Abstract

The Data Processing Inequality (DPI) says that the Umegaki relative entropy $S(\rho||\sigma) := \text{Tr}[\rho(\log \rho - \log \sigma)]$ is non-increasing under the action of completely positive trace preserving (CPTP) maps. Let $\mathcal{M}$ be a finite dimensional von Neumann algebra and $\mathcal{N}$ a von Neumann subalgebra of it. Let $\mathcal{E}_\tau$ be the tracial conditional expectation from $\mathcal{M}$ onto $\mathcal{N}$. For density matrices $\rho$ and $\sigma$ in $\mathcal{M}$, let $\rho_\mathcal{N} := \mathcal{E}_\tau \rho$ and $\sigma_\mathcal{N} := \mathcal{E}_\tau \sigma$. Since $\mathcal{E}_\tau$ is CPTP, the DPI says that $S(\rho||\sigma) \geq S(\rho_\mathcal{N}||\sigma_\mathcal{N})$, and the general case is readily deduced from this. A theorem of Petz says that there is equality if and only if $\sigma = \mathcal{R}_\rho(\sigma_\mathcal{N})$, where $\mathcal{R}_\rho$ is the Petz recovery map, which is dual to the Accardi-Cecchini coarse graining operator $\mathcal{A}_\rho$ from $\mathcal{M}$ to $\mathcal{N}$. We prove a quantitative version of Petz’s theorem. In its simplest form, our bound is

$$S(\rho||\sigma) - S(\rho_\mathcal{N}||\sigma_\mathcal{N}) \geq \left(\frac{\pi}{8}\right)^4 \|\Delta_{\sigma,\rho}\|^{-2} \|\mathcal{R}_\rho(\sigma_\mathcal{N}) - \sigma\|_1^4,$$

where $\Delta_{\sigma,\rho}$ is the relative modular operator. Since $\|\Delta_{\sigma,\rho}\| \leq \|\rho^{-1}\|$, this bound implies a bound with a constant that is independent of $\sigma$. We also prove an analogous result with a more complicated constant in which the roles of $\rho$ and $\sigma$ are interchanged on the right.

Explicitly describing the solutions set of the Petz equation $\sigma = \mathcal{R}_\rho(\sigma_\mathcal{N})$ amounts to determining the set of fixed points of the Accardi-Cecchini coarse graining map. Building on previous work, we provide a thoroughly detailed description of the set of solutions of the Petz equation $\mathcal{A}_\rho(\mathcal{E}_\tau \gamma) = \gamma$, and obtain all of our results in a simple, self contained manner. Finally, we prove a theorem characterizing state $\rho$ for which the orthogonal projection from $\mathcal{M}$ onto $\mathcal{N}$ in the GNS inner product is a conditional expectation.
1 Introduction

1.1 The Data Processing Inequality

Let $\mathcal{M}$ be a finite dimensional von Neumann algebra, which we may regard as a subalgebra of $M_n(\mathbb{C})$, the $n \times n$ complex matrices. The Hilbert-Schmidt inner product $\langle \cdot, \cdot \rangle_{HS}$ on $M_n(\mathbb{C})$ is given in terms of the trace by $\langle X, Y \rangle_{HS} = \text{Tr}[X^*Y]$. Let 1 denote the identity.

A state on $\mathcal{M}$ is a linear functional $\varphi$ on $\mathcal{M}$ such that $\varphi(A^*A) \geq 0$ for $A \in \mathcal{M}$ and such that $\varphi(1) = 1$. A state $\varphi$ is faithful in case $\varphi(A^*A) > 0$ whenever $A \neq 0$, and is tracial in case $\varphi(AB) = \varphi(BA)$ for all $A, B \in \mathcal{M}$. Every state on $\mathcal{M}$ is of the form $\rho \mapsto \text{Tr}[\rho X]$, where $\rho$ is a density matrix in $\mathcal{M}$; i.e., a non-negative element $\rho$ of $\mathcal{M}$ such that $\text{Tr}[\rho] = 1$. This state is faithful if and only if $\rho$ is invertible. It will be convenient to write $\rho(X) = \text{Tr}[\rho X]$ to denote the state corresponding to a density matrix $\rho$.

Let $\mathcal{N}$ be a von Neumann subalgebra of $\mathcal{M}$. Let $\mathcal{E}$ be any norm-contractive projection from $\mathcal{M}$ onto $\mathcal{N}$. (Norm contractive means that $\|\mathcal{E}(X)\| \leq \|X\|$ for all $X \in \mathcal{M}$. Throughout the paper, $\| \cdot \|$ without any subscript denotes the operator norm.) By a theorem of Tomiyama [37], $\mathcal{E}$ preserves positivity, $\mathcal{E}(1) = 1$, and

$$\mathcal{E}(AXB) = A\mathcal{E}(X)B \quad \text{for all} \quad A, B \in \mathcal{N}, \ X \in \mathcal{M} . \quad (1.1)$$

Moreover, as Tomiyama noted, it follows from (1.1) and the positivity preserving property of $\mathcal{E}$ that

$$\mathcal{E}(X)^*\mathcal{E}(X) \leq \mathcal{E}(X^*X) \quad \text{for all} \ X \in \mathcal{M} , \quad (1.2)$$

In fact, more is true. As is well known, every norm contractive projection is completely positive.

A conditional expectation from $\mathcal{M}$ onto $\mathcal{N}$, in the sense of Umegaki [41, 42, 43], is a unital projection from $\mathcal{M}$ onto $\mathcal{N}$ that is order preserving and such that (1.1) and (1.2) are satisfied. Since every conditional expectation $\mathcal{E}$ is a unital completely positive map, its adjoint with respect to the Hilbert-Schmidt inner product, $\mathcal{E}^\dagger$, is a completely positive trace preserving (CPTP) map, also known as a quantum operation. (Throughout this paper, a dagger $\dagger$ always denotes the adjoint with respect to the Hilbert-Schmidt inner product.)

Let $\mathcal{E}_{\tau}$ denote the orthogonal projection from $\mathcal{M}$ onto $\mathcal{N}$ with respect to the GNS inner product determined by $\tau$. It is easy to see, using the tracial nature of $\tau$, that $\mathcal{E}_{\tau}$ is in fact a conditional expectation, and since $\mathcal{E}_{\tau} = \mathcal{E}_{\tau}^\dagger$, $\mathcal{E}_{\tau}$ is a quantum operation.

1.1 Definition. For any state $\rho$ on $\mathcal{M}$, $\rho_{\mathcal{N}}$ denotes the state on $\mathcal{N}$ given by $\rho_{\mathcal{N}} := \mathcal{E}_{\tau}(\rho)$ where, as always $\mathcal{E}_{\tau}$ denotes the tracial conditional expectation onto $\mathcal{N}$.

The restriction of a state $\rho$ on $\mathcal{M}$ to $\mathcal{N}$ is of course a state on $\mathcal{N}$, and as such, it is represented by a unique density matrix belonging to $\mathcal{N}$, which is precisely $\rho_{\mathcal{N}}$. 

1.2 Example. Let $\mathcal{H} = \mathcal{H}_1 \otimes \mathcal{H}_2$ be the tensor product of two finite dimensional Hilbert spaces. Let $\mathcal{M} = \mathcal{B}(\mathcal{H})$ be the algebra of all linear transformations on $\mathcal{H}$, and let $\mathcal{N}$ be the subalgebra $1_{\mathcal{H}_1} \otimes \mathcal{B}(\mathcal{H}_2)$ consisting of all operators in $\mathcal{M}$ of the form $1_{\mathcal{H}_1} \otimes A$, $A \in \mathcal{B}(\mathcal{H}_2)$. Then for the normalized trace $\tau$, $\mathcal{E}_\tau(X) = d_1^{-1} 1_{\mathcal{H}_1} \otimes \text{Tr}_1 X$ for all $X \in \mathcal{M}$ where $d_1$ is the dimension of $\mathcal{H}_1$ and where $\text{Tr}_1$ denotes the partial trace over $\mathcal{H}_1$.

Given two states $\rho$ and $\sigma$ on $\mathcal{M}$, the Umegaki relative entropy of $\rho$ with respect to $\sigma$ is defined by

$$S(\rho || \sigma) := \text{Tr}[\rho(\log \rho - \log \sigma)] .$$

(1.3)

Lindblad’s inequality [19] states that with $\mathcal{E}_\tau$ being the tracial conditional expectation onto $\mathcal{N}$,

$$S(\rho || \sigma) \geq S(\mathcal{E}_\tau(\rho) || \mathcal{E}_\tau(\sigma)) .$$

(1.4)

Lindblad showed that the monotonicity (1.4) is equivalent to the joint convexity of the relative entropy $(\rho, \sigma) \mapsto S(\rho || \sigma)$, and this in turn is an immediate consequence of Lieb’s Concavity Theorem [16]. In the case that $\mathcal{M} = \mathcal{B}(\mathcal{H}_1 \otimes \mathcal{H}_2)$ and $\mathcal{N} = \{1_{\mathcal{H}_1} \otimes A, A \in \mathcal{B}(\mathcal{H}_2)\}$, (1.4) was proved by Lieb and Ruskai [18], who showed it to be equivalent to the Strong Subadditivity (SSA) of the von Neumann entropy; more information on SSA is contained in Section 5.

Using the fact that Stinespring’s Dilation Theorem [33] relates general CPTP maps to tracial expectation, Lindblad [20] was able to prove, using (1.4) that for any CPTP map $\mathcal{P}$,

$$S(\rho || \sigma) \geq S(\mathcal{P}(\rho) || \mathcal{P}(\sigma)) .$$

(1.5)

This is known as the Data Processing Inequality (DPI). Because of the simple relation between (1.4) and (1.5) the problem of determining the cases of equality in the Data Processing Inequality largely comes down the problem of determining the cases of equality in (1.4), which was solved by Petz [27, 28]. His necessary and sufficient condition for equality in (1.4) is closely connected with the problem of quantum coarse graining, and in particular a quantum coarse graining operation introduced by Acardi and Cecchini [2], whose dual is now known as the Petz recovery channel, the CPTP map $\mathcal{R}_\rho$ given by

$$\mathcal{R}_\rho(\gamma) = \rho^{1/2}(\rho_N^{-1/2}\gamma\rho_N^{-1/2})\rho^{1/2} .$$

(1.6)

It is obvious that $\mathcal{R}_\rho(\rho_N) = \rho$, so that $\mathcal{R}_\rho$ “recovers” $\rho$ from $\rho_N$. Petz proved [27, 28] that there is equality in (1.4) if and only if

$$\mathcal{R}_\rho(\sigma_N) = \sigma$$

(1.7)

and that this is true if and only if

$$\mathcal{R}_\sigma(\rho_N) = \rho .$$

(1.8)

There has been much recent work on stability for for the DPI: [13, 17, 32, 34, 35, 46]. Suppose that $\rho$ and $\sigma$ are such that there is approximate equality in (1.4). To what extent do $\rho$ and $\sigma$ provide approximate solutions to Petz’s equation (1.7) and (1.8)?
1.2 Main results

In this paper we further develop an approach that we introduced in [9] for proving stability for analogs of the DPI for Rényi relative entropies. The Rényi relative entropies include the Umegaki relative entropy (1.3) as a limiting case, but taking advantage of the special structure on the Umegaki relative entropy, we are able to sharpen the stability bounds obtained in [9] for this case. Our results in this direction are given in Theorem 1.5 and Corollary 1.7. These results are proved in Section 2.

