Abstract

A unified fluid-structure interaction (FSI) formulation is presented for solid, liquid and mixed membranes. Nonlinear finite elements (FE) and the generalized- α scheme are used for the spatial and temporal discretization. The membrane discretization is based on curvilinear surface elements that can describe large deformations and rotations, and also provide a straightforward description for contact. The fluid is described by the incompressible Navier-Stokes equations, and its discretization is based on stabilized Petrov-Galerkin FE. The coupling between fluid and structure uses a conforming sharp interface discretization, and the resulting non-linear FE equations are solved monolithically within the Newton-Raphson scheme. An arbitrary Lagrangian-Eulerian formulation is used for the fluid in order to account for the mesh motion around the structure. The formulation is very general and admits diverse applications that include contact at free surfaces. This is demonstrated by two analytical and three numerical examples exhibiting strong coupling between fluid and structure. The examples include balloon inflation, droplet rolling and flapping flags. They span a Reynolds-number range from 0.001 to 2000. One of the examples considers the extension to rotation-free shells using isogeometric FE.

Keywords: arbitrary Lagrangian-Eulerian formulation, contact mechanics, incompressible Navier-Stokes equations, isogeometric finite elements, nonlinear membranes, surface tension

1 Introduction

Fluid-structure interaction (FSI) problems are challenging problems due to various reasons. They combine the computational challenges of (generally non-linear) fluid and structural mechanics, and they introduce new challenges, both physical and numerical, due to the coupling. If the structure is highly flexible, such as a thin membrane, large deformations can be expected. Those, in turn, have a large influence on the fluid flow. A comprehensive overview of FSI and its challenges is given by the monographs of Ohayon (2004), Bazilevs et al. (2013) and Bazilevs and Takizawa (2016). The classical focus in FSI problems is on solid structures. However, some structures are not solids but rather fluids or fluid-like objects. Examples are liquid menisci, soap films and lipid bilayers. Lipid bilayers surround biological cells. They are characterized by both solid-like (i.e. elastic bending) and fluid-like behavior (i.e. in-plane flow). Further, liquid

(and solid) membranes can come into contact with surrounding objects. A classical example is a liquid droplet rolling on a substrate. The problem is characterized by fluid flow, surface tension and contact.

While there are various formulations available in the present literature that capture all these aspects, there is no formulation that unifies them all into a single framework. This is the objective of the present work. In doing so, we build on our recent computational work on contact, membranes, shells and fluid dynamics.

The presented formulation is based on finite elements (FE) using an interface tracking technique based on a sharp interface formulation. There is a large literature body on FE-based work on membrane-FSI that is surveyed in the following. The computational approaches on interactions between fluids and membrane-like structures can be sorted into two groups. The first group deals with solid structures like elastic membranes and flexible shells, while the second group is concerned with liquid membranes and menisci. The first group can be further sorted into approaches that use surface formulations (based on shell and membrane theories) and contributions that use bulk formulations. The second group can be further sorted into approaches that only account for the shape equation in order to characterize the liquid membrane (like the Young-Laplace equation), and approaches that also account for in-plane equations (such as the surface Navier-Stokes equations). The latter case is necessary for liquid membranes that are not surrounded by a fluid, and consequently the FSI problem is due to the interplay of membrane shape and surface flow. If a surrounding medium is considered, and no-slip conditions are applied on the membrane surface, the flow within the membrane is already captured by the bulk flow, and so no further equations are needed. The method presented here is based on a surface formulation that accounts for both shape and in-plane equations.

The following references deal with solid membranes using surface formulations. In Liang et al. (1997) the authors employ a deformable spatial domain space-time FEM to study the interaction of an incompressible fluid with an elastic membrane. Bletzinger et al. (2006) compute the flow around a tent structure using a staggered coupling between a shell code and a CFD code. Tezduyar and Sathe (2007) review their FSI formulation based on space-time FE and introduce advancements regarding accuracy, robustness and efficiency. Benchmark examples include the inflation of a balloon, the flow through a flexible diaphragm in a tube as well as a descending parachute. Parachutes are also analyzed in Karagiozis et al. (2011) and Takizawa and Tezduyar (2012) using thin-shell formulations. Le et al. (2009) developed an implicit immersed boundary method for the incompressible Navier-Stokes equations to simulate membrane-fluid interactions. Their examples include an oscillating spherical ball immersed in a fluid and the stretching of a red blood cell in a pressure driven shear flow. van Opstal et al. (2015) present a hybrid isogeometric finite-element/boundary element method for fluid-structure interaction problems of inflatable structures such as airbags and balloons. Boundary elements are also used in a recent isogeometric FSI formulation for Stokes flow around thin shells (Heltai et al., 2017). The following references deal with solid membranes using bulk formulations. Kloeppel and Wall (2011) numerically investigate the flow inside red blood cells (RBC) by means of monolithically coupling an incompressible fluid to a lipid bilayer represented by incompressible solid shell elements. In Franci et al. (2016) the authors develop a monolithic strategy for the description

of purely Lagrangian FSI problems. For the solid, the FEM is used, while the fluid is discretized using the so-called Particle FEM (Idelsohn et al., 2004). Yang et al. (2016) introduce a finitediscrete element method for bulk solids and combine the developed numerical model with a finite element multiphase flow model. Only 2D examples are considered, such as a rigid structure floating on a liquid-gaseous interface.

Recent reviews on computational FSI methods for solids have been given by Dowell and Hall (2001), van Loon et al. (2007) and Bazilevs et al. (2013). For an introduction to immersed-

boundary methods as an alternative to conforming FE discretizations we refer to Peskin (2003).

The following references deal with liquid membranes governed only by a shape equation. Walkley et al. (2005) present an arbitrary Lagrangian-Eulerian (ALE) framework for the solution of free surface flow problems including a dynamic contact line model and show its capabilities for the case of a sliding droplet. Saksono and Perić (2006) propose a 2D finite element formulation for surface tension and apply it to oscillating droplets and stretched liquid bridges. Montefuscolo et al. (2014) introduce high-order ALE FEM schemes for capillary flows. The schemes are demonstrated on oscillating and sliding droplets accounting for varying contact angles.

The following references deal with liquid membranes governed by shape and in-plane equations. Barett et al. (2015) present a numerical study of the dynamics of lipid bilayer vesicles. A parametric finite element formulation is introduced to discretize the surface Navier-Stokes equations. Rangarajan and Gao (2015) introduce a spline-based finite-element formulation to compute equilibrium configurations of liquid membranes. Sauer et al. (2017) present a 3D isogeometric finite element formulation for liquid membranes that accounts for the in-plane viscosity and incompressibility of the liquid.

A general introduction to fluid membranes and vesicles and their configurations observed in nature is given by Seifert (1997). For a review on the droplet dynamics within flows, see Cristini and Tan (2004).

There is also earlier work on combining contact and FSI. It can be grouped into two categories: Either contact is considered between solids submerged within the fluid (e.g. see Tezduyar et al. (2006); Mayer et al. (2010)), or contact is considered at free liquid surfaces. For liquid surfaces the same classical contact algorithms as for solid surfaces can be used (Sauer, 2014). An alternative treatment of free surface contact appears naturally in the Particle FEM (Idelsohn et al., 2006). Additionally, the contact behavior between liquids and solids is also governed by a contact angle and its hysteresis during sliding contact. A general computational algorithm for contact angle hysteresis is given in Sauer (2016).

Existing work is motivated by specific examples that either focus on solid or liquid membranes. The aim of this paper therefore is to provide a new unified FSI formulation that is suitable to describe solid membranes – such as sheets, fabrics and tissues – liquid membranes – such as menisci and soap films – and membranes with both solid- and liquid-like character, like lipid bilayers. The formulation is based on a new membrane model that has been recently proposed to unify solid and liquid membranes (Sauer et al., 2014). The membrane model readily admits general constitutive laws (Sauer and Duong, 2017), it extends to Kirchhoff-Love shells (Duong et al., 2017) and it is suitable to describe the coupling with other field equations (Sahu et al., 2017). Further, the explicit surface formulation of the membrane provides a natural framework for free-surface contact such that any existing contact algorithm can be used. The present work considers a monolithic coupling scheme between fluid and structure, and solves the resulting non-linear system of equations with the Newton-Raphson method. Finite elements and the generalized- α scheme are used for the spatial and temporal discretization. The formulation uses a conforming interface discretization and an ALE formulation for the mesh motion.

Compared to partitioned solvers, monolithic solvers are more complicating to implement (as they require the full tangent matrix and thus need a single code environment). But in terms of robustness, monolithic solvers are superior since the coupling between fluid and structure is fully accounted for without further approximation (beyond the usual FE discretization error). Also in terms of computational efficiency, recent works have shown that pre-conditioned monolithic solvers are competitive to partitioned ones (Heil et al., 2008; Küttler et al., 2010; Ha et al., 2017). For these reasons the present work uses a monolithic FSI solver.

The following aspects are new in this work:

- A unified monolithic FSI formulation for liquid and solid membranes is presented.
- It includes contact on free liquid surfaces, and
- it easily extends to rotation-free shells with general constitutive behavior.
- Two simple analytical FSI examples are presented.
- The formulation is suitable for a wide range of applications, including free-surface flows, liquid menisci, flags and flexible wings.
- The examples include a flow and contact analysis of a rolling 3D droplet.

The remainder of this paper is structured as follows. Sec. 2 presents the governing theory of incompressible fluid flow, nonlinear membranes and their coupling. The theory is used to solve two simple analytical FSI examples in Sec. 3. The computational treatment is then presented in Sec. 4 using finite elements for the spatial discretization of fluid and membrane, and the generalized- α scheme for the temporal discretization of the coupled system. Sec. 5 presents three numerical examples ranging from very low to quite large Reynolds numbers. The paper concludes with Sec. 6.

2 Governing equations

This section summarizes the governing equations for fluid flow, membrane deformation, membrane contact and their coupling. The symbols \mathcal{F} and \mathcal{S} are used to denote the fluid domain and the membrane surface, cf. Fig. 1 in Sec. 3.1 and Fig. 12 in Sec. 5.3.

2.1 Fluid flow

The fluid motion is described by an arbitrary Lagrangian-Eulerian (ALE) formulation. It is therefore necessary to distinguish between the material motion and the mesh motion. An ALE formulation contains the special cases of a purely Lagrangian description, for which the material and mesh motion coincide, and a purely Eulerian description, for which the mesh motion is zero.

2.1.1 Fluid kinematics

The material motion of a fluid particle X within domain \mathcal{F} is characterized by the deformation mapping

$$\boldsymbol{x} = \boldsymbol{\varphi}(\boldsymbol{X}, t) \tag{1}$$

and the corresponding deformation gradient (or Jacobian)

$$\boldsymbol{F} := \frac{\partial \boldsymbol{\varphi}}{\partial \boldsymbol{X}} \,. \tag{2}$$

The volume change during deformation is captured by the Jacobian determinant $J := \det F$. The velocity of the material is given by the time derivative of x for fixed X, written as

$$\boldsymbol{v} := \frac{\partial \boldsymbol{x}}{\partial t} \Big|_{\boldsymbol{X}} \tag{3}$$

and commonly referred to as the *material time derivative*. It is also often denoted by the dot notation $\mathbf{v} = \dot{\mathbf{x}}$. An important object characterizing the fluid flow is the velocity gradient

$$\boldsymbol{L} := \nabla \boldsymbol{v} = \frac{\partial \boldsymbol{v}}{\partial \boldsymbol{x}} \tag{4}$$

that can also be written as $\boldsymbol{L} = \dot{\boldsymbol{F}} \boldsymbol{F}^{-1}$, where $\dot{\boldsymbol{F}}$ is the material time derivative of the deformation gradient. The symmetric part of the velocity gradient is denoted by $\boldsymbol{D} := (\boldsymbol{L} + \boldsymbol{L}^{\mathrm{T}})/2$. Likewise to Eq. (3), the material acceleration is given by

$$\boldsymbol{a} := \dot{\boldsymbol{v}} = \frac{\partial \boldsymbol{v}}{\partial t} \Big|_{\boldsymbol{X}} \,. \tag{5}$$

It is related to the acceleration for fixed x,

$$\boldsymbol{v}' := \frac{\partial \boldsymbol{v}}{\partial t} \Big|_{\boldsymbol{x}},\tag{6}$$

according to

$$\dot{\boldsymbol{v}} = \boldsymbol{v}' + \boldsymbol{L} \left(\boldsymbol{v} - \boldsymbol{v}_{\mathrm{m}} \right), \tag{7}$$

where $v_{\rm m}$ is the mesh velocity (Donea and Huerta, 2003). For a purely Lagangian description $v_{\rm m} = v$, while for a purely Eulerian description $v_{\rm m} = 0$.

Remark 2.1: The gradient operator appearing in Eq. (4) (and likewise in Eq. (2)), is defined here as $\nabla \boldsymbol{v} := v_{i,j} \boldsymbol{e}_i \otimes \boldsymbol{e}_j$.⁴ In matrix notation this corresponds to the square 3×3 matrix $[v_{i,j}]$.

2.1.2 Fluid equilibrium

From the balance of linear momentum within \mathcal{F} follows the equilibrium equation

$$\operatorname{div} \boldsymbol{\sigma} + \bar{\boldsymbol{f}} = \rho \, \boldsymbol{\dot{v}} \quad \text{in } \mathcal{F} \,, \tag{8}$$

which governs the fluid flow together with the boundary conditions

Here, $\boldsymbol{\sigma}$ denotes the stress tensor within \mathcal{F} , \boldsymbol{t} denotes the traction vector on the surface characterized by normal vector \boldsymbol{n} , and ρ denotes the fluid density, while $\bar{\boldsymbol{f}}$, $\bar{\boldsymbol{v}}$ and $\bar{\boldsymbol{t}}$ are prescribed body forces, surface velocities and surface tractions. $\partial_x \mathcal{F}$ and $\partial_t \mathcal{F}$ denote the corresponding Dirichlet and Neumann boundary regions of the fluid domain \mathcal{F} . Boundary $\partial_x \mathcal{F}$ can be split into the two parts

$$\partial_x \mathcal{F} = \mathcal{S} \cup \partial_{\hat{x}} \mathcal{F} \,, \tag{10}$$

where S is the surface of the membrane, which is considered to impose its velocity onto the fluid, and $\partial_{\hat{x}} \mathcal{F}$ denotes the remaining Dirichlet boundary of the fluid domain. In order to solve PDE (8) for $\boldsymbol{v}(\boldsymbol{x},t)$, the initial condition

$$\boldsymbol{v}(\boldsymbol{x},0) = \boldsymbol{v}_0(\boldsymbol{x}) \tag{11}$$

is needed.

⁴Following index notation, summation is implied on repeated indices. Latin indices range from 1 to 3 and refer to Cartesian coordinates. Greek indices range from 1 to 2 and refer to curvilinear surface coordinates.

