**W–ALGEBRAS ASSOCIATED TO SURFACES**

ANDREI NEGUT

**Abstract.** We define an integral form of the deformed $W$–algebra of type $\mathfrak{g}_{1r}$, and construct its action on the $K$–theory groups of moduli spaces of rank $r$ stable sheaves on a smooth projective surface $S$, under certain assumptions. Our construction generalizes the action studied by Nakajima, Grojnowski and Baranovsky in cohomology, although the appearance of deformed $W$–algebras by generators and relations is a new feature. Physically, this action encodes the AGT correspondence for 5d supersymmetric gauge theory on $S \times \text{circle}$.

1. Introduction

The purpose of the present paper is to study the representation theory of the $K$–theory groups of moduli spaces of sheaves on a smooth surface $S$ over an algebraically closed field of characteristic 0 (henceforth denoted by $\mathbb{C}$). For any $r > 0$, we study a certain $\mathbb{Z}[q_{1}^{\pm 1}, q_{2}^{\pm 1}]$-algebra $A_{r}$ and construct a module for the specialization of $A_{r}$ when $q_{1}$ and $q_{2}$ are set equal to the Chern roots of $\Omega_{S}^{1}$. When $S = \mathbb{A}^{2}$, this module is the $\mathbb{C}^{\ast} \times \mathbb{C}^{\ast}$ equivariant $K$–theory of the moduli space of rank $r$ framed sheaves on $\mathbb{P}^{2}$. When $S$ is projective, the module is defined as follows. Fix $c_{1} \in H^{2}(S, \mathbb{Z})$ and an ample divisor $H \subset S$ such that $\gcd(r, c_{1} \cdot H) = 1$. Let:

\[ K_{M} = \bigoplus_{c_{2} = \left\lfloor \frac{r-1}{2} c_{1} \right\rfloor}^{\infty} K_{0}(\mathcal{M}(r, c_{1}, c_{2})) \]

where $\mathcal{M}(r, c_{1}, c_{2})$ denotes the moduli space of stable sheaves on $S$ with Chern classes $(r, c_{1}, c_{2})$ (see [15] for a review of the theory). The fact that stable sheaves have $c_{2}$ bounded below by $\frac{r-1}{2} c_{1}$ is called the Bogomolov inequality. The coprimality of $r$ and $c_{1}$ · $H$ is called Assumption A in [23], and it implies that:

- every semistable sheaf is stable, hence $\mathcal{M}$ is projective
- there exists a universal sheaf $\mathcal{U}$ on $\mathcal{M} \times S$

where (once we have fixed $r$ and $c_{1}$) we will always write:

\[ \mathcal{M} = \bigcup_{c_{2} = \left\lfloor \frac{r-1}{2} c_{1} \right\rfloor}^{\infty} \mathcal{M}(r, c_{1}, c_{2}) \]

As we recall in Section 3, $\mathcal{A}_{r}$ is closely related to the deformed $W$–algebra of type $\mathfrak{g}_{1r}$ ([1], [8]). It is generated over $\mathbb{Z}[q_{1}^{\pm 1}, q_{2}^{\pm 1}]$ by symbols $W_{n,k}$ indexed by a “degree”

---

2010 Mathematics Subject Classification: 14J60
There exists an $r \to \infty$ limit of this construction, which we denote by $\mathcal{A}_\infty$, with generators $W_{n,k}$ indexed by $n \in \mathbb{Z}$, $k \in \mathbb{N}$. We have:

\[(1.2)\quad \mathcal{A}_r = \frac{\mathcal{A}_\infty}{\langle W_{n,k} \rangle_{n \in \mathbb{Z}, k > r}}\]

Our construction for the action $\mathcal{A}_r \curvearrowright K_M$ can be summarized logically as follows:

\[(1.3)\quad \left\{ \mathcal{A} \curvearrowright K_M, \mathcal{A}_\infty \rightarrow \hat{\mathcal{A}} \right\} \Rightarrow \mathcal{A}_\infty \curvearrowright K_M\]

\[(1.4)\quad \{W_{n,k}\}_{n \in \mathbb{Z}}^{k > r} \text{ act by 0 in } K_M \Rightarrow \mathcal{A}_r \curvearrowright K_M\]

where $\mathcal{A}$ is the double shuffle algebra of (3.1), and $\hat{\mathcal{A}}$ is its completion.

**Conjecture 1.1.** There exists an “action” of the double shuffle algebra:

\[(1.5)\quad \mathcal{A} \curvearrowright K_M\]

given explicitly in Subsection 5.4.

The fact that the action (1.5) extends to the completion $\hat{\mathcal{A}}$ is a consequence of the fact that $K_M$ is a good $\mathcal{A}$-module (see Definition 3.9), which in turn follows from Bogomolov’s inequality. Explicitly, to each generator $W_{n,k} \in \mathcal{A}$, we associate in Section 5 an abelian group homomorphism via certain explicit correspondences:

\[(1.6)\quad K_M \xrightarrow{w_{n,k}} K_{M \times S}\]

satisfying the compatibility conditions spelled out in Definition 5.2. This is the meaning of the quotes around the word “action” in the statement of Conjecture 1.1. When $S = \mathbb{A}^2$, the same construction was done in [24] in the context of the equivariant $K$–theory of the moduli space of framed sheaves, but the arbitrary surface case poses interesting features: for instance, the parameters $q_1$ and $q_2$ of the algebra $\mathcal{A}_r$ are identified with the Chern roots of $\Omega^1_S$, viewed as elements in $K_S$.

**Theorem 1.2.** Assuming Conjecture 1.1, we have $w_{n,k} = 0$ in (1.6) for all $n \in \mathbb{Z}$ and $k > r$, hence the “action” (1.5) factors through an “action” $\mathcal{A}_r \curvearrowright K_M$.

The group $K_M$ may be interpreted as the Hilbert space of 5d supersymmetric gauge theory on the projective surface $S$ times a circle. Our placing an action of the deformed $W$–algebra on $K_M$ yields a mathematical generalization of the Alday-Gaiotto-Tachikawa (AGT) correspondence between gauge theory and conformal field theory (along the lines of [17], [24], [31], which treated the $S = \mathbb{A}^2$ case). Historically, this correspondence has usually been studied for toric surfaces using Nekrasov’s equivariant generalization of partition functions. Therefore, the projective surface situation treated in the present paper is a new phenomenon, which to the author’s knowledge has not previously been studied for rank $r > 1$. In our follow-up paper [22], Theorem 1.2 will be used to compute the interaction between the action $\mathcal{A}_r \curvearrowright K_M$ with the Carlsson-Okounkov Ext operator ([5]), thus establishing the equality of partition functions that AGT stipulates for bifundamental matter. However, one should note that, in order to completely
set up the AGT correspondence for an arbitrary surface $S$, the deformed $W$–algebra studied herein needs to be enlarged. Such an enlargement should probably deform the vertex operator algebras (VOAs) associated to 4-manifolds (see [7]).

The action $\mathcal{A} \acts K_M$ is defined via the correspondences $Z_1$ and $Z_2^*$ (Definitions 4.11 and 4.16 respectively), which yield resolutions of singularities of the cohomological constructions of Nakajima [20] and Grojnowski [14] in rank 1, and Baranovsky [2] in rank $r$. In general, the correspondences $Z_1$ and $Z_2^*$ are defined as dg schemes, but we show in Propositions 4.19 and 4.20 that they are smooth schemes whenever the moduli spaces $\mathcal{M}$ are smooth (more precisely, under Assumption S of (4.27)). The proof of the smoothness of $Z_1$ and $Z_2^*$ relies on presenting their tangent spaces in terms of cones of Ext groups, which is an idea that has appeared repeatedly in the literature (see [13] for a development in the context of virtual degeneration loci).

Through an analysis of the relation between the double shuffle algebra and $W$–algebras, which we perform in Sections 2 and 3, we show that Conjecture 1.1 boils down to Conjecture 5.7. We prove both Conjectures under Assumption B of Subsection 5.10, which we expect to hold for rational surfaces (see [16]). In general, the full statement of Conjecture 1.1 would follow if one knew that the shuffle algebra is a localization of the $K$–theoretic Hall algebra in the sense of [29], but this fact is open (see [19] for certain results when $S = T^*C$ is the cotangent bundle to a curve).

When $S = \mathbb{A}^2$, Theorem 1.2 was proved in [24] using the fact that the group $K_M$ is (generically) an irreducible module for the $W$–algebra. We do not have this feature for a general surface $S$, and we have little control on the size of the abelian group $K_M$. Instead, we give a geometric proof of Theorem 1.2 in Section 6 which admits an obvious lift to the level of functors between derived categories. Let us mention certain possible avenues for generalizing our results.

1. Do the results in the present paper hold without Assumption A, namely the fact that $\gcd(r, c_1 \cdot H) = 1$? This would involve replacing universal sheaves by quasi-universal or twisted sheaves in all our definitions and computations, and we make no claims about the technical difficulties that may arise.

2. Do the results in the present paper hold for $r = 0$? What about when one replaces $S$ by a quasi-projective surface endowed with a torus action with projective fixed point set? Although the philosophy clearly generalizes, in either case, care must be taken in choosing the moduli space $\mathcal{M}$ correctly.

3. Do the results hold if the moduli space $\mathcal{M}$ of stable sheaves is replaced by the moduli stack of all sheaves? It is conceivable that $\mathcal{A}$ still acts on $K_M$, but whether the algebra $\mathcal{A}_\infty$ still acts is unclear. The reason for this is that elements of $\mathcal{A}_\infty$ are certain infinite sums inside $\mathcal{A}$, which act correctly on $(1.1)$ due to the fact that the grading by $c_2$ is bounded below.

I would like to thank Sergei Gukov, Tamas Hausel, Davesh Maulik, Alexander Minets, Georg Oberdieck, Francesco Sala, Olivier Schiffmann, Richard Thomas and Alexander Tsymbaliuk for many interesting discussions on the subject, and for all their help in my understanding the framework of $W$–algebras and sheaves on surfaces. I gratefully acknowledge the support of NSF grant DMS–1600375.
2. Shuffle Algebras

Let \( q = q_1 q_2 \). Throughout this paper, we will often encounter the ring:

\[ K = \mathbb{Z}[q_1^{\pm 1}, q_2^{\pm 1}] \text{ symmetric in } q_1, q_2 \]

and its field of fractions:

\[ F = \mathbb{Q}(q_1, q_2) \text{ symmetric in } q_1, q_2 \]

Let us recall the trigonometric version of the Feigin-Odesskii shuffle algebra \[ [11] \]:

**Definition 2.1.** Consider the rational function:

\[ \zeta(x) = \frac{(1 - xq_1)(1 - xq_2)}{(1 - x)(1 - xq)} \]

and the vector space:

\[ S_{\text{big}} = \bigoplus_{k=0}^{\infty} F(z_1, ..., z_k)^{\text{Sym}} \]

where the superscript Sym refers to rational functions that are symmetric with respect to \( z_1, ..., z_k \). We endow the vector space \( S_{\text{big}} \) with the shuffle product:

\[ R(z_1, ..., z_k) \ast R'(z_1, ..., z_{k'}) = \text{Sym} \left( R(z_1, ..., z_k)R'(z_{k+1}, ..., z_{k+k'}) \prod_{1 \leq i \leq j \leq k+k'} \zeta \left( \frac{z_i}{z_j} \right) \right) \]

Define the **shuffle algebra**:

\[ S \subset S_{\text{big}} \]

to be the \( K \)-subalgebra generated by the elements:

\[ E_{d_*} = \text{Sym} \left[ \frac{z_1^{d_1} ... z_k^{d_k}}{(1 - z_2q^{-1}) ... (1 - z_{k-1}q^{-1})} \prod_{1 \leq i < j \leq k} \zeta \left( \frac{z_i}{z_j} \right) \right] \]

as \( d_* = (d_1, ..., d_k) \) ranges over \( \mathbb{Z}^k \).

The shuffle algebra in Definition 2.1 has been studied in numerous papers, most relevant to our purposes here being \[ [9], [12], [24], [30] \]. However, these papers were mostly studying the shuffle algebra over a field, namely:

\[ S \otimes_K F \]

It was shown in \[ [27] \] that the localized shuffle algebra \( (2.7) \) is actually generated by \( \{ E_{(d)} = z_1^{d_1} \}_{d \in \mathbb{Z}} \). For example, the identity:

\[ E_{(0)} \ast E_{(1)} - E_{(1)} \ast E_{(0)} = \frac{(1 - q_1)(1 - q_2)(1 - q)z_1 z_2(z_1 + z_2)}{(z_1 - z_2q)(z_2 - z_1q)} = (1 - q_1)(1 - q_2)E_{(1,0)} \]

suggests that one can obtain the generator \( E_{(1,0)} \) from shuffle products of \( E_{(1)} \) and \( E_{(0)} \) iff one inverts the element \( (1 - q_1)(1 - q_2) \) in the ground ring. We will not do so in the present paper, and therefore emphasize the fact that the shuffle algebra \( S \) of \( (2.5) \) has a more complicated description than the algebra \( (2.7) \). For example, the latter admits a straightforward description in terms of Feigin-Odesskii type...
wheel conditions, but we do not know an analogous description of the former.

**Proposition 2.2.** The algebra $S$ is generated over $K$ by the elements:

\[(2.8) \quad E_{k,n} = q^{\gcd(k,n)-1} E_{(d_1, \ldots, d_k)}\]

where $d_i = \left\lceil \frac{n_i}{k} \right\rceil - \left\lceil \frac{n(i-1)}{k} \right\rceil + \delta_i^k - \delta_i^1$, as $k$ ranges over $\mathbb{N}$, and $n$ ranges over $\mathbb{Z}$.