Moreover, we show how the approach introduced in [9] yields a simple specification of the structure of the pairs of densities $\rho$ and $\sigma$ that satisfy Petz’s equations (1.7) and (1.8). This is a question that was first dealt with by Hayden, Jozsa, Petz and Winter in [14]. The question arose there because, although it is known (and explained in the appendix) that the DPI is equivalent to the quantum Strong Subadditivity of the Entropy (SSA) [18], it is not so simple to translate Petz’s condition for equality in the DPI into the condition for equality in SSA. This was done in [14], but Petz himself, together with Mosnyi, returned to the problem of determining the structure of solutions of (1.7) and (1.8) in [23]. Here we give simple specification of the structure of solutions providing some new information. Our main results in this direction are given in Theorem 1.9 and Corollary 1.10. These results are proved in Section 3.

As explained in the next two subsections, the questions considered here are closely related to several questions concerning quantum conditional expectations and quantum “coarse graining”. In Section 4, we prove a theorem specifying conditions under which the orthogonal projection of $\mathcal{M}$ onto $\mathcal{N}$ is a conditional expectations, and hence, when expectation preserving conditional expectations exist. The full statement is given in Theorem 4.1.

Before giving precise statements, it will be useful to recall the relatively simple situation regarding the classical DPI.

1.3 The classical DPI

It will be useful to recall some aspects of the classical analog of the DPI. Let $\Omega$ be a finite set. Let $\mathcal{F}$ be a non-trivial partition of $\Omega$. Let $\mathcal{M}$ denote the functions on $\Omega$, and let $\mathcal{N}$ the functions on $\Omega$ that are constant on each set of the partition $\mathcal{F}$. Then $\mathcal{M}$ and $\mathcal{N}$ are commutative von Neumann algebras, and $\mathcal{N}$ is a subalgebra of $\mathcal{M}$. Let $X$ be a function on $\Omega$ such that $X(\omega) = X(\omega')$ if and only $\omega$ and $\omega'$ belong to the same set in $\mathcal{F}$. Then $X$ generates $\mathcal{F}$ in the sense that the sets constituting $\mathcal{F}$ are precisely the non-empty sets of the form $\{ \omega \mid X(\omega) = x \}$.

Let $\rho$ and $\sigma$ be two strictly positive probability densities on the set $\Omega$. Let $\tau$ denote the uniform probability density on $\Omega$; i.e., $\tau(\omega) = |\Omega|^{-1}$ for all $\omega$, where $|\Omega|$ is the cardinality of $\Omega$. As above, let $\mathcal{E}_\tau$ denote the orthogonal projection of $\mathcal{M}$ onto $\mathcal{N}$, which is nothing other than the conditional expectation with respect the random variable $Y$ and the probability measure $\tau$. As above, let $\rho_N = \mathcal{E}_\tau \rho$ and $\sigma_N = \mathcal{E}_\tau \sigma$. It is clear the $\rho_N$ is a “coarse grained” version of $\rho$, obtained by averaging $\rho$ on the sets of the partition $\mathcal{F}$, making it constant on these.

Let $f(\omega | y)$ be the conditional density under $\rho$ for $\omega$ given $Y(\omega)$, and likewise let $g(\omega | y)$ be the
which, for each $x$ in the range of $X$ are both probability densities on the set $\{\omega : X(\omega) = x\}$.

Then we have $\rho(\omega) = \rho_N(X(\omega))f(\omega|X(\omega))$ and $\sigma(\omega) = \sigma_N(X(\omega))g(\omega|X(\omega))$, and hence

$$S(\rho||\sigma) = \sum_{\omega \in \Omega} \rho(\omega)(\log \rho(\omega) - \log \sigma(\omega))$$

$$= \sum_{\omega \in \Omega} \rho(\omega)(\log \rho_N(\omega) - \log \sigma_N(\omega) + \log f(\omega|X(\omega)) - \log g(\omega|X(\omega)))$$

$$= S(\rho_N||\sigma_N) + \sum_{\omega \in \Omega} \rho_n(X(\omega)) [f(\omega|X(\omega)) \log f(\omega|X(\omega)) - \log g(\omega|X(\omega))]$$

For each $x$ in the range of $X$, it follows from Jensen’s inequality that

$$\sum_{\{\omega : X(\omega) = x\}} f(\omega|x) [\log f(\omega|x) - \log g(\omega|x)] \geq 0,$$

and there is equality if and only if $f(\omega|x) = g(\omega|x)$ everywhere on $\{\omega : X(\omega) = x\}$. It follows that $S(\rho||\sigma) \geq S(\rho_N||\sigma_N)$ with equality if and only if for each $x$ in the range of $X$, $f(\omega|x) = g(\omega|x)$ everywhere on $\{\omega : X(\omega) = x\}$.

In this case, $X$ is called a sufficient statistic for the pair $\{\rho, \sigma\}$. Suppose we are given an independent identically distributed sequence of points $\{\omega_j\}$, drawn according to one of the two probability densities $\rho$ or $\sigma$, and we want to determine which it is. If we know the function $f(\omega|x)$, it suffices to observe the sequence $\{X(\omega_j)\}$, and to determine which of $\rho_N(x)$ or $\sigma_N(x)$ is governing its distribution.

Indeed, we can define a classical recovery map as follows: For any probability density $\gamma \in \mathcal{N}$, regarded as a probability density on the range of $X$, define $\mathcal{R}_\rho \gamma$ to be the probability density in $\mathcal{M}$ given by

$$\mathcal{R}_\rho \gamma(\omega) = \gamma(X(\omega))f(\omega|X(\omega)).$$

Therefore, we can express the condition for equality in the classical DPI as $\mathcal{R}_\rho \sigma_N = \rho$, and evidently this is true if and only if $\mathcal{R}_\sigma \rho_N = \rho$. This is the classical analog of Petz’s result. Moreover, in this notation, we have that

$$\sum_{\omega \in \Omega} \rho_n(X(\omega)) [f(\omega|X(\omega)) \log f(\omega|X(\omega)) - \log g(\omega|X(\omega))] = S(\rho||\mathcal{R}_\sigma \rho),$$

so that (1.10) becomes

$$S(\rho||\sigma) - S(\rho_N||\sigma_N) \geq S(\rho||\mathcal{R}_\sigma \rho).$$

Then by the classical Pinsker inequality,

$$S(\rho||\sigma) - S(\rho_N||\sigma_N) \geq \frac{1}{2} \left( \sum_{\omega \in \Omega} |\rho(\omega) - \mathcal{R}_\sigma \rho(\omega)| \right)^2.$$
It remains an open problem to prove quantum analogs of (1.12) or (1.13), even with worse constants on the right. Here we prove a quantum analog of (1.13) with a worse constant, and with the power raised from 2 to 4 on the right. The line of argument has to be entirely different from the one we have just employed in the classical case because there is no effective quantum replacement for “conditioning on the observable X”.

It is therefore useful to find a way of describing the classical recovery map that does not refer explicitly to conditioning on the random variable X. Define $E_\sigma$ to be the orthogonal projection of $M$ onto $N$ in $L^2(\sigma)$. Then for any random variable $Y$ (i.e., any function on $\Omega$), $E_\sigma Y$ is the condition expectation of $Y$ given the sigma-algebra $M$. The operation $Y \mapsto E_\sigma Y$ yields a “coarse grained version” of $Y$ that is constant on the sets in $F$: With $X$ and $g$ as in (1.9),

$$E_\sigma Y(\omega) = \sum_{\omega': X(\omega')=X(\omega)} g(\omega')X(\omega)Y(\omega').$$

It is clear from this formula that $E_\sigma$ preserves positivity, and preserves expectations with respect to $\sigma$, That is,

$$\sigma(Y) = \sigma(E_\sigma Y).$$

Now let $E_\sigma^\dagger$ be the dual operation taking states on $M$ (probability densities on the range of $X$) to states on $M$ (probability densities on $\Omega$). It is easily seen that this is nothing other than $R_\sigma$. That is, the classical recovery map $R_\sigma$ is nothing other than the dual of the conditional expectation $E_\sigma$, which is nothing other than the orthogonal projection of $M$ onto $N$ in $L^2(\sigma)$. This analytic specification of $R_\sigma$, making no explicit mention of conditioning on $X$, provides a starting point for the construction of a quantum recovery map.

### 1.4 Quantum conditional expectations and quantum coarse graining

The discussion of the classical DPI brings us to the question as to whether for any faithful state $\rho$ on $M$ there exists a conditional expectation $\mathcal{E}$ from $M$ onto $N$ that preserves expectations with respect to $\rho$, i.e. such that

$$\rho(X) = \rho(\mathcal{E}(X)) \quad \text{for all } X \in M. \quad (1.15)$$

The property (1.15) says that “the expectation of a conditional expectation of an observable equals the expectation of the observable”. If such a conditional expectation exists, then it is unique: Any such conditional expectation must be the orthogonal projection of $M$ on $N$ with respect to the GNS inner product for the state $\rho$. To see this, note that for all $X \in M$ and all $A \in N$, using (1.1),

$$\langle A, X \rangle_{GNS,\rho} = \rho(A^\ast X) = \rho(\mathcal{E}(A^\ast X)) = \rho(A^\ast \mathcal{E}(X)) = \langle A, \mathcal{E}(X) \rangle_{GNS,\rho}. \quad (1.16)$$

Suppose that $\mathcal{E}$ is a conditional expectation satisfying (1.15). Then since $\mathcal{E}$ is a unital completely positive map, $\mathcal{E}^\dagger$ is a CPTP map; i.e., a quantum channel. For any state $\gamma$ on $N$, and any $A \in M$, we then have

$$\mathcal{E}^\dagger(A) = \gamma(\mathcal{E}(A)).$$
Then when (1.15) is satisfied, taking $\gamma = \rho_N$, we have
\[
E^\dagger \rho_N(A) = \rho_N(E(A)) = \rho(A),
\]
and this means that $E^\dagger$ is a quantum channel that “recovers” $\rho$ from $\rho_N$.

As we have already noted, $E_\tau$ is a conditional expectation with the property (1.15). However, for non-tracial states $\rho$, a conditional expectation satisfying (1.15) need not exist.

A theorem of Takesaki [36] says, in our finite dimensional context, that for a faithful state $\rho$, there exists a conditional expectation $E$ from $M$ onto $N$ if and only if $\rho A \rho^{-1} \in N$ for all $A \in N$, and in general this is not the case. We give a short proof of this and somewhat more in Section 4. In Theorem 4.1, we prove that $E_\rho$, the orthogonal projection from $M$ onto $N$ in the GNS inner product with respect to $\rho$, is real (that is, it preserves self-adjointness) if and only if $\rho A \rho^{-1} \in N$ for all $A \in N$. Since every order preserving linear transformation is real, this precludes the general existence of conditional expectations satisfying (1.15) whenever $N$ is not invariant under $X \mapsto \rho X \rho^{-1}$, thus implying Takesaki’s Theorem (in this finite dimensional setting).

There is another inner product on $M$ that is naturally induced by a faithful state $\rho$, namely the Kubo-Martin-Schwinger (KMS) inner product. It is defined by
\[
\langle X, Y \rangle_{KMS,\rho} = \text{Tr}[\rho^{1/2}X^*\rho^{1/2}Y] = \text{Tr}[(\rho^{1/4}X\rho^{1/4})^*(\rho^{1/4}Y\rho^{1/4})]. \tag{1.17}
\]
Evidently, for any $X \in M$ and $Y \in N$,
\[
|\langle X, Y \rangle_{KMS,\rho}| = |\text{Tr}[\rho^{1/2}X^*\rho^{1/2}Y]| = |\text{Tr}[(\rho^{1/4}_N\rho^{-1/4}_N)^*(\rho^{1/4}_N\rho^{-1/4}_N)Y]| \leq \|\rho^{-1/4}_N\rho^{1/2}X\rho^{1/2}\rho^{-1/4}_N\|_{HS}\|Y\|_{KMS,\rho_N}.
\]
Hence $Y \mapsto \langle X, Y \rangle_{KMS,\rho}$ is a bounded linear functional on $(N, \langle \cdot, \cdot \rangle_{KMS,\rho_N})$, and then there is a uniquely determined $\mathcal{A}_\rho(X) \in N$ such that for all $X \in M$ and all $Y \in N$,
\[
\langle X, Y \rangle_{KMS,\rho} = \langle \mathcal{A}_\rho(X), Y \rangle_{KMS,\rho_N}. \tag{1.18}
\]

The map $\mathcal{A}_\rho$ was introduced by Accardi and Cecchini [2], building on previous work by Accardi [1].