2.1.3 Fluid constitution

We consider an incompressible Newtonian fluid with kinematic viscosity ν and dynamic viscosity $\eta = \nu \rho$. In that case the stress tensor is given by

$$\boldsymbol{\sigma} = -p\,\mathbf{1} + 2\eta\,\boldsymbol{D}\,,\tag{12}$$

where p is the Lagrange multiplier to the incompressibility constraint

$$g := J - 1 = 0, \tag{13}$$

which is equivalent to the condition

$$\operatorname{div} \boldsymbol{v} = 0. \tag{14}$$

A consequence of this condition is that the fluid pressure, defined as $-\text{tr} \sigma/3$, is equal to the Lagrange multiplier p. It is an additional unknown that needs to be solved for together with v. In case of pure Dirichlet boundary conditions $(\partial_t \mathcal{F} = \emptyset)$, the value of p needs to be specified at one point in the fluid domain in order for the pressure field to be uniquely determinable.

2.1.4 Fluid weak form

In order to solve the problem with finite elements the strong form equations (8), (9.2) and (14) are reformulated in weak form. They are therefore multiplied by the test functions \boldsymbol{w} and q, and integrated over the domain \mathcal{F} . Function \boldsymbol{w} is assumed to be zero on the Dirichlet boundary $\partial_{\hat{x}}\mathcal{F}$, but non-zero on the surface \mathcal{S} . Functions \boldsymbol{w} and q are further assumed to possess sufficient regularity for the following integrals to be well defined. In the framework of SUPG⁵ and PSPG⁶ stabilization, the weak form takes the form

$$G_{\mathcal{F}} := G_{\mathcal{F}in} + G_{\mathcal{F}int} + G_{supg} - G_{\mathcal{F}s} - G_{\mathcal{F}ext} = 0 \quad \forall \ \boldsymbol{w} \in \mathcal{W},$$

$$G_{\mathcal{G}} := G_g + G_{pspg} = 0 \quad \forall \ q \in \mathcal{Q},$$
 (15)

where

$$G_{\mathcal{F}\mathrm{in}} := \int_{\mathcal{F}} \boldsymbol{w} \cdot \rho \, \dot{\boldsymbol{v}} \, \mathrm{d}\boldsymbol{v} \tag{16}$$

is the virtual work associated with inertia,

$$G_{\mathcal{F}\text{int}} := \int_{\mathcal{F}} \nabla \boldsymbol{w} : \boldsymbol{\sigma} \, \mathrm{d} \boldsymbol{v}$$
(17)

is internal virtual work,

$$G_{\mathcal{F}_{\mathrm{S}}} := \int_{\mathcal{S}} \boldsymbol{w} \cdot \boldsymbol{t} \, \mathrm{d}\boldsymbol{a} \tag{18}$$

is the virtual work of the fluid traction $t = \sigma n$ on boundary S,

$$G_{\mathcal{F}\text{ext}} := \int_{\mathcal{F}} \boldsymbol{w} \cdot \bar{\boldsymbol{f}} \, \mathrm{d}\boldsymbol{v} + \int_{\partial_t \mathcal{F}} \boldsymbol{w} \cdot \bar{\boldsymbol{t}} \, \mathrm{d}\boldsymbol{a}$$
(19)

is the external virtual work⁷,

$$G_{\rm g} := \int_{\mathcal{F}} q \operatorname{div} \boldsymbol{v} \, \mathrm{d}v \tag{20}$$

⁵Streamline upwind/Petrov-Galerkin (Brooks and Hughes, 1982)

⁶Pressure stabilizing/Petrov-Galerkin (Hughes et al., 1986)

⁷In the following examples we consider zero Neumann BC ($\bar{t} = 0$) and constant gravity loading with $\bar{f} = \rho g$.

is the virtual work associated with incompressibility constraint (14),

$$G_{\text{supg}} := \int_{\mathcal{F}} \tau_{\text{v}} \, \boldsymbol{f}_{\text{res}} \cdot \nabla \boldsymbol{w} \, (\boldsymbol{v} - \boldsymbol{v}_{\text{m}}) \, \mathrm{d}\boldsymbol{v}$$
(21)

is the SUPG term,

$$G_{\text{pspg}} := \int_{\mathcal{F}} \tau_{\text{p}} \nabla q \cdot \boldsymbol{f}_{\text{res}} \, \mathrm{d}v \tag{22}$$

is the PSPG term, and

$$\boldsymbol{f}_{\text{res}} := \rho \, \boldsymbol{\dot{\boldsymbol{v}}} - \operatorname{div} \boldsymbol{\sigma} - \bar{\boldsymbol{f}} \tag{23}$$

is the residual of Eq. (8). Dimensionally, the residual is a force per volume. Since in theory $\mathbf{f}_{\text{res}} = \mathbf{0}$, stabilization terms G_{supg} and G_{pspg} do not affect the physical behavior of the system. In Cartesian coordinates $\mathbf{f}_{\text{res}} \cdot \nabla \mathbf{w} (\mathbf{v} - \mathbf{v}_{\text{m}}) = f_i^{\text{res}} w_{i,j} (v_j - v_{\text{m}j})$. The scalars τ_{v} and τ_{p} are stabilization parameters that are discussed in Sec. 4.

2.2 Deforming membranes

This work focuses on pure membranes that do not resist bending and out-of-plane shear. The description of those membranes is based on the formulation of Sauer et al. (2014), which admits both solid and liquid membranes. What follows is a brief summary.

2.2.1 Membrane kinematics

The motion of a membrane surface \mathcal{S} is fully described by the mapping

$$\boldsymbol{x} = \boldsymbol{x}(\xi^{\alpha}, t) \,, \tag{24}$$

where ξ^{α} , for $\alpha = 1, 2$, are curvilinear coordinates that can be associated with material points on the surface. They can be conveniently taken from the parameterization of the finite element shape functions. Based on mapping (24), the tangent vectors $\mathbf{a}_{\alpha} := \partial \mathbf{x}/\xi^{\alpha}$ to surface S, the metric tensor components $a_{\alpha\beta} := \mathbf{a}_{\alpha} \cdot \mathbf{a}_{\beta}$,⁸ and the surface normal $\mathbf{n} = \mathbf{a}_1 \times \mathbf{a}_2/\sqrt{\det[a_{\alpha\beta}]}$ can be determined. From the matrix inverse $[a^{\alpha\beta}] = [a_{\alpha\beta}]^{-1}$, the dual tangent vectors $\mathbf{a}^{\alpha} := a^{\alpha\beta}\mathbf{a}_{\beta}$ can be defined such that $\mathbf{a}^{\alpha} \cdot \mathbf{a}_{\beta}$ is equal to the Kronecker delta δ^{α}_{β} .

In order to characterize deformation, a stress-free reference configuration S_0 is introduced. It will be considered here as the initial membrane surface, i.e. $S_0 := S|_{t=0}$. In the reference configuration the tangent vectors, metric tensor components, inverse components and normal vector are denoted by capital letters, i.e. A_{α} , $A_{\alpha\beta}$, $A^{\alpha\beta}$ and N. The in-plane deformation of surface S is fully characterized by the relation between $A^{\alpha\beta}$ and $a^{\alpha\beta}$. The surface stretch for instance is given by $J_{\rm s} := \sqrt{\det[a_{\alpha\beta}]/\det[A_{\alpha\beta}]}$.

Following definitions (3) and (5), the membrane velocity v and acceleration a are obtained from Eq. (24).

2.2.2 Membrane equilibrium

From the balance of linear momentum within $\mathcal S$ follows the equilibrium equation

$$(\boldsymbol{\sigma}_{\mathrm{s}} \boldsymbol{a}^{\alpha})_{;\alpha} + \boldsymbol{f}_{\mathrm{s}} = \rho_{\mathrm{s}} \, \boldsymbol{\dot{v}} \quad \text{in } \mathcal{S} \,, \tag{25}$$

⁸ following the notation where g_{ij} is the metric in the bulk, and $a_{\alpha\beta}$ is the metric on the surface

which governs the membrane deformation together with the boundary conditions

e.g. see Sauer and Duong (2017). Here, $\sigma_{\rm s}$ denotes the stress tensor within S, $(...)_{;\alpha}$ denotes the covariant derivative w.r.t. ξ^{α} , $t_{\rm s}$ denotes the traction vector on the membrane boundary characterized by normal vector $\boldsymbol{\nu}$, and $\rho_{\rm s}$ denotes the membrane density, while $\bar{\boldsymbol{x}}$ and $\bar{t}_{\rm s}$ are prescribed boundary velocities and boundary tractions. The body force $\boldsymbol{f}_{\rm s}$ is considered here to have contributions coming from the flow field, contact and external sources, i.e.

$$\boldsymbol{f}_{\rm s} = \boldsymbol{f}_{\rm f} + \boldsymbol{f}_{\rm c} + \bar{\boldsymbol{f}}_{\rm s} \,. \tag{27}$$

In order to solve PDE (25) for $\boldsymbol{x}(\xi^{\alpha}, t)$, the initial conditions

$$\begin{aligned} \boldsymbol{x}(\xi^{\alpha},0) &= \boldsymbol{X}(\xi^{\alpha}), \\ \boldsymbol{v}(\xi^{\alpha},0) &= \boldsymbol{v}_0(\xi^{\alpha}), \end{aligned}$$
(28)

are needed.

2.2.3 Membrane constitution

For pure membranes, the stress tensor only has in-plane components, i.e. it has the format $\sigma_s = \sigma^{\alpha\beta} a_{\alpha} \otimes a_{\beta}$. Two material models are considered in this work. The first,

$$\sigma^{\alpha\beta} = \frac{\mu}{J_{\rm s}} \left(A^{\alpha\beta} - \frac{1}{J_{\rm s}^2} a^{\alpha\beta} \right),\tag{29}$$

is suitable for solid membranes. It can be derived from the 3D incompressible Neo-Hookean material model (Sauer et al., 2014). The second,

$$\sigma^{\alpha\beta} = \gamma \, a^{\alpha\beta} \,, \tag{30}$$

models isotropic surface tension, and is suitable to describe liquid membranes, e.g. see Sauer (2014). The parameters μ and γ denote the shear stiffness and the surface tension, respectively. Both are considered constant here.

2.2.4 Membrane contact

This work also considers that sticking contact can occur on the membrane surface $S_c \subset S$. During sticking contact no relative motion occurs between the membrane and a neighboring substrate surface S_{sub} . Mathematically this corresponds to the constraint

$$\boldsymbol{g} = \boldsymbol{0} \quad \forall \, \boldsymbol{x} \in \mathcal{S}_{\mathrm{c}} \,, \tag{31}$$

where

$$\boldsymbol{g}(\boldsymbol{x}) = \boldsymbol{x} - \boldsymbol{x}_{\mathrm{p}}^{0} \tag{32}$$

denotes the contact gap between the membrane point $\boldsymbol{x} \in S_{c}$ and its initial projection point on the substrate surface, $\boldsymbol{x}_{p}^{0} \in S_{sub}$, i.e. \boldsymbol{x}_{p}^{0} is the location where \boldsymbol{x} initially touched S_{sub} . Here, constraint (31) will be enforced by a penalty regularization. For this, the contact traction at $\boldsymbol{x} \in S$ is given by

$$\boldsymbol{f}_{\rm c} = \begin{cases} -\epsilon \, \boldsymbol{g} & \text{if } \boldsymbol{g} \cdot \boldsymbol{n}_{\rm c} < 0 \,, \\ \boldsymbol{0} & \text{else} \,, \end{cases}$$
(33)

where n_c is the surface normal of S_{sub} . Instead of the penalty formulation, also any other contact formulation can be used to enforce (31). Further details on large deformation contact theory can be found in the textbooks of Laursen (2002) and Wriggers (2006).

2.2.5 Membrane weak form

In order to employ finite elements, the strong form equations (25) and (26.2) are reformulated in weak from. As shown in Sauer and Duong (2017), the weak form for the membrane can be written as

$$G_{\mathcal{S}} := G_{\mathcal{S}in} + G_{\mathcal{S}int} + G_{c} - G_{\mathcal{S}f} - G_{\mathcal{S}ext} = 0 \quad \forall \ \boldsymbol{w} \in \mathcal{W},$$
(34)

with the virtual work contributions

$$G_{\mathcal{S}in} := \int_{\mathcal{S}} \boldsymbol{w} \cdot \rho_{s} \, \boldsymbol{\dot{v}} \, da \,,$$

$$G_{\mathcal{S}int} := \int_{\mathcal{S}} \sigma^{\alpha\beta} \, \boldsymbol{w}_{;\alpha} \cdot \boldsymbol{a}_{\beta} \, da \,,$$

$$G_{c} := -\int_{\mathcal{S}} \boldsymbol{w} \cdot \boldsymbol{f}_{c} \, da \,,$$

$$G_{\mathcal{S}f} := \int_{\mathcal{S}} \boldsymbol{w} \cdot \boldsymbol{f}_{f} \, da \,,$$

$$G_{\mathcal{S}ext} := \int_{\mathcal{S}} \boldsymbol{w} \cdot \boldsymbol{\bar{f}}_{s} \, da + \int_{\partial_{t}\mathcal{S}} \boldsymbol{w} \cdot \boldsymbol{\bar{t}}_{s} \, ds \,,$$

(35)

due to inertia, internal forces, contact forces, fluid forces and external forces acting on S and $\partial_t S$. Test function w is the same as in (15). Therefore, space W needs to additionally satisfy the requirement that all integrals appearing above are well defined. Further w is assumed to be zero on $\partial_x S$.

Pure membranes are inherently unstable in the quasi-static case ($\boldsymbol{v} = \boldsymbol{\dot{v}} = \boldsymbol{0}$) and therefore need to be stabilized (Sauer et al., 2014; Sauer, 2014). Here, no stabilization is required as the fluid forces $\boldsymbol{f}_{\rm f}$ stabilize the membrane, even when $\rho_{\rm s} = 0$ (as is considered in some of the following examples). In the numerical examples following later, $\bar{\boldsymbol{f}}_{\rm s}$ and $\bar{\boldsymbol{t}}_{\rm s}$, and consequently $G_{\mathcal{S}\text{ext}}$, are considered zero.

Remark 2.2: It is straight forward to extend weak form (34) to Kirchhoff-Love shells: G_{Sint} and G_{Sext} simply need to be extended by the bending moments acting within S and on ∂S , e.g. see Duong et al. (2017). Kirchhoff-Love shells are suitable for thin membrane-like surface structures. Such a structure is considered in Sec. 5.3 using isogeometric finite elements.