**Proof.** Since $S$ is generated by $E_{d \cdot}$ for arbitrary $d \cdot = (d_1, \ldots, d_k) \in \mathbb{Z}^k$, it is enough to show that any given $E_{d \cdot}$ can be written as a $K$-linear combination of products of (2.8). We will prove this statement by induction on $k$. The case $k = 1$ is trivial, and for the induction step, consider arbitrary $k$, $d \cdot$ and let $n = d_1 + \ldots + d_k$. Then:

\[
z_1^d_1 \ldots z_k^d_k - q^n \prod_{i=1}^{k} \left( z_i - \left\lceil \frac{n_i}{k} \right\rceil + \delta_i^k - \delta_i^1 \right) =
\]

\[(2.9) = \sum_{i=1}^{k-1} \left( 1 - \frac{z_{i+1}q}{z_i} \right) \cdot \text{(Laurent polynomial in } q, z_1, \ldots, z_k) \]

for some suitably chosen $a \in \mathbb{Z}$. Plugging formula (2.9) in (2.6) gives us:

\[(2.10) \quad E_{d \cdot} - q^n E_{k,n} = \sum_{i=1}^{k-1} \sum_{d' \cdot, d'' \cdot} E_{d' \cdot} \ast E_{d'' \cdot} \]

where in the right-hand side, $d'_ \cdot = (d'_1, \ldots, d'_i)$ and $d'' \cdot = (d''_1, \ldots, d''_{k-i-1})$ are certain vectors of integers modeled after the monomials that appear in the right-hand side of (2.9). By the induction hypothesis, the right-hand side of (2.10) can be written as a $K$-linear combination of products of the elements (2.8), hence so can $E_{d \cdot}$.

\[\square\]

2.3. After establishing Proposition 2.2, the next step is to work out the relations between the generators $E_{k,n}$. The idea for doing so is inspired by [3], and combining their construction with the results of [27], allows us to conclude that, as $F$-modules:

\[(2.11) \quad S \otimes_{\mathbb{K}} F = \bigoplus_{\frac{n_1}{k} \leq \ldots \leq \frac{n_t}{k}} F \cdot E_{k_1,n_1} \ldots E_{k_t,n_t} \]

In other words, any element of $S$ can be written as a linear combination of ordered monomials $E_{k_1,n_1} \ldots E_{k_t,n_t}$ if one allows the coefficients to be rational functions in $q_1$ and $q_2$. Our main purpose for the remainder of this section is to show that the equality (2.11) still holds without localization, i.e. the fact that, as $\mathbb{K}$-modules:

\[(2.12) \quad S = \bigoplus_{\frac{n_1}{k} \leq \ldots \leq \frac{n_t}{k}} \mathbb{K} \cdot E_{k_1,n_1} \ldots E_{k_t,n_t} \]

By Proposition 2.2 any element of $S$ can be written as a $\mathbb{K}$-linear combination of products of $E_{k,n}$. Our task thus reduces to establishing an integral version of the “straightening lemma” of [3]: we must show that an arbitrary product of $E_{k,n}$’s is equal to a sum of ordered products of $E_{k,n}$’s, in non-decreasing order of $\frac{n}{k}$. This statement follows by repeated applications of the following result:
Theorem 2.4. For any $k, k' \in \mathbb{N}$ and $n, n' \in \mathbb{Z}$ such that $\frac{n}{k} > \frac{n'}{k'}$, we have:

\[
\begin{align*}
[E_{k,n}, E_{k',n'}] &= \Delta \sum_{\frac{n}{k} + \frac{n'}{k'} \leq \frac{n_1}{k_1} \leq \ldots \leq \frac{n_t}{k_t} \leq \frac{n}{k}, \ldots, k, k', n, n'] p_{n,n_1,\ldots,n_t,n'}^{k,k_1,\ldots,k_t,k'}(q_1, q_2) \cdot E_{k_1,n_1} \ldots E_{k_t,n_t},
\end{align*}
\]

where $p_{n,n_1,\ldots,n_t,n'}^{k,k_1,\ldots,k_t,k'}(q_1, q_2) \in \mathbb{K}$, and $\Delta = (1 - q_1)(1 - q_2)$.

2.5. Theorem 2.4 will be proved at the end of the current Section. The main idea is that the commutation relations (2.13) for all $\frac{n}{k} > \frac{n'}{k'}$ are implied by the special case when the triangle spanned by the vectors $(k, n)$ and $(k', n')$ contains no lattice points inside and on one of the edges. These special cases are usually presented in terms of the generators $P_{k,n}, H_{k,n}, Q_{k,n}$ defined as follows for all $\gcd(k,n) = 1$:

\[
\begin{align*}
\sum_{s=0}^{\infty} \frac{E_{ks,ns}}{(-x)^s} &= \exp \left[ -\sum_{s=1}^{\infty} \frac{P_{ks,ns}}{sx^s} \right] \\
\sum_{s=0}^{\infty} \frac{H_{ks,ns}}{x^s} &= \exp \left[ \sum_{s=1}^{\infty} \frac{P_{ks,ns}}{sx^s} \right] \\
\sum_{s=0}^{\infty} \frac{Q_{ks,ns}}{x^s} &= \exp \left[ \sum_{s=1}^{\infty} \frac{P_{ks,ns}}{sx^s} (1 - q^{-s}) \right]
\end{align*}
\]

For fixed slope $\frac{n}{k}$, the P’s, H’s and Q’s are in relation to E’s as power sum, complete symmetric, and plethystically modified complete symmetric polynomials are in relation to elementary symmetric polynomials. In other words, presenting relations between E’s is equivalent with presenting relations between the other generators. These relations were first constructed in [3] (see [24] for our conventions):

\[
[P_{k,n}, P_{k',n'}] = 0
\]

if $\frac{n}{k} = \frac{n'}{k'}$, and:

\[
[P_{k,n}, P_{k',n'}] = \frac{(1 - q_1^k)(1 - q_2^k)}{1 - q} \cdot Q_{k+k',n+n'}
\]

when the triangle $(0, 0)$, $(k, n)$, $(k + k', n + n')$ is oriented clockwise, and contains no lattice points inside or on one of the edges (we write $s = \gcd(k,n)\gcd(k',n')$).

Proposition 2.6. Relations (2.17) and (2.18) imply the following relations in terms of the E generators, for all $s \in \mathbb{N}$:

\[
\begin{align*}
[E_{ks,ns}, E_{k',n'}] &= \Delta \sum_{t=1}^{s} \frac{q_1^t - q_2^t}{q_1 - q_2} (-1)^{t-1} E_{kt+k',nt+n'} E_{k(s-t),n(s-t)} \\
(E_{k',n'})^{s,t} &= \Delta \sum_{t=1}^{s} \frac{q_1^t - q_2^t}{q_1 - q_2} (-1)^{t-1} E_{k'(s-t),n'(s-t)} E_{k+k't,n+n't}
\end{align*}
\]

whenever the triangle spanned by the vectors $(k, n)$ and $(k', n')$ is oriented clockwise, and has the property that $\gcd(k, n) = \gcd(k', n') = \gcd(k + k', n + n') = 1$. Under
the same assumptions, but allowing \( \gcd(k + k', n + n') = s \geq 1 \), we have:

\[
[\mathcal{E}_{k,n}, \mathcal{E}_{k',n'}] = \Delta \frac{\Delta}{1 - q^{-1} \left[ \text{coefficient of } \frac{1}{x^s} \text{ in } \frac{E(xq)}{E(x)} \right]}
\]

where we set \( E(x) = \sum_{s=0}^{\infty} \frac{E(k+k',n+n')}{y^s} \).

**Proof.** Under our assumptions on the vectors \((k, n), (k', n')\), the triangle spanned by the vectors \((ks, ns), (kt + k', nt + n')\) satisfies the assumptions of (2.18):

\[
[\mathcal{E}_{k,n}, \mathcal{E}_{k'+nt+n'q}] = (1 - q^s_1)(1 - q^s_2)P_{k(s+t)+k',n(s+t)+n'}
\]

for all \(s \in \mathbb{N}, t \in \mathbb{Z}\). Summing this relation over all \(s \in \mathbb{N}\) and \(t \in \mathbb{Z}\), we obtain:

\[
\sum_{s=0}^{\infty} \frac{P_{k,n,s}}{(-x)^s} \sum_{t \in \mathbb{Z}} P_{k'+nt+n'} = \zeta \left( \frac{y}{x} \right)\sum_{s=0}^{\infty} \frac{E_{k+k',nt+n'}}{y^s} = \sum_{t \in \mathbb{Z}} E_{k+k',nt+n'q}.
\]

Indeed, we have \( P_{k+k',nt+n'} = E_{k+k',nt+n'}\) for all \(t\) because our assumption on the vectors \((k, n)\) and \((k', n')\) implies \(\gcd(kt + k', nt + n') = 1, \forall t\). Using the expansion:

\[
\zeta \left( \frac{y}{x} \right) = 1 - (1 - q_1)(1 - q_2) \sum_{s=0}^{\infty} \frac{q_1^s - q_2^s}{x^s}
\]

and taking the coefficient of \(x^{-y} y^0\) in equality (2.22) yields (2.19). Relation (2.20) is proved analogously. As for (2.21), this follows directly from (2.18) since \(E_{k,n} = P_{k,n}, E_{k',n'} = P_{k',n'}\) and (2.10) implies:

\[
\sum_{t=0}^{\infty} \frac{Q_{k+k',nt+n'}(q_1,q_2)}{x^t} = \frac{E(xq)}{E(x)}
\]

2.7. If we expand the ratio of series \(E(xq)/E(x)\) in (2.21), we see that it implies:

\[
[\mathcal{E}_{k,n}, \mathcal{E}_{k',n'}] = \Delta \left( \mathcal{E}_{k+k',n+n'} \right)
\]

where \([q]^s = 1 + q^{-1} + \ldots + q^{-s+1}\) and the ellipsis in (2.23) stands for a sum of products of the form \(E_{k_1,n_1} \ldots E_{k_t,n_t}\) with \(t > 1\) and all lattice points \((k_i, n_i)\) lying on the line segment from \((0,0)\) to the lattice point \((k + k', n + n')\).

**Proof. of Theorem 2.7.** For the first half of the proof, we closely follow [3], which will allow us to obtain the following slightly weaker version of (2.13):

\[
[\mathcal{E}_{k,n}, \mathcal{E}_{k',n'}] = \Delta \sum_{k_i \in \mathbb{N}, n_i \in \mathbb{Z}} \frac{p_{k,k_1 \ldots k_t,n_1 \ldots n_t}}{(q_1, q_2) E_{k_1,n_1} \ldots E_{k_t,n_t}}
\]
Therefore, to prove (2.24) by induction on convex paths. Given any lattice path \( P \)
products that appear in the right-hand side of (2.13) and (2.24) all correspond to
and lattice paths starting at the origin and pointing in the right half plane. The
this order. This is clearly a one-to-one correspondence between products (2.26)
path built out of the same segments \((k, n)\) is also \( K \)-orderable whenever
\( \bar{\epsilon} = E_{k, n} E_{k', n'} \)
is \( K \)-orderable whenever \( a(\bar{\gamma}(\bar{\epsilon})) \leq \delta \), then any product (2.20) such that \( a(\bar{\gamma}(\bar{\epsilon})) \leq \delta \)
is also \( K \)-orderable. The same proof works if we replace the ring \( K \) with \( K_{\text{loc}} \).
Therefore, to prove (2.21) by induction on \( \delta \in \mathbb{N} \), it suffices to prove the following:
Assume that any \( \epsilon \) as in (2.20) with \( a(\bar{\gamma}(\bar{\epsilon})) < \delta \) is \( K_{\text{loc}} \)-orderable,
then any \( \bar{\epsilon} \) as in (2.27) with \( a(\bar{\gamma}(\bar{\epsilon})) = \delta \) is \( K_{\text{loc}} \)-orderable
Let us now prove the claim in boldface letters above. Choose any \( \bar{\epsilon} \) as in (2.27) such that \( a(P) = \delta \), where \( P \) is the path with segments \( v = (k, n) \) and \( v' = (k', n') \).
From now on, the phrase the triangle determined by vectors \( v \) and \( v' \) will refer to the
triangle with a vertex at \((0, 0)\) and with edges given by drawing the vectors \( v \) and \( v' \) in this order. Choose a lattice point \( v_0 = (k_0, n_0) \) inside the triangle determined by the vectors \( v \) and \( v' \), such that the area of the triangle determined by \( v_0 \) and \( v - v_0 \) is minimal. This implies that the latter triangle respects the hypothesis of relation (2.21) (or its equivalent form (2.22)), and so we have:
\[
E_v \in \frac{(-1)^{s-1}}{[q]_s} \left( \frac{[E_{v-v_0}, E_{v_0}]}{\Delta} + \sum_{t>1, v_1, \ldots, v_t = v} \in \mathbb{K} \cdot E_{v_1} \cdots E_{v_t} \right)
\]
where \( s = \gcd(k, n) \), and we write \( E_v \) instead of \( E_{k,n} \) if \( v = (k, n) \). Taking the commutator of (2.28) with \( E_{v'} \) yields the following, in virtue of the Jacobi identity:
\[
[E_v, E_{v'}] = \frac{(-1)^{s-1}}{[q]_s} \left( \frac{[E_{v-v_0}, E_{v_0}], E_{v'}}{\Delta} + \sum_{t>1, v_1, \ldots, v_t = v} \in \mathbb{K} \cdot [E_{v_1} \cdots E_{v_t}, E_{v'}] \right) \subset \]
\[
\subset \frac{(-1)^{s-1}}{[q]_s} \left( \frac{[E_{v'}, E_{v_0}], E_{v_0}}{\Delta} + \frac{[E_{v-v_0}, E_{v'}], E_{v_0}}{\Delta} \right) \]

We claim that all summands in the right-hand side of (2.29) are $\mathbb{K}_{\text{loc}}$-orderable. Indeed, by our choice of the vector $v_0$, all commutators that appear in the right-hand side correspond to paths whose area is $< \delta$. Therefore, by the induction hypothesis in boldface letters, we may express such a commutator as a sum over convex paths, and it was shown in [3] that all paths obtained in this manner in the right-hand side of expression (2.29) will still have area $< \delta$. The key geometric statement here, proved in loc. cit., is that if one takes two consecutive segments which violate convexity in a path $P'$, and one replaces them by an arbitrary convex path $P''$ between the same endpoints, the resulting path $P''$ has $a(P'') < a(P')$. We conclude that the right-hand side of (2.29) can be written as a sum over convex paths $P$ of the elements $\Upsilon^{-1}(P)$. Because every commutator brings down a factor of $\Delta$ (as follows from relation (2.13)) when the area of the triangle determined by $(k, n)$ and $(k', n')$ is $< \delta$, which we may assume as part of our induction hypothesis), we see that the coefficient of any $\Upsilon^{-1}(P)$ in the right-hand side of (2.29) lies in:

$$
\frac{(-1)^{s-1}\Delta}{[q]_s} \cdot \mathbb{K}_{\text{loc}} = \Delta \cdot \mathbb{K}_{\text{loc}}
$$