1.3 Definition. Let $\rho$ be a faithful state on $M$. The Accardi-Cecchini coarse graining operator $\mathcal{A}_\rho$ from $M$ to $N$ is defined by (1.18).

The map $\mathcal{A}_\rho$ was introduced by Accardi and Cecchini [2], building on previous work by Accardi [1]. It is a “coarse graining” operation in that to each observable $X$ in the larger algebra $M$, it associates an observable $\mathcal{A}_\rho(X)$, in the smaller algebra $N$, and measurement of $\mathcal{A}_\rho(X)$ will yield coarser information than a measurement of $X$ itself. The same, of course, is true for conditional expectations.

Since $1 \in N$ by definition, for all $X \in M$, $\langle 1, X \rangle_{KMS,\rho} = \langle 1, \mathcal{A}_\rho(X) \rangle_{KMS,\rho}$, and for all $X \in M$,
\[
\langle 1, X \rangle_{KMS,\rho} = \text{Tr}[\sigma^{1/2}1\sigma^{1/2}X] = \rho(X).
\]
Therefore
\[
\rho(\mathcal{A}_\rho(X)) = \rho(X). \tag{1.19}
\]
Thus, unlike conditional expectations in general, the Accardi-Cecchini coarse-graining operator always preserves expectations with respect to $\rho$.

In the matricial setting, it is a particularly simple matter to derive an explicit expression for $A_\rho$. By definition, for all $X \in M$ and all $Y \in N$,

$$\text{Tr}[\rho_N^{1/2} Y \rho_N^{1/2} A_\rho(X)] = \text{Tr}[\rho^{1/2} Y \rho^{1/2} X] .$$

(1.20)

Make the change of variables $Z = \rho_N^{1/2} Y \rho_N^{1/2}$. Since $\rho_N^{1/2}$ is invertible and $Y$ ranges over $N$, $Z$ ranges over $N$. Hence

$$\text{Tr}[Z A_\rho(X)] = \text{Tr}[(\rho^{1/2} \rho_N^{-1/2} Z \rho_N^{-1/2} \rho^{1/2}) X] = \text{Tr}[(\rho_N^{-1/2} \rho^{1/2} X \rho^{1/2} \rho_N^{-1/2})].$$

(1.21)

Since the above holds for all $Z \in N$, it follows that

$$A_\rho(X) = \rho_N^{-1/2} \mathcal{E}_r(\rho^{1/2} X \rho^{1/2}) \rho_N^{-1/2} .$$

(1.22)

It is evident from this formula that $A_\rho$ is a completely positive unital map from $M$ to $N$, and therefore it is actually a contraction from $M$ to $N$. By Tomiyama’s Theorem, it cannot in general be a projection of $M$ onto $N$. That is, if $X \in N$, it is not necessarily the case that $A_\rho(X) = X$. The set of $X \in N$ for which this is true turns out to be a subalgebra of $N$, as was shown by Accardi and Cecchini [2]. This subalgebra will be of interest in what follows.

1.4 Definition. The Petz recovery map $R_\rho$ is the Hilbert-Schmidt adjoint of $A_\rho$ [28]. That is, $R_\rho = A_\rho^\dagger$, or equivalently, for all density matrices $\gamma \in N$

$$\text{Tr}[\gamma A_\rho(X)] = \text{Tr}[R_\rho(\gamma) X] .$$

A dagger $\dagger$ always denotes the adjoint with respect to the Hilbert-Schmidt inner product.

As the dual of a unital completely positive map, $R_\rho$ is a CPTP map. Moreover, it follows immediately from the definition and (1.22) that for all density matrices $\gamma \in N$,

$$R_\rho(\gamma) = \rho^{1/2} (\rho_N^{-1/2} \gamma \rho_N^{-1/2}) \rho^{1/2} .$$

(1.23)

It is evident from this formula not only that $R_\rho$ is a CPTP map, but that $R_\rho(\rho_N) = \rho$; i.e., $R_\rho$ recovers $\rho$ from $\rho_N$. Now suppose that $\sigma$ is another density matrix in $M$ and that

$$R_\rho(\sigma_N) = \sigma .$$

(1.24)

Then by the Data Processing Inequality and (1.24), $S(\rho || \sigma) \leq S(R_\rho(\rho_N) || R_\rho(\sigma_N)) = S(\rho || \sigma)$. Hence when $R_\rho(\sigma_N) = \sigma$, there is equality in (1.4). The deeper result of Petz [27, 28] is that there is equality in (1.4) only in this case.

Our goal is to prove a stability bound for Petz’s theorem on the cases of equality in (1.4). Our result involves the relative modular operator $\Delta_{\rho, \sigma}$ on $M$ defined by

$$\Delta_{\rho, \sigma}(X) = \sigma X \rho^{-1}$$

(1.25)

for all $X \in M$. This is the matricial version of an operator introduced in a more general von Neumann algebra context by Araki [3]. Our main result is:
1.5 Theorem. Let $\rho$ and $\sigma$ be two states on $\mathcal{M}$. Let $\mathcal{E}_\tau$ be the tracial conditional expectation onto a von Neumann subalgebra $\mathcal{N}$, and let $\rho_\mathcal{N} = \mathcal{E}_\tau \rho$ and $\sigma_\mathcal{N} = \mathcal{E}_\tau \sigma$. Then, with $\| \cdot \|_2$ denoting the Hilbert-Schmidt norm,

$$
S(\rho || \sigma) - S(\rho_\mathcal{N} || \sigma_\mathcal{N}) \geq \left( \frac{\pi}{4} \right)^4 \| \Delta_{\sigma, \rho} \|^{-2} \| \sigma_\mathcal{N}^{1/2} \rho_\mathcal{N}^{-1/2} \rho^{1/2} - \sigma^{1/2} \|_2^4 .
$$

(1.26)

The quantity on the right hand side may be estimated in terms of the Petz recovery map. In Section 2 we prove:

1.6 Lemma. Let $\rho$, $\sigma$ and $\sigma_\mathcal{N}$ be specified as in Theorem 1.5. Then, with $\| \cdot \|_1$ denoting the trace norm,

$$
\|(\sigma_\mathcal{N})^{1/2} (\rho_\mathcal{N})^{-1/2} \rho^{1/2} - \sigma^{1/2}\|_2 \geq \frac{1}{2} \| \mathcal{R}_\rho(\sigma_\mathcal{N}) - \sigma \|_1 .
$$

As an immediate Corollary of Theorem 1.5 and Corollary 1.6 we obtain

1.7 Corollary. Let $\rho$ and $\sigma$ be two states on $\mathcal{M}$. Let $\mathcal{E}_\tau$ be the tracial conditional expectation onto a von Neumann subalgebra $\mathcal{N}$, and let $\rho_\mathcal{N} = \mathcal{E}_\tau \rho$ and $\sigma_\mathcal{N} = \mathcal{E}_\tau \sigma$. Then, with $\| \cdot \|_1$ denoting the trace norm,

$$
S(\rho || \sigma) - S(\rho_\mathcal{N} || \sigma_\mathcal{N}) \geq \left( \frac{\pi}{8} \right)^4 \| \Delta_{\sigma, \rho} \|^{-2} \| \mathcal{R}_\rho(\sigma_\mathcal{N}) - \sigma \|_1^4 .
$$

(1.27)

Note how the right hand side of (1.27) differs from the right hand side of (1.13): Apart from the constant and the power 4 in place of 2, the most striking difference is that the roles of $\rho$ and $\sigma$ are reversed. The expected result, with a worse constant, is obtained in Corollary 1.8.

Recall that the modular operator is the right multiplication by $\rho^{-1}$ and left multiplication by $\sigma$, so $\| \Delta_{\sigma, \rho} \| \leq \| \rho^{-1} \|$, since $\| \sigma \| \leq 1$. While $\| \rho^{-1} \|$ might be considerably larger than $\| \Delta_{\sigma, \rho} \|$, a bound in terms of $\| \rho^{-1} \|$ has the merit that it is independent of $\sigma$:

$$
S(\rho || \sigma) - S(\rho_\mathcal{N} || \sigma_\mathcal{N}) \geq \left( \frac{\pi}{8} \right)^4 \| \rho^{-1} \|^{-2} \| \mathcal{R}_\rho(\sigma_\mathcal{N}) - \sigma \|_1^4 .
$$

(1.28)

Corollary 1.7 yields a result of Petz: With $\mathcal{M}$, $\mathcal{N}$, $\rho$ and $\sigma$ as above, $S(\rho || \sigma) = S(\rho_\mathcal{N} || \sigma_\mathcal{N})$ if and only if $\sigma$ satisfies the Petz equation

$$
\sigma = \mathcal{R}_\rho(\sigma_\mathcal{N}) .
$$

(1.29)

Theorem 1.5 gives what appears to be a stronger condition on relating $\rho$, $\sigma$, $\rho_\mathcal{N}$ and $\sigma_\mathcal{N}$, namely that

$$
\rho_\mathcal{N}^{-1/2} \rho^{1/2} = \sigma_\mathcal{N}^{-1/2} \sigma^{1/2} .
$$

(1.30)

While validity of (1.30) immediately implies that $\sigma$ satisfies the Petz equation (1.29), the converse is also true: By what we have noted above, when (1.29) is satisfied, $S(\rho || \sigma) = S(\rho_\mathcal{N} || \sigma_\mathcal{N})$, and then by Theorem 1.5 (1.30) is satisfied.

This may be made quantitative as follows: Letting $L_A$ denote the operator of left multiplication by $A$,

$$
L_{\rho_\mathcal{N}^{-1/2}} L_{\sigma_\mathcal{N}^{-1/2}} (\sigma_\mathcal{N}^{1/2} \rho_\mathcal{N}^{-1/2} \rho^{1/2} - \sigma^{1/2}) = (\rho^{1/2} - \rho_\mathcal{N}^{-1/2} \sigma_\mathcal{N}^{-1/2} \sigma^{1/2}) ,
$$
onto a von Neumann subalgebra \( N \) and the general element \( \rho \).

1.8 Corollary. Let \( \rho \) and \( \sigma \) be two states on \( \mathcal{M} \). Let \( \varepsilon_\tau \) be the tracial conditional expectation onto a von Neumann subalgebra \( N \), and let \( \rho_N = \varepsilon_\tau \rho \) and \( \sigma_N = \varepsilon_\tau \sigma \). Then

\[
S(\rho||\sigma) - S(\rho_N||\sigma_N) \geq \left( \frac{\pi}{4} \right)^4 \| \Delta_{\sigma,\rho} \|^{-2} \| \rho_N \|^{-2} \| \sigma_N^{-1} \|^{-2} \| \mathcal{R}_\sigma(\rho_N) - \rho \|_1^4.
\]

As above, bounding the norms of states by 1, we get a constant that depends only on the smallest eigenvalues of \( \rho \) and \( \sigma_N \)

\[
S(\rho||\sigma) - S(\rho_N||\sigma_N) \geq \left( \frac{\pi}{4} \right)^4 \| \rho^{-1} \|^{-2} \| \sigma_N^{-1} \|^{-2} \| \mathcal{R}_\sigma(\rho_N) - \rho \|_1^4.
\]

We noted above that \( \sigma \) solves the Petz equation if and only if (1.30) is satisfied, and then since (1.30) is symmetric in \( \rho \) and \( \sigma \), \( \sigma = \mathcal{R}_\rho \sigma_N \) if and only if \( \rho = \mathcal{R}_\sigma \rho_N \), and hence

\[
S(\rho||\sigma) = S(\rho_N||\sigma_N) \iff S(\sigma||\rho) = S(\sigma_N||\rho_N).
\]

The reasoning leading to Corollary 1.8 show that moreover, \( \| \rho = \mathcal{R}_\sigma \rho_N \|_1 \) and \( \| \sigma = \mathcal{R}_\rho \sigma_N \|_1 \) are comparable in size.