2.3 Coupling conditions

The membrane deformation \boldsymbol{x} moves the fluid such that

$$\boldsymbol{v} = \dot{\boldsymbol{x}} \quad \text{on } \mathcal{S} \tag{36}$$

is a Dirichlet BC for the fluid. This choice assumes no tangential slip between membrane and fluid. In response, the flow exerts a traction on the membrane such that

$$\boldsymbol{f}_{\mathrm{f}} = -\boldsymbol{t} \quad \mathrm{on} \ \boldsymbol{\mathcal{S}} \tag{37}$$

is a 'body force' of the membrane. Eq. (36) is the kinematic coupling condition between the two domains, while Eq. (37) is the kinetic coupling condition. If the membrane is surrounded by fluid on both sides, t in (37) is replaced by the traction jump $[t] := t^+ - t^-$, where t^+ is the traction on the front side (with outward normal n) and t^- is the traction on the back side

(with outward normal -n) of the membrane. The combined FSI problem is then characterized by the two governing equations

$$\begin{aligned}
G_{\mathcal{F}} + G_{\mathcal{S}} &= 0 \quad \forall \ \boldsymbol{w} \in \mathcal{W}, \\
G_{\mathcal{G}} &= 0 \quad \forall \ \boldsymbol{q} \in \mathcal{Q},
\end{aligned} \tag{38}$$

which can be solved for the unknown velocity \boldsymbol{v} and pressure p in \mathcal{F} . The membrane deformation can then be obtained from integrating \boldsymbol{v} . Coupling condition (37) simply leads to the cancelation of terms $G_{\mathcal{F}_{S}}$ and $G_{\mathcal{S}_{f}}$ in the combined weak form (38). This cancelation will carry over to the discretized weak form, as long as surface \mathcal{S} is discretized conformingly on the fluid and membrane side.

3 Analytical examples

This section presents the analytical solution of two simple examples. They serve as verification examples for the computational implementation discussed later.

3.1 Solid membrane example: Fluid-inflated cylinder

As a first example we consider the radial inflation of a membrane cylinder due to a constant radial inflow as is illustrated in Fig. 1. The example is chosen since it can be fully solved

Figure 1: Fluid-inflated cylinder: Membrane deformation $S_0 \to S$ and fluid velocity v(r) due to a radial inflow at R_{in} .

analytically and thus used for verification of the computational formulation, which is then considered in Sec. 5.1. Given the inflow velocity v_{in} at the inner boundary R_{in} , the radial fluid velocity at location r is given by

$$v(r) = \frac{v_{\rm in} R_{\rm in}}{r} \tag{39}$$

due to continuity. Since $v = \dot{r}$, we obtain

$$r(R,t) = \sqrt{R^2 + 2v_{\rm in} R_{\rm in} t}, \qquad (40)$$

as the current position of the fluid particle initially at R. The current membrane position is thus given by $r_s = r(R_s, t)$, where R_s is the initial position of the membrane. In vectorial notation, the flow field can thus be characterized by the position, velocity and acceleration

$$\begin{aligned} \boldsymbol{x}(R,t) &= r \, \boldsymbol{e}_r \,, \\ \boldsymbol{v}(R,t) &= v \, \boldsymbol{e}_r \,, \\ \boldsymbol{a}(R,t) &= -\frac{v^2}{r} \, \boldsymbol{e}_r \,, \end{aligned}$$
(41)

where $e_r = \cos \theta e_1 + \sin \theta e_2$ is the radial unit vector. From this follows

$$\boldsymbol{D} = \frac{v}{r} \left(\bar{\boldsymbol{1}} - 2 \, \boldsymbol{e}_r \otimes \boldsymbol{e}_r \right), \tag{42}$$

with the 2D identity $\mathbf{\overline{1}} := \mathbf{e}_1 \otimes \mathbf{e}_1 + \mathbf{e}_2 \otimes \mathbf{e}_2$, such that div $\mathbf{D} = \mathbf{0}$. The equation of motion thus reduces to $-\nabla p = \rho \mathbf{a}$, which can be integrated to give the pressure field

$$p(R,t) = p_{\rm s} + \frac{\rho}{2} \left(v_{\rm s}^2 - v^2 \right), \tag{43}$$

where $v_{\rm s} = v(r_{\rm s})$ is the current membrane velocity, and $p_{\rm s}$ is the pressure acting on the membrane. Neglecting membrane inertia, this pressure equilibrates the membrane stress

$$\sigma = \mu \left(\lambda - \frac{1}{\lambda^3} \right) \tag{44}$$

caused by the membrane stretch $\lambda = r_s/R_s$ according to Eq. (29); see Appendix A. From $p_s = \sigma/r_s$ follows

$$p_{\rm s} = \frac{\mu}{R_{\rm s}} \left[1 - \left(\frac{R_{\rm s}}{r_{\rm s}}\right)^4 \right] \,. \tag{45}$$

3.2 Liquid membrane example: Spinning droplet

As a second example we consider a spinning droplet. This example is considered for comparison with the computational example of a rolling droplet in Sec. 5.2. At very small length scales the influence of gravity is negligible, so that a rolling droplet remains approximately spherical. Considering the axis of rotation to be e_2 , the motion of a spinning droplet can be expressed as

$$\boldsymbol{x}(r,t) = r \, \boldsymbol{e}_r \,, \tag{46}$$

where $e_r = \cos \theta e_1 - \sin \theta e_3$, $\theta = \omega t$ and ω denotes the angular velocity around e_2 . Consequently,

where $e_{\theta} = -\sin \theta e_1 - \cos \theta e_3$. Since we can write $x_1 = r \cos \theta$ and $x_2 = -r \sin \theta$, we find $\nabla v = \omega (e_1 \otimes e_3 - e_3 \otimes e_1)$ such that D = 0 and

$$\boldsymbol{\sigma} = -p\,\mathbf{1}\,.\tag{48}$$

The spin tensor, defined as $\boldsymbol{W} := (\boldsymbol{L} - \boldsymbol{L}^T)/2$, then becomes $\boldsymbol{W} = \boldsymbol{L} = \nabla \boldsymbol{v}$. The axial vector of \boldsymbol{W} , denoted by $\boldsymbol{\omega}$, thus is $\boldsymbol{\omega} = \boldsymbol{\omega} \boldsymbol{e}_2$. It denotes the orientation and magnitude of the droplet's spin, and it is equal to half of the vorticity $\nabla \times \boldsymbol{v}$. Solving Eq. (8) (with $\bar{\boldsymbol{f}} = \boldsymbol{0}$) for p now gives

$$p(r) = \omega^2 \rho \frac{r^2}{2} + p_0 \,. \tag{49}$$

The constant p_0 follows from the boundary condition $p(r_0) = 2\gamma/r_0$, where γ is the surface tension of the droplet and r_0 is the droplet radius. This condition enforces the Young-Laplace equation, which is contained inside Eq. (25), see Sauer (2014). Applying the boundary condition, we find

$$p(r) = \frac{2\gamma}{r_0} - \frac{\rho \,\omega^2}{2} \left(r_0^2 - r^2 \right). \tag{50}$$

If desired, the constant velocity $v_0 = \omega r_0 e_1$ can be added to v(r, t), such that the resulting velocity is zero at the contact point (where $\theta = \pi/2$).

4 Finite element formulation

The coupled fluid-membrane problem of Sec. 2 is solved with the finite element method using the generalized- α scheme. This section presents the required discretization steps and the resulting algebraic equations.

4.1 Spatial discretization

The computational domain is discretized into $n_{\rm el}$ finite elements, numbered $e = 1, ..., n_{\rm el}$. Some of these elements are 3D fluid elements, others are 2D surface elements or 1D line elements. Element e contains n_e nodes and occupies the domain Ω_e in the current configuration. Each fluid element has four degrees-of-freedom (dofs) per node (three velocity components and a pressure), while the membrane elements each have three unknown displacements per node. Each fluid element therefore contributes $4n_e$ force components, while each membrane element contributes $3n_e$ force components that need to be assembled into the global system. Those elemental forces are discussed in the following two sections.

4.1.1 Fluid flow

4.1.1.1 Basic flow variables

Within a fluid element, the fluid velocity is approximated by the interpolation

$$\boldsymbol{v} \approx \boldsymbol{v}^h = \sum_{I=1}^{n_e} N_I \, \boldsymbol{v}_I \,,$$
 (51)

where N_I and \boldsymbol{v}_I are the nodal shape function and nodal velocity, respectively. In short, this can also be written as

$$\boldsymbol{v} \approx \boldsymbol{v}^h = \mathbf{N} \, \mathbf{v}_e \,, \tag{52}$$

where $\mathbf{N} := [N_1 \mathbf{1}, N_2 \mathbf{1}, ..., N_{n_e} \mathbf{1}]$ and $\mathbf{v}_e := [\mathbf{v}_1, \mathbf{v}_2, ..., \mathbf{v}_{n_e}]^{\mathrm{T}}$. The corresponding test function (or variation) is approximated in the same fashion, i.e.

$$\boldsymbol{w} \approx \boldsymbol{w}^h = \mathbf{N} \, \mathbf{w}_e \,. \tag{53}$$

The fluid pressure is approximated by the interpolation

$$p \approx p^h = \mathbf{N} \,\mathbf{p}_e \,, \tag{54}$$

where $\tilde{\mathbf{N}} := [N_1, N_2, ..., N_{n_e}]$. Likewise,

$$q \approx q^h = \mathbf{N} \, \mathbf{q}_e \,. \tag{55}$$

The structure of (52) is also used to interpolate the mesh motion, i.e.

$$\boldsymbol{v}_{\mathrm{m}} \approx \boldsymbol{v}_{\mathrm{m}}^{h} = \mathbf{N} \, \mathbf{v}_{\mathrm{m}e} \,.$$
 (56)

In the present work, the \mathbf{v}_{me} are not treated as unknowns. Instead they will be defined through the membrane motion.

4.1.1.2 Derived flow variables

As a consequence of the above expressions, we find the approximation of the acceleration (from Eq. (7))

$$\dot{\boldsymbol{v}} \approx \dot{\boldsymbol{v}}^h = \mathbf{N} \, \mathbf{v}'_e + \boldsymbol{L} \mathbf{N} \big(\mathbf{v}_e - \mathbf{v}_{\mathrm{m}e} \big) \,,$$
 (57)

the velocity gradient

$$\boldsymbol{L} \approx \boldsymbol{L}^{h} = \sum_{I=1}^{n_{e}} \boldsymbol{v}_{I} \otimes \nabla N_{I} , \qquad (58)$$

the pressure gradient

$$\nabla p \approx \nabla p^h = \mathbf{G} \, \mathbf{p}_e \,, \tag{59}$$

and the velocity divergence

$$\operatorname{div} \boldsymbol{v} \approx \operatorname{div} \boldsymbol{v}^h = \mathbf{D} \, \mathbf{v}_e \,, \tag{60}$$

where

$$\nabla N_I = \begin{bmatrix} N_{I,1} \\ N_{I,2} \\ N_{I,3} \end{bmatrix}, \tag{61}$$

 $\mathbf{G} := [\nabla N_1, \nabla N_2, ..., \nabla N_{n_e}]$ and $\mathbf{D} := [(\nabla N_1)^{\mathrm{T}}, (\nabla N_2)^{\mathrm{T}}, ..., (\nabla N_{n_e})^{\mathrm{T}}]$. Further, we introduce the classical B-matrix $\mathbf{B} := [\mathbf{B}_1, \mathbf{B}_2, ..., \mathbf{B}_{n_e}]$, with

$$\mathbf{B}_{I} := \begin{bmatrix} N_{I,1} & 0 & 0\\ 0 & N_{I,2} & 0\\ 0 & 0 & N_{I,3}\\ 0 & N_{I,3} & N_{I,2}\\ N_{I,3} & 0 & N_{I,1}\\ N_{I,2} & N_{I,1} & 0 \end{bmatrix},$$
(62)

in order to express the symmetric velocity gradient and its corresponding variation in Voigt notation (indicated by index 'v') as

$$\nabla^{s} \boldsymbol{v}_{v} \approx \nabla^{s} \boldsymbol{v}_{v}^{h} = \mathbf{B} \mathbf{v}_{e},$$

$$\nabla^{s} \boldsymbol{w}_{v} \approx \nabla^{s} \boldsymbol{v}_{w}^{h} = \mathbf{B} \mathbf{w}_{e},$$
(63)

i.e. arranged as $\nabla^s \boldsymbol{v}_{v} := [v_{1,1}, v_{2,2}, v_{3,3}, v_{2,3} + v_{3,2}, v_{1,3} + v_{3,1}, v_{1,2} + v_{2,1}]^{\mathrm{T}}$. The stress tensor, arranged as $\sigma_{v} := [\sigma_{11}, \sigma_{22}, \sigma_{33}, \sigma_{23}, \sigma_{13}, \sigma_{12}]$, can thus be written as

$$\boldsymbol{\sigma}_{\mathrm{v}} \approx \boldsymbol{\sigma}_{\mathrm{v}}^{h} = \mathbb{C} \,\mathbf{B} \,\mathbf{v}_{e} - \mathbf{1}_{\mathrm{v}} \,\tilde{\mathbf{N}} \,\mathbf{p}_{e} \,, \tag{64}$$

with $\mathbb{C} := \operatorname{diag}(2\eta \mathbf{1}, \eta \mathbf{1})$ and $\mathbf{1}_{v} = [1, 1, 1, 0, 0, 0]^{\mathrm{T}}$. Here, $\mathbf{1}$ is the usual identity tensor in \mathbb{R}^{3} . Due to the symmetry of the stress and since $\mathbf{B}^{\mathrm{T}}\mathbf{1}_{v} = \mathbf{D}^{\mathrm{T}}$, the integrand of $G_{\mathcal{F}_{\mathrm{int}}}$ becomes

$$\nabla \boldsymbol{w}^{h} : \boldsymbol{\sigma}^{h} = \mathbf{w}_{e}^{\mathrm{T}} \mathbf{B}^{\mathrm{T}} \mathbb{C} \mathbf{B} \mathbf{v}_{e} - \mathbf{w}_{e}^{\mathrm{T}} \mathbf{D}^{\mathrm{T}} \tilde{\mathbf{N}} \mathbf{p}_{e}$$
(65)

within element Ω^e .