Now assume, for the purpose of contradiction, that a certain $P_{n,n_1,...,n_t}^{k,k_1,...,k_t,k'_1,...,k'_t}(q_1,q_2)$ that appears in the right-hand side of (2.29) lies in $\mathbb{K}_{\text{loc}} \setminus \mathbb{K}$, i.e. has a pole when $q$ is a non-trivial root of unity. Then the pole will remain when we change the right-hand side of (2.29) from the basis $E_{k_1,n_1}E_{k_t,n_t}$ to $P_{k_1,n_1}...P_{k_t,n_t}$, because the matrix transforming elementary symmetric polynomials $E_{k_i,n_i}$ into power-sum functions $P_{k_i,n_i}$ is invertible and has rational coefficients. Note that $[E_{k,n}, E_{k',n'}] \in \mathbb{S}$ is a rational function of the form:

$$
R = \frac{r(z_1,...,z_k)}{\prod_{1 \leq i \neq j \leq k}(z_i q - z_j)}
$$

where $r \in \mathbb{K}[z_1^{\pm 1},...,z_k^{\pm 1}]^{\text{Sym}}$. By (2.27), we may express any such element as:

$$
R = \sum_{\frac{k_1+k_2+...+k_t}{k_1}}^{k_1 \leq k_2 \leq ... \leq k_t} \gamma_{k_1,...,k_t} P_{k_1,n_1}...P_{k_t,n_t}
$$

where $\gamma_{k_1,...,k_t} \in \mathbb{F}$. Then all that remains to prove is that the coefficients $\gamma_{k_1,...,k_t}$ do not have any poles at $q$ is a non-trivial root of unity. There exists a pairing:

$$
\langle \cdot, \cdot \rangle : \mathbb{S} \otimes \mathbb{S} \rightarrow \mathbb{F}
$$

for which the basis vectors $P_{k_1,n_1}...P_{k_t,n_t}$ are orthogonal (see [27]) and the coefficients we wish to express are given by:

$$
\gamma_{k_1,...,k_t}^{n_1,...,n_t} = \frac{\langle R, P_{k_1,n_1}...P_{k_t,n_t} \rangle}{\langle P_{k_1,n_1}...P_{k_t,n_t}, P_{k_1,n_1}...P_{k_t,n_t} \rangle}
$$
The goal is to show that the right-hand side of (2.32) does not have poles when \( q \) is a non-trivial root of unity. According to formula (7.15) of [24], we have:

\[
(2.33) \quad \langle P_{k_1, n_1} ... P_{k_r, n_r}, P_{k_1, n_1} ... P_{k_r, n_r} \rangle = \text{integer} \prod_{i=1}^r \frac{(1 - q_1^{s_i})(1 - q_2^{s_i})(1 - q^{-1})^{k_i}}{(1 - q_1)^{k_i}(1 - q_2)^{k_i}(1 - q^{-s_i})}
\]

where \( s_i = \gcd(k_i, n_i) \). According to formula (2.8) of [24], we have for all \( k, n \) with greatest common divisor \( s \), the equality:

\[
(2.34) \quad P_{k, n} = \text{Sym} \left[ \frac{\prod_{i=1}^k z_i^{[\frac{i-1}{s}] - [\frac{(i-1)n}{s}]} \sum_{i=0}^{s-1} q^{i} \frac{\prod_{i=1}^s z_{a(s-1)+1} ... z_{a(s-t)+1}}{\prod_{i<s} \zeta(z_i/z_j)} }{\prod_{i=1}^{k-1} (1 - \frac{q^{i+1}}{z_i})} \right]
\]

where \( a = \frac{k}{s} \). We claim that the right-hand side of (2.34) equals:

\[
(2.35) \quad P_{k, n} = c \cdot \text{Sym} \left[ \frac{\prod_{i=1}^k z_i^{[\frac{i-1}{s}] - [\frac{(i-1)n}{s}]} \sum_{i=0}^{s-1} q^{i} \frac{\prod_{i=1}^s z_{a(s-1)+1} ... z_{a(s-t)+1}}{\prod_{i<s} \zeta(z_i/z_j)} }{\prod_{i=1}^{k-1} (1 - \frac{q^{i+1}}{q_2 z_i})} \right]
\]

where the coefficient \( c \) is given by:

\[
(2.36) \quad c = \frac{(1 - q_2)^{s}(1 - q^{-1})^{k}}{(1 - q_2)^{k}(1 - q^{-s})}
\]

Indeed, let us denote \( p_1 = \text{RHS of (2.34)} \) and \( p_2 = \text{RHS of (2.35)} \), and we must prove that \( p_1 \) and \( p_2 \) are equal: both \( p_1 \) and \( p_2 \) are shuffle elements in \( k \) variables of homogeneous degree \( n \) whose coproduct is given by formula (5.4) of [27] (to recall the coproduct on the shuffle algebra, as well as the computation of the coproduct of \( p_1 \) and \( p_2 \), we refer to Proposition 6.4 of loc. cit.). Therefore, Lemma 5.5 of loc. cit. implies that \( p_1 \) and \( p_2 \) are equal up to a constant multiple. To prove that this constant is 1, we apply the linear map:

\[
R(z_1, ..., z_k) \xrightarrow{\varphi} R(1, q_1^{-1}, ..., q_1^{-k+1})
\]
to \( p_1 \) and \( p_2 \). Because \( \zeta(q_1) = 0 \), only one of the \( k! \) summands that make up the symmetrizations defining \( p_1 \) and \( p_2 \) is not annihilated by the linear map \( \varphi \), namely the summand corresponding to the identity permutation. Then the fact that \( \varphi(p_1) = \varphi(p_2) \) is easy to check, thus implying the equivalence of formulas (2.34) and (2.35). Combining (2.32), (2.33), (2.35), (2.36), all that remains to prove is:

**Claim 2.8.** For any shuffle element \( R \) as in (2.30) and any \( \rho \in \mathbb{K}[z_1^{\pm1}, ..., z_k^{\pm1}] \) let:

\[
(2.37) \quad P = \text{Sym} \left[ \frac{\rho(z_1, ..., z_k)}{\prod_{i=1}^{k-1} (1 - \frac{z_{i+1}}{q_2 z_i})} \prod_{i<s} \zeta(z_i/z_j) \right]
\]

Then the quantity \( \langle R, P \rangle \) has no poles when \( q \) is a root of unity (and \( q_1 \) is generic).
At this step, we must recall that the pairing (2.31) was defined in [27] by:

\[
(2.38) \quad \left< R, \text{Sym} \left[ z_1^{d_1} \ldots z_k^{d_k} \prod_{1 \leq i < j \leq k} \zeta \left( \frac{z_i}{z_j} \right) \right] \right> =
\]

\[
= \int_{|z_1| \gg \ldots \gg |z_k|} \frac{R(z_1, \ldots, z_k)z_1^{-d_1} \ldots z_k^{-d_k}}{\prod_{1 \leq i < j \leq k} \zeta \left( \frac{z_i}{z_j} \right)} \prod_{i=1}^{k} \frac{dz_i}{2\pi i z_i}
\]

for any \(d_1, \ldots, d_k \in \mathbb{Z}\), and \(F\)-linearity in the second argument.

**Claim 2.9.** For any \(R(z_1, \ldots, z_k), R'(z_1, \ldots, z_k) \in S\), we have:

\[
(2.39) \quad \langle R, R' \rangle = \frac{1}{k!} \int \frac{R(z_1, \ldots, z_k)R' \left( \frac{1}{z_1}, \ldots, \frac{1}{z_k} \right)}{\prod_{1 \leq i \neq j \leq k} \zeta \left( \frac{z_i - p z_j}{z_i - q z_j} \right)} \prod_{i=1}^{k} \frac{dz_i}{2\pi i z_i} |_{p \to q}
\]

The integral must be computed by residues under the assumptions \(|q_1|, |q_2| > 1 > |p|\), and only after one evaluates the integral, one must specialize \(p \to q\).

**Proof. of Claim 2.9** It suffices to show that formula (2.38) matches (2.39) when:

\[
R' = \text{Sym} \left[ z_1^{d_1} \ldots z_k^{d_k} \prod_{1 \leq i < j \leq k} \zeta \left( \frac{z_i}{z_j} \right) \right]
\]

for arbitrary \(d_1, \ldots, d_k \in \mathbb{Z}\). In this case, we have:

\[
\text{RHS of (2.39)} = \int_{|z_1| = \ldots = |z_k|} \frac{R(z_1, \ldots, z_k)z_1^{-d_1} \ldots z_k^{-d_k}}{\prod_{1 \leq i < j \leq k} \zeta \left( \frac{z_i}{z_j} \right)} \prod_{i=1}^{k} \frac{dz_i}{2\pi i z_i} |_{p \to q} =
\]

\[
= \int_{|z_1| \gg \ldots \gg |z_k|} \frac{R(z_1, \ldots, z_k)z_1^{-d_1} \ldots z_k^{-d_k}}{\prod_{1 \leq i < j \leq k} \zeta \left( \frac{z_i}{z_j} \right)} \prod_{i=1}^{k} \frac{dz_i}{2\pi i z_i} |_{p \to q}
\]

The second equality above is due to the fact that because of our choice on the sizes of the complex numbers \(q_1, q_2, p\), we do not pick up any poles as we move the contours from \(|z_1| = \ldots = |z_k|\) to \(|z_1| \gg \ldots \gg |z_k|\). Finally, in the limit \(|z_1| \gg \ldots \gg |z_k|\), we can even exclude the fractions \(\frac{z_i - p z_j}{z_i - q z_j}\) from the integrand, since we specialize \(p \to q\) at the end. Therefore, (2.40) matches the RHS of (2.38).

**Proof. of Claim 2.9** Let us re-run the argument that proved Claim 2.9 with \(R'\) replaced by \(P\) of (2.39). Because of the extra factors \(1 - \frac{z_i}{q z_j}\) in the denominator of \(P\), equality (2.40) does not hold as stated anymore. Instead, we have:

\[
\langle R, P \rangle = \int \frac{R(z_1, \ldots, z_k)\rho \left( \frac{1}{z_1}, \ldots, \frac{1}{z_k} \right)}{\prod_{i=1}^{k} \left( 1 - \frac{z_i}{q z_i} \right) \prod_{i < j} \zeta \left( \frac{z_i}{z_j} \right) \prod_{i \neq j} \frac{z_i - p z_j}{z_i - q z_j}} \prod_{i=1}^{k} \frac{dz_i}{2\pi i z_i} |_{p \to q} =
\]
residues in the limit

(2.41) \[ \sum_{k=n_1+\ldots+n_t} \left[ \int_{|w_1| \gg \ldots \gg |w_t|} \frac{1}{2\pi i w_s} \prod_{s=1}^{t} dw_s \right] R(z_1, \ldots, z_k) \rho \left( \frac{1}{z_1}, \ldots, \frac{1}{z_k} \right) \prod_{s=1}^{t-1} \left( 1 - \frac{z_{n_1+\ldots+n_s}}{q^{2z_{n_1+\ldots+n_s+1}}} \right) \prod_{i<j} (z_i q_1 - z_j) (z_i q_2 - z_j) \prod_{i \neq j} (z_i - p z_j) \right] \bigg|_{p \to q} \]

because as we move the contours toward \(|z_1| \gg \ldots \gg |z_k|\), we can now pick up residues from the poles \(z_{i+1} = q_2^{-1} z_i\). To prove Claim 2.3 it suffices to prove that none of the summands in the right-hand side of (2.41) has a pole when \(q\) is a root of unity. Corresponding to any composition \(k = n_1 + \ldots + n_t\), the integrand that appears in (2.41) takes the form:

(2.42) \[ \frac{\text{Laurent polynomial in } z_1, \ldots, z_k}{\prod_{s=1}^{t-1} \left( 1 - \frac{z_{n_1+\ldots+n_s}}{q^{2z_{n_1+\ldots+n_s+1}}} \right) \prod_{i<j} (z_i q_1 - z_j) (z_i q_2 - z_j) \prod_{i \neq j} (z_i - p z_j) \} \]

and then we specialize the variables to \(z_{n_1+\ldots+n_{s-1}+q} = w_s q_2^{a+1}\) and evaluate the residues in the limit \(|w_1| \gg \ldots \gg |w_t|\). The limit does not produce any poles, for the same reason why the residue at \(\infty\) of \((x - \gamma y)^{-1}\) first in the variable \(x\) and then in the variable \(y\) is a Laurent polynomial, regardless of the constant \(\gamma\). Therefore, the only thing we have to check is that none of the linear factors in the denominator of (2.42) vanishes when \(q\) is a root of unity, which is clear since all of these linear factors are of the form \(1 - q_1 q_2^n, 1 - q_2^n, 1 - pq_2^n\) for various integers \(a\).

3. \(W\)-algebras

3.1. One of the main results of [24] was to realize the deformed \(W\)-algebra inside a double shuffle algebra, a construction which we will now recall. Starting from the shuffle algebra \(S\) of (3.1), one constructs the \(K\)-algebra:

(3.1) \[ A = A^+ \otimes A^\text{diag} \otimes A^\rightarrow \]

where:

- \(A^+ = S\) with generators denoted by \(\{E_{-k,n}\}_{n \in \mathbb{Z}}^{k \in \mathbb{N}}\)
- \(A^\rightarrow = S^\text{op}\) with generators denoted by \(\{E_{k,n}\}_{n \in \mathbb{Z}}^{k \in \mathbb{N}}\)
- \(A^\text{diag} = K[c^{\pm 1}, E_{0,k}]_{k \in \mathbb{Z} \setminus \{0\}}\)

Both algebras \(S\) and \(A\) are generated over \(K\) by symbols \(E_{k,n}\), but the former has \(k \in \mathbb{N}\) and the latter has \(k \in \mathbb{Z}\). The relations between these generators in the algebra \(A\) are modeled after the relations (2.17) and (2.18), but with certain small modifications (originally defined in [3], but see [24] for our conventions):

(3.2) \[ [P_{k,n}, P_{k',n'}] = \delta_{k+k',s}^0 \frac{(1 - q_1^n)(1 - q_2^n)}{1 - q^{-s}} \cdot (1 - c^k) \]

if \(kn' = k' n\) and \(k < 0\), where \(s = \gcd(k, n)\), and:

(3.3) \[ [P_{k,n}, P_{k',n'}] = \frac{(1 - q_1^n)(1 - q_2^n)}{1 - q^{-1}} \cdot c^s Q_{k+k',n+n'} \]
if \( kn' < k'n \) and the triangle with vertices \((0,0), (k,n), (k+k',n+n')\) contains no lattice points inside or on one of the edges, and \( s \) denotes \( \gcd(k,n) \gcd(k'n') \). The particular power \( c' \) in formula (3.3) can be found in (2.21) of [24], but it will not be relevant to us. Throughout the present paper, we will set \( c = q^r \) for a natural number \( r \), in order to cancel the denominator of (3.2). Since the \( Q_{k,n} \) are still defined by (2.10), they are also multiples of \( 1 - q^s \), and this cancels the denominator in (3.2)

The generators \( P_{k,n} \) and \( Q_{k,n} \) are connected with the generators \( E_{k,n} \) by formulas (2.14) and (2.10), respectively. The observant reader will note that the \( P \)'s and \( Q \)'s are not really in the algebra \( \mathcal{A} \) because they are polynomials of the \( E \) generators with rational coefficients, and \( Q \not\subset \mathbb{K} \). However, it is elementary to convert (3.2) and (3.3) into formulas for the commutators \([E_{k,n}, E_{k',n'}] \): akin to Proposition 2.6, these commutators will be expressible as products of \( E \)'s with coefficients in \( \mathbb{K} \). We leave the case of (3.3) as an exercise to the interested reader (it will differ from (2.19)–(2.21) by some powers of \( c \)), but we will now show how to convert (3.2):

**Proposition 3.2.** Assume \( s \in -\mathbb{N}, k \in \mathbb{N} \) and \( \gcd(k,n) = 1 \). Then (3.2) implies:

\[
(E_{k,s,n}, E_{k,s',n'}) \bigg|_{c \mapsto q^s} = \begin{cases} 0 & \text{if } s' < 0 \\ \Delta \sum_{i=1}^{\min(s,s')} \gamma_i E_{k(s+i),n(s+i)} E_{k(s'-i),n(s'-i)} & \text{if } s' > 0 \end{cases}
\]

for some \( \gamma_i \in \mathbb{K} \).