To state our results on the structure of the solution set of the Petz equation, we introduce the fixed point set

\[
\mathcal{C} := \{ X \in \mathcal{M} : \mathcal{A}_\rho(X) = X \}.
\]

Standard results (see Section 3) show that \( \mathcal{C} \) is a von Neumann subalgebra of \( \mathcal{N} \). Let \( \Delta_\rho \) denote the modular operator on \( \mathcal{M} \),

\[
\Delta_\rho(X) = \rho X \rho^{-1}.
\]

Then \( \mathcal{C} \) may also be characterized (Theorem 3.3) as the largest von Neumann subalgebra of \( \mathcal{N} \) that is invariant under \( \Delta_\rho \).

Let \( \mathcal{Z} \) denote the center of \( \mathcal{C} \). Then by standard results (see Section 3), \( \mathcal{Z} \) is generated by a finite family \( \{ P_1, \ldots, P_J \} \) of mutually orthogonal projections. Define \( \mathcal{H}^{(j)} \), \( j = 1, \ldots, J \), to be the range of \( P_j \). The restriction of \( \mathcal{C} \) to each \( \mathcal{H}^{(j)} \) is a factor, and hence each \( \mathcal{H}^{(j)} \) factors as \( \mathcal{H}_{j,\ell} \otimes \mathcal{H}_{j,r} \), and the general element \( A \) of \( \mathcal{C} \) has the form

\[
A = \sum_{j=1}^J 1_{\mathcal{H}_{j,\ell}} \otimes A_{j,r}.
\]
where \( A_{j,r} \in \mathcal{B}(H_{j,r}) \). All of this follows from the standard theory of the structure of finite dimensional von Neumann algebras, and we emphasize that \( \mathcal{C} \) and the decomposition \( \mathcal{H} = \bigoplus_{j=1}^{J} H_{j,\ell} \otimes H_{j,r} \) is canonically associated to \( \rho \).

Since \( \mathcal{C} \) is invariant under \( \Delta_{\rho} \), the orthogonal projection from \( \mathcal{M} \) onto \( \mathcal{N} \) in the GNS inner product induced by \( \rho \) is a conditional expectation (see Theorem 4.1) that we denote by \( \mathcal{E}_{C,\rho} \), and which we call the conditional expectation given \( \mathcal{C} \) under \( \rho \). We shall prove:

**1.9 Theorem.** Let \( \rho \) be a faithful state on \( \mathcal{M} \), and let \( \mathcal{N} \) be a von Neumann subalgebra of \( \mathcal{M} \). Let \( \mathcal{C} \) be the fixed-point algebra of the Accardi-Cecchini coarse graining operator \( A_{\rho} \). Let \( \mathcal{H} \) be the finite dimensional Hilbert space on which \( \mathcal{M} \) acts, and let \( \mathcal{H} = \bigoplus_{j=1}^{J} H_{j,\ell} \otimes H_{j,r} \) induced by the decomposition of \( \mathcal{C} \) as a direct sum of factors. Then there are uniquely determined density matrices \( \{ \gamma_{1,r}, \ldots, \gamma_{J,r} \} \), where \( \gamma_{j,r} \) acts on \( H_{j,r} \) and \( \gamma_{j,\ell} \otimes \mathbf{1}_{H_{j,r}} \in \mathcal{M} \) so that

\[
\rho = \bigoplus_{j=1}^{J} \gamma_{j,\ell} \otimes \text{Tr}_{H_{j,\ell}}(P_{j}\rho P_{j}).
\]  

Moreover, \( \mathcal{E}_{\tau}(\gamma_{j,\ell} \otimes \mathbf{1}_{H_{j,r}}) \) has the form \( \tilde{\gamma}_{j,\ell} \otimes \mathbf{1}_{H_{j,r}} \) and

\[
\rho_N = \bigoplus_{j=1}^{J} \tilde{\gamma}_{j,\ell} \otimes \text{Tr}_{H_{j,\ell}}(P_{j}\rho P_{j}).
\]

A state \( \sigma \) on \( \mathcal{M} \) solves the Petz equation \( R_{\rho}\sigma_{N} = \sigma \) if and only if for all \( X \) in \( \mathcal{M} \), \( \sigma(X) = \sigma(\mathcal{E}_{C,\rho}) \); i.e., if and only if expectations with respect to \( \sigma \) are preserved under the conditional expectation given \( \mathcal{C} \) under \( \rho \). Every such state \( \sigma \) has the form \( \sigma = \bigoplus_{j=1}^{J} \gamma_{j,\ell} \otimes \text{Tr}_{H_{j,\ell}}(P_{j}\sigma P_{j}) \) for the same \( \{ \gamma_{1,r}, \ldots, \gamma_{J,r} \} \)

**1.10 Corollary.** Let \( \rho, \sigma \) be faithful states on \( \mathcal{M} \), and let \( \mathcal{N} \) be a von Neumann subalgebra of \( \mathcal{M} \). Let \( \mathcal{C} \) be the fixed-point algebra of the Accardi-Cecchini coarse graining operator \( A_{\rho} \) for \( \mathcal{N} \). Let \( \mathcal{E}_{\mathcal{C},\rho}, \mathcal{E}_{\mathcal{C},\sigma} \) be the conditional expectation given \( \mathcal{C} \) under \( \rho \) and \( \sigma \), respectively. Define \( \rho_{\mathcal{C}} = \mathcal{E}_{\mathcal{C},\rho}, \sigma_{\mathcal{C}} = \mathcal{E}_{\mathcal{C},\sigma} \). Then

\[
S(\rho||\sigma) = S(\rho_{\mathcal{N}}||\sigma_{\mathcal{N}}) \iff S(\rho||\sigma) = S(\rho_{\mathcal{C}}||\sigma_{\mathcal{C}}).
\]

In particular, if \( \mathcal{C} \) is spanned by \( \mathbf{1} \), \( S(\rho||\sigma) = S(\rho_{\mathcal{N}}||\sigma_{\mathcal{N}}) \) if and only if \( \rho = \sigma \).

We close the introduction with some further comments on recovery map stability bounds for the Data Processing Inequality. In physical applications, instead of the trace distance, one often consider an alternative measure of the closeness between two quantum states, the fidelity [39]. For two states \( \rho \) and \( \sigma \) on \( \mathcal{B}(\mathcal{H}) \), the fidelity between them is defined as

\[
F(\rho, \sigma) = \|\sqrt{\rho} \sqrt{\sigma}\|_{1}^{2}.
\]

\[ (1.41) \]
For all states \( \rho \) and \( \sigma \), we have \( 0 \leq F(\rho, \sigma) \leq 1 \). The fidelity equal to one if and only if the states are equal, and it is equal to zero if and only is the support of \( \rho \) is orthogonal to the support of \( \sigma \). So in other words, the fidelity is zero when states are perfectly distinguishable, and zero when they cannot be distinguished. Note that the fidelity itself satisfies the monotonicity relation under a completely positive trace preserving maps, but we will not discuss it here. Moreover, there is a relation between the trace distance \( \| \rho - \sigma \|_1 \) and fidelity
\[
1 - \sqrt{F(\rho, \sigma)} \leq \frac{1}{2} \| \rho - \sigma \|_1 \leq \sqrt{1 - F(\rho, \sigma)} .
\] (1.42)

From here and the Corollary 1.7 we obtain the quantitative version of the Petz’s Theorem involving the fidelity between states
\[
S(\rho || \sigma) - S(\rho_N || \sigma_N) \geq \left( \frac{\pi}{4} \right)^4 \| \Delta_{\sigma, \rho} \|^2 \left( 1 - \sqrt{F(\sigma, R_{\rho}(\sigma_N))} \right)^4 .
\] (1.43)

Recent results [13, 17, 45, 46] provide sharpening of the monotonicity inequality, but the lower bounds provided there involve quantities that are hard to compute, e.g. rotated and twirled Petz recovery maps. for another fidelity type bound not explicitly involving the recover map, see [8, Theorem 2.2]. The appeal of the above bound is that it involves simple distance measure between the original state \( \sigma \) and Petz recovered state \( R_{\rho}(\sigma_N) \).

The proof of the theorem 1.5 also implies that satisfaction of the Petz equation \( R_{\rho}\sigma_N = \sigma \) is the necessary and sufficient condition for cases of equality in the monotonicity inequality for a large class of quasi-relative entropies, as we now briefly explain.

Let \( f : (0, +\infty) \to \mathbb{R} \) be an operator convex function, so that for all \( n \in \mathbb{N} \), and all positive \( n \times n \) matrices \( A \) and \( B \), \( f(\frac{1}{2}A + \frac{1}{2}B) \leq \frac{1}{2}f(A) + \frac{1}{2}f(B) \). We say that \( f \) is strictly operator convex in case there is equality if and only if \( A = B \).

Petz [25, 26] has defined the \( f \)-relative quasi-entropy as
\[
S_f(\rho || \sigma) = \text{Tr}[f(\Delta_{\sigma, \rho})\rho] = \langle \rho^{1/2}, f(\Delta_{\sigma, \rho})\rho^{1/2} \rangle_{HS} .
\] (1.44)

Since \( -\log(\Delta_{\sigma, \rho})\rho^{1/2} = \rho^{1/2} \log \rho - \log \sigma \rho^{1/2} \), the choice \( f(x) = -\log x \) yields the Umegaki relative entropy.

Since for each \( t > 0 \), the function \( x \mapsto (t + x)^{-1} \) is operator convex, this construction yields a one parameter family a quasi relative entropies, \( S_{(t)} \), defined by
\[
S_{(t)}(\rho || \sigma) = \text{Tr} [(t + \Delta_{\sigma, \rho})^{-1}\rho] .
\] (1.45)

From the integral representation of the logarithm
\[
-\log(A) = \int_0^\infty \left( \frac{1}{t + A} - \frac{1}{1 + t} \right) dt ,
\]
it follows that
\[
S(\rho || \sigma) = \int_0^\infty \left( S_{(t)}(\rho || \sigma) - \frac{1}{1 + t} \right) dt ,
\] (1.46)
and we may use this representation to study monotonicity for the Umegaki relative entropy in terms of monotonicity for the one parameter family of quasi relative entropies $S_{(t)}$. The proof of Theorem 1.5 is ultimately derived from a stability bound for the variant of the Data Processing Inequality that is valid for the quasi relative entropies $S_{(t)}$. Since the Rényi relative entropies can be expressed in terms of a similar integral representation, the Petz equation $\sigma = R_{\rho} \sigma_N$ again characterizes the condition for cases of equality in these variants of the Data Processing Inequality; this will be developed in detail in a companion paper.

2 Stability for the Data Processing Inequality

We begin this section by recalling Petz’s proof of the monotonicity of the quasi relative entropies $S_f$ for operator convex $f$.

Throughout this section $\mathcal{N}$ is a von Neumann subalgebra of the finite dimensional von Neumann algebra $\mathcal{M}$, and $\rho$ and $\sigma$ are two density matrices in $\mathcal{M}$. $\mathcal{E}_\tau$ is the tracial conditional expectation onto $\mathcal{N}$, and $\rho_N = \mathcal{E}_\tau \rho$ and $\sigma_N = \mathcal{E}_\tau \sigma$. Finally $\mathcal{H}$ denotes $(\mathcal{M}, \langle \cdot, \cdot \rangle_{HS})$.