In order to represent the SUPG term, we introduce the arrays $\mathbf{B}_{f} := [\mathbf{B}_{f1}, \mathbf{B}_{f2}, ..., \mathbf{B}_{fn_{e}}]$, with the 3×3 blocks

$$\mathbf{B}_{\mathrm{f}I} := \nabla N_I \otimes \boldsymbol{f}_{\mathrm{res}} \,, \tag{66}$$

and $\mathbf{B}_{\mathbf{v}} := [B_{\mathbf{v}1}\mathbf{1}, B_{\mathbf{v}2}\mathbf{1}, ..., B_{\mathbf{v}n_e}\mathbf{1}]$, with

$$B_{\mathbf{v}I} := \nabla N_I \cdot (\boldsymbol{v} - \boldsymbol{v}_{\mathrm{m}}) \,. \tag{67}$$

The last term can also be used to rewrite the $\boldsymbol{L}(\boldsymbol{v}-\boldsymbol{v}_{\mathrm{m}})$ term as

$$\boldsymbol{L}^{h}\left(\boldsymbol{v}^{h}-\boldsymbol{v}_{\mathrm{m}}^{h}\right)=\mathbf{B}_{\mathrm{v}}\mathbf{v}_{e}\,.$$
(68)

4.1.1.3 Weak form contribution of a fluid element

Given the above expressions, the contributions from element Ω^e to the fluid weak form (15) can be written as

$$G_{\mathcal{F}}^{e} + G_{\mathcal{G}}^{e} = \mathbf{w}_{e}^{\mathrm{T}} \mathbf{f}_{\mathcal{F}}^{e} + \mathbf{q}_{e}^{\mathrm{T}} \mathbf{g}^{e} , \qquad (69)$$

with the $(3n_e \times 1)$ FE force vector

$$\mathbf{f}_{\mathcal{F}}^{e} := \begin{cases} \mathbf{f}_{\mathcal{F}\mathrm{in}}^{e} + \mathbf{f}_{\mathcal{F}\mathrm{int}}^{e} + \mathbf{f}_{\mathrm{supg}}^{e} - \mathbf{f}_{\mathcal{F}\mathrm{ext}\bar{f}}^{e} & \text{for } \Omega^{e} \subset \mathcal{F}^{h} ,\\ -\mathbf{f}_{\mathcal{F}\mathrm{ext}\bar{t}}^{e} & \text{for } \Omega^{e} \subset \partial_{t}\mathcal{F}^{h} ,\\ -\mathbf{f}_{\mathcal{F}\mathrm{s}}^{e} & \text{for } \Omega^{e} \subset \mathcal{S}^{h} , \end{cases}$$
(70)

and the $(n_e \times 1)$ FE pseudo force vector

$$\mathbf{g}^e := \mathbf{g}_g^e + \mathbf{g}_{pspg}^e \,. \tag{71}$$

They are composed of the FE forces

$$\begin{aligned} \mathbf{f}_{\mathcal{F}_{in}}^{e} &:= \mathbf{m}_{e} \mathbf{v}_{e}^{\prime} + \mathbf{f}_{con}^{e} ,\\ \mathbf{f}_{con}^{e} &:= \int_{\Omega^{e}} \rho \mathbf{N}^{\mathrm{T}} \mathbf{B}_{v} \mathbf{v}_{e} \, \mathrm{d}v ,\\ \mathbf{f}_{\mathcal{F}_{int}}^{e} &:= \mathbf{c}_{e} \mathbf{v}_{e} - \mathbf{d}_{e} \mathbf{p}_{e} ,\\ \mathbf{f}_{supg}^{e} &:= \int_{\Omega^{e}} \tau_{v} \mathbf{B}_{f}^{\mathrm{T}} (\boldsymbol{v} - \boldsymbol{v}_{m}) \, \mathrm{d}v = \int_{\Omega^{e}} \tau_{v} \mathbf{B}_{v}^{\mathrm{T}} \boldsymbol{f}_{res} \, \mathrm{d}v ,\\ \mathbf{f}_{\mathcal{F}_{s}}^{e} &:= \int_{\Omega^{e}} \mathbf{N}^{\mathrm{T}} \boldsymbol{t} \, \mathrm{d}a ,\\ \mathbf{f}_{\mathcal{F}_{ext}\bar{f}}^{e} &:= \int_{\Omega^{e}} \mathbf{N}^{\mathrm{T}} \, \boldsymbol{\bar{f}} \, \mathrm{d}v \\ \mathbf{f}_{\mathcal{F}_{ext}\bar{t}}^{e} &:= \int_{\Omega^{e}} \mathbf{N}^{\mathrm{T}} \, \boldsymbol{\bar{t}} \, \mathrm{d}a ,\end{aligned}$$

$$(72)$$

the FE pseudo forces

$$\begin{aligned} \mathbf{g}_{\mathrm{g}}^{e} &:= \mathbf{d}_{e}^{\mathrm{T}} \mathbf{v}_{e} \,, \\ \mathbf{g}_{\mathrm{pspg}}^{e} &:= \int_{\Omega^{e}} \tau_{\mathrm{p}} \, \mathbf{G}^{\mathrm{T}} \boldsymbol{f}_{\mathrm{res}} \, \mathrm{d}v \,, \end{aligned}$$
(73)

and the elemental mass, damping and pressure-force matrices

$$\mathbf{m}_{e} := \int_{\Omega^{e}} \rho \, \mathbf{N}^{\mathrm{T}} \mathbf{N} \, \mathrm{d}v \,,$$

$$\mathbf{c}_{e} := \int_{\Omega^{e}} \mathbf{B}^{\mathrm{T}} \, \mathbb{C} \, \mathbf{B} \, \mathrm{d}v \,,$$

$$\mathbf{d}_{e} := \int_{\Omega^{e}} \mathbf{D}^{\mathrm{T}} \tilde{\mathbf{N}} \, \mathrm{d}v \,.$$
(74)

The tangent matrices of $\mathbf{f}_{\mathcal{F}}^e$ and \mathbf{g}^e , needed for linearization, can be found in Appendix B.1.

Remark 4.1: One may simply change the sign of both \mathbf{g}_{g}^{e} and \mathbf{g}_{pspg}^{e} in order to highlight the symmetry between the second part of $\mathbf{f}_{\mathcal{F}int}^{e}$ and \mathbf{g}_{g}^{e} .

4.1.1.4 Stabilization terms

In order to evaluate the residual f_{res} that appears in the stabilization terms \mathbf{f}_{supg}^{e} and \mathbf{g}_{pspg}^{e} , we note that

$$2\operatorname{div} \boldsymbol{D}^{h} = (v_{j,ij}^{h} + v_{i,jj}^{h}) \boldsymbol{e}_{i} = (\mathbf{G}^{2} + \mathbf{H}) \mathbf{v}_{e}, \qquad (75)$$

where $\mathbf{G}^2 := [\mathbf{G}_1^2, \, \mathbf{G}_2^2, \, ..., \, \mathbf{G}_{n_e}^2]$, with

$$\mathbf{G}_{I}^{2} := \nabla(\nabla N_{I}) = \begin{bmatrix} N_{I,11} & N_{I,12} & N_{I,13} \\ N_{I,21} & N_{I,22} & N_{I,23} \\ N_{I,31} & N_{I,32} & N_{I,33} \end{bmatrix}$$
(76)

and $\mathbf{H} := [H_1 \mathbf{1}, H_2 \mathbf{1}, ..., H_{n_e} \mathbf{1}]$, with

$$H_I := \operatorname{tr} \mathbf{G}_I^2 = N_{I,11} + N_{I,22} + N_{I,33} \,. \tag{77}$$

With this we can write

$$\operatorname{div} \boldsymbol{\sigma}^{h} = \eta \, \mathbf{F} \, \mathbf{v}_{e} - \mathbf{G} \, \mathbf{p}_{e} \,, \tag{78}$$

where $\mathbf{F} = \mathbf{G}^2 + \mathbf{H}$. Thus we obtain

$$\boldsymbol{f}_{\text{res}} \approx \boldsymbol{f}_{\text{res}}^{h} = \rho \, \mathbf{N} \, \mathbf{v}_{e}' + \rho \, \mathbf{B}_{v} \mathbf{v}_{e} - \eta \, \mathbf{F} \, \mathbf{v}_{e} + \mathbf{G} \, \mathbf{p}_{e} - \bar{\boldsymbol{f}} \,.$$
(79)

The stabilization parameters $\tau_{\rm v}$ and $\tau_{\rm p}$ appearing inside $\mathbf{f}_{\rm supg}^e$ and $\mathbf{g}_{\rm pspg}^e$ are computed from

$$\tau_{\rm v} = \tau_{\rm p} = \left[\left(\frac{2}{\Delta t} \right)^2 + \left(\frac{2 \| \boldsymbol{v} \|}{m_e \, h_e} \right)^2 + \left(\frac{4\nu}{m_e \, h_e^2} \right)^2 \right]^{-\frac{1}{2}} \tag{80}$$

(Shakib, 1988; Tezduyar, 1992; Rasool et al., 2016), where Δt is the time step size, h_e is the "element length" in the local flow direction taken from

$$\frac{1}{h_e} = \frac{1}{2} \sum_{I=1}^{n_e} \left| \nabla N_I \cdot \frac{\boldsymbol{v}}{\|\boldsymbol{v}\|} \right| \tag{81}$$

(Tezduyar, 1992) and m_e depends on the polynomical order of the shape functions. I.e. for L1 (linear Lagrange) and L2 (quadratic Lagrange) elements we have $m_e = 1/3$ and $m_e = 1/12$, respectively.⁹ According to this, parameters τ_v and τ_p are local parameters that change from quadrature point to quadrature point.

4.1.1.5 Transformation of derivatives

In the above expressions ∇N_I denotes the gradient w.r.t. the current configuration \boldsymbol{x} , which is discretized by $\boldsymbol{x}^h = \sum_I N_I \mathbf{x}_{mI}$, where \mathbf{x}_{mI} are the nodal positions of the FE mesh. Since it is convenient to define the shape functions on a master element in $\boldsymbol{\xi} = [\xi, \eta, \zeta]^T$ space, where $\partial N_I / \partial \boldsymbol{\xi}$ is easily obtained, ∇N_I needs to be determined from

$$\nabla N_I = \frac{\partial N_I}{\partial \boldsymbol{x}} = \boldsymbol{j}^{-\mathrm{T}} \, \frac{\partial N_I}{\partial \boldsymbol{\xi}} \,, \tag{82}$$

⁹In Eqs. (80) and (81), v is taken from the previous time step in order to avoid the linearization of $\tau_{\rm v}$ and $\tau_{\rm p}$.

where

$$\boldsymbol{j} = \frac{\partial \boldsymbol{x}^h}{\partial \boldsymbol{\xi}} = \sum_{I=1}^{n_e} \boldsymbol{x}_{\mathrm{m}I} \otimes \frac{\partial N_I}{\partial \boldsymbol{\xi}}$$
(83)

denotes the Jacobian of the mapping $\boldsymbol{\xi} \to \boldsymbol{x}$. Likewise, the second derivative $\mathbf{G}_I^2 = \nabla(\nabla N_I)$ is obtained from the formula

$$\mathbf{G}_{I}^{2} = \frac{\partial^{2} N_{I}}{\partial \boldsymbol{x} \, \partial \boldsymbol{x}} = \boldsymbol{j}^{-\mathrm{T}} \left[\sum_{J=1}^{n_{e}} \left(\delta_{IJ} - \nabla N_{I} \cdot \boldsymbol{x}_{\mathrm{m}J} \right) \frac{\partial^{2} N_{J}}{\partial \boldsymbol{\xi} \, \partial \boldsymbol{\xi}} \right] \boldsymbol{j}^{-1}$$
(84)

that follows from differentiating (82). Eq. (84) is equivalent to the expression given in Dhatt and Touzot (1984).

4.1.2 Membrane deformation

Following the notation of Eq. (52), the reference position and the current position within a membrane element are approximated by the interpolations

$$\begin{aligned} \mathbf{X} &\approx \mathbf{X}^h = \mathbf{N} \, \mathbf{X}_e \,, \\ \mathbf{x} &\approx \mathbf{x}^h = \mathbf{N} \, \mathbf{x}_e \,, \end{aligned}$$
 (85)

where \mathbf{X}_e and \mathbf{x}_e are arranged just like \mathbf{v}_e . From this follows

$$\begin{aligned}
\mathbf{A}_{\alpha} &\approx \mathbf{A}_{\alpha}^{h} = \mathbf{N}_{,\alpha} \mathbf{X}_{e}, \\
\mathbf{a}_{\alpha} &\approx \mathbf{a}_{\alpha}^{h} = \mathbf{N}_{,\alpha} \mathbf{x}_{e},
\end{aligned} \tag{86}$$

where $\mathbf{N}_{,\alpha} := [N_{1,\alpha}\mathbf{1}, N_{2,\alpha}\mathbf{1}, ..., N_{n_e,\alpha}\mathbf{1}]$. Likewise,

$$\boldsymbol{w}_{,\alpha} \approx \boldsymbol{w}_{,\alpha}^h = \mathbf{N}_{,\alpha} \, \mathbf{w}_e$$
(87)

follows from Eq. (53). Given A_{α} and a_{α} , the metric tensor components $A^{\alpha\beta}$ and $a^{\alpha\beta}$ can be determined and the stress can be evaluated as discussed in Sec. 2.2.

Inserting the discretized expressions for \dot{v} , a_{α} , w and w_{α} into the membrane weak form (34) yields the elemental weak form contribution

$$G^e_{\mathcal{S}} = \mathbf{w}^{\mathrm{T}}_e \, \mathbf{f}^e_{\mathcal{S}} \,, \tag{88}$$

with the $(3n_e \times 1)$ FE force vector

$$\mathbf{f}_{\mathcal{S}}^{e} := \begin{cases} \mathbf{f}_{\mathcal{S}\mathrm{in}}^{e} + \mathbf{f}_{\mathcal{S}\mathrm{int}}^{e} + \mathbf{f}_{\mathrm{c}}^{e} - \mathbf{f}_{\mathcal{S}\mathrm{f}}^{e} - \mathbf{f}_{\mathcal{S}\mathrm{ext}\bar{f}}^{e} & \text{for } \Omega^{e} \subset \mathcal{S}^{h} ,\\ -\mathbf{f}_{\mathcal{S}\mathrm{ext}\bar{t}}^{e} & \text{for } \Omega^{e} \subset \partial_{t}\mathcal{S}^{h} , \end{cases}$$
(89)

that is composed of

$$\begin{aligned} \mathbf{f}_{\mathcal{S}\mathrm{in}}^{e} &:= \int_{\Omega^{e}} \rho_{\mathrm{s}} \mathbf{N}^{\mathrm{T}} \mathbf{N} \, \mathrm{d}v \, \dot{\mathbf{v}}_{e} \,, \\ \mathbf{f}_{\mathcal{S}\mathrm{int}}^{e} &:= \int_{\Omega^{e}} \sigma^{\alpha\beta} \, \mathbf{N}_{,\alpha}^{\mathrm{T}} \, \mathbf{N}_{,\beta} \, \mathrm{d}a \, \mathbf{x}_{e} \,, \\ \mathbf{f}_{\mathrm{c}}^{e} &:= -\int_{\Omega^{e}} \mathbf{N}^{\mathrm{T}} \, \boldsymbol{f}_{\mathrm{c}} \, \mathrm{d}a \,, \\ \mathbf{f}_{\mathcal{S}\mathrm{f}}^{e} &:= \int_{\Omega^{e}} \mathbf{N}^{\mathrm{T}} \, \boldsymbol{f}_{\mathrm{f}} \, \mathrm{d}a \,, \\ \mathbf{f}_{\mathcal{S}\mathrm{ext}\bar{f}}^{e} &:= \int_{\Omega^{e}} \mathbf{N}^{\mathrm{T}} \, \boldsymbol{f}_{\mathrm{f}} \, \mathrm{d}a \,, \\ \mathbf{f}_{\mathcal{S}\mathrm{ext}\bar{f}}^{e} &:= \int_{\Omega^{e}} \mathbf{N}^{\mathrm{T}} \, \boldsymbol{\bar{f}}_{\mathrm{s}} \, \mathrm{d}a \,, \\ \mathbf{f}_{\mathcal{S}\mathrm{ext}\bar{t}}^{e} &:= \int_{\Omega^{e}} \mathbf{N}_{\mathrm{t}}^{\mathrm{T}} \, \boldsymbol{\bar{t}}_{\mathrm{s}} \, \mathrm{d}s \,. \end{aligned}$$

Using a quadrature-point-based contact formulation, the discretization of the contact traction f_c is straight forward (expression (33) is simply evaluated at each quadrature point), but an active set strategy needs to be implemented in order to handle the state changes between contact and no contact (Wriggers, 2006).