**Proof.** Formula (3.4) is easy when \( s, s' < 0 \), since if \( P_{k,n}, P_{2k,2n}, P_{3k,3n}, \ldots \) all commute, then formula (2.14) implies that \( E_{k,n}, E_{2k,2n}, E_{3k,3n}, \ldots \) also all commute. On the other hand, when \( s < 0 < s' \), relation (3.2) reads:

\[
[P_{k,s,n}, P_{k,s',n'}] \bigg|_{c \mapsto q^s} = \delta_{s+s'}^0 s(1 - q_1^s)(1 - q_2^s)(1 + q^{-s} + \ldots + q^{-s(kr-1)}) \Rightarrow \sum_{s=-\infty}^{-1} \frac{P_{k,s,n}}{sx^{-s}} \sum_{s'=1}^{\infty} \frac{P_{k,s',n'}}{-s' y^{s'}} = \sum_{s=1}^{\infty} \left(1 - q_1^s\right)(1 - q_2^s)(1 + q^{-s} + \ldots + q^{-s(kr-1)}) sx^{-s} y^{s'}
\]

We leave the following claim as an easy exercise: if \([P,P'] = \gamma \) with \( \gamma \) central, then \( \exp(P) \exp(P') = \exp(\gamma) \exp(P') \exp(P) \). With this in mind, we obtain:

\[
\sum_{s=-\infty}^{-1} \frac{E_{k,s,n}}{(-x)^{-s}} \sum_{s'=1}^{\infty} \frac{E_{k,s',n'}}{(-y)^{s'}} \bigg|_{c \mapsto q^s} = \phi(xy) \sum_{s'=1}^{\infty} \frac{E_{k,s',n'}}{(-y)^{s'}} \sum_{s=-\infty}^{-1} \frac{E_{k,s,n}}{(-x)^{-s}} \bigg|_{c \mapsto q^s}
\]

where:

\[
\phi(z) = \exp \left( \sum_{s=1}^{\infty} \frac{(1 - q_1^s)(1 - q_2^s)(1 + q^{-s} + \ldots + q^{-s(kr-1)})}{sz^s} \right)
\]

is equal to \( 1 + a \) power series in \( z^{-1} \) whose coefficients are all in \( \Delta \cdot \mathbb{K} \). Taking the coefficient of \( (-x)^s(-y)^{-s'} \) in (3.3), we obtain (3.3).
Theorem 3.5. For any lattice points \( n, k \in \mathbb{Z} \), we have:

\[
[P_{0, k}, R(z_1, ..., z_n)] = (1 - q_1^k)(1 - q_2^k)(z_1^k + ... + z_n^k)R(z_1, ..., z_n)
\]

for all \( R(z_1, ..., z_n) \in S^{op} \cong A^\rightarrow \), and:

\[
[P_{0, k}, R(z_1, ..., z_n)] = -(1 - q_1^k)(1 - q_2^k)(z_1^k + ... + z_n^k)R(z_1, ..., z_n)
\]

for all \( R(z_1, ..., z_n) \in S \cong A^\leftarrow \).

Proof. Since the algebra \( A \) is a free \( \mathbb{K} \)-module, it is enough to prove the required formulas over \( \mathbb{F} \). According to Theorem 2.5 of [27], the shuffle algebra is generated by \( \{ z_i^k \} \) \( k \in \mathbb{Z} \) over \( \mathbb{F} \), and so the required formulas follow from the particular case \( n = 1 \). In this case, the required relations boil down to:

\[
[P_{0, k}, E_{1, k'}] = (1 - q_1^k)(1 - q_2^k)E_{1, k + k'}
\]

\[
[P_{0, k}, E_{-1, k'}] = -(1 - q_1^k)(1 - q_2^k)E_{-1, k + k'}
\]

which are just particular cases of (3.6).

\[ \square \]

3.4. Formulas (2.12) and (3.1) allow us to find a \( \mathbb{K} \)-basis of \( A \):

\[
A \mid_{c \to q^r} = \bigoplus_{(n_1, k_1) \cdots (n_t, k_t)} \mathbb{K} \cdot E_{n_1, k_1} \cdots E_{n_t, k_t}
\]

where the sum goes over all collections \( (n_1, k_1), \ldots, (n_t, k_t) \in \mathbb{Z}^2 \setminus (0, 0) \) ordered clockwise. Here and below, we say that two lattice points \( (n, k) \) and \( (n', k') \) are ordered clockwise, denoted by:

\[
(n, k) \prec (n', k')
\]

if one can reach the latter from the former by turning clockwise around the origin, without crossing the negative \( y \) axis. If we wish to exclude the situation when \( (n, k) \) and \( (n', k') \) lie on the same ray through the origin, then we will use the notation:

\[
(n, k) \succeq (n', k')
\]

instead. Formulas (3.9) and (3.10) are simply inequalities \( \leq \) and \( < \) on the slopes, appropriately defined, of the lattice points \( (n, k) \) and \( (n', k') \). Just like one can deduce (2.12) from Theorem 2.4 one can deduce (3.8) from the following Theorem:

Theorem 3.5. For any lattice points \( (n', k') \succeq (n, k) \), we have:

\[
[E_{n, k}, E_{n', k'}]_{c \to q^r} = \Delta \sum_{(n', k') \succeq (n, k)} \mathbb{K} \cdot E_{n_1, k_1} \cdots E_{n_t, k_t}
\]

for certain \( p_{n_1, k_1, ..., n_t, k_t}^{n, n_1, ..., n_t} \) \( (q_1, q_2) \) \( \in \mathbb{K} \), and \( \Delta = (1 - q_1)(1 - q_2) \). Moreover, the equations (3.11) generate the ideal of relations between the elements \( E_{n, k} \in A \).
Note that we specialize $c = q^r$ in (3.11) for two reasons: firstly, when $kn' = k'n$, we make the convention that formula (3.11) be identical to formula (3.4), which requires $c = q^r$ in order to not have denominators. Secondly, formula (3.3) and the equivalent formula with $P$’s replaced with $E$’s, feature certain powers of $c$ in the right-hand side, which only becomes elements of $K$ upon specialization $c = q^r$.

Proof. The generators $E_{n,k}$ (alternatively $P_{n,k}$) of the algebra $A$ are permuted by $SL_2(\mathbb{Z})$ acting on the indices. As observed in [3], the relations (3.2) and (3.3) are not quite invariant under this $SL_2(\mathbb{Z})$ due to the various powers of $c$ that appear in the right-hand sides of these formulas, but they are invariant under the universal cover of $SL_2(\mathbb{Z})$. As a consequence of this fact, the subalgebras:

$$A^<_{\frac{1}{r}} = \mathbb{K}\{E_{n,k}\}_{n<ka} \subset A, \quad A^>_{\frac{1}{r}} = \mathbb{K}\{E_{n,k}\}_{nb>ka} \subset A$$

are all isomorphic to the shuffle algebra $S$ and its opposite $S^{\text{op}}$, respectively (which by definition are isomorphic to $A^< = A^{<\infty}$ and $A^> = A^{>\infty}$, respectively). Any pair of vectors $(n,k)$, $(n',k')$ either lie on the same line passing through the origin, in which case (3.11) reduces to (3.4), or they lie in the half-plane defined by the line of some slope $b/a \in \mathbb{Q}$, in which case (3.11) is an equality in the subalgebra:

$$A^<_{\frac{1}{r}} \cong S \quad \text{or} \quad A^>_{\frac{1}{r}} \cong S^{\text{op}}$$

Such an equality holds due to (2.13). The final statement of the Theorem, concerning the fact that relations (3.11) generate the ideal of relations between the generators $E_{n,k} \in A$, was shown in [24] following the ideas of [3].

Recall the elements $E_{d*} \in S$ from (2.6). Since the negative (respectively positive) half of the algebra $A$ is isomorphic to $S$ (respectively $S^{\text{op}}$), we will write:

(3.13) \hspace{1cm} E_{d*} \in A^< \subset A

(3.14) \hspace{1cm} F_{d*} \in A^> \subset A

for the corresponding elements of $A$. Combining Proposition 2.2 with (3.8) yields:

(3.15) \hspace{1cm} E_{d*} = \sum_{n_i \in \mathbb{N}, k_i \in \mathbb{Z}} s^{n_1,\ldots,n_t}_{k_1,\ldots,k_t,d_*}(q_1,q_2) \cdot E_{-n_1,k_1 \ldots E_{-n_t,k_t}}

(3.16) \hspace{1cm} F_{d*} = \sum_{n_i \in \mathbb{N}, k_i \in \mathbb{Z}} s^{n_1,\ldots,n_t}_{k_1,\ldots,k_t,d_*}(q_1,q_2) \cdot E_{n_1,k_1 \ldots E_{n_t,k_t}}

for any $d_* = (d_1, \ldots, d_n)$, where $s^{n_1,\ldots,n_t}_{k_1,\ldots,k_t,d_*}(q_1,q_2) \in \mathbb{K}$ are uniquely determined.

3.6. In this paper, we will mostly be concerned with the top half of the algebra $A$:

$$A^\uparrow := \mathbb{K}\text{-subalgebra generated by } \{E_{n,k}^{k \in \mathbb{N}}\}_{n \in \mathbb{Z}} \subset A$$

which coincides with $A^{<0}$ of (3.12). Therefore, there exists an isomorphism:

(3.17) \hspace{1cm} A^\uparrow \cong S, \hspace{1cm} E_{n,1} \mapsto z_1^n
We will often extend the subalgebra $A^\uparrow$ by adding the elements $E_{n,0}$ on the $x$-axis:

$$A^\uparrow : = \mathbb{K}\text{-subalgebra generated by } \langle c^{\pm 1}, E_{n,k} \rangle_{n \in \mathbb{Z}} \subset A$$

As a consequence of (3.18), we have:

(3.18) $A^\uparrow =$

\[
\bigoplus_{-\infty < \frac{n_k}{n} \leq \frac{m}{n} < \infty} \mathbb{K} \cdot E_{n_1,k_1} \ldots E_{n_t,k_t}
\]

(3.19) $A^\uparrow \bigg|_{c \rightarrow q^r} =$

\[
\bigoplus_{-\infty < \frac{n_k}{n} \leq \frac{m}{n} \leq \infty} \mathbb{K} \cdot E_{n_1,k_1} \ldots E_{n_t,k_t}
\]

(note that we do not need to specialize $c = q^r$ in (3.18) because the commutation relations (3.3) do not involve any powers of $c$ if the indices $(n, k)$ and $(n', k')$ are both in the upper half plane, see [24]). The algebra $A^\uparrow$ is $\mathbb{Z} \times \mathbb{N}$ graded:

$$\text{deg } E_{n,k} = (n, k)$$

and the graded pieces $A^\uparrow_{n,k}$ have infinite rank over $\mathbb{K}$. However, the subspaces:

(3.20) $A^\uparrow_{\leq \mu} =$

\[
\bigoplus_{-\infty < \frac{n_k}{n} \leq \frac{m}{n} \leq \mu} \mathbb{K} \cdot E_{n_1,k_1} \ldots E_{n_t,k_t}
\]

are finite rank free $\mathbb{K}$-modules. Consider the $\mathbb{K}$-linear map $A^\uparrow_{\leq \mu + 1} \rightarrow A^\uparrow_{\leq \mu}$ which sends every product $E_{n_1,k_1} \ldots E_{n_t,k_t}$ of (3.18) either to 0 or to itself, and define:

$$\hat{A}^\uparrow_{n,k} = \lim_{\mu \rightarrow -\infty} A^\uparrow_{\leq \mu} \quad \hat{A}^\uparrow = \bigoplus_{n \in \mathbb{Z}} \hat{A}^\uparrow_{n,k}$$

In more practical terms, we may think of $\hat{A}^\uparrow$ as consisting of infinite $\mathbb{K}$-linear combinations of basis monomials (3.18) for bounded above $k_1 + \ldots + k_t$:

(3.21) $\hat{A}^\uparrow =$

\[
\bigoplus_{-\infty < \frac{n_k}{n} \leq \frac{m}{n} < \infty} \mathbb{K} \cdot E_{n_1,k_1} \ldots E_{n_t,k_t}
\]

Similarly, we define $\hat{A}^{\text{ext}} \supset \hat{A}^\uparrow$ by allowing $k_i = 0$, and the analogue of (3.21) is:

(3.22) $\hat{A}^{\text{ext}} \bigg|_{c \rightarrow q^r} =$

\[
\bigoplus_{-\infty < \frac{n_k}{n} \leq \frac{m}{n} \leq \infty} \mathbb{K} \cdot E_{n_1,k_1} \ldots E_{n_t,k_t}
\]

**Proposition 3.7.** $\hat{A}^\uparrow$ and $\hat{A}^{\text{ext}}$ are closed under multiplication, and thus algebras.

_Proof._ We will prove the statement for $\hat{A}^\uparrow$, as the case of $\hat{A}^{\text{ext}}$ is analogous. From now on, we will consider paths $v$ in the upper half plane that start at the origin, and are built up of steps $\{(n_1, k_1), \ldots, (n_t, k_t)\} \subset \mathbb{Z} \times \mathbb{N}$. Such a path is called convex if:

$$\frac{n_1}{k_1} \leq \ldots \leq \frac{n_t}{k_t}$$

which corresponds to $(n_1, k_1) \leq \ldots \leq (n_t, k_t)$. The size of the path is the lattice point $(n, k)$ with $n = \sum n_i$ and $k = \sum k_i$, where the path ends. As in Section 2 there is a one-to-one correspondence between paths and basis vectors of $A^\uparrow$, given by:

$$v \mapsto E_v = E_{n_1,k_1} \ldots E_{n_t,k_t}$$
Formulas (3.18) and (3.22) say that elements of the algebras $\mathcal{A}^\dagger$ and $\hat{\mathcal{A}}^\dagger$ are linear combinations (finite in the former case, infinite in the latter case) of the elements $E_v$ corresponding to convex paths. Let us recall from (3.11) that formula (3.11) (see also the proof of Theorem 2.4) implies that we can “convexify” any path $v$, i.e. write $E_v$ as a linear combination $\sum_{v_0 \text{ convex}} c_{v_0} v_0$ for convex paths $v_0$. The main thing we will need to take from their argument is that the coefficients $c_{v_0}$ are non-zero only if the path $v_0$ lies to the left of $v$. More precisely, we will show:

**Claim 3.8.** For any convex paths $v, v'$ of sizes $(n, k), (n', k')$, let $v \sqcup v'$ denote their concatenation, and let $(v \sqcup v')^{\text{conv}}$ denote the convexification of $v \sqcup v'$. Then:

$$E_v \cdot E_{v'} = E_{v \sqcup v'} \in E_{(v \sqcup v')^{\text{conv}}} + \Delta \sum_{(n+n', k+k') \text{ to the left of } v \sqcup v'} K \cdot E_{v_0}$$

For lattice paths that start at $(0, 0)$ and end $(n+n', k+k')$, the notion of one being to the left of another is unambiguous, once left is defined as “the negative $n$ direction”.

