel \sigma$ is $\square$-split for some $\sigma$; this is the case if and only if $\chi \parallel \text{coker} \chi$ is $\square$-split. Dually, an epimorphism is called allowable if $(\ker \sigma) \parallel \sigma$ is $\square$-split. Therefore, the class of allowable short exact sequences is determined by the allowable monomorphisms or the allowable epimorphisms.

The following conditions on a morphism $\alpha$ are equivalent:

1. $\text{im} \alpha$ is an allowable monomorphism and $\text{coim} \alpha$ is an allowable epimorphism;
2. $\ker \alpha$ is an allowable monomorphism and $\text{coker} \alpha$ is an allowable epimorphism;

A morphism is called allowable when it satisfies any of these conditions (see [15, p. 264]).

An relative projective object $P$ is any object of $\mathcal{A}$ such that, for every allowable epimorphism $\sigma : B \to C$, each morphism $\epsilon : P \to C$ of $\mathcal{A}$ can be factored through $\sigma$ as $\epsilon = \sigma \epsilon'$ for some $\epsilon' : P \to A$.

In order to construct enough relative projectives, we consider the following definition. A resolvent pair is a relative abelian category $\square : \mathcal{A} \to \mathcal{M}$ together with a covariant functor $F : \mathcal{M} \to \mathcal{A}$ left adjoint to $\square$. This means that there exist a isomorphism $\varphi$,

\[
\varphi : \text{Hom}_{\mathcal{A}}(FM, A) \xrightarrow{\sim} \text{Hom}_{\mathcal{M}}(M, \square A),
\]

natural in both arguments. We can think of $\square$ as a forgetful functor, and $F$ as the corresponding “free” functor.

**Proposition B.2.** Let $\square : \mathcal{A} \to \mathcal{M}$ be a relative abelian category. The following conditions are equivalent:

1. there exists a covariant functor $F : \mathcal{M} \to \mathcal{A}$ left adjoint to $\square$;
2. there exist a covariant functor $F : \mathcal{M} \to \mathcal{A}$, and a natural transformation $\epsilon : 1_{\mathcal{M}} \to \square F$ (where $1_{\mathcal{M}}$ is the identity functor), such that every $u : M \to A_{\square}$ in $\mathcal{M}$ has a factorization $u = \alpha \square e_M$, with $\alpha : F(M) \to A$ unique.

**Proof.** Suppose (1); taking $A = FM$ in (B.2), define $e_M$ as $\varphi(1_{FM})$. Now, for arbitrary $A \in \text{Ob}(\mathcal{A})$, take $\alpha := \varphi^{-1}(u)$; the naturality of $\varphi$ implies $u = \alpha \square e_M$. 

The implication $[2] \Rightarrow [1]$ follows immediately taking $\varphi^{-1}(u) := \alpha$. More details can be found in [10, p. 266].

Example B.3 (continuation of B.1). Take $F(M) = R \otimes_S M$ and $e_M = 1 \otimes m \in F(M)$. Given a map of $S$-modules $u : M \to A$, define $\alpha : FM \to A$ by $\alpha(1 \otimes m) = u(m)$.

The following proposition exploits the properties of the allowable morphisms that we are studying (\(\square\)-split), and give us “free” objects, as suggested by the notation above.

A complex $\epsilon : X \to A$ over $A$ (in $\mathcal{A}$) is a sequence of $\mathcal{A}$-objects and $\mathcal{A}$-morphisms $\ldots X_n \to X_{n-1} \to \ldots \to X_1 \to X_0 \xrightarrow{\epsilon} A \to 0$, such that the composite of any two successive morphisms is zero. This complex is called:

1. a \textbf{resolution} of $C$, if the sequence is exact;
2. relatively \textbf{free} if each $X_n$ has the form $F(M_n)$ for certain $M_n$ in $\mathcal{M}$ (we write $e_n$ for $e_{M_n} : M_n \to X_n$);
3. \textbf{allowable} if all its morphisms are allowable.