The tangent matrix of \mathbf{f}_{S}^{e} , needed for the linearization, can be found in Appendix B.2.

4.1.3 Coupled system

Combining contributions (69) and (88) yields the coupled weak form

$$G^e = \mathbf{w}_e^{\mathrm{T}} \, \mathbf{f}^e + \mathbf{q}_e^{\mathrm{T}} \, \mathbf{g}^e \,, \tag{91}$$

with the $(3n_e \times 1)$ FE force vector

$$\mathbf{f}^{e} := \mathbf{f}_{\mathcal{F}}^{e} + \mathbf{f}_{\mathcal{S}}^{e} = \begin{cases} \mathbf{f}_{\mathcal{F}\mathrm{int}}^{e} + \mathbf{f}_{\mathcal{F}\mathrm{int}}^{e} + \mathbf{f}_{\mathrm{supg}}^{e} - \mathbf{f}_{\mathcal{F}\mathrm{ext}\bar{f}}^{e} & \text{for } \Omega^{e} \subset \mathcal{F}^{h} ,\\ -\mathbf{f}_{\mathcal{F}\mathrm{ext}\bar{t}}^{e} & \text{for } \Omega^{e} \subset \partial_{t}\mathcal{F}^{h} ,\\ \mathbf{f}_{\mathrm{Sin}}^{e} + \mathbf{f}_{\mathrm{Sint}}^{e} + \mathbf{f}_{\mathrm{c}}^{e} - \mathbf{f}_{\mathcal{S}\mathrm{ext}\bar{f}}^{e} & \text{for } \Omega^{e} \subset \mathcal{S}^{h} ,\\ -\mathbf{f}_{\mathcal{S}\mathrm{ext}\bar{t}}^{e} & \text{for } \Omega^{e} \subset \partial_{t}\mathcal{S}^{h} . \end{cases}$$
(92)

It can be seen that for a conforming FE discretization of surface S, such as is considered here, coupling condition (37) implies that the force vector \mathbf{f}_{Sf}^e of a membrane element cancels exactly with $\mathbf{f}_{\mathcal{F}_S}^e$ of the corresponding fluid boundary element. In the coupled system, both \mathbf{f}_{Sf}^e and $\mathbf{f}_{\mathcal{F}_S}^e$ therefore do not appear anymore.

4.1.4 Double pressure nodes

Since the membrane is described here as a 2D surface that is discretized by 2D surface finite elements, the membrane nodes carry a special role. Unless the membrane is located at the boundary of the fluid, it is surround by fluid on both sides and generally supports pressure jumps. A finite element node on S^h therefore must carry two pressure dofs. One for each side of the membrane. Otherwise, the formulation does not properly account for pressure jumps. This is especially important for flexible membranes, where pressure jumps tend to become large. In practice, each FE node on S^h that is not located at boundary ∂S^h (where both fluid sides connect), is assigned two pressure dofs.¹⁰ When the elemental connectivity is then set up, care has to be taken in order to connect the element on each side of S^h with the correct dofs.

As long as a no-slip condition is considered on both sides of S, as is done here, the velocity field is continuous across S and no extra velocity degrees of freedom are needed on S^h .

4.2 Temporal discretization

The elemental force vectors \mathbf{f}^e and \mathbf{g}^e are assembled into the global vectors

$$\mathbf{f} = \mathbf{f}_{\mathcal{F}in} + \mathbf{f}_{\mathcal{S}in} + \mathbf{f}_{\mathcal{F}int} + \mathbf{f}_{\mathcal{S}int} + \mathbf{f}_{c} + \mathbf{f}_{supg} - \mathbf{f}_{ext}$$
(93)

and

$$\mathbf{g} = \mathbf{g}_{g} + \mathbf{g}_{pspg} \,, \tag{94}$$

¹⁰Tezduyar and Sathe (2007) propose to also use double pressure dofs at the boundary of ∂S^h in order to provide additional numerical stability.

where $\mathbf{f}_{\text{ext}} := \mathbf{f}_{\mathcal{F}\text{ext}\bar{f}} + \mathbf{f}_{\mathcal{F}\text{ext}\bar{f}} + \mathbf{f}_{\mathcal{S}\text{ext}\bar{f}}$. The former can be written as $\mathbf{f} = [\mathbf{f}_{\text{br}}^{\text{T}}, \mathbf{f}_{\text{r}}^{\text{T}}]^{\text{T}}$, where \mathbf{f}_{br} are the boundary reactions of the nodes on $\partial_{\hat{x}}\mathcal{F}$ and $\partial_x\mathcal{S}$, and \mathbf{f}_{r} are the residual forces of all the remaining nodes. Accordingly, the global residual vector

$$\mathbf{r} := \begin{bmatrix} \mathbf{f}_{\mathrm{r}} \\ \mathbf{g} \end{bmatrix},\tag{95}$$

can be defined. The finite element forces are in equilibrium if $\mathbf{r} = \mathbf{0}$. In general, $\mathbf{r} = \mathbf{0}$ is a coupled system of ordinary differential equations for the unknown nodal positions $\mathbf{x} := [\mathbf{x}_I]$, velocities $\mathbf{v} := [\mathbf{v}_I]$, accelerations $\mathbf{a} := [\mathbf{v}_I']$ (for fixed \mathbf{x}) and pressures $\mathbf{p} := [p_I]$, for $I = 1, ..., n_{no}$, that are all functions of time. The generalized- α scheme (Chung and Hulbert, 1993; Jansen et al., 2000; Cottrell et al., 2009) is used to discretize $\mathbf{r} = \mathbf{0}$ in time. Instead of solving for the functions $\mathbf{x}(t)$, $\mathbf{v}(t)$, $\mathbf{a}(t)$ and $\mathbf{p}(t)$, the approximations $\mathbf{x}^n \approx \mathbf{x}(t_n)$, $\mathbf{v}^n \approx \mathbf{v}(t_n)$, $\mathbf{a}^n \approx \mathbf{a}(t_n)$ and $\mathbf{p}^n \approx \mathbf{p}(t_n)$ are determined at discrete time steps t_n , $n = 0, ..., n_t$. This is based on the Newmark update formulas for step $t_n \to t_{n+1}$

$$\mathbf{x}^{n+1} = \mathbf{x}^n + \Delta t \, \mathbf{v}^n + \frac{\Delta t^2}{2} \left((1 - 2\beta) \, \mathbf{a}^n + 2\beta \, \mathbf{a}^{n+1} \right),$$

$$\mathbf{v}^{n+1} = \mathbf{v}^n + \Delta t \left((1 - \gamma) \, \mathbf{a}^n + \gamma \, \mathbf{a}^{n+1} \right),$$

(96)

where β and γ are non-dimensional parameters.¹¹ According to the generalized- α scheme, **r** is then evaluated for **p**^{*n*+1} and

$$\mathbf{x}^{n+\alpha_{\rm f}} = \mathbf{x}^n + \alpha_{\rm f} \left(\mathbf{x}^{n+1} - \mathbf{x}^n \right),$$

$$\mathbf{v}^{n+\alpha_{\rm f}} = \mathbf{v}^n + \alpha_{\rm f} \left(\mathbf{v}^{n+1} - \mathbf{v}^n \right),$$

$$\mathbf{a}^{n+\alpha_{\rm m}} = \mathbf{a}^n + \alpha_{\rm m} \left(\mathbf{a}^{n+1} - \mathbf{a}^n \right),$$
(97)

where $0<\alpha_m\leq 1$ and $0<\alpha_f\leq 1$ are chosen parameters. 12 The global force vectors thus take the form

$$\mathbf{f} = \mathbf{f}_{\mathcal{F}in}(\mathbf{a}^{n+\alpha_{m}}, \mathbf{v}^{n+\alpha_{f}}) + \mathbf{f}_{\mathcal{S}in}(\mathbf{a}^{n+\alpha_{m}}) + \mathbf{f}_{\mathcal{F}int}(\mathbf{v}^{n+\alpha_{f}}, \mathbf{p}^{n+1}) + \mathbf{f}_{\mathcal{S}int}(\mathbf{x}^{n+\alpha_{f}}) + \mathbf{f}_{c}(\mathbf{x}^{n+\alpha_{f}}) + \mathbf{f}_{supg}(\mathbf{a}^{n+\alpha_{m}}, \mathbf{v}^{n+\alpha_{f}}, \mathbf{p}^{n+1}) - \mathbf{f}_{ext},$$

$$\mathbf{g} = \mathbf{g}_{g}(\mathbf{v}^{n+\alpha_{f}}) + \mathbf{g}_{pspg}(\mathbf{a}^{n+\alpha_{m}}, \mathbf{v}^{n+\alpha_{f}}, \mathbf{p}^{n+1}).$$
(98)

The temporal inconsistency that is introduced if $\alpha_m \neq \alpha_f \neq 1$ is a deliberate feature of the generalized- α method. The system $\mathbf{r} = \mathbf{0}$ thus reduces to a system of algebraic equations that can be solved for \mathbf{x}^{n+1} , \mathbf{v}^{n+1} , \mathbf{a}^{n+1} and \mathbf{p}^{n+1} given the previous values \mathbf{x}^n , \mathbf{v}^n , \mathbf{a}^n and \mathbf{p}^n . One option is to pick $\mathbf{u} := [\mathbf{v}, \mathbf{p}]$ as the primary unknowns, solve $\mathbf{r} = \mathbf{0}$ for \mathbf{u}^{n+1} , and then obtain \mathbf{a}^{n+1} and \mathbf{x}^{n+1} (which is really only needed for the membrane nodes) from (96). Since the system $\mathbf{r} = \mathbf{0}$ is non-linear, the Newton-Raphson method is used.¹³ This requires the tangent matrix \mathbf{k} that is assembled from the elemental entries

$$\mathbf{k}^e := \frac{\partial \mathbf{r}^e}{\partial \mathbf{u}_e^{n+1}} \,. \tag{99}$$

It is given in Appendix C for the considered fluid and membrane elements. In the following computations, the Newmark parameters are taken as (Chung and Hulbert, 1993)

$$\gamma = \frac{1}{2} - \alpha_{\rm f} + \alpha_{\rm m},$$

$$\beta = \frac{1}{4} (1 - \alpha_{\rm f} + \alpha_{\rm m})^2$$
(100)

¹¹They should not be confused with the physical parameters β and γ used for the surface inclination and surface tension in other sections.

¹²Note that the α introduced by Chung and Hulbert (1993) corresponds to $1 - \alpha$ here.

 $^{^{13}}$ A direct sparse solver is used in all subsequent examples apart from the finest droplet discretization in Sec. 5.2, which uses the conjugate gradient method preconditioned by an incomplete LU factorization.

using the generalized- α parameters¹⁴

$$\alpha_{\rm f} = \frac{2}{3}, \quad \alpha_{\rm m} = \frac{5}{6}.$$
(101)

This choice ensures second order accuracy in time and unconditional stability (for linear problems).

4.3 Normalization

In order to implement the above expressions within a computer code^{15} they have to be normalized. The normalization can also help to improve the conditioning of the monolithic system of equations. We therefore chose a length scale L_0 , time scale T_0 and force F_0 , and use those to normalize all lengths, times and forces in the system. Velocities, masses, fluid densities, fluid viscosities, fluid pressures, membrane densities and membrane stresses are then normalized by the scales

$$v_0 := \frac{L_0}{T_0}, \quad m_0 := \frac{F_0 T_0^2}{L_0}, \quad \rho_0 := \frac{m_0}{L_0^3}, \quad \eta_0 := \frac{F_0 T_0}{L_0^2}, \quad p_0 := \frac{F_0}{L_0^2}, \quad \rho_0^{\mathrm{s}} := \frac{m_0}{L_0^2}, \quad \gamma_0 := \frac{F_0}{L_0}.$$
(102)

System (98) can then be expressed in the normalized form

$$\bar{\mathbf{f}}(\bar{\mathbf{u}}^{n+1}) = \bar{\mathbf{f}}_{\mathcal{F}\mathrm{in}} + \bar{\mathbf{f}}_{\mathcal{S}\mathrm{in}} + \bar{\mathbf{f}}_{\mathcal{F}\mathrm{int}} + \bar{\mathbf{f}}_{\mathrm{S}\mathrm{int}} + \bar{\mathbf{f}}_{\mathrm{c}} + \bar{\mathbf{f}}_{\mathrm{supg}} - \bar{\mathbf{f}}_{\mathrm{ext}},
\bar{\mathbf{g}}(\bar{\mathbf{u}}^{n+1}) = \bar{\mathbf{g}}_{\mathrm{g}} + \bar{\mathbf{g}}_{\mathrm{pspg}},$$
(103)

where a bar denotes normalization with the corresponding scale from above, e.g.

$$\bar{\mathbf{f}}^e_{\mathcal{F}\mathrm{in}} = \bar{\mathbf{m}}_e \, \bar{\mathbf{a}}_e + \bar{\mathbf{f}}^e_{\mathrm{con}} \,, \tag{104}$$

with

$$\bar{\mathbf{m}}_{e} := \int_{\bar{\Omega}^{e}} \bar{\rho} \, \mathbf{N}^{T} \mathbf{N} \, \mathrm{d}\bar{v} \,,$$

$$\bar{\mathbf{f}}_{\mathrm{con}}^{e} := \int_{\bar{\Omega}^{e}} \bar{\rho} \, \mathbf{N}^{T} \bar{\mathbf{B}}_{\mathrm{v}} \, \bar{\mathbf{v}}_{e} \, \mathrm{d}\bar{v} \,,$$
(105)

and $\bar{\rho} = \rho/\rho_0$, $d\bar{v} = dv/L_0^3$, $\bar{\mathbf{B}}_v = \mathbf{B}_v T_0$, $\bar{\mathbf{v}}_e = \mathbf{v}_e/v_0$ and $\bar{\mathbf{a}}_e = \mathbf{a}_e T_0/v_0$. All the other quantities appearing in (103) are normalized in the same fashion. Solving (103) then gives the normalized unknowns $\bar{\mathbf{v}} = \mathbf{v}/v_0$ and $\bar{\mathbf{p}} = \mathbf{p}/p_0$, while (96) can be solved for $\bar{\mathbf{x}} = \mathbf{x}/L_0$ and $\bar{\mathbf{a}} = \mathbf{a} T_0/v_0$.

4.4 Mesh motion

Apart from the unknown material velocity \mathbf{v} and pressure \mathbf{p} , the discrete mesh velocity \mathbf{v}_{m} can also be regarded as an unknown. In that case suitable (differential) equations have to be formulated for \mathbf{v}_{m} . A simpler approach is to determine the mesh velocity from the membrane velocity using linear interpolation: On the membrane surface the mesh motion is considered Lagrangian, i.e. $\mathbf{v}_{m} = \mathbf{v}$, whereas it is treated Eulerian ($\mathbf{v}_{m} = \mathbf{0}$) beyond a certain distance from the membrane. In-between, simple linear interpolation is used. Details of this are reported in the following examples. Linear interpolation, and ALE in general, does not work for some FSI problems. An example are solids revolving within the fluid. For such cases, other techniques need to be considered.

¹⁴They are obtained taking a spectral radius of $\rho_{\infty} = \frac{1}{2}$ for the first order system, see Jansen et al. (2000).