Indeed, the Claim implies Proposition 3.7 because it establishes the following fact: given an infinite sum of $E_v$’s (resp. $E_{v'}$’s) over paths $v$ (resp. $v'$) of fixed size $(n, k)$ (resp. $(n', k')$), then any given convex path $v_0$ appears in the right-hand side of (3.23) with non-zero coefficient only for finitely many $v$ and $v'$. This means that the product of infinite sums of $E_v$’s and $E_{v'}$’s is a well-defined infinite sum.

**Proof. of Claim 3.8.** Let $v = \{(n_1, k_1), \ldots, (n_t, k_t)\}$, $v' = \{(n'_1, k'_1), \ldots, (n'_t, k'_t)\}$. If:

$$\frac{n_k}{k} \leq \frac{n'_1}{k'_1}$$

then $v \sqcup v'$ is already a convex path, and the claim holds trivially. If the opposite inequality holds, then we may apply (3.11) to obtain:

$$E_v E_{v'} = E_{v \setminus (n_t, k_t)} E_{n_t, k_t} E_{n'_1, k'_1} E_{v' \setminus (n'_1, k'_1)} \in E_{v \setminus (n_t, k_t)} E_{n_t, k_t} E_{n'_1, k'_1} E_{v' \setminus (n'_1, k'_1)} + \Delta \sum_{v_0 \text{ convex path}} K \cdot E_{v \setminus (n_t, k_t)} E_{v_0} E_{v' \setminus (n'_1, k'_1)}$$

where the sum goes over convex paths $v_0$ of size $(n_t + n'_1, k_t + k'_1)$ which stay to the left of the path spanned by the two vectors $(n_t, k_t), (n'_1, k'_1)$. Consider the paths:

- $\tilde{v}$ obtained by concatenating $v \setminus (n_t, k_t), (n'_1, k'_1), (n_t, k_t), v' \setminus (n'_1, k'_1)$
- $\tilde{v}_0$ obtained by concatenating $v \setminus (n_t, k_t), v_0, v' \setminus (n'_1, k'_1)$

for any convex path $v_0$ that appears in the right-hand side of (3.24). All such paths $\tilde{v}$ and $\tilde{v}_0$ are strictly to the left of $v \sqcup v'$. If any of these paths is convex, we stop, otherwise we choose two consecutive vectors in the path which spoil convexity:

$$(\tilde{n}, \tilde{k}) \text{ and } (\tilde{n}', \tilde{k}') \text{ such that } \frac{\tilde{n}}{\tilde{k}} > \frac{\tilde{n}'}{\tilde{k}'}$$

and repeat the argument of (3.24). The reason why this recursive procedure will end after finitely many steps is that all our paths have fixed size, and the slopes of all the vectors in the paths obtained at every step cannot be greater (respectively smaller) than the greatest (respectively smallest) of the slopes of the vectors in the
paths \( v \) and \( v' \). Finally, note that \( E_{\tilde{v}} \) is the only summand in the right-hand side of (3.24) which does not have a prefactor \( \Delta \) in front. Since \( \tilde{v} \) consists of the same vectors as \( v \sqcup v' \), but in some other order, at the end of the recursive procedure this summand will have transformed into \( E_{(v \sqcup v')^{\text{conv}}} \) modulo \( \Delta \).

\[ \square \]

**Definition 3.9.** A representation \( F \) of \( \mathcal{A} \) is called **good** if it has a grading:

\[
F = \bigoplus_{n=0}^{\infty} F_n
\]

for some \( n_0 \in \mathbb{Z} \), such that every \( E_{n,k} \in \mathcal{A} \) acts of \( F \) by decreasing the grading by \( n \).

**Proposition 3.10.** The action of \( \mathcal{A} \) on any good module extends to \( \hat{\mathcal{A}}^\uparrow \) and \( \hat{\mathcal{A}}^{\text{ext}} \).

*Proof.* Let \( i_n \) and \( pr_n \) denote the inclusion and projection, respectively, to the \( n \)-th direct summand of (3.25). Then we note that:

\[
pr_n \circ E_{n_1,k_1} \cdots E_{n_t,k_t} \circ i_{n'} = 0
\]
as soon as \( n_1 < n_0 - n \) or \( n_t > n' - n_0 \). Since any element of \( \hat{\mathcal{A}}^\uparrow \) is a finite linear combination of monomials \( E_{n_1,k_1} \cdots E_{n_t,k_t} \) modulo those monomials which satisfy either \( n_1 < n_0 - n \) or \( n_t > n' - n_0 \), the Proposition follows.

\[ \square \]

3.11. The main reason we have introduced the completion \( \hat{\mathcal{A}}^\uparrow \) of \( \mathcal{A}^\uparrow \) is that it contains the following elements, studied in [24]:

\[
\{ W_{n,k} \} \quad k \in \mathbb{N} \quad n \in \mathbb{Z} \in \hat{\mathcal{A}}^\uparrow
\]
given by:

\[
W_{n,k} = \sum_{k_i \in \mathbb{N}, \sum k_i = k} \sum_{n_i \in \mathbb{Z}, \sum n_i = n} E_{n_1,k_1} \cdots E_{n_t,k_t} \cdot q^{\alpha(v)}
\]

where the integer \( \alpha(v) \) associated to the convex path \( v = \{(n_1,k_1), \ldots, (n_t,k_t)\} \) is:

\[
\alpha(v) = \sum_{1 \leq i < j \leq t} k_i n_j + \sum_{i=1}^t k_i n_i + k_i - n_i - \tfrac{\gcd(n_i,k_i)}{2}
\]

The relations between the elements (3.27) are best phrased via the currents:

\[
W_k(x) = \sum_{n \in \mathbb{Z}} \frac{W_{n,k}}{x^n}
\]

and they were shown in [24] to match, up to a renormalization, the relations in the quantum deformed \( W \)-algebra of type \( \mathfrak{gl}_r \) as \( r \to \infty \) (which was defined in [1], [8]):

\[
W_k(x)W_{k'}(y) \cdot f_{kk'}(\frac{y}{x}) = W_{k'}(y)W_k(x) \cdot f_{k'k}(\frac{x}{y}) =
\]
for all \( k, k' \geq 0 \) (one sets \( W_0(x) = 1 \)). In formula (3.29), we write \( \delta(z) = \sum_{n \in \mathbb{Z}} z^n \),
(3.30) \[
\theta(s) = \Delta \left( \frac{1}{1-q^s} \right) \cdot \zeta(q) \cdots \zeta(q^{s-1})
\]
while for all \( k, k' \geq 0 \), we define the following power series in \( z \):
(3.31) \[
f_{kk'}(z) = \exp \left[ \sum_{n=1}^{\infty} \frac{z^n}{n} \cdot \frac{(1-q^n)(1-q^{kn})}{1-q^n} \right]
\]
3.12. Relation (3.29) is quadratic in the generating series \( W_k(x) \), but one must carefully interpret it to obtain an infinite family of relations between the coefficients \( W_{n,k} \). The idea is to equate the coefficients of \( x^{-n} y^{-n'} \) in the left and right-hand sides of (3.29), for all \( n, n' \in \mathbb{Z} \). In the left-hand side, this is achieved by expanding:
(3.32) \[
W_k(x)W_{k'}(y)f_{kk'}\left( \frac{x}{xq} \right) \quad \text{in non-negative powers of } \frac{x}{x}
\]
(3.33) \[
W_{k'}(y)W_k(x)f_{kk'}\left( \frac{y}{yq} \right) \quad \text{in non-negative powers of } \frac{y}{y}
\]
This is the only reasonable choice one can make in order for the expansion of either term to be an infinite sum of the form:
\[
\sum_{a \geq 0} \text{coefficient} \cdot W_{n-a,k}W_{n'+a,k'} \quad \text{or} \quad \sum_{a \geq 0} \text{coefficient} \cdot W_{n'-a,k'}W_{n+a,k}
\]
which are acceptable expressions in the completion \( \hat{A}^+ \) of \( A^+ \). What is not immediately clear, and will be discussed in the proof of Theorem 3.13 below, is how to make sense of the product of \( W \)-algebra currents in the right-hand side of (3.29). The only exception is when \( k' = 1 \), in which case the relation unambiguously reads:
(3.34) \[
W_k(x)W_1(y)\zeta\left( \frac{x}{xq^k} \right) - W_1(y)W_k(x)\zeta\left( \frac{y}{qx} \right) = \Delta \left( \frac{1}{1-q} \right) \left[ \delta\left( \frac{y}{xq} \right) W_{k+1}(y) - \delta\left( \frac{x}{yq^k} \right) W_{k+1}(x) \right]
\]
Extracting the coefficients of \( x^{-n} y^{-n'} \) according to the rules (3.32) and (3.33) yields:
\[
[W_{n,k}, W_{n',1}] + \Delta \sum_{a=1}^{\infty} \frac{1-q^n}{1-q} \left( q^{a(k-1)} W_{n-a,k} W_{n'+a,1} - W_{n'-a,1} W_{n+a,k} \right) = \Delta q^{-n} - q^{-kn'} \cdot W_{n+n', k+1}
\]
(3.35)
What is surprising about formula (3.35) is that all the coefficients lie in \( \mathbb{K} \) instead of \( \mathbb{F} \), even though \( \theta(s) \) could a priori have produced poles of the form \( 1 - q^n \) in (3.29). In fact, this is a general phenomenon, as evidenced by the result below:
Theorem 3.13. Relations (3.29) are equivalent with the following family of equalities, which hold for all \( k, k' > 0 \) and \( n, n' \in \mathbb{Z} \):

\[
(W_{n,k}, W_{n',k'}) = \Delta \left[ \sum_{m+l' = l+k', m+m' = n+n'} c_{n,n',k,k'}^{m,m',l,l'}(q_1, q_2) \cdot W_m W_{l,l'} \right]
\]

for certain \( c_{n,n',k,k'}^{m,m',l,l'}(q_1, q_2) \in \mathbb{K} \) which we will compute algorithmically. The right-hand side allows \( \min(l, l') = 0 \), in which case we recall that \( W_{m,0} = \delta_m^0 \).

3.14. Theorem 3.13 will be proved at the end of the present Section. Let us define:

\[
\mathcal{A}_\infty = \mathbb{K} \langle W_{n,k} \rangle_{k \in \mathbb{N}}^{n \in \mathbb{Z}} / \text{relations (3.36)}
\]

and let us note that Theorem 3.13 states that there is a well-defined homomorphism \( \mathcal{A}_\infty \to \hat{\mathcal{A}}^\uparrow \) given by (3.27). After tensoring with \( \mathbb{F} \), this embedding is completely determined by sending \( W_{n,1} \mapsto E_{n,1} \), because (3.35) implies that any \( W_{n,k} \) can be obtained as a sum of products of \( W_{n,1} \), upon inverting \( \Delta \) and rational functions in \( q \).

Proposition 3.15. The generators of \( \mathcal{A}_\infty \to \hat{\mathcal{A}}^\uparrow \) interact with:

\[
[p_n, p_n] = n(1 - q_1^n)(1 - q_2^n) \frac{1 - c^n}{1 - q^n}
\]

for all \( n \in \mathbb{N} \).

Define:

\[
\mathcal{A}_{\infty}^{\text{ext}} = \mathbb{K} \langle W_{n,k}, p_n \rangle_{k \in \mathbb{N}}^{n \in \mathbb{Z}} / \text{relations (3.36), (3.39), (3.40), (3.41)}
\]

Throughout this paper, we will always specialize the central charge \( c \) to \( q^r \) for some \( r \in \mathbb{N} \), so the structure constants of the algebra \( \mathcal{A}_{\infty}^{\text{ext}} \) will all lie in \( \mathbb{K} \) (if \( c \neq q^r \), then (3.41) would contradict this fact). By Proposition 3.15, the homomorphism:

\[
\mathcal{A}_\infty \to \hat{\mathcal{A}}^\uparrow \quad \text{extends to} \quad \mathcal{A}_{\infty}^{\text{ext}} \to \hat{\mathcal{A}}^\uparrow, \text{ext}
\]
Proof. of Proposition 3.15. We will prove (3.39), as (3.40) is analogous and (3.41) is a trivial application of (3.32). We will do so by induction on $k$ (the case when $k = 1$ is simply (3.33)), and start by commuting relation (3.34) with $p_n$:

$$\frac{\Delta}{1-q} \left[ \delta \left( \frac{y}{xq} \right) \right] [W_{k+1}(y), p_n] - \delta \left( \frac{x}{yq^k} \right) \left[ W_{k+1}(x), p_n \right] =$$

$$= [W_k(x) W_1(y), p_n] \zeta \left( \frac{x}{yq^k} \right) - [W_1(y) W_k(x), p_n] \zeta \left( \frac{y}{xq} \right) \text{ Leibniz rule}$$

$$= W_k(x) [W_1(y), p_n] \zeta \left( \frac{y}{xq} \right) + [W_k(x), p_n] W_1(y) \zeta \left( \frac{y}{xq} \right) - W_1(y) [W_k(x), p_n] W_k(x) \zeta \left( \frac{y}{xq} \right) \text{ induction hypothesis of (3.39)}$$

$$- (1 - q^n)(1 - q^k) \left( \frac{1}{y^n} + \frac{1 - q^{kn}}{(1 - q^n)x^n} \right) \left[ W_k(x) W_1(y), xq \right] \zeta \left( \frac{x}{yq^k} \right) - W_1(y) W_k(x) \zeta \left( \frac{y}{xq} \right)$$

$$= - \frac{\Delta (1 - q^{k+1})(1 - q^2)}{1-q} \left( \frac{1}{y^n} + \frac{1 - q^{kn}}{(1 - q^n)x^n} \right) \delta \left( \frac{y}{xq} \right) W_{k+1}(y) - \delta \left( \frac{x}{yq^k} \right) W_{k+1}(x)$$

If we multiply both sides of the equation above with $1 - yq^k / x$, the second $\delta$ function vanishes in both sides of the equation above, and we are left with:

$$\frac{\Delta (1 - q^{k+1})}{1-q} \delta \left( \frac{y}{xq} \right) [W_{k+1}(y), p_n] =$$

$$= - \frac{\Delta (1 - q^{k+1})(1 - q^2)(1 - q^2)}{1-q} \left[ 1 + \frac{1 - q^{kn}}{(1 - q^n)q^{-n}} \right] \delta \left( \frac{y}{xq} \right) W_{k+1}(y)$$

Extracting the coefficient of $x^0$ from the equation above yields precisely (3.39) with $k$ replaced by $k + 1$, thus establishing the induction step.