Each object $C$ of $\mathcal{A}$ has a canonical relatively free resolution. Writing $F^C$ for $F \square C$, and $F^n$ for its $n$-fold iteration, construct the objects

\begin{equation}
B_n(C) = F^{n+1}C, \quad n \in \mathbb{N}.
\end{equation}

Define $\mathcal{M}$-morphisms $s_\bullet$ between the corresponding objects

\begin{equation}
\begin{array}{cccc}
\square C & s_{-1} & \square B_0(C) & s_0 \\
\downarrow & & \downarrow & \downarrow \\
\square B_1(C) & s_1 & \square B_2(C) & s_2
\end{array}
\end{equation}

as $s_{-1} := \epsilon(\square C)$ and $s_n := \epsilon(\square B_n(C))$ (here $\epsilon$ is the natural transformation in Proposition B.2).

\textbf{Proposition B.4. [15] p. 268} There are unique $\mathcal{A}$-morphisms

\begin{equation}
\epsilon : B_0(C) \to C, \quad \partial_{n+1} : B_{n+1}(C) \to B_n(C) \quad \text{for } n \in \mathbb{N},
\end{equation}

which make $B(C) := \{B_n(C)\}_{n}$ a relatively free allowable resolution of $C$ with $s$ as contracting homotopy in $\mathcal{M}$. This resolution, with its contracting homotopy, is a covariant functor of $C$.

\textbf{Proof.} We simply quote here the construction of $\epsilon$ and $\partial_n$. They form the following schematic diagram (solid arrows belong to $\mathcal{A}$, and dashed arrows belong to $\mathcal{M}$):

\begin{equation}
0 \leftarrow C \xleftarrow{\epsilon} B_0(C) \xleftarrow{\partial_1} B_1(C) \xleftarrow{\partial_2} B_2(C) \xleftarrow{\partial_3} \ldots
\end{equation}

By Proposition B.2 $1_{\square C}$ factors through a unique $\epsilon : B_0 \to C$; the formula $1_{\square C} = \epsilon \circ \epsilon_C$ shows that $\epsilon$ is allowable (note that $\epsilon$ is an epimorphism). Boundary operators are defined by recursion so that $s$ will be a contracting homotopy. Given $\epsilon$, the morphism $1_{\square B_0} - s_{-1} \epsilon_{\square C}$ factors uniquely as $\partial_1 \square s_0$, for some $\partial_1 : B_1 \to B_0$.

Similarly, $1_{\square B_n} - s_{n-1} \partial_{n-1} \square C$ determines $\partial_{n+1}$ given $\partial_n$, as the unique $\mathcal{A}$-morphism such that $\partial_{n+1} \square s_n = 1_{\square B_n} - s_{n-1} \partial_n \square$.

\begin{equation}
\begin{array}{cccc}
\square B_{n+1} & \partial_1 \square & \square B_n \\
\downarrow & & \downarrow \\
\square B_n & & \square B_n
\end{array}
\end{equation}

\end{proof}
The resolution $B(C)$ is called the (unnormalized) bar resolution. A **relative Ext bifunctor** may be defined by

\[(B.7) \quad \text{Ext}^n_{\square}(C, A) := H^n(\text{Hom}_\mathcal{A}(B(C), A)).\]

A “relative” version of the comparison theorem (see [15, Ch. IX, Th. 6.2]) shows that one can use any other allowable and relatively projective resolution $\epsilon : X \to C$ to compute $\text{Ext}^n_{\square}$ as

\[(B.8) \quad \text{Ext}^n_{\square}(C, A) \cong H^n(\text{Hom}_\mathcal{A}(X, A)).\]

Note that $\text{Hom}_\mathcal{A}(X, A)$ stands for *all* the $\mathcal{A}$-morphisms, not just the allowable ones. It is clear that $\text{Ext}^0_{\square}(C, A) \cong \text{Ext}^0(C, A)$, but in general the groups $\text{Ext}^n_{\square}(C, A)$ depend on $\square$.