Define the operator $U$ mapping $\mathcal{H}$ to $\mathcal{H}$ by

$$ U(X) = \mathcal{E}_\tau(X) \rho_N^{-1/2} \rho^{1/2}. \quad (2.1) $$

Note that for all $X \in \mathcal{N}$, $U(X) = X \rho_N^{-1/2} \rho^{1/2}$. The adjoint operator on $\mathcal{H}$ is given by

$$ U^*(Y) = \mathcal{E}_\tau(Y \rho^{1/2}) \rho_N^{-1/2} \quad (2.2) $$

for all $Y \in \mathcal{H} = \mathcal{M}$.

For $X \in \mathcal{M}$, $U^* U(X) = \mathcal{E}_\tau(\rho_N^{-1/2} \mathcal{E}_\tau(X) \rho_N^{-1/2} \rho) = \mathcal{E}_\tau(X)$. Hence $U^* U = \mathcal{E}_\tau$, the orthogonal projection in $\mathcal{H}$ onto $\mathcal{N}$. That is, $U$, restricted to $\mathcal{N}$, is an isometric embedding of $\mathcal{N}$ into $\mathcal{H} = \mathcal{M}$, but it is not the trivial isometric embedding by inclusion. Also, we see that on $\mathcal{N}$ the map $U$ is isometric.

Now observe that for all $X \in \mathcal{N}$, $\Delta^{1/2}_{\sigma, \rho}(U(X)) = \sigma^{1/2} X \rho_N^{-1/2}$, and hence for all $X \in \mathcal{N}$,

$$ \langle \Delta^{1/2}_{\sigma, \rho}(U(X)), \Delta^{1/2}_{\sigma, \rho}(U(X)) \rangle = \text{Tr}((\rho_N)^{-1/2} X^* \sigma X (\rho_N)^{-1/2}) \]
$$

$$ = \text{Tr}((\rho_N)^{-1/2} X^* \sigma N X (\rho_N)^{-1/2}) \]
$$

$$ = \langle \Delta^{1/2}_{\sigma N, \rho N}(X), \Delta^{1/2}_{\sigma N, \rho N}(X) \rangle. \quad (2.3) $$

That is, on $\mathcal{N}$,

$$ U^* \Delta_{\sigma, \rho} U = \Delta_{\sigma N, \rho N}. \quad (2.3) $$

By the operator Jensen inequality, as operators on $(\mathcal{N}, \langle \cdot, \cdot \rangle_{HS})$,

$$ U^* f(\Delta_{\sigma, \rho}) U \geq f(U^* \Delta_{\sigma, \rho} U). \quad (2.4) $$
Combining (2.3) and (2.4), and using the fact that $U(\rho_N)^{1/2} = \rho^{1/2}$,

$$S_f(\rho_N||\sigma_N) = \langle \rho_N^{1/2}, f(\Delta_{\sigma_N,\rho_N})(\rho_N)^{1/2} \rangle$$
$$\leq \langle U(\rho_N)^{1/2}, f(\Delta_{\sigma,\rho})U(\rho_N)^{1/2} \rangle$$
$$= \langle \rho^{1/2}, f(\Delta_{\sigma,\rho})\rho^{1/2} \rangle = S_f(\rho||\sigma).$$

This proves, following Petz, his monotonicity theorem for the quasi relative entropy $S_f$ for the operator convex function.

Now consider the family of quasi relative entropies defined by functions $f_i(x) = (t+x)^{-1}$. Our immediate goal is to prove the inequality

$$S_{(t)}(\rho||\sigma) = \langle \rho^{1/2}, (t + \Delta_{\sigma,\rho})^{-1}\rho^{1/2} \rangle \geq \langle \rho_N^{1/2}, (t + \Delta_{\sigma_N,\rho_N})^{-1}\rho_N^{1/2} \rangle = S_{(t)}(\rho_N||\sigma_N). \quad (2.5)$$

**2.1 Lemma.** Let $U$ be a partial isometry embedding a Hilbert space $\mathcal{K}$ into a Hilbert space $\mathcal{H}$. Let $B$ be an invertible positive operator on $\mathcal{K}$, $A$ be an invertible positive operator on $\mathcal{H}$, and suppose that $U^*AU = B$. Then for all $v \in \mathcal{K}$,

$$\langle v, U^*A^{-1}Uv \rangle = \langle v, B^{-1}v \rangle + \langle w, Aw \rangle, \quad (2.6)$$

where

$$w := UB^{-1}v - A^{-1}Uv. \quad (2.7)$$

**Proof.** We compute, using $U^*U = 1_\mathcal{K}$,

$$\langle w, Aw \rangle = \langle UB^{-1}v - A^{-1}Uv, AUB^{-1}v - Uv \rangle$$
$$= \langle v, B^{-1}U^*AUB^{-1}v \rangle - 2\langle v, B^{-1}v \rangle + \langle v, U^*A^{-1}Uv \rangle$$
$$= -\langle v, B^{-1}v \rangle + \langle v, U^*A^{-1}Uv \rangle$$

$\square$

**Proof of Theorem 1.5.** We apply Lemma 2.1 with $A := (t + \Delta_{\sigma,\rho})$, $B := (t + \Delta_{\sigma_N,\rho_N})$ and $v := (\rho_N)^{1/2}$, and with $U$ defined as above. The lemma’s condition, $U^*AU = B$, follows from (2.3) and the fact that $U^*U = 1_\mathcal{K}$. Therefore, applying Lemma 2.1 with $U(\rho_N)^{1/2} = \rho^{1/2}$,

$$S_{(t)}(\rho||\sigma) - S_{(t)}(\rho_N||\sigma_N) = \langle \rho^{1/2}, (t + \Delta_{\sigma,\rho})^{-1}\rho^{1/2} \rangle - \langle \rho_N^{1/2}, (t + \Delta_{\sigma_N,\rho_N})^{-1}\rho_N^{1/2} \rangle$$
$$= \langle w_t, (t + \Delta_{\sigma,\rho})w_t \rangle \geq t\|w_t\|^2, \quad (2.8)$$

where, recalling that $U(\rho_N)^{1/2} = \rho^{1/2}$,

$$w_t := U(t + \Delta_{\sigma_N,\rho_N})^{-1}(\rho_N)^{1/2} - (t + \Delta_{\sigma,\rho})^{-1}\rho^{1/2}. \quad (2.9)$$

Using the integral representation of the square root function,

$$X^{1/2} = \frac{1}{\pi} \int_0^\infty t^{1/2} \left( \frac{1}{t} - \frac{1}{t + X} \right) dt,$$
and $U(N\rho)^{1/2} = \rho^{1/2}$ once more, we conclude that

$$U(\Delta_{\sigma_N,\rho_N})^{1/2}(\rho_N)^{1/2} - (\Delta_{\sigma,\rho})^{1/2} \rho^{1/2} = \frac{1}{\pi} \int_0^\infty t^{1/2} w_1 dt.$$ 

On the other hand,

$$U(\Delta_{\sigma_N,\rho_N})^{1/2}(\rho_N)^{1/2} - (\Delta_{\sigma,\rho})^{1/2} \rho^{1/2} = U(\sigma_N)^{1/2} - \sigma^{1/2} = (\sigma_N)^{1/2}(\rho_N)^{-1/2} \rho^{1/2} - \sigma^{1/2}.$$ 

Therefore, combining the last two equalities and taking the Hilbert space norm associated with $\mathcal{H}$, for any $T > 0$,

$$\| (\sigma_N)^{1/2}(\rho_N)^{-1/2} \rho^{1/2} - \sigma^{1/2} \|_2 = \frac{1}{\pi} \left\| \int_0^\infty t^{1/2} w_1 dt \right\|_2 
\leq \frac{1}{\pi} \int_0^T t^{1/2} \| w_1 \|_2 dt + \frac{1}{\pi} \left\| \int_T^\infty t^{1/2} w_1 dt \right\|_2. \quad (2.10)$$

We estimate these two terms separately. For the first term, by the Cauchy-Schwarz inequality,

$$\left( \int_0^T t^{1/2} \| w_1 \|_2 dt \right)^2 \leq T \int_0^T t \| w_1 \|^2_2 dt \leq T \int_0^\infty (S(t)(\rho||\sigma) - S(t)(\rho_N||\sigma_N)) dt = T(S(\rho||\sigma) - S(\rho_N||\sigma_N)). \quad (2.11)$$

For the second term in (2.10), note that for any positive operator $X$

$$t^{1/2} \left( \frac{1}{t - \frac{1}{t + X}} \right) \leq t^{1/2} \left( \frac{1}{t - \frac{1}{t + \| X \|}} \right) \mathbf{1} = \frac{\| X \|}{t^{1/2}(\| X \| + t)} \mathbf{1},$$

and hence

$$\int_T^\infty t^{1/2} \left( \frac{1}{t - \frac{1}{t + X}} \right) dt \leq \| X \|^{1/2} \left( \int_T^\infty \frac{1}{t^{1/2}(1 + t)} dt \right) \mathbf{1} \leq \frac{2\| X \|}{T^{1/2}} \mathbf{1}.$$

The spectra of $\sigma_N$ and $\rho_N$ lie in the convex hulls of the spectra of $\sigma$ and $\rho$ respectively. It follows that $\| \Delta_{\sigma_N,\rho_N} \| \leq \| \Delta_{\sigma,\rho} \|$. Therefore, recalling the definition of $w_t$ in (2.9), we obtain

$$\left\| \int_T^\infty t^{1/2} w_1 dt \right\|_2 \leq \frac{4\| \Delta_{\sigma,\rho} \|}{T^{1/2}}. \quad (2.12)$$

Combining (2.10), (2.11) and (2.12) we obtain

$$\| (\sigma_N)^{1/2}(\rho_N)^{-1/2} \rho^{1/2} - \sigma^{1/2} \|_2 \leq \frac{1}{\pi}T^{1/2}(S(\rho||\sigma) - S(\rho_N||\sigma_N))^{1/2} + \frac{4\| \Delta_{\sigma,\rho} \|}{\pi T^{1/2}}.$$
Optimizing in $T$,
\[
\|(\sigma_N)^{1/2}(\rho_N)^{-1/2}\rho^{1/2} - \sigma^{1/2}\|_2 \leq \frac{4}{\pi} \|\Delta_{\sigma,\rho}\|^{1/2} (S(\rho||\sigma) - S(\rho_N||\sigma_N))^{1/4}
\]
Rearranging terms
\[
S(\rho||\sigma) - S(\rho_N||\sigma_N) \geq \left(\frac{\pi}{4}\right)^4 \|\Delta_{\sigma,\rho}\|^{-2} \|(\sigma_N)^{1/2}(\rho_N)^{-1/2}\rho^{1/2} - \sigma^{1/2}\|_2^4.
\]
(2.13)

We now prove the lemma leading from (1.26) to (1.27).