3.16. Finally, we realize the deformed $W$–algebra of type $gl_r$ as a quotient of $A_{\infty}$.

**Definition 3.17.** For arbitrary $r \in \mathbb{N}$, define:

$$A_r = A_{\infty} \big/ \text{ relation (3.45)}$$

$$A_r^{\text{ext}} = A_r^{\text{ext}} \big/ \text{ relations (3.45) and (3.46) and } c = q^r$$

where:

$$W_0(x) = 0, \quad \forall k > r$$

$$W_r(x) = u \exp \left[ \sum_{n=1}^{\infty} \frac{p_n}{n x^{-n}} \right] \exp \left[ \sum_{n=1}^{\infty} \frac{p_n}{n x^n} \right]$$

The parameter $u$ in (3.46) will not be crucial (it will be identified with a line bundle in the next Section) and so we will not mention it explicitly in our notation.
Definition \[3.17\] explains the appeal of presenting the algebra \(A_r\) in terms of the generators \(W_{n,k}\): to show that \(A_r\) acts on a certain module, it is enough to show that the module is a good representation of \(A_r\), and then check that relations \(3.45\) holds (if one wants an action of \(A_r^\text{ext}\), then one also has to check \(3.46\)).

**Proof of Theorem 3.13** By \(3.27\), the element \(W_{n,k} \in \hat{A}^\uparrow\) is a certain infinite \(\mathbb{K}\)-linear combination of the elements:

\[
E_v = E_{n_1,k_1} ... E_{n_t,k_t}
\]

as \(v = \{(n_1,k_1),..., (n_t,k_t)\}\) runs over convex paths of size \((n,k)\). Moreover, the leading order coefficient, i.e. the coefficient of \(E_{n,k}\) itself, is a power of \(q\). By successive applications of Claim \[3.8\] this implies that there exists \(* \in \mathbb{Z}\) such that:

\[
W_v := W_{n_1,k_1} ... W_{n_t,k_t} = q^* E_v + \Delta \sum_{\text{convex paths } v'} E_{v'} \cdot \text{element of } \mathbb{K}
\]

Therefore, the \(\mathbb{K}\)-basis \(\{W_v\}_{v \text{ convex}}\) is upper triangular in terms of \(\{E_v\}_{v \text{ convex}}\), with respect to the partial ordering on convex paths of the same size, where one path is to the left of another. Since \(\{E_v\}_{v \text{ convex}}\) form a basis of \(\hat{A}^\uparrow\) over \(\mathbb{K}\), therefore:

\[
\hat{A}^\uparrow = \bigoplus_{k \in \mathbb{N}, n \in \mathbb{Z}} \sum_{\text{min}(k,n) < y < \uparrow \infty} \mathbb{K} \cdot W_{n_1,k_1} ... W_{n_t,k_t}
\]

Combining this statement with Claim \[3.8\] we infer that:

\[
[W_{n,k}, W_{n',k'}] = \Delta \sum_{\text{min}(k,n) < y < \uparrow \infty} r_{n_1}^{k_1} ... r_{n_t}^{k_t} (q_1,q_2) W_{n_1,k_1} ... W_{n_t,k_t}
\]

for certain Laurent polynomials \(r_{n_1}^{k_1} ... r_{n_t}^{k_t} (q_1,q_2) \in \mathbb{K}\). To prove \[3.36\], we must show that the only terms in the right-hand side of \[3.49\] with non-zero coefficient are products of exactly two generators \(W_{n_1,k_1} W_{n_2,k_2}\), with \(\min(k_1,k_2) \leq \min(k,k')\). To do so, we must properly interpret \[3.29\]. It was shown in \[23\] that:

\[
R_{kk'} (x,y) = W_k(x) W_{k'}(y) f_{kk'} \left( \frac{y}{x} \right)
\]

is a linear combination of the basis elements \(\{E_v\}_{v \text{ convex path}}\), whose coefficients are rational functions in \(x\) and \(y\). These rational functions have poles at:

\[
y - x q^{-i} \quad \text{for } i \in \{\max(0,k-k') + 1, ... , k\}
\]

\[
y - x q^i \quad \text{for } i \in \{\max(0,k'-k) + 1, ... , k'\}
\]

and satisfy the following symmetry relation:

\[
R_{kk'} (x,y) = R_{k'k} (y,x)
\]

and the evaluation properties:

\[
\text{Res}_{y = x q^{-i}} R_{kk'} (x,y) = R_{k-i,k'+i} (x q^{-i},x) \theta(i,k'-k+i) \quad \text{for } i \text{ as in } (3.50)
\]
To fix this issue, let us recall the normal-ordered integrals that appeared in [28]: once we expand the left-hand side (unless we are in the simple situation of (3.35)). Combining (3.52), (3.53) and (3.54), we interpret formula (3.29) as saying that:

\[ \text{Res}_{y=x^i} \frac{R_{kk'}(x, y)}{y} = -R_{k'-i,k+i}(x, xq^i)\theta(\min(i, k-k'+i)) \quad \text{for } i \text{ as in (3.51)} \]

Combining (3.52), (3.53) and (3.54), we interpret formula (3.29) as saying that:

\[ \left[R_{kk'}(x, y) \right] \text{ expanded in } |y| \ll |x| - \left[R_{kk'}(x, y) \right] \text{ expanded in } |y| \gg |x| = \]

\[ \sum_{\alpha \notin \{0, \infty\}} \delta \left( \frac{y}{x\alpha} \right) \text{Res}_{y=x\alpha} \frac{R_{kk'}(x, y)}{y} \]

which is simply a reformulation of the residue theorem for rational functions. Note that the interpretation given above was known to [1] (see [28] for a review), although in the somewhat different context of operator product expansions corresponding to the free field realization of the deformed \( W \)-algebra.

Formula (3.56) shows how to make sense of the relation (3.29), and how to deduce it from (3.52), (3.53) and (3.54). However, the down-side is that the right-hand side of (3.56) is not readily expressed in terms of the generators \( W_{a,k} \) which appear once we expand the left-hand side (unless we are in the simple situation of (3.55)). To fix this issue, let us recall the normal-ordered integrals that appeared in [28]:

\[ : R_{kk'}(x, y) : = : W_k(x)W_{k'}(y)f_{kk'} \left( \frac{y}{x} \right) : = \]

\[ = \int_{|z| \ll |x|, |y|} W_{k'}(z)W_k(x)f_{kk'} \left( \frac{x}{z} \right) \frac{Dz}{1 - \frac{x}{z}} - \int_{|z| \gg |x|, |y|} W_k(x)W_{k'}(z)f_{kk'} \left( \frac{z}{x} \right) \frac{Dz}{1 - \frac{z}{x}} \]

where \( Dz = \frac{dz}{2\pi i} \). On one hand, by explicitly computing the integrals, we obtain:

\[ \text{Res}_{y=x\alpha} \frac{R_{kk'}(x, y)}{y} = \]

\[ = \sum_{a,b \in \mathbb{N} \cup \{0\}} \left[ x^{a+c} y^b f_{kk'}^a W_{a-b,k'} W_{c,k} + x^{-a-c} y^{-b} f_{kk'}^a W_{c,k} W_{a+b+1,k'} \right] \]

where we consider the power series expansion of (3.31):

\[ f_{kk'}(x) = \sum_{a=0}^{\infty} f_{kk'}^a x^a \in 1 + x\Delta \mathbb{K}[|x|] \]

On the other hand, as observed in (3.52), the two integrands in equation (3.56) represent the same rational function. Therefore, the difference between the two integrals is given by the sum of the residues in the variable \( z \), similar to (3.55):

\[ : R_{kk'}(x, y) : = R_{kk'}(x, y) + \sum_{\alpha \notin \{0, \infty\}} \text{Res}_{z=x\alpha} \frac{R_{kk'}(x, z)}{x\alpha - y} \]

The residues are prescribed by (3.53) and (3.54), so we obtain:

\[ R_{kk'}(x, y) = : R_{kk'}(x, y) : + \]

\[ + \sum_{i=\max(0,k'-k)+1}^{k'} \frac{R_{k'-i,k+i}(x, xq^i)}{1 - \frac{x}{xq^i}} \theta(\min(i, k-k'+i)) - \]

\[ - \sum_{i=\max(0,k-k')+1}^{k} \frac{R_{k-i,k'+i}(xq^{-i}, x)}{1 - \frac{x}{xq^i}} \theta(\min(i, k'-k+i)) \]
One can iterate relation (3.58) to express the right-hand side as:

\[ R_{kk'}(x, y) = R_{kk'}(x, y) : + \sum_{k+k'=l+l', a, b, l \in \mathbb{Z}} : R_{l'}(xq^a, xq^b) : g_{l'}^{ab}(q_1, q_2) \prod_{c} \left( 1 - \frac{y}{xq^c} \right) \]

for some \( g_{l'}^{ab}(q_1, q_2) \in \mathbb{F} \). We conjecture that \( g_{l'}^{ab}(q_1, q_2) \in \mathbb{K} \) for all \( a, b, l, l' \), but we will not prove this result. Instead, we observe that relation (3.59) gives the correct interpretation of (3.29). Indeed, expanding (3.59) for \(|y| \ll |x|\) (respectively \(|y| \gg |x|\)) gives us the first (respectively second) term in the left-hand side of (3.29), and taking the difference of these two expansions gives us:

\[ W_k(x)W_{k'}(y)f_{kk'} \left( \frac{x}{y} \right) - W_{k'}(y)W_k(x)f_{k'k} \left( \frac{x}{y} \right) = \]

\[ \sum_{k+k'=l+l', a, b, l \in \mathbb{Z}} : R_{l'}(xq^a, xq^b) : \left( \sum_c \delta \left( \frac{y}{xq^c} \right) \prod_{c' \neq c} \left( 1 - \frac{y}{xq^{c'}} \right) \right) g_{l'}^{ab}(q_1, q_2) \]

The normal-ordered products in the right-hand side are quadratic expressions in the \( W \)–algebra generators according to (3.57), and so taking the coefficient of \( x^{-n}y^{-n'} \) for any \( n, n' \in \mathbb{Z} \) in the above expression gives us:

\[ [W_{n,k}, W_{n',k'}] + \sum_{a=1}^{\infty} [W_{n-a,k}W_{n'+a,k'}f_{kk'} - W_{n'-a,k}W_{n+a,k}f_{k'k}] = \]

\[ \sum_{k+k'=l+l', a, b, l \in \mathbb{Z}} : R_{l'}(xq^a, xq^b) : \left( \sum_{d \leq 0} W_{d,l}W_{n+n'-d,l} \cdot \text{coeff} + \sum_{d > 0} W_{n+n'-d,l}W_{d,l'} \cdot \text{coeff} \right) \]

where the coefficients denoted by “coeff” lie in \( \mathbb{F} \). For any fixed \( n + n' \) and \( k + k' \), formula (3.60) allows us to prove by induction on \( \min(k, k') \) that:

\[ [W_{n,k}, W_{n',k'}] = \sum_{k+k'=l+l', a, b, l \in \mathbb{Z}} : R_{l'}(xq^a, xq^b) : \left( \sum_{d \leq 0} W_{d,l}W_{n+n'-d,l} \cdot \text{coeff} + \sum_{d > 0} W_{n+n'-d,l}W_{d,l'} \cdot \text{coeff} \right) \]

The normal-ordered products in the right-hand side are quadratic expressions in the \( W \)–algebra generators according to (3.57), and so taking the coefficient of \( x^{-n}y^{-n'} \) for any \( n, n' \in \mathbb{Z} \) in the above expression gives us:

\[ [W_{n,k}, W_{n',k'}] + \sum_{a=1}^{\infty} [W_{n-a,k}W_{n'+a,k'}f_{kk'} - W_{n'-a,k}W_{n+a,k}f_{k'k}] = \]

\[ \sum_{k+k'=l+l', a, b, l \in \mathbb{Z}} : R_{l'}(xq^a, xq^b) : \left( \sum_{d \leq 0} W_{d,l}W_{n+n'-d,l} \cdot \text{coeff} + \sum_{d > 0} W_{n+n'-d,l}W_{d,l'} \cdot \text{coeff} \right) \]

where the coefficients denoted by “coeff” lie in \( \mathbb{F} \). For any fixed \( n + n' \) and \( k + k' \), formula (3.60) allows us to prove by induction on \( \min(k, k') \) that:

\[ [W_{n,k}, W_{n',k'}] = \sum_{k+k'=l+l', a, b, l \in \mathbb{Z}} : R_{l'}(xq^a, xq^b) : \left( \sum_{d \leq 0} W_{d,l}W_{n+n'-d,l} \cdot \text{coeff} + \sum_{d > 0} W_{n+n'-d,l}W_{d,l'} \cdot \text{coeff} \right) \]

4. The moduli space of sheaves

4.1. Having constructed shuffle and deformed \( W \)–algebras in the previous Sections, let us now construct the modules on which they are expected to act. Consider a smooth projective surface \( S \) over an algebraically closed field (denoted by \( \mathbb{C} \)) and an ample divisor \( H \subset S \). The Hilbert polynomial of a coherent sheaf \( F \) on \( S \) is:

\[ P_F(n) := \chi(S, F \otimes O(nH)) = an^2 + bn + c \]

where \( a, b, c \) are rational numbers that one can compute from the Grothendieck-Hirzebruch-Riemann-Roch theorem. One can find formulas for these numbers in the Appendix to [23], but the only thing we will need in the present paper is that
they can be expressed in terms of $S, H$ and the rank and Chern classes $r, c_1, c_2$ of $\mathcal{F}$. The reduced Hilbert polynomial is defined as:

$$p_\mathcal{F}(n) = \frac{P_\mathcal{F}(n)}{a}$$

A rank $r > 0$ torsion free coherent sheaf $\mathcal{F}$ on $S$ is called stable (respectively semistable) if for all proper subsheaves $\mathcal{G} \subset \mathcal{F}$ we have:

$$p_\mathcal{G}(n) < p_\mathcal{F}(n) \quad \text{(respectively } p_\mathcal{G}(n) \leq p_\mathcal{F}(n))$$

for all $n \gg 0$. Since the reduced Hilbert polynomials are monic and quadratic, stability (respectively semistability) is determined by checking the respective inequalities for the linear term and constant term coefficients. Note that stability depends on the polarization $H$, but we will fix a choice throughout this paper.

**Definition 4.2.** (see [15]): Let $\mathcal{M}_{(r,c_1,c_2)}$ denote the quasiprojective variety which corepresents the moduli functor of stable sheaves on $S$ with the invariants $r, c_1, c_2$.