### B.2. Example: Presheaves of modules

We develop now the particular case relevant to our theory. Let $\mathcal{S}$ be a category equipped with the trivial topology, such that every presheaf is a sheaf. Consider two sheaves of rings $R, S : \mathcal{S}^{op} \to \text{Rings}$, such that $S_X$ is a subring of $R_X$ with the same unity, for every $X \in \text{Ob}(\mathcal{S})$. Take $\mathcal{A} = \text{Mod}(R)$, the category of (pre)sheaves of $R$-modules, and $\mathcal{M} = \text{Mod}(S)$, the category of (pre)sheaves of $S$-modules. A relative abelian category is obtained when $\square : \mathcal{A} \to \mathcal{M}$ is the forgetful functor over each $X$, as defined in Example [B.1]. The functor $F : \mathcal{M} \to \mathcal{A}$ sends a sheaf $P$ to the new sheaf $X \mapsto R_X \otimes_{S_X} P_X$ [16] and each morphism of $S$-sheaves (in short, $S$-morphism) $f : M \to N$ to the $R$-morphism defined by

\[F f(X)(1 \otimes m) = 1 \otimes f(m), \quad \text{for } X \in \mathcal{S}.\]

The natural transformation $\epsilon$ mentioned in Proposition [B.2] corresponds to a collection of $S$-morphisms $\epsilon_P : P \to \square F(P)$, one for each presheaf $P$ of $S$-modules; given $X$ in $\mathcal{S}$, we define $\epsilon_P(X)(m) = 1 \otimes m$. [7]

Fix now a sheaf $C$ in $\text{Mod}(R)$. We denote by $X$ a generic element in $\text{Ob}(\mathcal{S})$. Then, $B_0 C(X) := F \square C(X) = R_X \otimes_{S_X} (\square C(X))$; this $R_X$-module is formed by finite $R_X$-linear combinations of tensors $1 \otimes c$, with $c \in C$. Generally, an element of $B_n C(X) = R_X \otimes \square B_{n-1} C(X)$, for $n \geq 1$, is a finite $R_X$-linear combination of tensors $1 \otimes r_1 \otimes r_2 \ldots \otimes r_n \otimes c$. The ring $R_X$ acts on $B_n C(X)$ by multiplication on the first factor of the tensor product; to highlight this fact, people usually write $r[r_1r_2\ldots r_n]c$ instead of $r \otimes r_1 \otimes r_2 \ldots \otimes r_n \otimes c$. This notation explains the name “bar resolution” adopted above. The definition of $\epsilon$ implies that

\[(B.9) \quad s^X_1 : \square C(X) \to \square B_0 C(X), \quad c \mapsto 1 \otimes c = [c],\]

and

\[(B.10) \quad s^X_n : \square B_n C(X) \to \square B_{n+1} C(X), \quad r[r_1r_2\ldots r_n]c \mapsto [r|r_1r_2\ldots r_n]c \quad \text{for } n \in \mathbb{N}.\]

These equalities determine $s_*$, since these functions are $S_X$-linear.

---

16. This is a left $R$-module with action defined by $r(r' \otimes p) = (rr') \otimes g$. For iterated tensor products, this definition is not canonical; for example, when considering $R_X \otimes R_X \otimes X$, the element $(sr) \otimes r' \otimes g$ does not equal $r \otimes (sr') \otimes g$ (for $s \in S$), unless $S$ is in the center of $R$. As in this work we only use commutative rings and algebras, these differences do not pose any problem.

17. Of course, one has to prove that $\epsilon$ is in fact a natural transformation and satisfies the properties required by Proposition [B.2]. This proof is rather trivial but complicated to write, and we omit it.
Now \( \epsilon \) is the unique \( R \)-morphism such that \( 1 \circ \epsilon = \epsilon \circ e \); this is clearly the case if \( \epsilon^X([c]) = c \). Similarly, \( \partial_1 \) is the unique \( R \)-morphism from \( B_1 C \) to \( B_0 C \) that satisfies
\[
\partial_1 \square \epsilon_0 \equiv \partial_1 \square s_0 = 1 - s_1^X \epsilon_1 \square
\]
Since \( B_1 C(X) \) is generated as a \( R_X \)-module by the elements \([r|c]\), and \( s_0^X(r|c) = [r|c] \), the equation (B.11) defines \( \partial_1 \) completely. Just remark that \( \epsilon([r|c]) = r \epsilon([c]) = r c(1 \otimes c) = r c \) and \( s_1(r c) = [r c] \). We conclude that
\[
\partial_1([r|c]) = r|c| - [r|c] .
\]

It can be proved by recursion that (cf. [15, p. 281])
\[
\partial[r_1 | ... | r_n|c] = r_1[r_2 | ... | r_n|c] + \sum_{k=1}^{n-1} (-1)^k [r_1 | ... | r_k r_{k+1} | ... | r_n|c] + (-1)^n[r_1 | ... | r_{n-1} | r_n|c] .
\]

In virtue of Proposition B.4 we obtain in this way a free allowable resolution of \( C \).