¹⁵In this work a self-written parallel Matlab code is used on a 12-core Apple workstation (2x 2.66 GHz 6-Core Intel Xeon, 64 GB DDR3 RAM).

5 Numerical examples

This section presents three numerical examples that range from very low to quite large Reynolds numbers. The first example considers a solid membrane (with no bending resistance), the second example considers a liquid membrane, and the third example considers a solid shell with low bending resistance. The examples exhibit large membrane deformations that lead to strong FSI coupling.

5.1 Fluid-inflated cylinder

The first numerical example considers the radial inflation of a cylindrical membrane due to radial inflow. The numerical solution will be compared to the analytical solution derived in Sec. 3.1. The initial inner radius of the cylinder $R_{\rm in}$, the maximum inflow velocity v_0 and the fluid density ρ are used for normalization, such that $L_0 = R_{\rm in}$, $T_0 = R_{\rm in}/v_0$ and $\rho_0 = \rho$. The outer radius of the membrane at initialization time t = 0 is taken as $R_{\rm s} = 2L_0$. Computationally, only a quarter of the cylindrical domain is modelled with a chosen height of $H = L_0$. Sliding wall conditions¹⁶ are applied to all fluid boundaries except the membrane surface, where coupling conditions apply, and the inflow boundary, where the radial inflow velocity

$$v_{\rm in}(t) = v_0 \begin{cases} \left(1 - \cos(\pi t/T_0)\right)/2 & \text{for } t < T_0 \\ 1 & \text{else} \end{cases}$$
(106)

is prescribed. The Reynolds number, $Re = \rho v_{\rm in} L_0/\eta$, is chosen as Re = 100 guaranteeing a purely laminar flow. For water at room temperature ($\rho \approx 1000 \, {\rm kg/m^3}$, $\eta = 1.00 \, {\rm mNs/m^2}$) this implies $v_0 = 10 \, {\rm m/s}$. The membrane is modelled as a massless, incompressible Neo-Hookean, rubber-like material according to (29). The membrane's nondimensional shear stiffness is taken as $\bar{\mu} = 0.1$. The fluid domain is discretized by $N_{\rm f} = n_r \times n_{\theta} \times 1$ quadratic volume elements in e_r , e_{θ} and e_3 direction (see Fig. 1), while the membrane domain is discretized by $N_{\rm s} = n_{\theta} \times 1$ quadratic surface elements along e_{θ} and e_3 . Tab. 1 shows the considered meshes. The time step

total elements	fluid elements	membrane elements	nodes	dofs
7	$6 \times 1 \times 1$	1×1	117	495
42	$13 \times 3 \times 1$	3×1	567	$2,\!331$
100	$24 \times 4 \times 1$	4×1	$1,\!323$	$5,\!373$

Table 1: Fluid-inflated cylinder: Considered FE meshes based on quadratic Lagrange elements.

is chosen as $\Delta \bar{t} = 0.0025$ for all cases. The radial mesh velocity at time step t_{n+1} is defined by the linear interpolation

$$v_{\rm m}(R, t_{n+1}) = \frac{R - R_{\rm in}}{R_{\rm s} - R_{\rm in}} v_{\rm s}(t_n) , \qquad (107)$$

where $v_{\rm s}(t_n)$ is the cylinder's radial velocity at the previous time step.

Fig. 2 shows the radial flow field and the membrane displacement due to the cylinder inflation at different time steps. The solid membrane is stretched by more than a factor of 3. For the membrane displacement (Fig. 3) and velocity (Fig. 4) the numerical result is in perfect agreement with the analytical solution derived in Sec. 3.1; see Eqs. (39) & (40). For the pressure shown in Fig. 5 we observe deviations from the analytical result (43) during the transient part and again nearly perfect agreement at the final simulation time. The numerical results improve

¹⁶The normal velocity and the tangential traction are set to zero.

Figure 2: Fluid-inflated cylinder: Radial flow field $\bar{v} = v/v_0$ and cylinder expansion at various time steps. Computationally, only a quarter of the system is modelled.

Figure 3: Fluid-inflated cylinder: (a) Membrane position $\bar{r} = r/L_0$ vs. time $\bar{t} = t/T_0$. (Analytical result: green \times , FE solution: red +). (b) Numerical error (L²-norm) vs. total number of L2 elements (radius r: red +, velocity v: green \times , acceleration a: blue \star , pressure p: magenta \square) at $R = R_s$ and $\bar{t} = 21$. The dash-dotted line marks quadratic convergence behavior.

Figure 4: Fluid-inflated cylinder: (a) Normalized membrane velocity vs. time; (b) Normalized fluid velocity vs. radial position at $t = 21 T_0$. (Analytical result: green ×, FE solution: red +)

for a higher mesh resolution. The finite element discretization and its implementation shows quadratic convergence behavior as expected, see Fig. 3b.

Figure 5: Fluid-inflated cylinder: (a) Normalized membrane pressure vs. time; (b) Normalized fluid pressure vs. radial position at $t = 21 T_0$. (Analytical result: green ×, FE solution: red +)

5.2 Rolling droplet

The second example simulates rolling contact of a liquid droplet on an inclined substrate considering a low Reynolds number and a contact angle of 180°. As we expect the motion to come close to the spinning solution of Sec. 3.2, a purely Lagrangian FE description is chosen $(v_m = v)$. This also allows to use a classical contact description between droplet and substrate. There is earlier computational work on rolling droplets (Rasool et al., 2012; Li et al., 2013; Thampi et al., 2013; Wind-Willassen and Sørensen, 2014). But it is either 2D, or non-FE. So the present study seems to be the first 3D FE simulation of rolling droplets. Novel is also the way contact is treated here – by using a computational contact algorithm with an active-set strategy. Within that, a no-slip (sticking) condition is assumed on the contact surface, i.e. (31). If slip occurs, a stick-slip algorithm is needed for the droplet (Sauer, 2016).

The droplet setup considers similar parameters as in Sauer (2016): An initially spherical droplet with radius $R = L_0$ and volume $V = 4\pi L_0^3/3$ is considered under gravity loading, such that $\rho g L_0^3 = \gamma L_0$. For water at room temperature, with $\rho = 1000 \text{ kg/m}^3$, $g = 9.81 \text{ m/s}^2$ and $\gamma = 72.8 \text{ mN/m}$, this corresponds to a droplet with $L_0 = 2.72 \text{ mm}$ and $V = 84.6 \,\mu$ l. The droplet surface has no additional mass, and so $\rho_s = 0$. For further normalization we choose $g_0 = g$ and $\gamma_0 = \gamma$, so that $T_0 = 16.7 \text{ ms}$, $F_0 = 0.198 \text{ mN}$ and $p_0 = 26.7 \text{ Pa}$. A high fluid viscosity is chosen, i.e. $\eta = 11.9 \text{ Ns/m}^2$, such that the Reynolds number becomes very small. A suitable definition for the Reynolds number of a rolling droplet is

$$Re = \frac{\rho L_{\rm c} \, v_{\rm mean}}{\eta} \,, \tag{108}$$

where L_c is the diameter of the contact surface and v_{mean} is the mean droplet velocity. The penalty parameter for sticking according to contact model (33) is taken as $\epsilon_c = 250 m^2 p_0/L_0$, where *m* characterizes the FE resolution according to Tab. 2. Quadratic Lagrange elements are used. The computational runtime per time step (accounting for residual and tangent matrix assembly, contact computation and Newton-Raphson iteration) is about 1 min. for m = 4, 20 mins. for m = 8 and 100 mins. for m = 16.

Initially the droplet is at rest. Rolling motion is then induced by inclining the substrate con-

m	fluid elements	membrane elements	nodes	dofs
2	128	48	1,241	4,964
4	832	192	$7,\!407$	$29,\!628$
8	6,656	768	$56,\!157$	$224,\!628$
16	53,248	3,072	437,433	1,749,732

Table 2: Rolling droplet: Considered FE meshes based on quadratic Lagrange elements.

sidering the time-varying inclination angle

$$\beta(t) = \frac{\beta_0}{2} \begin{cases} 1 - \cos\frac{\pi t}{t_1} & \text{for } 0 \le t < t_1, \\ 2 & \text{for } t_1 \le t \le t_2, \\ 1 + \cos\frac{\pi(t - t_2)}{t_1} & \text{for } t_2 \le t \le t_1 + t_2, \\ 0 & \text{for } t_1 + t_2 < t \le t_3, \end{cases}$$
(109)

with $t_1 = 50 T_0$, $t_2 = 200 T_0$, $t_3 = 350 T_0$ and the two cases: 1. $\beta_0 = 10^\circ$ with $\Delta t = 8 T_0/m$, and

2. $\beta_0 = 20^{\circ}$ with $\Delta t = 4 T_0/m$.

Fig. 6 shows the finite element results for the mean droplet velocity v_{mean} for the two cases.¹⁷ As

Figure 6: Rolling droplet: Mean droplet velocity vs. time for $\beta_0 = 10^{\circ}$ and $\beta_0 = 20^{\circ}$ using the meshes from Tab. 2. The right hand side shows an enlargment for $\beta_0 = 20^{\circ}$. As seen, the FE results converge upon mesh refinement.

seen the FE results converge upon mesh refinement. The figure also shows that steady rolling motion is attained at about $t = 150 T_0$ for $\beta_0 = 20^\circ$, while it is attained almost instantaneously for $\beta_0 = 10^\circ$ (i.e. at $t = t_1$). The instantaneous response of v_{mean} on β , for low β_0 , can be also seen from the $v_{\text{mean}}(\beta)$ -plot in Fig. 7. Both branches (for increasing β and decreasing β , respectively) are almost identical. For $\beta_0 = 20^\circ$ on the other hand, the two branches are different.

For further illustration, Fig. 8 shows the droplet deformation and velocity field ||v|| during rolling. The deformation is considerable and should not be neglected, as has been done in earlier work (Rasool et al., 2012, 2013). The figure also shows how the contact surface changes.

¹⁷The mean droplet velocity v_{mean} is determined by computing the volume average of the fluid velocity v and then taking its component parallel to the substrate surface.

Figure 7: Rolling droplet: Mean droplet velocity vs. β for $\beta_0 = 10^\circ$ (a) and $\beta_0 = 20^\circ$ (b) using m = 16. The return branch (for decreasing β) is marked by a dashed line.

Figure 8: Rolling droplet: Velocity magnitude $\|\boldsymbol{v}\|/v_0$ at t = 0, $t = 50 T_0$, $t = 100 T_0$, $t = 200 T_0$ and $t = 350 T_0$ (left to right) for $\beta_0 = 20^\circ$ and m = 8. Only half of the symmetric droplet is shown. In the top panel the symmetry surface is removed and instead a selected material plane is tracked during deformation. A single fluid particle is marked by ' \circ '.

Initially the contact surface is circular with a diameter of $L_c = 1.36 L_0$. During steady rolling the diameter in rolling direction reduces to $L_c = 1.04 L_0$. Since $v_{\text{mean}} = 0.0268 L_0/T_0$, the Reynolds number thus becomes $Re = 1.04 \cdot 10^{-3}$ according to (108). Fig. 8 clearly shows that the advancing and receding droplet halves are not symmetric during rolling.

This can also be seen from the pressure distribution shown in Fig. 9. The fluid pressure is largest at the advancing front of the contact surface. Since the contact surface is flat, the fluid pressure is equal to the contact pressure. Close inspection shows that the pressure is oscillatory in the vicinity of the contact line C. Those oscillations do not converge with mesh refinement, as the velocity field does. So it seems that the pressure stabilization scheme, described in Sec. 2.1.4, is not sufficient to handle the contact boundary of a rolling droplet, even though the static droplet (at t = 0 and $t = 350 T_0$) poses no problem. The problem may be related to the discontinuity of the contact pressure: it jumps to zero at the contact boundary. The way the fluid velocity, fluid pressure and contact pressure are interpolated (quadratic Lagrange interpolation is used here) seem incompatible. It seems that this problem has not yet been addressed in the literature. Further study is required on the topic. Perhaps C^1 -continuous interpolation, such as is provided by NURBS, would help. We note that for $\beta = 10^\circ$, pressure oscillations also appear, but they are less pronounced.

To remove the pressure oscillations, Gaussian smoothing can be used for post-processing. Se-

Figure 9: Rolling droplet: pressure field p/p_0 at t = 0, $t = 50 T_0$, $t = 100 T_0$, $t = 200 T_0$ and $t = 350 T_0$ (left to right) for $\beta_0 = 20^\circ$ and m = 8

lecting the variance of the Gaussian distribution as $\sigma = 1/m$, i.e. on the order of the nodal distance, gives non-oscillatory pressures; see Fig. 10. The smoothed pressure converges with

Figure 10: Rolling droplet: smoothed pressure field at t = 0, $t = 50 T_0$, $t = 100 T_0$, $t = 200 T_0$ and $t = 350 T_0$ (left to right) for $\beta_0 = 20^\circ$ and m = 8. See also supplementary movie file drop_roll_p.mpg.

mesh refinement. The pressure distribution shows that the advancing contact surface carries most of the droplet weight (component $\cos \beta \times \rho g V$). Component $\sin \beta \times \rho g V$ is equilibrated by a tangential sticking force. The moment caused by these external forces is equilibrated by the internal moment of the fluid stress.

The last plot shows the vorticity (i.e. spin) component $2\omega_2 := e_2 \cdot (\nabla \times v)$ (along the axis of rotation e_2) and the dissipation $\mathcal{D} = \boldsymbol{\sigma} : \boldsymbol{D}$ during rolling; see Fig. 11. Also here smoothing is used.

Figure 11: Rolling droplet: a. smoothed vorticity component $2\omega_2$ at $t = 50 T_0$ and $t = 200 T_0$; b. smoothed dissipation $\mathcal{D} = \boldsymbol{\sigma} : \boldsymbol{D}$ at $t = 50 T_0$ and $t = 200 T_0$; both for $\beta_0 = 20^\circ$ and m = 8. The units of $2\omega_2$ are $1/T_0$; the units of \mathcal{D} are p_0/T_0 .

According to Sec. 3.2 the vorticity of a spinning sphere is a constant vector with magnitude 2ω . In contrast, the vorticity of a rolling droplet is non-constant: A maximum is attained at the contact boundary and a minimum occurs on the contact surface. Although, away from the contact surface, the vorticity approaches a constant. The behavior is similar for the dissipation: Away from the contact surface, the dissipation is zero and thus agrees with the spinning sphere solution. Non-zero dissipation, associated with shear flow, occurs in the vicinity of the contact surface, with a maximum occurring at the advancing contact front. For longer rolling droplets, or for higher β , the shear flow becomes more pronounced, such that an ALE formulation is needed for the mesh. On the free surface (which is tracked explicitly within the present scheme) such a formulation needs to be Lagrangian in the normal direction but Eulerian in-plane. The formulation of such an ALE scheme is outside the present scope.