We will denote the moduli space by $\mathcal{M}$ when the particular invariants will not be important to us. We impose the following assumption throughout this paper:

(4.1) **Assumption A:** $\gcd(r, c_1, H) = 1$

This assumption has two important consequences: firstly, any semistable sheaf is stable. Secondly, there exists a universal sheaf:

(4.2)

$$\begin{array}{ccc}
\mathcal{M} \times S \\
\downarrow \\
\mathcal{M}\times S \\
\downarrow \\
\mathcal{M} \times S
\end{array}$$

which is flat over $\mathcal{M}$, and its fiber over any closed point $\{\mathcal{F}\} \times S$ is isomorphic to $\mathcal{F}$ as a coherent sheaf over $S$. This leads to the following fact (see [15]):

**Proposition 4.3.** Under Assumption A, $\mathcal{M}_{(r,c_1,c_2)}$ is a projective variety, which also represents the moduli functor of stable sheaves on $S$ with the invariants $r, c_1, c_2$.

**Remark 4.4.** Note that the universal sheaf $\mathcal{U}$ is only determined up to tensoring with a line bundle pulled back from $\mathcal{M}$. This means that one has the freedom to choose such a line bundle on any component $\mathcal{M}_{(r,c_1,c_2)}$ of the moduli space, and this represents the ambiguity in choosing the universal sheaf on the whole of $\mathcal{M}$. Throughout the present paper, we will fix such a choice, requiring only that the chosen universal sheaves on $\mathcal{M}_{(r,c_1,c_2)}$ and $\mathcal{M}_{(r,c_1,c_2+1)}$ be compatible with each other as described in the Appendix to [23]. This compatibility is precisely what allows us to define Hecke correspondences in the following Subsection.

**Remark 4.5.** Since many of the constructions in the present paper are local on the moduli space of stable sheaves, one can replace the category of coherent sheaves by that of twisted coherent sheaves (see [1] for an overview). In this case, there exists a twisted universal sheaf on $\mathcal{M} \times S$, even without imposing Assumption A.
The interested reader may try to generalize the results in the present paper to that setting, but we do not expect any fundamentally new constructions to arise.

Because the universal sheaf $U$ is flat over $\mathcal{M}$, it inherits certain properties from the stable sheaves it parametrizes, such as having projective dimension 1 (indeed, any torsion free sheaf on a smooth projective surface has projective dimension 1, see Example 1.1.16 of [15]):

Proposition 4.6. There exists a short exact sequence:

$$0 \to \mathcal{W} \to \mathcal{V} \to U \to 0$$

with $\mathcal{W}$ and $\mathcal{V}$ locally free sheaves on $\mathcal{M} \times S$ (see [23] for a proof).

4.7. Consider the moduli space of elementary modifications:

$$\bar{Z}_1 = \{(F, F') \text{ s.t. } F \supsetneq F' \text{ for some } x \in S\} \subset \mathcal{M} \times \mathcal{M}'$$

where the notation:

$$F \supsetneq F'$$

means that $F \supset F'$ and $F/F' \cong \mathbb{C}_x$

Consider the natural projection maps:

$$\begin{align*}
\bar{Z}_1 & \xrightarrow{p^-} \mathcal{M} \quad \mathcal{M}' \xrightarrow{p^+} \\
\mathcal{S} & \xrightarrow{p_S} \quad \mathcal{F} \xrightarrow{\mathcal{F}'}
\end{align*}$$

Moreover, we have the tautological line bundle on $\bar{Z}_1$:

$$\begin{align*}
\mathcal{L} & \\
\mathcal{L}|(F, F') = F_x/F'_x = \Gamma(S, F/F')
\end{align*}$$

The space $\bar{Z}_1$ was denoted by $\bar{Z}$ in [23], but in the present paper we have changed the notation because we will shortly encounter a related space, denoted by $\bar{Z}_2$.

Remark 4.3 refers to fixing choices of the universal sheaves $U$ on all components of the moduli space $\mathcal{M}$, so that these choices are compatible with $\bar{Z}_1$. Specifically, this entails the existence of a short exact sequence:

$$0 \to (p_+ \times \text{Id})^*(U) \to (p_- \times \text{Id})^*(U) \to \Gamma_S(\mathcal{L}) \to 0$$

on $\bar{Z}_1 \times S$, where $\bar{Z}_1 \xrightarrow{p_S} \bar{Z}_1 \times S$ denotes the graph of $p_S$. We will often abuse notation and denote the first two terms in (4.7) by $\mathcal{U}'$ and $\mathcal{U}$, thought of as sheaves on $\bar{Z}_1 \times S$. 
4.8. Recall that a dg scheme \( X \) (defined over a base scheme \( Y \), which will be clear from context) is locally defined by a dg algebra:

\[
\mathcal{O}_X = \left[ \ldots \xrightarrow{d} \mathcal{O}_X^{(2)} \xrightarrow{d} \mathcal{O}_X^{(1)} \xrightarrow{d} \mathcal{O}_X^{(0)} \right]
\]

(the ring of functions on the base scheme \( Y \) will map into \( \mathcal{O}_X^{(0)} \)). The scheme \( \bar{X} \) whose coordinate ring is locally given by:

\[
\mathcal{O}_{\bar{X}} = \mathcal{O}_X^{(0)}/\text{Im } d
\]

will be called the support of the dg scheme \( X \). This means that there exists a map of dg schemes \( \bar{X} \to X \), and we will therefore say that \( X \) is supported on \( \bar{X} \).

**Example 4.9.** If \( V \) is a locally free sheaf on the scheme \( Y \), and we are given a section \( \sigma \in \Gamma(V) \), then the derived zero locus of \( \sigma \) is defined as the dg scheme:

\[
Z = \text{Spec}_Y \left[ \ldots \xrightarrow{\sigma^\vee} \wedge^2 (V^\vee) \xrightarrow{\sigma^\vee} V^\vee \xrightarrow{\sigma^\vee} \mathcal{O}_Y \right]
\]

Alternatively, we will say that \( Z \) is cut out (in a derived sense) by the vanishing of \( \sigma \). Meanwhile, the scheme-theoretic zero locus of \( \sigma \) refers to the scheme:

\[
\bar{Z} = \text{Spec}_Y (\mathcal{O}_Y / \text{Im } \sigma^\vee)
\]

It is easy to see that \( Z \) is supported on \( \bar{Z} \).

4.10. We will now define a dg scheme \( Z_1 \) supported on the scheme \( \bar{Z}_1 \).

**Definition 4.11.** Let \( \text{Sym} \) denote the symmetric algebra. Consider the dg scheme:

\[
Z_1 = \mathbb{P}_{M \times S}(U) = \text{Proj} \left( \text{Sym}^\bullet_{M \times S}(U) \right)
\]

Since \( U \) is not a vector bundle, but a coherent sheaf of projective dimension 1 as in Proposition 4.6, relation (4.8) is taken to mean that:

\[
Z_1 \twoheadleftarrow \mathbb{P}_{M \times S}(V)
\]

The vertical arrow is a projective bundle, and the horizontal arrow is the dg subscheme cut out by the vanishing of the following map of vector bundles on \( \mathbb{P}_{M \times S}(V) \):

\[
\sigma^\vee : \rho_-^* (W) \to \rho_+^* (V) \to \mathcal{O}(1)
\]

Define \( L = \iota^* (O(1)) \), where \( O(1) \) is the tautological line bundle on \( \mathbb{P}_{M \times S}(V) \).

Similarly, the non-derived zero locus of the section (4.10) is the scheme \( \bar{Z}_1 \), which will therefore be the support of \( Z_1 \). The line bundles denoted by \( L \) in (4.6) and Definition 4.11 are compatible under the natural map \( \bar{Z}_1 \to Z_1 \).
4.12. Define the map $p_- \times p_S : \mathcal{Z}_1 \to \mathcal{M} \times S$ as the diagonal arrow in (4.9). The following Proposition claims that there also exists a map $p_+ \times p_S : \mathcal{Z}_1 \to \mathcal{M}' \times S$. In order to define it, let us write $U' = V'/W'$ for the analogue of (4.3) on $\mathcal{M}' \times S$. We will write $\omega_S$ both for the canonical line bundle on $S$, and for its pull-back to $\mathcal{M}' \times S$.

Proposition 4.13. We have the diagram below:

\[
\begin{array}{c}
\mathcal{Z}_1 \\
\downarrow p_- \quad \downarrow p_+ \\
\mathcal{M} \times S \\
\end{array}
\]

where the vertical arrow is a projective bundle, and the horizontal arrow $\iota_+$ is the dg subscheme cut out by the vanishing of the following map of vector bundles:

\[
\sigma' : \mathcal{O}(-1) \hookrightarrow \rho_+^*(\mathcal{V}' \otimes \omega_S^{-1}) \rightarrow \rho_+^*(\mathcal{V} \otimes \omega_S^{-1})
\]
on $\mathbb{P}_{\mathcal{M}' \times S}(\mathcal{V}' \otimes \omega_S)$. Moreover, we have $\mathcal{L} \cong \iota_+^*(\mathcal{O}(-1))$ in the notation of (4.11).

We refer the reader to [23] for the proof of Proposition 4.13, which states that the derived zero loci of the sections (4.10) and (4.12) are isomorphic dg schemes.

Combining Definition 4.11 and Proposition 4.13, we conclude that there exist maps as in the diagram below, which are compatible with those of (4.5) under the support map $\bar{\mathcal{Z}}_1 \to \mathcal{Z}_1$ (we will use the same symbols, namely $p_-, p_S, p_+$, for these maps):

\[
\begin{array}{c}
\mathcal{Z}_1 \\
\downarrow p_- \\
\mathcal{M} \\
\end{array}
\]

4.14. Let us consider the following closed subscheme of $\mathcal{M} \times \mathcal{M}' \times \mathcal{M}''$:

\[
\bar{\mathcal{Z}}_2 = \left\{ (\mathcal{F}, \mathcal{F}', \mathcal{F}'') \text{ s.t. } \mathcal{F} \supset x_1, \mathcal{F}' \supset x_2, \mathcal{F}'' \text{ for some } x_1, x_2 \in S \right\}
\]

Moreover, we define the dg scheme $\bar{\mathcal{Z}}_2$ that completes the derived fiber square below:

\[
\begin{array}{c}
\mathcal{Z}_1 \\
\downarrow p_- \\
\mathcal{M} \\
\end{array} \quad \begin{array}{c}
\mathcal{Z}_1 \\
\downarrow p_+ \\
\mathcal{M}' \\
\end{array} \quad \begin{array}{c}
\mathcal{Z}_1 \\
\downarrow p_+ \\
\mathcal{M}'' \\
\end{array}
\]

Since $\mathcal{Z}_1$ is supported on $\bar{\mathcal{Z}}_1$, it is easy to see that $\bar{\mathcal{Z}}_2$ is supported on $\bar{\mathcal{Z}}_2$. The map $p^1_S \times p^2_S$ in (4.15) records the support points $(x_1, x_2)$ of the quotients in (4.14).
Consider the derived restriction of $\mathcal{Z}_2$ to the diagonal $\Delta: S \hookrightarrow S \times S$, i.e. the derived fiber product of $p^1_S \times p^2_S$ and $\Delta$. Definition 4.11 and Proposition 4.13 imply:

\[(4.16) \quad \mathcal{Z}_2|\Delta \hookrightarrow \mathbb{P}_{M' \times S}(V') \times \mathbb{P}_{M' \times S}(W'^\vee \otimes \omega_S) \xrightarrow{\rho} M' \times S\]

where the embedding is defined as the derived zero locus of the section:

\[(4.17) \quad \mathcal{O} \xrightarrow{\sigma \oplus \sigma'} \rho^*(W'^\vee) \otimes \mathcal{O}_1(1) \bigoplus \rho^*(V' \otimes \omega_S^{-1}) \otimes \mathcal{O}_2(1) =: \mathcal{E}\]

The notation $\mathcal{O}_1(1)$, $\mathcal{O}_2(1)$ stands for the tautological line bundles on the projectivizations that appear in (4.10), and $\sigma$, $\sigma'$ are the sections in (4.10), (4.12).

**Proposition 4.15.** The composition of the section $\sigma' \oplus \sigma'$ with the map:

\[\rho^*(W'^\vee) \otimes \mathcal{O}_1(1) \bigoplus \rho^*(V' \otimes \omega_S^{-1}) \otimes \mathcal{O}_2(1) \xrightarrow{\text{taut}_2 \oplus \text{taut}_1} \mathcal{O}_1(1) \otimes \mathcal{O}_2(1) \otimes \rho^*(\omega_S^{-1})\]

vanishes. Above, taut$_{1.2}$ refers to the tautological surjective homomorphisms:

\[(4.18) \quad \rho^*(V') \xrightarrow{\text{taut}_1} \mathcal{O}_1(1) \quad \text{and} \quad \rho^*(W'^\vee \otimes \omega_S) \xrightarrow{\text{taut}_2} \mathcal{O}_2(1)\]

on $\mathbb{P}_{M' \times S}(V')$ and $\mathbb{P}_{M' \times S}(W'^\vee \otimes \omega_S)$, respectively (we abuse notation by also writing taut$_{1.2}$ for the homomorphisms (4.18) tensored by arbitrary line bundles).

**Proof.** Explicitly, the Proposition states that the following compositions coincide:

\[\mathcal{O}_1(-1) \xrightarrow{\text{taut}_1^\vee} \rho^*(V'^\vee) \xrightarrow{j^\vee} \rho^*(W'^\vee) \xrightarrow{\text{taut}_2} \mathcal{O}_2(1) \otimes \rho^*(\omega_S^{-1})\]

\[\mathcal{O}_2(-1) \xrightarrow{\text{taut}_2^\vee} \rho^*(W'^\vee \otimes \omega_S^{-1}) \xrightarrow{j^\vee} \rho^*(V' \otimes \omega_S^{-1}) \xrightarrow{\text{taut}_1} \mathcal{O}_1(1) \otimes \rho^*(\omega_S^{-1})\]

up to tensoring with a suitable line bundle. The map $j$ is induced by the map of vector bundles $W' \to V'$ that features in (4.3), and $j^\vee$ denotes its dual. Then the equality of the two compositions above is a consequence of the standard linear algebra fact that:

\[\lambda \cdot A \cdot v = u^T \cdot A^T \cdot \lambda^T\]

where $\mathbb{C} \xrightarrow{v} \mathbb{C}^m$ is a vector, $\mathbb{C}^m \xrightarrow{A} \mathbb{C}^n$ is a matrix, and $\mathbb{C}^n \xrightarrow{\lambda} \mathbb{C}$ is a covector. \qed

**Definition 4.16.** Define the derived scheme:

\[(4.19) \quad \mathcal{Z}^*_2 \hookrightarrow \mathbb{P}_{M' \times S}(V') \times \mathbb{P}_{M' \times S}(W'^\vee \otimes \omega_S) \xrightarrow{\rho} M' \times S\]

where the embedding is the derived zero locus of the section:

\[(4.20) \quad \mathcal{O} \xrightarrow{\sigma \oplus \sigma'} \mathcal{E}\]
given by the formula (4.17), but mapping into the vector bundle $E$ given by:

$$0 \rightarrow E \xrightarrow{i} E_{\text{taut}_2 \oplus \text{taut}_1} O_1(1) \otimes O_2(1) \otimes \rho^*(\omega_{\Sigma}^{-1}) \rightarrow 0$$

(the maps $\text{taut}_{1,2}$ are defined in Proposition 4.15).