**Appendix C. Modular Group and Generalized Information Functions**

Fix \( \alpha > 0 \). We are interested in the measurable solutions of
\[
(C.1) \quad u(1 - x) + (1 - x)^\alpha u \left( \frac{y}{1 - x} \right) = u(y) + (1 - y)^\alpha u \left( \frac{1 - x - y}{1 - y} \right) .
\]
for all \( x, y \in [0, 1] \) such that \( x + y \in [0, 1] \), subject to the boundary condition \( u(0) = u(1) = 0 \).

In this section, we show that the only measurable solutions to (C.1) are multiples of the corresponding entropy \( s_\alpha \). This rests on two preliminary results.

**Proposition C.1** (Regularity). Any measurable solution of (C.1) is infinitely differentiable on \( (0, 1) \).

**Proposition C.2** (Symmetry). Any solution of (C.1) satisfies \( u(x) = u(1 - x) \) for all \( x \in \mathbb{Q} \cap [0, 1] \).

The first is proved analytically, by means of standard techniques in the field of functional equations, and the second by a geometrical argument, relating the equation to the action of the modular group on the projective line.

The Propositions above imply that any measurable solution of (C.1) must satisfy \( u(x) = u(1 - x) \) for all \( x \in [0, 1] \) and therefore
\[
(C.2) \quad u(x) + (1 - x)^\alpha u \left( \frac{y}{1 - x} \right) = u(y) + (1 - y)^\alpha u \left( \frac{x}{1 - y} \right) ,
\]
with \( u(1) = u(0) = 0 \). By continuity, \( u \) attains a finite value on \( \frac{1}{2} \), say \( K \). For \( \alpha = 1 \), Kannappan and Ng [12] showed that \( u(x) = K s_1(x) \). For \( \alpha \neq 1 \), Daróczy [3] proved that
\[
(C.3) \quad u(x) = \frac{K}{21 - \alpha - 1} (p^\alpha + (1 - p)^\alpha - 1) .
\]

\(^{18}\text{In fact, he does the case } K = 1, \text{ but the argument works in general.}\)
Proof of Lemma C.1. Lemma 3 in [12] implies that $u$ is locally bounded on $(0,1)$ and hence locally integrable. Their proof is for $\alpha = 1$, but the argument applies to the general case with almost no modification, just replacing $\alpha$ for all $y$

$$|u(y)| = |u(1-x) + (1-x)u\left(\frac{y}{1-x}\right) - (1-y)u\left(\frac{1-x-y}{1-y}\right)| \leq 3N,$$

where $x,y$ are such that $u(1-x) \leq N$, $u\left(\frac{y}{1-x}\right) \leq N$ and $u\left(\frac{1-x-y}{1-y}\right) \leq N$, by

$$|u(y)| = |u(1-x) + (1-x)^\alpha u\left(\frac{y}{1-x}\right) - (1-y)^\alpha u\left(\frac{1-x-y}{1-y}\right)| \leq 3N,$$

that is evidently valid too.

To prove the differentiability, we also follow the method of [12]. Let’s fix an arbitrary $y_0 \in (0,1)$; then, it is possible to chose $s, t \in (0,1)$, $s < t$, such that

$$\frac{1-y-s}{1-y}, \frac{1-y-t}{1-y} \in (0,1),$$

for all $y$ in certain neighborhood of $y_0$. We integrate (C.1) with respect to $x$, between $s$ and $t$, to obtain

$$(C.4) \quad (s-t)u(y) = \int_{1-t}^{1-s} u(x)dx + y^{1+\alpha} \int_{\frac{y}{1-x}}^{\frac{y}{1-y}} \frac{u(z)}{z^\alpha}dz + (1-y)^{1+\alpha} \int_{\frac{1-x-y}{1-y}}^{\frac{1-x-s}{1-y}} u(z)dz.$$