5.3 Flapping flag

The third example simulates the flapping motion of a flag. The problem setup of this example is shown in Fig. 12. The flag is modeled as a flexible sheet that is supported on the left hand

Figure 12: Flapping flag: Side, top and front view of the problem setup. The flag is fixed on the left and its lateral displacement and velocity are monitored at point A.

side. It is excited by a uniform inflow with velocity $v_{\rm in}$. The length scale L_0 , the fluid density ρ_0 and the time scale T_0 are used to normalize the problem. The remaining parameters are chosen according to Tab. 3. Considering $L_0 = 0.1$ m, $T_0 = 1$ s and $\rho_0 = 1.2 \text{ kg/m}^3$, the fluid

parameter	normalized value	
inflow velocity	$\bar{v}_{\rm in} = 1$	
density of the fluid	$\bar{\rho} = 1$	
viscosity of the fluid	$\bar{\eta} = 1.531 \cdot 10^{-3}$	
density of the flag	$\bar{\rho}_{\rm s} = 1$	
shear stiffness of the flag	$\bar{\mu}=4.167\cdot 10^3$	
bending stiffness of the flag	$\bar{c} = 0.02$	

Table 3: Flapping flag: Considered inflow and material parameters.

parameters become $\rho = \rho_0$ and $\eta = 18.37 \,\mu \text{Ns/m}^2$, which correspond to the values of air at sea level and 20°C, while the flag parameters become $\rho_s = 0.12 \,\text{kg/m}^2$, $\mu = 5 \,\text{N/m}$ and $c = 0.24 \,\mu \text{Nm}$

according to Sec. 4.3.¹⁸ The Reynolds number of the problem is

$$Re = \frac{\rho L_{\rm c} v_{\rm in}}{\eta} \,, \tag{110}$$

where L_c is the chord length of the flag. For $L_c = 3L_0$ and the considered ρ and η follows $Re = 1960 \bar{v}_{in}$. At this Re and density ratio¹⁹, the flag motion can be expected to be chaotic according to the phase diagram of Connell and Yue (2007).

The flapping flag example is a good test case since the flag motion and the surrounding flow field can become very complex, as the experimental data reported in Shelley and Zhang (2011) show. There have been recent 3D simulations that study the problem in detail (Hoffman et al., 2011; Banerjee et al., 2015; Gilmanov et al., 2015; de Tullio and Pascazio, 2016). In some of those works immersed boundary methods are used instead of ALE. Such methods are advantageous for very large flag motions that may even involve self-contact. In contrast to earlier work, the flag is discretized here with C^1 -continuous isogeometric shell elements. Their formulation is the same as the one of Eq. (90) with the only exception that \mathbf{f}_{Sint}^e is extended by the internal bending moments according to the formulation of Duong et al. (2017) using the Canham bending model. A shell formulation is used in order to regularize the system with bending stiffness. A low stiffness value is used such that the structure remains very flexible. Below a certain threshold value of c, the flapping behavior becomes independent of c as is shown later.

The fluid domain is discretized with $n_{\mathcal{F}el} = 8m \times 2m \times 4m$ quadratic 3D NURBS elements, while the flag is discretized with $n_{\mathcal{S}el} = 3m \times 2m$ quadratic 2D NURBS elements. The number of nodes and dofs resulting from this discretization²⁰ are listed in Tab. 4. On the surface of

m	fluid elements	membrane elements	nodes	dofs
2	512	24	$1,\!680$	6,744
4	4096	96	$7,\!920$	31,776
8	32,768	384	$46,\!512$	$186,\!432$

Table 4: Flapping flag: Considered FE meshes based on quadratic NURBS elements.

the flag, double pressure dofs are used to account for pressure jumps as described in Sec. 4.1.4. The time step is taken as $\Delta t = 0.16 T_0/m$. The computational runtime per time step is about 3 mins. for m = 4 and 25 mins. for m = 8.

Fig. 13 shows the flag deformation at selected time steps. Those are snap-shots of the supple-

Figure 13: Flapping flag: Deformation at t = 44.36 s, t = 44.92 s, t = 45.48 s, t = 46.04 s and t = 46.60 s (left to right) for m = 8; see also supplementary movie file flag_v.mpg. The coloring shows the lateral velocity component in the range $\{-1, 1\}v_0$ (from blue to red). The streamlines of the flow are also shown.

mentary movie file flag_v.mpg. As expected, the structure performs flag-typical oscillations

¹⁸Following Sec. 4.3, the bending stiffness needs to be normalized by $c_0 = F_0 L_0$, where $F_0 = \rho_0 L_0^4/T_0^2$.

¹⁹The density ratio $R_1 := \rho_s/(\rho L_c)$, as defined in Shelley and Zhang (2011), is 1/3 here.

²⁰The number of nodes is $n_{no} = (8m + 4)(2m + 3)(4m + 4)$; the number of dofs is $n_{dof} = 4n_{no} + n_{Sel}$, due to the double pressure nodes on the flag surface.

along its length. Close inspection shows that the flag motion also varies in vertical direction. The pressure field around the flag is shown in Fig. 14. The figure also shows the mesh motion

Figure 14: Flapping flag: Fluid pressure in the mid-plane at t = 44.36 s, t = 44.92 s, t = 45.48 s, t = 46.04 s, t = 46.60 s and t = 47.16 s (top left to bottom right) for m = 8. The coloring is in the range $\{-.7, 1.2\}p_0$ (from blue to red).

around the flag. It is based on the interpolation scheme given in App. D. For the chosen parameters, the flapping behavior is still (quite) periodic, as Fig. 15 shows. The

Figure 15: Flapping flag: Lateral displacement (a) and velocity (b) at point A for various FE discretizations. Symbol ' \circ ' marks the configurations shown in Fig. 13.

period of the main oscillation is 5.60 s. Apart from the main oscillations, there are also fine scale oscillations, as Fig. 15b shows. Fig. 15 also shows that the simulation results converge with mesh refinement. For the first 20 seconds, mesh m = 4 already gives quite good results.

The model parameters of Tab. 3 affect the flapping behavior of the flag. The influence of Re has been discussed in detail in earlier work, e.g. see Shelley and Zhang (2011), so the following discussion focuses on the membrane parameters. Three aspects are noteworthy:

1. For sufficiently low c, the flapping behavior (for given Re) remains unchanged, i.e. it becomes independent of c. According to Fig. 16a this occurs below $\bar{c} \approx 10^{-3}$. Below that c, the flag is effectively a membrane without bending stiffness, and c is only helpful for regularizing the numerical solution.

2. Increasing μ leads to increased fine scale oscillations, as Fig. 16b shows. Since μ controls the in-plane stiffness of the flag, those oscillations can be associated with longitudinal vibrations of the flag.

3. Increasing the ratio between fluid and membrane density does not degrade the computational robustness of the proposed monolithic scheme: Fig. 17 shows the flapping behavior for various density ratios. For $\bar{\rho}_{\rm s} = \bar{\rho}$ (= 1 here), the nodal FE forces due to fluid and membrane inertia are equal in the limit $h_e \to 0$ (since $\dot{\boldsymbol{v}} \approx \text{const.}$ across the element thickness). For all

Figure 16: Flapping flag: Influence of membrane parameters \bar{c} (a) and $\bar{\mu}$ (b). The influence of c vanishes below a threshold value of c. Increasing μ leads to smaller velocities but increased fine scale oscillations.

Figure 17: Flapping flag: Influence of membrane density $\bar{\rho}_s$ on the flag displacement (a) and velocity (b). The density ratio affects the frequency and amplitude of vibration as expected. For $\bar{\rho}_s = 3$ and above, the simulation terminates after the flag penetrates the boundary at $\pm L_0$.

the considered density ratios, the Newton-Raphson iteration at each time step converges to a normalized energy residual of $10^{-27.7}$ within an average of six iterations. The density ratio therefore does not have a negative affect on the computational stability or the conditioning of the system. This is different to partitioned FSI schemes, which have been shown to suffer from a loss of robustness as the inertia forces of the flow become comparable or larger than those of the structure (Le Tallec and Mouro, 2001; Causin et al., 2005). The reason lies in the strong effect of the fluid on the structure for high fluid densities that is not well captured by weakly coupled partitioned schemes or requires many staggering steps in strongly coupled partitioned schemes. The extreme case of this effect occurs when $\bar{\rho}_s = 0$, which was considered in the droplet example of Sec. 5.2. Also in this case no stability issues were encountered in all simulations.

6 Conclusion

A unified FSI formulation is presented that is suitable for solid, liquid and mixed membranes. At free liquid surfaces, sticking contact can be accounted for. The fluid flow and the structure are discretized with finite elements using a stabilized fluid formulation and a surface-based membrane formulation. A conforming interface discretization is used between fluid and membrane, which leads to a simple monolithic coupling formulation. On membrane surfaces surrounded by fluid on both sides, double pressure nodes are required. The temporal discretization is based on the generalized- α scheme. Two analytical and three numerical examples are presented in order to illustrate and verify the proposed formulation. They consider fluid flow at low and high Reynolds numbers exhibiting strong FSI coupling.

The proposed formulation is very general and thus suitable as a basis for further research. In order to increase efficiency, the formulation can be extended to boundary elements (for low Re) or turbulence models (for high Re). Under current study is the use of enriched finite element discretizations (Harmel et al., 2017) that are suitable to efficiently capture boundary layers (Rasool et al., 2016). Another extension of the present formulation is to re-examine the pressure stabilization scheme at contact boundaries. This would be especially important in the presence of sharp contact angles. Such a formulation would then allow for a detailed flow analysis of droplets on rough surfaces.

Acknowledgements

The authors are grateful to the German Research Foundation (DFG) for supporting this research under grants GSC 111 and SA1822/3-2. The authors also wish to thank Maximilian Harmel and Raheel Rasool for proofreading the manuscript.

A Uniform membrane stretch

For the analytical example of Sec. 3.1, the initial and the current membrane position are described by

$$\begin{aligned} \boldsymbol{X}(\theta, z) &= R_{\rm s} \, \boldsymbol{e}_r + z \, \boldsymbol{e}_3 \,, \\ \boldsymbol{x}(\theta, z) &= r_{\rm s} \, \boldsymbol{e}_r + z \, \boldsymbol{e}_3 \,. \end{aligned}$$
 (111)

From this follows $A_1 = R_s e_{\theta}$, $a_1 = r_s e_{\theta}$ and $A_2 = a_2 = e_3$ with $e_{\theta} = -\sin \theta e_1 + \cos \theta e_2$. We further find

$$\begin{bmatrix} A_{\alpha\beta} \end{bmatrix} = \begin{bmatrix} R_{s}^{2} & 0 \\ 0 & 1 \end{bmatrix}, \quad \begin{bmatrix} a_{\alpha\beta} \end{bmatrix} = \begin{bmatrix} r_{s}^{2} & 0 \\ 0 & 1 \end{bmatrix}, \quad \begin{bmatrix} A^{\alpha\beta} \end{bmatrix} = \begin{bmatrix} R_{s}^{-2} & 0 \\ 0 & 1 \end{bmatrix}, \quad \begin{bmatrix} a^{\alpha\beta} \end{bmatrix} = \begin{bmatrix} r_{s}^{-2} & 0 \\ 0 & 1 \end{bmatrix}, \quad (112)$$

such that $J_{\rm s} = r_{\rm s}/R_{\rm s} =: \lambda$ and

$$\left[\sigma^{\alpha\beta}\right] = \frac{\mu}{\lambda} \begin{bmatrix} \frac{1}{R_{\rm s}^2} \left(1 - \lambda^{-4}\right) & 0\\ 0 & 1 - \lambda^{-2} \end{bmatrix}.$$
 (113)

The stress component along \boldsymbol{e}_{θ} is $\sigma := \boldsymbol{e}_{\theta} \cdot \left(\sigma^{\alpha\beta} \boldsymbol{a}_{\alpha} \otimes \boldsymbol{a}_{\beta} \right) \boldsymbol{e}_{\theta}$, which yields expression (44).

B FE tangent matrices for the time-continuous system

B.1 Fluid element

In order to evaluate the tangent matrix of the finite element force vector $\mathbf{f}_{\mathcal{F}}^{e}$ defined in (70), we require

$$\mathbf{L}_{\mathbf{v}} := \frac{\partial(\mathbf{B}_{\mathbf{v}}\mathbf{v}_{e})}{\partial\mathbf{v}_{e}},\tag{114}$$

which can be written as $\mathbf{L}_{v} := [\mathbf{L}_{v1}, \, \mathbf{L}_{v2}, \, ..., \, \mathbf{L}_{vn_e}]$ with

$$\mathbf{L}_{\mathbf{v}I} := N_I \, \mathbf{L} + B_{\mathbf{v}I} \, \mathbf{1} \,. \tag{115}$$

Therefore

$$\frac{\partial \boldsymbol{f}_{\text{res}}^h}{\partial \mathbf{v}_e} = \rho \, \mathbf{L}_{\text{v}} - \eta \, \mathbf{F} \,. \tag{116}$$

Based on this, we find the tangent matrices of the fluid forces defined in (72)-(74)

$$\begin{split} \mathbf{m}_{\mathcal{F}}^{e} &:= \frac{\partial \mathbf{f}_{\mathrm{Fin}}^{e}}{\partial \mathbf{v}_{e}^{\prime}} = \mathbf{m}_{e} \,, \\ \mathbf{m}_{\mathrm{supg}}^{e} &:= \frac{\partial \mathbf{f}_{\mathrm{supg}}^{e}}{\partial \mathbf{v}_{e}^{\prime}} = \int_{\Omega^{e}} \tau_{\mathrm{v}} \rho \, \mathbf{B}_{\mathrm{v}}^{\mathrm{T}} \, \mathrm{N} \, \mathrm{d}v \,, \\ \mathbf{m}_{\mathrm{pspg}}^{e} &:= \frac{\partial \mathbf{g}_{\mathrm{pspg}}^{e}}{\partial \mathbf{v}_{e}^{\prime}} = \int_{\Omega^{e}} \tau_{\mathrm{p}} \rho \, \mathbf{G}^{\mathrm{T}} \, \mathbf{N} \, \mathrm{d}v \,, \\ \mathbf{c}_{\mathrm{con}}^{e} &:= \frac{\partial \mathbf{f}_{\mathrm{con}}^{e}}{\partial \mathbf{v}_{e}} = \int_{\Omega^{e}} \rho \, \mathbf{N}^{\mathrm{T}} \, \mathbf{L}_{\mathrm{v}} \, \mathrm{d}v \,, \\ \mathbf{c}_{\mathcal{F}\mathrm{int}}^{e} &:= \frac{\partial \mathbf{f}_{\mathrm{Fint}}^{e}}{\partial \mathbf{v}_{e}} = \mathbf{c}_{e} \,, \\ \mathbf{c}_{\mathrm{supg}}^{e} &:= \frac{\partial \mathbf{g}_{\mathrm{g}}^{e}}{\partial \mathbf{v}_{e}} = \int_{\Omega^{e}} \tau_{\mathrm{v}} \left(\mathbf{B}_{\mathrm{f}}^{\mathrm{T}} \, \mathbf{N} + \rho \, \mathbf{B}_{\mathrm{v}}^{\mathrm{T}} \, \mathbf{L}_{\mathrm{v}} - \eta \, \mathbf{B}_{\mathrm{v}}^{\mathrm{T}} \, \mathbf{F} \right) \, \mathrm{d}v \,, \end{split}$$
(117)
$$\mathbf{c}_{\mathrm{g}}^{e} &:= \frac{\partial \mathbf{g}_{\mathrm{g}}^{e}}{\partial \mathbf{v}_{e}} = \mathbf{d}_{e}^{\mathrm{T}} \,, \\ \mathbf{c}_{\mathrm{pspg}}^{e} &:= \frac{\partial \mathbf{g}_{\mathrm{pspg}}^{e}}{\partial \mathbf{v}_{e}} = \int_{\Omega^{e}} \tau_{\mathrm{p}} \left(\rho \, \mathbf{G}^{\mathrm{T}} \, \mathbf{L}_{\mathrm{v}} - \eta \, \mathbf{G}^{\mathrm{T}} \, \mathbf{F} \right) \, \mathrm{d}v \,, \\ \mathbf{d}_{\mathrm{Fint}}^{e} &:= \frac{\partial \mathbf{g}_{\mathrm{pspg}}^{e}}{\partial \mathbf{p}_{e}} = \int_{\Omega^{e}} \tau_{\mathrm{p}} \left(\rho \, \mathbf{G}^{\mathrm{T}} \, \mathbf{L}_{\mathrm{v}} - \eta \, \mathbf{G}^{\mathrm{T}} \, \mathbf{F} \right) \, \mathrm{d}v \,, \\ \mathbf{d}_{\mathrm{supg}}^{e} &:= \frac{\partial \mathbf{f}_{\mathrm{supg}}^{e}}{\partial \mathbf{p}_{e}} = \int_{\Omega^{e}} \tau_{\mathrm{v}} \, \mathbf{B}_{\mathrm{v}}^{\mathrm{T}} \, \mathbf{G} \, \mathrm{d}v \,, \\ \mathbf{d}_{\mathrm{pspg}}^{e} &:= \frac{\partial \mathbf{g}_{\mathrm{pspg}}^{e}}{\partial \mathbf{p}_{e}} = \int_{\Omega^{e}} \tau_{\mathrm{p}} \, \mathbf{G}^{\mathrm{T}} \, \mathbf{G} \, \mathrm{d}v \,. \end{split}$$