2.2 Lemma. For any operators $X$ and $Y$ with $\text{Tr}[X^*X] = \text{Tr}[Y^*Y] = 1$. Then
\[
\|X^*X - Y^*Y\|_1 \leq 2\|X - Y\|_2.
\]
(2.14)

Proof. Recall that for any operator $A$, $\|A\|_1 = \sup\{|\text{Tr}[ZA]| : \|Z\| \leq 1\}$ where $\|\cdot\|$ denotes the operator norm. For any contraction $Z$, using cyclicity of the trace we have
\[
|\text{Tr}[Z(X^*X - Y^*Y)]| \leq |\text{Tr}[Z(X^* - Y^*)X + ZY^*(X - Y)]|
\leq |\text{Tr}[(X^* - Y^*)XZ]| + |\text{Tr}[ZY^*(X - Y)]|
\leq (\text{Tr}[(X^* - Y^*)(X - Y)])^{1/2}(\text{Tr}[X^*ZX])^{1/2}
+ (\text{Tr}[(X^* - Y^*)(X - Y)])^{1/2}(\text{Tr}[Y^*ZY])^{1/2}
\leq 2\|X - Y\|_2.
\]

Applying this with $X = (\sigma_N)^{1/2}(\rho_N)^{-1/2}\rho^{1/2}$ and $Y = \sigma^{1/2}$, we get
\[
\|(\sigma_N)^{1/2}(\rho_N)^{-1/2}\rho^{1/2} - \sigma^{1/2}\|_2 \geq \frac{1}{2}\|\mathcal{R}_\rho(\sigma_N) - \sigma\|_1.
\]

3 Structure of the solution set of the Petz equation

Define the CPTP map $\Phi : \mathcal{M} \to \mathcal{M}$ by
\[
\Phi := \mathcal{R}_\rho \circ \mathcal{E}_\tau.
\]
(3.1)

The Petz equation (1.29) can be written as $\Phi(\sigma) = \sigma$. The adjoint of $\Phi$, is the completely positive unital map $\Phi^\dagger = \Psi : \mathcal{N} \to \mathcal{N}$ given by
\[
\Psi := \iota_{\mathcal{N},\mathcal{M}} \circ \mathcal{A}_\rho.
\]
(3.2)

where $\iota_{\mathcal{N},\mathcal{M}}$ is the inclusion of $\mathcal{N}$ in $\mathcal{M}$.
The problem of determining all of the states fixed by $\Phi$ is closely related to the problem of determining all of the fixed points of $\Psi$ in $\mathcal{M}$. This problem has been investigated in a general context by Lindblad [21] in the proof of his General No-cloning Theorem, drawing on earlier work by Choi and Kadison. It was also investigated in this specific context by Accardi and Cecchini. For now, we need not assume that $\Psi$ is given by (3.2). For now, all we require is that $\Psi$ is a unital completely positive map from $\mathcal{M}$ to $\mathcal{M}$, and that its Hilbert-Schmidt dual $\Phi$ has a faithful invariant state $\rho$.

Then, by an often used argument, the map $\Psi$ is a contraction on $(\mathcal{M}, \langle \cdot, \cdot \rangle_{GNS,\rho})$: By the operator Schwarz inequality, for all $X \in \mathcal{M}$, $\Psi(X)^* \Psi(X) \leq \Psi(X^* X)$. Then

$$
\|\Psi(X)\|_{GNS,\rho}^2 = \rho(\Psi(X)^* \Psi(X)) \leq \rho(\Psi(X^* X)) = \Phi(\rho)(X^* X) = \|X\|_{GNS,\rho}^2.
$$

Define

$$
C = \{ X \in \mathcal{N} : \Psi(X) = X \},
$$

which is evidently a subspace. Let $\mathcal{E}_C$ be the orthogonal projection in $(\mathcal{M}, \langle \cdot, \cdot \rangle_{GNS,\rho})$ onto $C$. Then, arguing as in [21], by the von Neumann Mean Ergodic Theorem,

$$
\mathcal{E}_C(X) = \lim_{N \to \infty} \frac{1}{N} \sum_{j=1}^N \Psi^j(X),
$$

The following lemma may be found in [21]; we give the short proof for the reader’s convenience.

**3.1 Lemma.** Let $\Phi$ be a CPTP map on $\mathcal{M}$, and let $\Psi = \Phi^\dagger$. A density matrix $\tau \in \mathcal{M}$ satisfies $\Phi(\tau) = \tau$ if and only if it satisfies $\mathcal{E}_C(\tau) = \tau$.

**Proof.** Let $\tau$ be any density matrix $\tau$ in $\mathcal{M}$ such that $\Phi(\tau) = \tau$ For all $N$ and all $X \in \mathcal{M},$

$$
\text{Tr}(\tau X) = \frac{1}{N} \sum_{j=1}^N \text{Tr}(\Phi^j(\tau) X) = \frac{1}{N} \sum_{j=1}^N \text{Tr}(\tau \Psi^j(X)) = \text{Tr}(\tau \mathcal{E}_C(X)).
$$

In the limit, we obtain $\text{Tr}(\tau X) = \text{Tr}(\tau \mathcal{E}_C(\tau)) = \text{Tr}(\mathcal{E}_C^\dagger(\tau) X)$. Hence $\tau = \mathcal{E}_C^\dagger \tau$.

Now suppose that $\tau$ is any density matrix in $\mathcal{M}$ satisfying $\tau = \mathcal{E}_C^\dagger \tau$. Since evidently, $\Psi \circ \mathcal{E}_C = \mathcal{E}_C \circ \Psi = \mathcal{E}_C$, for all $X \in \mathcal{M},$

$$
\text{Tr}(\tau X) = \text{Tr}(\mathcal{E}_C^\dagger(\tau) X) = \text{Tr}(\tau, (\mathcal{E}_C^\dagger X)) = \text{Tr}(\tau, (\mathcal{E}_C^\dagger(\Psi X))) = \text{Tr}(\tau, (\Psi X)) = \text{Tr}(\Phi(\tau) X).
$$

since $X$ is arbitrary, $\Phi(\tau) = \tau$. \qed

Furthermore, by results of Choi [5] and Lindblad [21], $\mathcal{C}$ is a unital $\ast$-subalgebra of $\mathcal{N}$. Let $\mathcal{Z}$ denote the center of $\mathcal{C}$, which is commutative von Neumann algebra. Because $\mathcal{Z}$ is commutative, it has a particularly simple structure: If $P$ and $Q$ are two orthogonal projections in $\mathcal{Z}$, then $PQ = QP$ is also an orthogonal projection in $\mathcal{Z}$. Since $\mathcal{Z}$ is the closed linear span of the projections contained in it, one easily deduces the existence of a family $\{ P_1, \ldots, P_J \}$ of mutually orthogonal projections summing to the identity such that $\mathcal{Z}$ is the span of these projections.
Define $\mathcal{H}^{(j)}$, $j = 1, \ldots, J$, to be the range of $P_j$. Then the Hilbert space $\mathcal{H}$ on which $\mathcal{M}$ acts can be decomposed as $\mathcal{H} = \bigoplus_{j=1}^{J} \mathcal{H}^{(j)}$. (The notation is chosen to avoid confusion with tensor product decompositions such as, e.g., $\mathcal{H} = \mathcal{H}_1 \otimes \mathcal{H}_2$ for bipartite systems.) Then each $\mathcal{H}^{(j)}$ is invariant under $C$, and the center of $C$ restricted to each $\mathcal{H}^{(j)}$ is trivial – it is spanned by $P_j$, the identity on $\mathcal{H}^{(j)}$. Therefore, the restriction of $C$ to each $\mathcal{H}^{(j)}$ is a factor – a $*$-subalgebra of $\mathcal{B}(\mathcal{H})$ with a trivial center. By the well-known structure theorem for finite dimensional factors, $\mathcal{H}^{(j)}$ can be factored as $\mathcal{H}^{(j)} = \mathcal{H}_{j,\ell} \otimes \mathcal{H}_{j,r}$ and

$$C_j = 1_{\mathcal{H}_{j,\ell}} \otimes \mathcal{B}(\mathcal{H}_{j,r}).$$

Using this decomposition and structure theorem, Lindblad proves [21, Section 4] the following, stated here in terms of the notation set above:

**3.2 Lemma.** Let $\Psi$ be a unital completely positive map on $\mathcal{M}$, where $\mathcal{M}$ acts on a finite dimensional Hilbert space $\mathcal{H}$, and where $\Psi^\dagger$ leaves a faithful state $\rho$ invariant. Let $E_C$ be the orthogonal projection onto $C$, the $C^*$ algebra of fixed points of $\Psi$, with respect to the GNS inner product induced by $\rho$. Then there are uniquely determined density matrices $\{\gamma_1, \ldots, \gamma_J\}$, where $\gamma_{j,r}$ acts on $\mathcal{H}_{j,r}$, such that for all $Y \in \mathcal{M}$,

$$E_C(Y) = \sum_{j=1}^{J} 1_{\mathcal{H}_{j,\ell}} \otimes \text{Tr}_{\mathcal{H}_{j,\ell}}[(\gamma_{j,\ell} \otimes 1_{\mathcal{H}_{j,r}})P_j Y P_j],$$

where $\text{Tr}_{\mathcal{H}_{j,\ell}}$ denotes the trace over $\mathcal{H}_{j,\ell}$.

From this explicit description of $E_C$, one readily deduces that

$$E_C^\dagger(\tau) = \sum_{j=1}^{J} \gamma_{j,\ell} \otimes \text{Tr}_{\mathcal{H}_{j,\ell}}(P_j \tau P_j)$$

(3.4)

where $\gamma_{j,\ell} \otimes \text{Tr}_{\mathcal{H}_{j,\ell}}(P_j \tau P_j)$ is defined as operators on all of $\mathcal{H}$ by setting it to zero on the orthogonal complement of $\mathcal{H}^{(j)}$. Hence $\tau = E_C^\dagger(\tau)$ if and only if $\tau$ is given by the right hand side of (3.4).

Now return to the case at hand, in which $\Phi$ and $\Psi$ are given by (3.1) and (3.2) respectively.

**Proof of Theorem 1.9.** Since $\Phi \rho = \rho$, Lemma 3.1, Lemma 3.2 and (3.4) yield

$$\rho = \sum_{j=1}^{J} \gamma_{j,\ell} \otimes \text{Tr}_{\mathcal{H}_{j,\ell}}(P_j \rho P_j)$$

(3.5)

with the set $\{\gamma_1, \ldots, \gamma_J\}$ determined by $C$, the fixed point algebra of $\Psi = \iota_{\mathcal{N},\mathcal{M}} \circ \mathcal{A}_\rho$.

Next observe that $C$ is a von Neumann subalgebra of $\mathcal{N}$, and is in fact that fixed point algebra of $\bar{\Psi} := \mathcal{A}_\rho \circ \iota_{\mathcal{N},\mathcal{M}}$ as well as of $\Psi = \iota_{\mathcal{N},\mathcal{M}} \circ \mathcal{A}_\rho$. Since $\bar{\Phi} := \bar{\Psi}^\dagger = \mathcal{E}_\tau \circ \mathcal{R}_{\rho}$, we have $\bar{\Phi} \rho_{\mathcal{N}} = \rho_{\mathcal{N}}$ and
\( \tilde{\Phi}_N = \sigma_N \). Using Lemma 3.1, Lemma 3.2 and (3.4) once more, we see that for some \( \{ \tilde{\gamma}_{j,\ell}, \ldots, \tilde{\gamma}_{J,\ell} \} \), where for each \( j \), \( \tilde{\gamma}_{j,\ell} \) is a density matrix on \( \mathcal{H}_{j,\ell} \)

\[
\rho_N = \sum_{j=1}^{J} \tilde{\gamma}_{j,\ell} \otimes \text{Tr}_{\mathcal{H}_{j,\ell}}(P_j \rho_P P_j) \quad .
\]  

(3.6)

Now observe that we may factor

\[
\rho = \sum_{j=1}^{J} (\gamma_{j,\ell} \otimes 1_{\mathcal{H}_{j,r}})(1_{\mathcal{H}_{j,\ell}} \otimes (\text{Tr}_{\mathcal{H}_{j,\ell}}(P_j \rho_P P_j)))
\]  

(3.7)