The continuity of the RHS of (C.4) as a function of $y$ at $y_0$, implies that $u$ is continuous at $y_0$ and therefore on $(0,1)$. The continuity of $u$ in the RHS of (C.4) implies that $u$ is differentiable at $y_0$. An iterated application of this argument shows that $u$ is infinitely differentiable on $(0,1)$. \hfill \square

Proof of Lemma C.2. We take $1-x = 1-y = z \in \left[\frac{1}{2}, 1\right]$ in (C.1), to obtain

$$u(z) - u(1-z) = z^\alpha \left[u(2-z^{-1}) - u(z^{-1} - 1)\right].$$

If we define $h(z) := u(z) - u(1-z)$, the previous equation reads

$$(C.5) \quad \forall z \in \left[\frac{1}{2}, 1\right], \quad h(z) = z^\alpha h(2-z^{-1}),$$

and, by definition,

$$(C.6) \quad \forall z \in [0,1], \quad h(z) = h(1-z).$$

The boundary conditions imply that $h(0) = h(1) = 0$. From (C.5), we deduce that $h(1/2) = h(0)/2^\alpha = 0$. Using (C.6) in the RHS of (C.5), we obtain

$$(C.7) \quad \forall x \in \left[\frac{1}{2}, 1\right], \quad h(x) = -x^\alpha h(x^{-1} - 1).$$

In principle $h$ is just defined on $[0,1]$, but we extend it imposing the periodicity:

$$(C.8) \quad \forall x \in ]-\infty, \infty[, \quad h(x+1) = h(x)$$

We establish now several results about this extended function.

Lemma C.3.

$$\forall x \in \mathbb{R}, \quad h(x) = -h(1-x).$$
Lemma C.4.
\[(C.9) \quad \forall x \in [1, 2], \quad h(x) = x^{\alpha}h(2 - x^{-1}).\]

Proof. For \(h\) is periodic, \(C.9\) is equivalent to \(\forall x \in [1, 2], \ h(x-1) = x^{\alpha}h(1 - x^{-1}),\)
and the change of variables \(u = x - 1\) gives
\[(C.10) \quad \forall u \in [0, 1], \quad h(u) = (u + 1)^{\alpha}h\left(\frac{u}{u + 1}\right).\]
Note that \(1 - \frac{u}{u + 1} = \frac{1}{u + 1} \in [1, 2].\) Therefore,
\(h\left(\frac{u}{u + 1}\right) = h\left(\frac{1}{u + 1}\right)^{\alpha} = h(u)\).
This establishes \(C.10.\)

Lemma C.5.
\[(C.11) \quad \forall x \in [2, \infty[, \quad h(x) = x^{\alpha}h(2 - x^{-1}).\]

Proof. If \(x \in [2, \infty[,\) then \(1 - \frac{1}{x} \in \left[\frac{1}{2}, 1\right]\) and we can apply equation \(C.5\) to obtain
\[(C.12) \quad h\left(1 - \frac{1}{x}\right)^{\alpha} = \left(1 - \frac{1}{x}\right)^{\alpha}h\left(2 - \left(1 - \frac{1}{x}\right)^{-1}\right) = \left(\frac{x - 1}{x}\right)^{\alpha}h\left(1 - \frac{1}{x - 1}\right).\]
We prove \(C.11\) by recurrence. The case \(x \in [1, 2]\) corresponds to Lemma \(C.4.\)
Suppose it is valid on \([n - 1, n]\). For \(x \in [n, n + 1],\) with \(n \geq 2,\) we have:
\(h(x) = h(x - 1)(x-1)^{\alpha}h(2-(x-1)^{-1}) \equiv (x-1)^{\alpha}h(2-(x-1)^{-1}) \equiv x^{\alpha}h(2-x^{-1}).\)

Lemma C.6.
\[(C.13) \quad \forall x \in \left[0, \frac{1}{2}\right), \quad h(x) = -x^{\alpha}h(x^{-1} - 1).\]