As seen, a major source of complexity are the stabilization terms \mathbf{f}_{supg}^{e} and \mathbf{g}_{pspg}^{e} .

B.2 Membrane element

Linearizing the membrane forces in (91) w.r.t. $\dot{\mathbf{v}}_e$ and \mathbf{x}_e yields the mass matrix

$$\mathbf{m}_{\mathcal{S}}^{e} := \frac{\partial \mathbf{f}_{\mathcal{S}\mathrm{in}}^{e}}{\partial \dot{\mathbf{v}}_{e}} = \int_{\Omega^{e}} \rho_{\mathrm{s}} \mathbf{N}^{\mathrm{T}} \mathbf{N} \,\mathrm{d}v \,, \tag{118}$$

and the stiffness matrix

$$\mathbf{k}^{e}_{\mathcal{S}} := \mathbf{k}^{e}_{\mathcal{S}\mathrm{int}} + \mathbf{k}^{e}_{\mathrm{c}} \,. \tag{119}$$

The first term of \mathbf{k}^{e}_{S} follows from Sauer et al. (2014) as

$$\mathbf{k}_{Sint}^{e} := \frac{\partial \mathbf{f}_{Sint}^{e}}{\partial \mathbf{x}_{e}} = \mathbf{k}_{geo}^{e} + \mathbf{k}_{mat}^{e}, \qquad (120)$$

with

$$\mathbf{k}_{\text{geo}}^{e} := \int_{\Omega_{0}^{e}} \tau^{\alpha\beta} \mathbf{N}_{,\alpha}^{\text{T}} \mathbf{N}_{,\beta} \, \mathrm{d}A,$$

$$\mathbf{k}_{\text{mat}}^{e} := \int_{\Omega_{0}^{e}} c^{\alpha\beta\gamma\delta} \mathbf{N}_{,\alpha}^{\text{T}} \left(\boldsymbol{a}_{\beta} \otimes \boldsymbol{a}_{\gamma} \right) \mathbf{N}_{,\delta} \, \mathrm{d}A,$$
(121)

$$\tau^{\alpha\beta} := J_{\rm s} \, \sigma^{\alpha\beta}$$
 and

$$c^{\alpha\beta\gamma\delta} := 2\frac{\partial\tau^{\alpha\beta}}{\partial a_{\gamma\delta}} \,. \tag{122}$$

Here,

$$c^{\alpha\beta\gamma\delta} = \frac{2\mu}{J_{\rm s}^2} \left(a^{\alpha\beta} a^{\gamma\delta} + a^{\alpha\gamma} a^{\beta\delta} + a^{\alpha\delta} a^{\beta\gamma} \right) \tag{123}$$

for model (29) and

$$c^{\alpha\beta\gamma\delta} = J_{\rm s}\gamma \left(a^{\alpha\beta} a^{\gamma\delta} - a^{\alpha\gamma} a^{\beta\delta} - a^{\alpha\delta} a^{\beta\gamma}\right) \tag{124}$$

for model (30), see Sauer et al. (2014) and Sauer and Duong (2017). Inserting these into (120), yields the simpler expression

$$\mathbf{k}_{\text{mat}}^{e} \coloneqq \int_{\Omega_{0}^{e}} \frac{2\mu}{J_{\text{s}}^{2}} \mathbf{N}_{,\alpha}^{\text{T}} \left(\boldsymbol{a}^{\alpha} \otimes \boldsymbol{a}^{\beta} + \boldsymbol{a}^{\beta} \otimes \boldsymbol{a}^{\alpha} + a^{\alpha\beta} \boldsymbol{i} \right) \mathbf{N}_{,\beta} \, \mathrm{d}A \tag{125}$$

for model (29) and

$$\mathbf{k}_{\mathrm{mat}}^{e} := \int_{\Omega_{0}^{e}} J_{\mathrm{s}} \gamma \, \mathbf{N}_{,\alpha}^{\mathrm{T}} \left(\boldsymbol{a}^{\alpha} \otimes \boldsymbol{a}^{\beta} - \boldsymbol{a}^{\beta} \otimes \boldsymbol{a}^{\alpha} - a^{\alpha\beta} \boldsymbol{i} \right) \mathbf{N}_{,\beta} \, \mathrm{d}A \tag{126}$$

for model (30). Here $i := a_{\gamma} \otimes a^{\gamma}$ is the identity tensor on surface S. With this, \mathbf{k}_{Sint}^{e} can be further simplified, in particular for model (30), see Sauer (2016).

The second term of \mathbf{k}_{S}^{e} depends on the contact description. Here, sticking contact is considered with a rigid substrate using the penalty regularization of Eq. (33). For this case, we have

$$\mathbf{k}_{c}^{e} := \frac{\partial \mathbf{f}_{c}^{e}}{\partial \mathbf{x}_{e}} = -\int_{\Omega^{e}} \mathbf{N}^{\mathrm{T}} \frac{\partial \mathbf{f}_{c}}{\partial \mathbf{x}} \mathbf{N} \,\mathrm{d}a - \int_{\Omega^{e}} \mathbf{N}^{\mathrm{T}} \left(\mathbf{f}_{c} \otimes \mathbf{a}^{\alpha}\right) \mathbf{N}_{,\alpha} \,\mathrm{d}a \,, \tag{127}$$

with

$$\frac{\partial \boldsymbol{f}_{c}}{\partial \boldsymbol{x}} = \begin{cases} -\epsilon \, \mathbf{1} & \text{if } \boldsymbol{g} \cdot \boldsymbol{n}_{c} < 0 \,, \\ \mathbf{0} & \text{else} \,. \end{cases}$$
(128)

The front term of \mathbf{k}_{c}^{e} follows directly from Eqs. (33) and (85), while the rear term is derived in Sauer and De Lorenzis (2015).

C FE tangent matrices for the time-discrete system

C.1 Fluid element

For a fluid element $\Omega^e \subset \mathcal{F}^h$, the tangent matrix \mathbf{k}^e defined by Eq. (99) is given by the $4n_e \times 4n_e$ matrix

$$\mathbf{k}^{e} = \begin{bmatrix} \frac{\partial \mathbf{f}^{e}}{\partial \mathbf{v}_{e}^{n+1}} & \frac{\partial \mathbf{f}^{e}}{\partial \mathbf{p}_{e}^{n+1}} \\ \frac{\partial \mathbf{g}^{e}}{\partial \mathbf{v}_{e}^{n+1}} & \frac{\partial \mathbf{g}^{e}}{\partial \mathbf{p}_{e}^{n+1}} \end{bmatrix},$$
(129)

with

$$\frac{\partial \mathbf{f}^{e}}{\partial \mathbf{v}_{e}^{n+1}} = \frac{\partial \mathbf{f}^{e}}{\partial \mathbf{a}_{e}^{n+\alpha_{m}}} \frac{\partial \mathbf{a}_{e}^{n+\alpha_{m}}}{\partial \mathbf{a}_{e}^{n+1}} \frac{\partial \mathbf{a}_{e}^{n+1}}{\partial \mathbf{v}_{e}^{n+1}} + \frac{\partial \mathbf{f}^{e}}{\partial \mathbf{v}_{e}^{n+\alpha_{f}}} \frac{\partial \mathbf{v}_{e}^{n+\alpha_{f}}}{\partial \mathbf{v}_{e}^{n+1}},$$

$$\frac{\partial \mathbf{g}^{e}}{\partial \mathbf{v}_{e}^{n+1}} = \frac{\partial \mathbf{g}^{e}}{\partial \mathbf{a}_{e}^{n+\alpha_{m}}} \frac{\partial \mathbf{a}_{e}^{n+\alpha_{m}}}{\partial \mathbf{a}_{e}^{n+1}} \frac{\partial \mathbf{a}_{e}^{n+1}}{\partial \mathbf{v}_{e}^{n+1}} + \frac{\partial \mathbf{g}^{e}}{\partial \mathbf{v}_{e}^{n+\alpha_{f}}} \frac{\partial \mathbf{v}_{e}^{n+\alpha_{f}}}{\partial \mathbf{v}_{e}^{n+1}}.$$
(130)

Based on (98), (117), (96) and (97) we obtain

$$\frac{\partial \mathbf{f}^{e}}{\partial \mathbf{v}_{e}^{n+1}} = \frac{\alpha_{\mathrm{m}}}{\gamma \Delta t} \left(\mathbf{m}_{\mathcal{F}}^{e} + \mathbf{m}_{\mathrm{supg}}^{e} \right) + \alpha_{\mathrm{f}} \left(\mathbf{c}_{\mathrm{con}}^{e} + \mathbf{c}_{\mathcal{F}\mathrm{int}}^{e} + \mathbf{c}_{\mathrm{supg}}^{e} \right),$$

$$\frac{\partial \mathbf{f}^{e}}{\partial \mathbf{p}_{e}^{n+1}} = \mathbf{d}_{\mathcal{F}\mathrm{int}}^{e} + \mathbf{d}_{\mathrm{supg}}^{e},$$

$$\frac{\partial \mathbf{g}^{e}}{\partial \mathbf{v}_{e}^{n+1}} = \frac{\alpha_{\mathrm{m}}}{\gamma \Delta t} \mathbf{m}_{\mathrm{pspg}}^{e} + \alpha_{\mathrm{f}} \left(\mathbf{c}_{\mathrm{g}}^{e} + \mathbf{c}_{\mathrm{pspg}}^{e} \right),$$

$$\frac{\partial \mathbf{g}^{e}}{\partial \mathbf{p}_{e}^{n+1}} = \mathbf{d}_{\mathrm{pspg}}^{e},$$
(131)

where the individual building blocks are given in (117).

C.2 Membrane element

For a membrane element $\Omega^e \subset S^h$, the tangent matrix \mathbf{k}^e defined by Eq. (99) is given by the $3n_e \times 3n_e$ matrix

$$\mathbf{k}^{e} = \frac{\partial \mathbf{f}^{e}}{\partial \mathbf{v}_{e}^{n+1}} = \frac{\partial \mathbf{f}^{e}}{\partial \mathbf{a}_{e}^{n+\alpha_{m}}} \frac{\partial \mathbf{a}_{e}^{n+\alpha_{m}}}{\partial \mathbf{a}_{e}^{n+1}} \frac{\partial \mathbf{a}_{e}^{n+1}}{\partial \mathbf{v}_{e}^{n+1}} + \frac{\partial \mathbf{f}^{e}}{\partial \mathbf{x}_{e}^{n+\alpha_{f}}} \frac{\partial \mathbf{x}_{e}^{n+\alpha_{f}}}{\partial \mathbf{x}_{e}^{n+1}} \frac{\partial \mathbf{x}_{e}^{n+1}}{\partial \mathbf{v}_{e}^{n+1}}.$$
 (132)

Based on (98), (117), (96) and (97) we find

$$\mathbf{k}^{e} = \frac{\alpha_{\rm m}}{\gamma \,\Delta t} \,\mathbf{m}_{\mathcal{S}}^{e} + \frac{\alpha_{\rm f} \,\beta \,\Delta t}{\gamma} \,\mathbf{k}_{\mathcal{S}}^{e} \,, \tag{133}$$

where \mathbf{m}_{S}^{e} and \mathbf{k}_{S}^{e} are given in Appendix B.2.

D Mesh motion for the flapping flag example

For the flapping flag example in Sec. 5.3, the mesh velocity $\boldsymbol{v}_{\rm m}$ (with Cartesian components $v_{{\rm m}i}$) at FE node (i.e. control point) $\boldsymbol{x}_{\rm m}$ is defined by the linear interpolation

$$v_{\rm m1}(\boldsymbol{x}_{\rm m},t) = v_{\rm s1}(\boldsymbol{X}_{\rm p},t) \begin{cases} 0 & \text{for } X_{\rm m1} \le L_0 \text{ or } X_{\rm m1} > 6L_0 ,\\ 1 & \text{for } L_0 < X_{\rm m1} < 4L_0 ,\\ 3 - X_{\rm m1}/(2L_0) & \text{for } 4L_0 < X_{\rm m1} < 6L_0 , \end{cases}$$
(134)

for the inflow direction, and

$$v_{\rm mj}(\boldsymbol{x}_{\rm m},t) = v_{\rm sj}(\boldsymbol{X}_{\rm p},t) \begin{cases} 0 & \text{for } d \ge L_0, \\ 1 - d/L_0 & \text{for } d < L_0, \end{cases}$$
(135)

for the other directions (j = 2, 3). Here X_{mi} are the components of $\mathbf{X}_{m} = \mathbf{x}_{m}|_{t=0}$, $d(\mathbf{X}_{m})$ is the distance of \mathbf{X}_{m} from the flag surface, and $\mathbf{v}_{s}(\mathbf{X}_{p}, t)$ is the current flag velocity at the initially nearest membrane gridpoint $\mathbf{X}_{p} = \mathbf{X}_{p}(\mathbf{X}_{m})$. Note that v_{m1} is smooth at $X_{m1} = 1$ since v_{s1} approaches 0 smoothly as $X_{m1} \to L_{0}$.