For each \( j \), \( 1_{\mathcal{H}_{j,\ell}} \otimes \text{Tr}_{\mathcal{H}_{j,\ell}}(P_j \rho_P P_j) \in \mathcal{C} \subset \mathcal{N} \). Therefore,

\[
\rho_N = \mathcal{E}_\tau \rho = \sum_{j=1}^{J} \mathcal{E}_\tau(\gamma_{j,\ell} \otimes 1_{\mathcal{H}_{j,r}})(1_{\mathcal{H}_{j,\ell}} \otimes (\text{Tr}_{\mathcal{H}_{j,\ell}}(P_j \rho_P P_j)))
\]  

(3.8)

We now claim that for each \( j \),

\[
\mathcal{E}_\tau(\gamma_{j,\ell} \otimes 1_{\mathcal{H}_{j,r}}) = \tilde{\gamma}_{j,\ell} \otimes 1_{\mathcal{H}_{j,r}}
\]  

(3.9)

To see this note that since \( \mathcal{Z} \subset \mathcal{C} \subset \mathcal{N}, \) \( \mathcal{N'} = \mathcal{C'} \subset \mathcal{Z'} = \{P_1, \ldots, P_J\}', \) every unitary in \( \mathcal{N}' \) commutes with each \( P_j \) and thus has the block form \( U = \sum_{j=1}^{J} P_j U P_j \). Moreover, again using the fact that \( \mathcal{N'} \subset \mathcal{C'} \), and that the commutator of \( 1_{\mathcal{H}_{j,\ell}} \otimes \mathcal{B}(\mathcal{H}_{j,r}) \) is \( \mathcal{B}(\mathcal{H}_{j,\ell}) \otimes 1_{\mathcal{H}_{j,r}} \), we see that \( U \) has the form

\[
U = \sum_{j=1}^{J} P_j(U_{j,\ell} \otimes 1_{\mathcal{H}_{j,r}}) P_j,
\]

where \( U_{j,\ell} \) is unitary on \( \mathcal{H}_{j,\ell} \), though in general, only a subset of the block unitaries of this form belong to \( \mathcal{N}' \). In any case, representing \( \mathcal{E}_\tau \) as an average over appropriate unitaries of this form \( [12, 38] \), we obtain (3.9). Now combining (3.7), (3.8) and (3.9) yields

\[
\rho_N = \sum_{j=1}^{J} (\gamma_{j,\ell} \otimes 1_{\mathcal{H}_{j,r}})(1_{\mathcal{H}_{j,\ell}} \otimes (\text{Tr}_{\mathcal{H}_{j,\ell}}(P_j \rho_P P_j)))
\]  

(3.10)

Combing (3.7) and (3.10) it follows that \( \rho^{-1} \rho_N = \sum_{j=1}^{J} (\gamma_{j,\ell}^{-1} \tilde{\gamma}_{j,\ell} \otimes 1_{\mathcal{H}_{j,r}}) \). The general element \( A \) of \( \mathcal{C} \) has the from \( A = \sum_{j=1}^{J} 1_{\mathcal{H}_{j,\ell}} \otimes A_{j,r} \) where each \( A_{j,r} \in \mathcal{B}(\mathcal{H}_{j,r}) \). For such \( A \),

\[
\Delta_p^{-1}(\Delta_{\rho_N}(A)) = \rho_N^{-1} \rho A \rho^{-1} \rho_N = A \quad ,
\]  

(3.11)

and this verifies that \( \Delta_p(A) = \Delta_{\rho_N}(A) \) for all \( A \in \mathcal{C} \), which we know must be valid by Theorem 4.1.

The same analysis applies to \( \sigma \) and \( \sigma_N \) yielding \( \sigma = \sum_{j=1}^{J} (\gamma_{j,\ell} \otimes 1_{\mathcal{H}_{j,r}})(1_{\mathcal{H}_{j,\ell}} \otimes (\text{Tr}_{\mathcal{H}_{j,\ell}}(P_j \sigma_P P_j))) \) and \( \sigma_N = \sum_{j=1}^{J} (\tilde{\gamma}_{j,\ell} \otimes 1_{\mathcal{H}_{j,r}})(1_{\mathcal{H}_{j,\ell}} \otimes (\text{Tr}_{\mathcal{H}_{j,\ell}}(P_j \sigma_P P_j))) \), and then \( \Delta_{\sigma}(A) = \Delta_{\sigma_N}(A) \) for all \( A \in \mathcal{C} \). \( \Box \)
3.3 Theorem. Let $C$ be defined by (3.3) and $\Psi := \iota_{N,M} \circ \mathcal{A}_\rho$, and let $B$ be any other von Neumann subalgebra of $N$ that is invariant under $\Delta_\rho$. Then $B \subset C$.

Proof. Let $E_{\tau,B}$ denote the tracial conditional expectation onto $B$, and define $\rho_B := E_{\tau,B} \rho$. Let $\mathcal{A}_{\rho,B,N}$, $\mathcal{A}_{\rho,N,M}$ and $\mathcal{A}_{\rho,B,M}$ be the Accardi-Cecchini coarse graining operators from $N$ to $B$, $M$ to $N$ and $M$ to $B$. A simple computation shows that

$$\mathcal{A}_{\rho,B,M} = \mathcal{A}_{\rho,B,N} \circ \mathcal{A}_{\rho,N,M} \quad (3.12)$$

Let $P_B$ denote the orthogonal projection of $M$ onto $B$ with respect to the GNS inner product induced by $\rho$. Since $\Delta_\rho$ leaves $B$ invariant, by (2) of Theorem 4.1 $\mathcal{A}_{\rho,B,M} = P_B$. We claim that $\mathcal{A}_{\rho,B,N}$ is the restriction of $P_\rho$ to $N$. Indeed, by the defining relation (1.18), for all $X \in M$ and all $Y \in B$,

$$\langle X, Y \rangle_{KMS,\rho} = \langle \mathcal{A}_{\rho,B,M}(X), Y \rangle_{KMS,\rho_B} \quad (3.13)$$

Tautologically, this holds for all $X \in N$ and all $Y \in B$, and so for all $X \in N$, $\mathcal{A}_{\rho,B,N}(X) = \mathcal{A}_{\rho,B,M}(X)$. We therefore have that for all $B \in B$

$$B = P_\rho B = P_\rho B \circ \mathcal{A}_{\rho,N,M}(B) \quad (3.14)$$

and this implies that $B = \mathcal{A}_{\rho,N,M}(B)$, which, by definition, means that $B \in C$. \hfill \square

4 Conditional expectations

Recall from the introduction that if $\rho$ is a faithful state on $M$ and $N$ is a von Neumann subalgebra of $M$, then there exists a conditional expectation $\mathcal{E}$ from $M$ to $N$ such that for all $X \in M$, $\rho(X) = \rho(\mathcal{E}(X))$ if and only if the orthogonal projection onto $N$ in the GNS inner product induced by $\rho$ is a conditional expectation.

This raises the question: For which faithful states $\rho$ is the orthogonal projection onto $N$ in the GNS inner product induced by $\rho$ actually a conditional expectation?

4.1 Theorem. Let $M$ be a finite dimensional von Neumann algebra, and let $N$ be a von Neumann subalgebra of $M$. Let $\rho$ be a faithful state on $M$, and let $\Delta_\rho$ be the modular operator on $M$ defined by $\Delta_\rho(X) = \rho X \rho^{-1}$. Let $P_\rho$ be the orthogonal projection from $M$ onto $N$ in the GNS inner product induced by $\rho$. Then:

(1) $P_\rho$ is real; i.e., it preserves self-adjointness, if and only if $N$ is invariant under $\Delta_\rho$.

(2) $N$ is invariant under $\Delta_\rho$ if and only if for all $A \in N$,

$$\Delta_\rho(A) = \Delta_{\rho,N}(A) \quad (4.1)$$

in which case $\Delta_\rho^t(A) = \Delta_{\rho,N}^t(A)$ for all $t \in \mathbb{R}$. Furthermore, (4.1) is valid for all $A \in N$ if and only if $\mathcal{A}_\rho(A) = A$ for all $A \in N$. 

4.2 Remark. Part (2) of Theorem 4.1 is due to Accardi and Cecchini [2, Theorem 5.1]. In our finite dimensional context, we give a very simple proof; most of the proof below is devoted to (1).

Proof of Theorem 4.1. Suppose that is arbitrary in $N$. Then, applying the Gram-Schmidt Algorithm, one can produce an orthonormal basis \{H_1, \ldots, H_m\} of $\text{Null}(\rho)$ consisting of self-adjoint elements of $M$. Let $m$ denote the dimension of $\text{Null}(\rho)$. Then, for all $x \in \text{Null}(\rho)$, it follows that $\rho$ is self-adjoint subspaces of $M$. Let $m$ denote the dimension of $\text{Null}(\rho)$. Then, applying the Gram-Schmidt Algorithm, one can produce an orthonormal basis \{H_1, \ldots, H_m\} of $\text{Null}(\rho)$ consisting of self-adjoint elements of $M$.

The map $X \mapsto X^{1/2}$ is unitary from $(M, \langle \cdot, \cdot \rangle_{GNS})$ to $(M, \langle \cdot, \cdot \rangle_{HS})$. Therefore for all $A \in N$, and each $j = 1, \ldots, m$, $\langle Ap^{1/2}, H_jp^{1/2}\rangle_{HS} = 0$. Then since the map $X \mapsto X^*$ is an (antilinear) isometry on $(M, \langle \cdot, \cdot \rangle_{HS})$,

$$0 = \langle (H_jp^{1/2})^*, (Ap^{1/2})^* \rangle_{HS} = \text{Tr}[H_jpA^*] = \text{Tr}[H_j\Delta_p(A^*)\rho] = \langle H_j, \Delta_p(A^*) \rangle_{GNS, \rho}.$$ 

Therefore, $\Delta_p(A^*)$ is orthogonal to $\text{Null}(\rho)$ in $(M, \langle \cdot, \cdot \rangle_{GNS})$, and hence $\Delta_p(A^*) \in N$. Since $A$ is arbitrary in $N$, it follows that $N$ is invariant under $\Delta_p$.

For the converse, suppose that $N$ is invariant under $\Delta_p$. Then $N$ is invariant under $\Delta_p^s$ for all $s \in \mathbb{R}$, and in particular, $N$ is invariant under $\Delta_p^{1/2}$. Then $\rho^{1/2}N = N\rho^{1/2}$ as subspaces of $M$; let $K$ denote this subspace of $M$, which is evidently self-adjoint. Let $H = H^* \in M$. Then there are uniquely determined $A, B \in N$ such that $H\rho^{1/2} - Ap^{1/2}$ and $\rho^{1/2}H - \rho^{1/2}B$ are both orthogonal to $K$ in the Hilbert-Schmidt inner product. Thus,

$$H\rho^{1/2} = (H\rho^{1/2} - Ap^{1/2}) + Ap^{1/2}$$

and

$$\rho^{1/2}H = (\rho^{1/2}H - \rho^{1/2}B) + \rho^{1/2}B$$

are the orthogonal decompositions of $H\rho^{1/2}$ and $\rho^{1/2}H$ with respect to $K$. Again since $X \mapsto X^{1/2}$ is unitary from $(M, \langle \cdot, \cdot \rangle_{GNS})$ to $(M, \langle \cdot, \cdot \rangle_{HS})$, $\rho(H) = A$. We must show that $A = A^*$.

Since $X \mapsto X^*$ is an isometry for the Hilbert-Schmidt inner product, and since $K$ is self adjoint,

$$\rho^{1/2}H = (\rho^{1/2}H - \rho^{1/2}A^*) + \rho^{1/2}A^*$$

is again an orthogonal decomposition of $\rho^{1/2}H$ with respect to $K$, and by uniqueness, $B = A^*$. Thus,

$$\rho^{1/2}H = (\rho^{1/2}H - \rho^{1/2}A^*) + \rho^{1/2}A^*.$$ 

Now apply $\Delta_p^{-1/2}$ to both sides to obtain $H\rho^{1/2} = (H\rho^{1/2} - A^*\rho^{1/2}) + A^*\rho^{1/2}$. We claim that $H\rho^{1/2} - A^*\rho^{1/2}$ is orthogonal to $K$. Once this is shown, it will follow that $H\rho^{1/2} = (H\rho^{1/2} - A^*\rho^{1/2}) + A^*\rho^{1/2}$ is the orthogonal decomposition of $H\rho^{1/2}$ with respect to $K$. Again by uniqueness of the orthogonal decomposition, it will follow that $A = A^*$.