Proof. The previous Lemma and periodicity imply that \(h(x - 1) = x^{\alpha}h(1 - x^{-1})\)
for all \(x \geq 2,\) i.e.
\[(C.14) \quad \forall u \geq 1, \quad h(u) = (u + 1)^{\alpha}h\left(1 - \frac{1}{u + 1}\right).\]
Then, for \(u \geq 1:\)
\[(C.15) \quad h\left(\frac{1}{u + 1}\right)^{\alpha} - h\left(1 - \frac{1}{u + 1}\right)^{\alpha} = \left(\frac{1}{u + 1}\right)^{\alpha}h(u).\]
We set \(y = (u + 1)^{-1} \in \left(0, \frac{1}{2}\right].\) Equation \(C.15\) reads
\[(C.16) \quad \forall y \in \left(0, \frac{1}{2}\right], \quad h(y) = -y^{\alpha}h(y^{-1} - 1).\]
Since \(h(0) = 0,\) the Lemma is proved.
Lemma C.7.

(C.17) \( \forall x \in \left[0, \frac{1}{2}\right], \ h(x) = x^\alpha h(2 - x^{-1}). \)

Proof. By Lemma C.3, \( h(2 - x^{-1}) = -h(x^{-1} - 1). \) This and \( (C.13) \) give:

\[
h(x) = -x^\alpha h \left( \frac{1}{x} - 1 \right) = x^\alpha h \left( 2 - \frac{1}{x} \right).
\]

\( \square \)

Lemma C.8.

\( \forall x \in [-\infty, 0], \ h(x) = -x^\alpha h(2 - x^{-1}). \)

Proof. On one hand, periodicity implies that \( h(x) = h(x + 1) = -h(1 - (x + 1)) = -h(-x). \) On the other, for \( x \leq 0, \) Lemmas C.4 and C.5 above imply that \( h(-x) = (-x)^\alpha h(2 - (-x)^{-1}) = |x|^\alpha h(2 - (-x)^{-1}). \) Therefore,

\[
h(x) = -h(-x) = -|x|^\alpha h \left( 2 + \frac{1}{x} \right) = |x|^\alpha h \left( 1 - \left( 2 + \frac{1}{x} \right) \right) = |x|^\alpha h \left( 2 - \frac{1}{x} \right).
\]

\( \square \)

All these results can be summarized as follows:

Proposition C.9. The function \( h, \) extended periodically to \( \mathbb{R}, \) satisfies the equations

(C.19) \( \forall x \in \mathbb{R}, \ h(x) = |x|^\alpha h \left( \frac{2x - 1}{x} \right), \)

(C.20) \( \forall x \in \mathbb{R}, \ h(x) = -|x|^\alpha h \left( \frac{1 - x}{x} \right). \)

The second equation is implied by \( (C.6). \)

The group \( G = \text{SL}_2(\mathbb{Z})/\{\pm I\} \) is called the modular group; it is the image of \( \text{SL}_2(\mathbb{Z}) \) in \( \text{PGL}_2(\mathbb{R}). \) We keep using the matrix notation for the images in this quotient. We make \( G \) act on \( \mathbb{P}^1(\mathbb{R}) \) as follows: an element \( g = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in G \) acting on \([x : y] \in \mathbb{P}^1(\mathbb{R}) \) (homogeneous coordinates) gives

\[
g[x : y] = [ax + by : cx + dy].
\]

Let \( S \) and \( T \) be the elements of \( G \) defined by the matrices

(C.21) \( S = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} \) and \( T = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}. \)

The group \( G \) is generated by \( S \) and \( T \) \( \text{[17], Ch. VII, Th. 2}; \) in fact, one can prove that \( \langle S, T; S^2, (ST)^3 \rangle \) is a presentation of \( G. \)

The transformations \( x \mapsto \frac{2x - 1}{x} \) and \( x \mapsto \frac{1 - x}{x} \) in Equations \( (C.19) \) and \( (C.20) \) are homographies of the real projective line \( \mathbb{P}^1(\mathbb{R}), \) that we denote respectively \( \alpha \) and \( \beta. \) They correspond to elements

(C.22) \( A = \begin{pmatrix} 2 & -1 \\ 1 & 0 \end{pmatrix}, \ B = \begin{pmatrix} -1 & 1 \\ 1 & 0 \end{pmatrix}. \)
in $G$, that satisfy
\begin{equation}
B^2 = \begin{pmatrix} 2 & -1 \\ -1 & 1 \end{pmatrix}, \quad BA^{-1} = \begin{pmatrix} -1 & 1 \\ 0 & 1 \end{pmatrix}.
\end{equation}
This last matrix corresponds to $x \mapsto 1 - x$.