Hence it remains to show that $H\rho^{1/2} - A^*\rho^{1/2}$ is orthogonal to $K$ in the Hilbert-Schmidt inner product. The general element of $K$ can be written as $\rho^{1/2}Z$ for $Z \in \mathbb{C}$. Then

$$\langle \rho^{1/2}Z, H\rho^{1/2} - A^*\rho^{1/2} \rangle_{HS} = \text{Tr}[Z^*(\rho^{1/2}H - \rho^{1/2}A^*)] = \langle Z\rho^{1/2}, (\rho^{1/2}H - \rho^{1/2}A^*) \rangle_{HS}.$$ 

But we have seen above that $\rho^{1/2}H - \rho^{1/2}A^*$ is orthogonal to $K$, and $Z\rho^{1/2} \in K$. This proves (1).

To prove (2), note first of all that when (11) is valid for all $A \in N$, then $\Delta_p$ preserves $N$ since the right side evidently belongs to $N$. 

Now suppose the $\Delta_\rho$ preserves $\mathcal{N}$. Let $A, B \in \mathcal{N}$. Then $A^*\Delta_{\rho_N}(\delta_{\rho}(B))) \in \mathcal{N}$, and then by the definition of $\varepsilon_\tau$ and cyclicity of the trace,
\[
\text{Tr}[\rho(A^*\rho_N\rho^{-1}B\rho\rho_N^{-1})] = \text{Tr}[A^*\rho_N\rho^{-1}B\rho] = \text{Tr}[\rho_N(\rho^{-1}B\rho A^*)].
\]
In the same way, using the fact that $(\rho^{-1}B\rho A) \in \mathcal{N}$ and cyclicity of the trace,
\[
\text{Tr}[\rho_N(\rho^{-1}B\rho A^*)] = \text{Tr}[B\rho A^*] = \text{Tr}[\rho A^* B].
\]
Altogether, $\langle A, \Delta_{\rho_N}(\Delta_\rho^{-1}(B))\rangle_{GNS, \rho} = \langle A, B\rangle_{GNS, \rho}$. Since $\Delta_{\rho_N}(\Delta_\rho^{-1}(B)) \in \mathcal{N}$, and $A$ is arbitrary in $\mathcal{N}$, $\Delta_{\rho_N}(\Delta_\rho^{-1}(B)) = B$, and hence $\Delta_\rho^{-1}(B) = \Delta_\rho^{-1}(B)$. Then $\Delta_\rho^{-n}(B) = \Delta_\rho^{-n}(B)$ for all $n \in \mathbb{N}$, and then it follows that $\Delta_\rho^t(B) = \Delta_{\rho_N}^t(B)$ for all $t \in \mathbb{R}$.

Finally, we show that (4.1) is valid for all $A \in \mathcal{N}$, then $\mathcal{A}_\rho(A) = A$ for all $A \in \mathcal{N}$:
\[
\varepsilon_\tau(\rho^{1/2}A\rho^{1/2}) = \varepsilon_\tau(\Delta_{\rho_N}^{1/2}(A)\rho) = \Delta_{\rho_N}^{1/2}(A)\varepsilon_\tau(\rho) = \rho_{cN}A^{1/2}A\rho_{cN}^{1/2}.
\]

By (2) of Theorem 4.1 for all $A \in \mathcal{N}$, $\Delta_{\rho_N}^{1/2}(A) = \Delta_\rho^{1/2}(A)$, and therefore
\[
\varepsilon_\tau(\rho^{1/2}A\rho^{1/2}) = \varepsilon_\tau(\Delta_{\rho_N}^{1/2}(A)\rho) = \Delta_{\rho_N}^{1/2}(A)\varepsilon_\tau(\rho) = \rho_{N}^{1/2}A\rho_{N}^{1/2}.
\]

That is, $A = \rho_{N}^{1/2}\varepsilon_\tau(\rho^{1/2}A\rho^{1/2})\rho_{N}^{-1/2} = \mathcal{A}_\rho(A)$. On the other hand, when $A = \mathcal{A}_\rho(A)$ for all $A \in \mathcal{N}$, $\mathcal{A}_\rho$ is a norm one projection onto $\mathcal{N}$, and by Tomiyama’s Theorem 37, it is a conditional expectation, and it satisfies $\rho(\mathcal{A}_\rho(X))X$ for all $X \in \mathcal{M}$. Therefore, it must coincide with $\mathcal{P}_\rho$, the orthogonal projection form $\mathcal{M}$ onto $\mathcal{N}$ in the GNS inner product induced by $\rho$. Hence $\mathcal{P}_\rho$ is a conditional expectation. By what we proved earlier, this means that $\mathcal{N}$ is invariant under $\Delta_\rho$, and then that (4.1) is valid for all $A \in \mathcal{N}$.

**4.3 Theorem.** Let $\mathcal{P}_\rho$ denote the orthogonal projection of $\mathcal{M}$ onto $\mathcal{N}$ in the GNS inner product induced by $\rho$. Then

1. $\mathcal{P}_\rho$ is a conditional expectation if and only if $\mathcal{N}$ is invariant under $\Delta_\rho$.

2. $\mathcal{P}_\rho$ is a conditional expectation if and only if $\mathcal{P}_\rho$ is real.

Proof. Theorem 4.1 says that when $\Delta_\rho$ does not leave $\mathcal{N}$ invariant, $\mathcal{P}_\rho$ is not even real, and hence is not a conditional expectation. On the other hand, when $\Delta_\rho$ leaves $\mathcal{N}$ invariant, a theorem of Takesaki says that there exists a projection $\varepsilon$ with unit norm from $\mathcal{M}$ onto $\mathcal{N}$ that satisfies (1.15). By Tomiyama’s Theorem and remarks we have made in the introduction, this means that $\varepsilon = \mathcal{P}_\rho$, and that $\mathcal{P}_\rho$ is a conditional expectation in the sense of Umegaki. This proves (1).

It is evident that if $\mathcal{P}_\rho$ is a conditional expectation, this $\mathcal{P}_\rho$ is real. On the other hand, if $\mathcal{P}_\rho$ is real, then by Theorem 4.1, $\mathcal{N}$ is invariant under $\Delta_\rho$, and now (2) follows from (1). 

**5 Strong Subadditivity**

We recall the proof of equivalence of the strong-subadditivity relation and the monotonicity of relative entropy under partial traces, according to [18], in which it is shown that strong subadditivity relation can be written in the following form: for $\mathcal{H} = \mathcal{H}_1 \otimes \mathcal{H}_2 \otimes \mathcal{H}_3$ and $\rho_{123} \in \mathcal{B}(\mathcal{H})$,
\[
S(\rho_{12}||\rho_1 \otimes \rho_2) \leq S(\rho_{123}||\rho_1 \otimes \rho_{23}),
\]
(5.1)
where $\rho_{12} = \text{Tr}_{H_3} \rho_{123}$ etc. (See [18]). With $\mathcal{N} := \mathcal{B}(H_1 \otimes H_2)$,

$$S(\rho_{12}||\rho_1 \otimes \rho_2) = S((\rho_{123})_\mathcal{N}||((\rho_1 \otimes \rho_{23})_\mathcal{N})_\mathcal{N}).$$

The DPI inequality yields

$$S(\rho_N||\sigma_N) \leq S(\rho||\sigma), \quad (5.2)$$

for $\rho, \sigma \in \mathcal{B}(\mathcal{H})$.

5.1 Lemma. (Lieb, Ruskai [18]) Let $\mathcal{H} = H_1 \otimes H_2 \otimes H_3$. The monotonicity of the relative entropy under partial traces holds for all states $\rho, \sigma \in \mathcal{B}(\mathcal{H})$ if and only if the strong sub-additivity inequality

$$S(\rho_{12}) + S(\rho_{23}) - S(\rho_{123}) - S(\rho_2) \geq 0. \quad (5.3)$$

holds for all states $\rho_{123} \in H_1 \otimes H_2 \otimes H_3$.

Proof. (MONO $\Rightarrow$ SSA) From here it is clear that taking the CPTP to be a partial trace over the third space and $\rho = \rho_{123}$, $\sigma = \rho_1 \otimes \rho_{23}$ in (5.2) leads to (5.1).

(SSA $\Rightarrow$ MONO) Let us take the space $H_3$ to be 2-dimensional and the state $\rho_{123}$ in the following form

$$\rho_{123} = \lambda \rho_{12}' \otimes E_3 + (1 - \lambda) \rho_{12}'' \otimes F_3, \quad (5.4)$$

where $E_3$ and $F_3$ are orthogonal one-dimensional projections on $H_3$ and $\lambda \in [0, 1]$. Then the SSA relation (5.1) for this $\rho_{123}$ is equivalent to the concavity property of the conditional entropy $S(\rho_{12}||\rho_1)$, i.e. for any $\lambda \in [0, 1]$ and any $\rho_{12}'$ and $\rho_{12}''$ above we have

$$\lambda(S(\rho_{12}') - S(\rho_2')) + (1 - \lambda)(S(\rho_{12}'') - S(\rho_2'')) \leq S(\rho_{12}) - S(\rho_2). \quad (5.5)$$

Recall that a function $f : [0, 1] \to \mathbb{R}$ is called operator convex if for all matrices $A, B$ with eigenvalues in $[0, 1]$ and $0 < \lambda < 1$ the following holds

$$f(\lambda A + (1 - \lambda)B) \leq \lambda f(A) + (1 - \lambda)f(B). \quad (5.6)$$

Note that if an operator concave function $f$ is homogeneous (i.e. $f(tA) = tf(A)$ for all $t > 0$), then for positive matrices $A$ and $B$

$$\frac{d}{dt} \bigg|_{t=0} f(A + t B) := \lim_{t \to 0} \frac{1}{t} \{f(A + tB) - f(A)\} \geq f(B) \quad (5.7)$$

the above limit exits. To see this, use the homogeneity first, and then the concavity of $f$ in the following way

$$f(A + tB) = (1 + t)f \left( \frac{1}{1+t} A + \frac{t}{1+t} B \right) \geq (1 + t) \left( \frac{1}{1+t} f(A) + \frac{t}{1+t} f(B) \right) \quad (5.8)$$

$$= f(A) + tf(B). \quad (5.9)$$
Take a conditional entropy as this function $f$:

$$f(\gamma_{12}) := S(\gamma_{12}) - S(\gamma_2).$$

Then the derivative is

$$\frac{d}{dt} f(\gamma_{12} + t\omega_{12}) = -\text{Tr}\omega_{12} \ln(\gamma_{12} + t\omega_{12}) + \text{Tr}\omega_2 \ln(\gamma_2 + t\omega_2).$$

Since the conditional entropy is concave and homogeneous, applying inequality (5.7) leads to the monotonicity of the relative entropy under partial traces (5.2). □

The stability bound proved here has obvious consequences for the SSA inequality, and can be used to give a quantitative version of the result [14] of Hayden, Josza, Petz and Winter. For another improvement to the SSA inequality, namely

$$S(\rho_{12}) + S(\rho_{23}) - S(\rho_{123}) - S(\rho_2) \geq 2 \max\{S(\rho_1) - S(\rho_{13}), S(\rho_3) - S(\rho_{13})\}, \quad (5.11)$$

see [7].