**Lemma C.10.** The matrices $A$ and $B^2$ generate $G$.

**Proof.** Let
\begin{equation}
P = S^{-1}T^{-1} = \begin{pmatrix} 0 & 1 \\ -1 & 1 \end{pmatrix}.
\end{equation}
One has
\begin{equation}
PAP^{-1} = \begin{pmatrix} 1 & -1 \\ 0 & 1 \end{pmatrix},
\end{equation}
and
\begin{equation}
PB^2P^{-1} = \begin{pmatrix} 3 & -1 \\ 1 & 0 \end{pmatrix}.
\end{equation}
Therefore, $PAP^{-1} = T^{-1}$ and $S = T^{-3}PB^{-2}P^{-1}$. Inverting these relations, we obtain
\begin{equation}
T = PA^{-1}P^{-1}, \quad S = PA^3B^{-2}P^{-1}.
\end{equation}
Let $X$ be an arbitrary element of $G$. Since $Y = PXP^{-1} \in G$ and $G$ is generated by $S$ and $T$, the element $Y$ is a word in $S$ and $T$. In consequence, $X$ is a word in $P^{-1}SP$ and $P^{-1}TP$, which in turn are words $A$ and $B^2$. The Lemma is proved.

One can find explicit formulas for $S$ and $T$ in terms of $A$ and $B^2$. Since $P = S^{-1}T^{-1}$, we deduce that $PSP^{-1} = S^{-1}T^{-1}STS$ and $PTP^{-1} = S^{-1}T^{-1}TTS = S^{-1}TS$. Hence, in virtue of (C.26),

\begin{align*}
S &= P^{-1}S^{-1}T^{-1}STSP \\
&= (P^{-1}S^{-1}P)(P^{-1}T^{-1}P)(P^{-1}SP)(P^{-1}TP)(P^{-1}SP) \\
&= B^2AB^{-2}A^2B^{-2}
\end{align*}

and
\begin{align*}
T &= P^{-1}S^{-1}TSP \\
&= (P^{-1}S^{-1}P)(P^{-1}TP)(P^{-1}SP) \\
&= B^2A^{-1}B^{-2}.
\end{align*}

\[\blacksquare\]

To finish our proof of Proposition C.2, we remark that the orbit of 0 by the action of $G$ on $P^1(\mathbb{R})$ is $\mathbb{Q} \cup \{\infty\}$, where $\mathbb{Q} \cup \{\infty\}$ has been identified with $\{[p : q] \in P^1(\mathbb{R}) \mid p, q \in \mathbb{Z}\} \subset P^1(\mathbb{R})$. This is a consequence of Bezout’s identity: for every point $[p : q] \in P^1(\mathbb{R})$ representing a reduced fraction $\frac{p}{q} \neq 0$ ($p, q \in \mathbb{Z} \setminus \{0\}$ and coprime), there are two integers $x, y$ such that $xq - yp = 1$. Therefore
\[g' = \begin{pmatrix} x & p \\ y & q \end{pmatrix}\]
is an element of $G$ and $g'[0 : 1] = [p : q]$. The case $q = 0$ is covered by
\[\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}[0 : 1] = [1 : 0].\]
The extended equations (C.19) and (C.20) are such that $h(x) = 0$ implies $h(\alpha x) = 0$, $h(\beta x) = 0$, $h(\alpha^{-1} x) = 0$ and $h(\beta^{-1} x) = 0$. Since the orbit in $\mathbb{R}$ of 0 by the group of homographies generated by $A$ and $B^2$ (i.e. $G$ itself) contains the whole set of rational numbers $\mathbb{Q}$ and $h(0) = 0$, we conclude that $h = 0$ on $[0, 1] \cap \mathbb{Q}$.