4.17. The closed subscheme $\bar{Z}^\bullet \hookrightarrow \bar{Z}_2$ consisting of flags (4.14) with $x_1 = x_2$ is the support of $\bar{Z}^\bullet_2$. Moreover, we have a natural map of dg schemes:

$$\bar{Z}^\bullet_2 \rightarrow \bar{Z}_2 \big\vert \Delta$$

arising from the fact that the former (respectively latter) dg scheme is the derived zero locus of the section (4.20) (respectively (4.17)). Moreover, the map of dg schemes (4.22) is compatible with the equality of their supports $\bar{Z}^\bullet_2 = \bar{Z}_2 \big\vert \Delta$. The line bundles $O_1(1), O_2(1)$ on the two projective bundles $P(M') \times P(W' \vee \otimes \omega_S)$ in (4.19) restrict to the line bundles $L_1, L_2$ on either of the dg schemes $\bar{Z}_2 \big\vert \Delta$ and $\bar{Z}^\bullet_2$. In terms of the support schemes $\bar{Z}_2 \big\vert \Delta = \bar{Z}^\bullet_2$, these line bundles are given by:

$$L_1\big|_{(F \supset x F' \supset x F''')} = F'_x / F_x$$
$$L_2\big|_{(F \supset x F' \supset x F''')} = F''_x / F_x$$

Finally, note that we have forgetful maps:

$$\bar{Z}^\bullet_2 \xrightarrow{\pi_-} \bar{Z}_1$$
$$\bar{Z}^\bullet_2 \xrightarrow{\pi_+} \bar{Z}_1$$

which underlie the following forgetful maps between their supports:

$$\bar{Z}^\bullet_2 \xrightarrow{\pi_-} \bar{Z}_1, \quad (F \supset x F' \supset x F'') \mapsto (F \supset x F')$$
$$\bar{Z}^\bullet_2 \xrightarrow{\pi_+} \bar{Z}_1, \quad (F \supset x F' \supset x F'') \mapsto (F' \supset x F'')$$

At the level of dg structures, the map (4.23) arises from the commutativity of the following diagram of projective bundles on $M' \times S$, coupled with (4.11) and (4.19):

In other words, the homomorphism between the dg structure sheaves of $\bar{Z}_1$ and $\bar{Z}^\bullet_2$ is induced by the duals of the maps labeled “projection” in the formula above. The same kind of diagram defines the map (4.24). At the level of $K$–theory, the map $\pi_- : \bar{Z}^\bullet_2 \rightarrow \bar{Z}_1$ is the projectivization of the virtual vector bundle:

$$[\mathcal{V}'] - [\mathcal{W}'] + [\mathcal{L} \otimes \omega_S]$$

where the locally free sheaves $\mathcal{W}', \mathcal{V}'$ on $\bar{Z}_1$ correspond to the sheaf denoted $\mathcal{F}'$ in:

$$\bar{Z}_1 = \text{supp} \bar{Z}_1 = \{F \supset \mathcal{F}'\}$$
Similarly, the map \( \pi_+ : \mathfrak{B}_2^* \to 3_1 \) is the projectivization of the virtual vector bundle:
\begin{equation}
(4.26) \quad \left[ W'^\vee \otimes \omega_S \right] - \left[ V'^\vee \otimes \omega_S \right] + \left[ \mathcal{L}^{-1} \otimes \omega_S \right] \quad \text{where} \quad \supp 3_1 = \{ F' \supset F'' \}
\end{equation}

where the locally free sheaves \( W', V' \) on \( 3_1 \) correspond to the sheaf denoted \( F' \) in:
\[ 3_1 = \supp 3_1 = \{ F' \supset F'' \} \]

**4.18.** For the remainder of the Section, we will operate under the following Assumptions, which also featured in the Heisenberg algebra construction of \([2]\):

\begin{equation}
(4.27) \quad \textbf{Assumption S} : \quad \begin{cases} \omega_S \cong \mathcal{O}_S & \text{or} \\ c_1(\omega_S) : H < 0 \end{cases}
\end{equation}

Since any endomorphism of a \( H \)-stable sheaf \( F \) is either 0 or an isomorphism, we conclude that \( \text{Hom}(F, F) = \mathbb{C} \). Meanwhile, Serre duality implies that:
\[ \text{Ext}^2(F, F) \cong \text{Hom}(F, F \otimes \omega_S)^\vee \]

The Hom space in the right-hand side is canonically isomorphic to either \( \mathbb{C} \) or 0, depending on which of the two options of \((4.27)\) holds. Since the tangent space to \( \mathcal{M} \) at the point \( F \) is isomorphic to \( \text{Ext}^1_{\mathcal{M}}(F, F) \), the descriptions of \( \text{Hom}(F, F) \) and \( \text{Ext}^2(F, F) \) above imply that \( \mathcal{M} \) is smooth (see \([15]\) for details).

**Proposition 4.19.** Under Assumption \( S \), the section \((4.10)\) is regular, hence the \( dg \) scheme \( 3_1 \) coincides with its support \( 3_1 \) (and the latter scheme is smooth).

Proposition 4.19 was proved in \([23]\). The method of attack was to estimate the dimensions of the tangent spaces to \( 3_1 \). Since \( 3_1 \) parametrizes nested sheaves, it is well-known that its tangent spaces are given by the formula:
\begin{equation}
(4.28) \quad \text{Tan}_{(F \supseteq F')}3_1 = \text{Ker} \left( \text{Ext}^1(F, F) \oplus \text{Ext}^1(F', F') \xrightarrow{(h, -v)} \text{Ext}^1(F', F) \right)
\end{equation}

where the maps \( h \) and \( v \) are given as in the following diagram, all of whose rows and columns are exact (we write \( C_x \) for the length 1 quotient \( F/F' \)):

\[
\begin{array}{ccccccc}
\text{Tan}_x S & \longrightarrow & \text{Ext}^1(F, C_x) & \longrightarrow & \text{Ext}^1(F', C_x) & \longrightarrow & \mathbb{C} \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
\text{Ext}^1(C_x, F) & \Longleftarrow & \text{Ext}^1(F, F) & \xrightarrow{h} & \text{Ext}^1(F', F) & \longrightarrow & \text{Ext}^2(C_x, F) \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
\text{Ext}^1(C_x, F') & \longrightarrow & \text{Ext}^1(F, F') & \xrightarrow{h'} & \text{Ext}^1(F', F') & \longrightarrow & \text{Ext}^2(C_x, F') \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
\mathbb{C} & \longrightarrow & \text{Hom}(F, C_x) & \longrightarrow & \text{Hom}(F', C_x) & \longrightarrow & \text{Tan}_x S \\
\end{array}
\]

The vector spaces in the corners of the diagram are:
\[
\text{Tan}_x S \cong \text{Ext}^1(C_x, C_x), \quad \text{and} \quad \mathbb{C} \cong \text{Hom}(C_x, C_x) \cong \text{Ext}^2(C_x, C_x)
\]
Moreover, it was shown in [23] that the differential of the map \( \bar{Z}_1 \to S \) is surjective:

\[
p_{S*} : \text{Tan}_S \to \text{Tan}_S
\]

and that the kernel of this map consists of pairs of Exts that come from \( \text{Ext}^1(F, F') \):

\[
(v', h') : \text{Ext}^1(F, F') \to \text{Ker} p_{S*} \subset \text{right-hand side of (4.28)}
\]

We will use (4.29) and (4.30) to prove the following analogue of Proposition 4.19.

**Proposition 4.20.** Under Assumption S, the section (4.20) is regular, hence the dg scheme \( \bar{Z}^\bullet_2 \) coincides with its support \( \bar{Z}^\bullet_2 \) (and the latter scheme is smooth).

**Proof.** By analogy with (4.16), the definition of \( \bar{Z}_2 \) as the derived fiber product \( \bar{Z}_1 \times_{M'} \bar{Z}_1 \) implies that we have the following commutative triangle of maps:

\[
\begin{array}{ccc}
\bar{Z}_2 & \hookrightarrow & \mathbb{P}_{M' \times S \times S} \left( W_1' \otimes \omega_S \right) \times \mathbb{P}_{M' \times S \times S} \left( V_2' \right) \\
& & \downarrow \rho \\
& & M' \times S \times S
\end{array}
\]

where \( W_1' \) (respectively \( V_2' \)) refers to the pull-back of the vector bundle \( W' \) (respectively \( V' \)) from \( M \times S \) to \( M \times S \times S \) via the first (respectively second) projection of \( S \times S \) onto \( S \). The embedding in (4.31) is the derived zero locus of the section:

\[
\mathcal{O} \xrightarrow{\sigma_1 \oplus \sigma_2} \rho^* (V_1' \otimes \omega_S^{-1}) \otimes O_2(1) \bigoplus \rho^* (W_2' \otimes \omega_S) \otimes O_1(1)
\]

and it is easy to see that the scheme-theoretic zero locus of the section (4.32) is \( \bar{Z}_2 \) of (4.14). Because of the Grothendieck-Hirzebruch-Riemann-Roch theorem, the dimension of the smooth variety \( M' \) at any point \( F' \) of second Chern class \( c_2 \) is:

\[
\text{dim Ext}^1(F', F') = 1 + \varepsilon - \text{dim } \chi(F', F') = 1 + \varepsilon + \text{const} + 2rc_2
\]

where the integer labeled “const” depends only on \( S, H, r, c_1, \) and the number \( \varepsilon \) is equal to the dimension of \( \text{Ext}^2(F', F') \), which is 1 or 0 depending on which of the two cases in Assumption S holds. The dimension of the derived scheme \( \bar{Z}_2 \) is the dimension of the projective bundle \( \mathbb{P} \times \mathbb{P} \) in (4.31) minus the rank of the vector bundle in the right-hand side of (4.32). Since rank \( V_2' - \text{rank } W_1' = r \), we have:

\[
\text{dim } \bar{Z}_2 = 1 + \varepsilon - \text{dim } \chi(F', F') = 1 + \varepsilon + \text{const} + 2rc_2 + 2
\]

(4.34)

(the two extra dimensions in the right-hand side come from \( 4 - 2 \): there are 4 extra dimensions in (4.31) due to the copies of the surface \( S \), but we must subtract two dimensions from each of the projectivizations). As for the scheme-theoretic zero locus, we conclude that the dimensions of all of its local rings satisfies:

\[
\text{dim } \bar{Z}_2 \geq \text{RHS of (4.34)} = 1 + \varepsilon + \text{const} + 2rc_2 + 2
\]

(4.35)
By a well-known deformation-theory argument, the tangent space to a point of $\mathfrak{F}_2$ parametrizing a flag $(\mathcal{F} \supseteq x_1, \mathcal{F}' \supseteq x_2, \mathcal{F}'')$ equals the space of triples of extensions:

$$
\begin{array}{ccccccc}
0 & \rightarrow & \mathcal{F} & \rightarrow & S & \rightarrow & \mathcal{F} & \rightarrow & 0 \\
& & \searrow & & \searrow & & \searrow & & \searrow \\
0 & \rightarrow & \mathcal{F}' & \rightarrow & S' & \rightarrow & \mathcal{F}' & \rightarrow & 0 \\
& & \searrow & & \searrow & & \searrow & & \searrow \\
0 & \rightarrow & \mathcal{F}'' & \rightarrow & S'' & \rightarrow & \mathcal{F}'' & \rightarrow & 0 \\
\end{array}
$$

(4.36)

By a simple diagram chase, one can see that this space is:

$$
\mathrm{Tan}_{(\mathcal{F} \supseteq x_1, \mathcal{F}' \supseteq x_2, \mathcal{F}'')} \mathfrak{F}_2 = \mathrm{Ker}\left[ \mathrm{Ext}^1(\mathcal{F}, \mathcal{F}) \oplus \mathrm{Ext}^1(\mathcal{F}', \mathcal{F}') \oplus \mathrm{Ext}^1(\mathcal{F}'', \mathcal{F}'') \xrightarrow{\lambda} \mathrm{Ext}^1(\mathcal{F}', \mathcal{F}) \oplus \mathrm{Ext}^1(\mathcal{F}'', \mathcal{F}') \right]
$$

(4.37)

where the map $\lambda$ is the alternating sum of the 4 natural maps induced by the inclusions $\mathcal{F} \supseteq \mathcal{F}' \supseteq \mathcal{F}''$ on the Ext spaces in question. By analogy with (4.33), we have the following formulas for the dimensions of the following Ext spaces:

- $\dim \mathrm{Ext}^1(\mathcal{F}, \mathcal{F}) = 1 + \varepsilon + \text{const} + 2rc_2 - 2r$
- $\dim \mathrm{Ext}^1(\mathcal{F}'', \mathcal{F}'') = 1 + \varepsilon + \text{const} + 2rc_2 + 2r$
- $\dim \mathrm{Ext}^1(\mathcal{F}', \mathcal{F}') = 1 + 0 + \text{const} + 2rc_2 - r$
- $\dim \mathrm{Ext}^1(\mathcal{F}'', \mathcal{F}') = 1 + 0 + \text{const} + 2rc_2 + r$
- $\dim \mathrm{Ext}^1(\mathcal{F}', \mathcal{F}') = 0 + \varepsilon + \text{const} + 2rc_2 - r$
- $\dim \mathrm{Ext}^1(\mathcal{F}', \mathcal{F}') = 0 + \varepsilon + \text{const} + 2rc_2 + r$

(the first two summands in each RHS represents the dimension of the corresponding Hom and Ext spaces, subject to Assumption S). Therefore, the tangent space (4.37) has expected dimension (4.34) if and only if $\lambda$ has cokernel of dimension $2 - 2\varepsilon$.

**Claim 4.21.** The map $\lambda$ of (4.37) has cokernel of dimension:

$$
\begin{align*}
3 - 2\varepsilon & \quad \text{if } x_1 = x_2 \text{ and } \mathcal{F}/\mathcal{F}' \cong \mathbb{C}_{x_1} \oplus \mathbb{C}_{x_2} \\
2 - 2\varepsilon & \quad \text{otherwise}
\end{align*}
$$

(4.38)

In the latter case, $\mathfrak{F}_2$ is smooth of expected dimension at the point $(\mathcal{F} \supseteq \mathcal{F}' \supseteq \mathcal{F}'')$, while in the former case its tangent space has dimension 1 greater than expected.

**Proof.** From the long exact sequences corresponding to the Ext functor, we obtain:

$$
\lambda \left( \mathrm{Ext}^1(\mathcal{F}, \mathcal{F}), 0, 0 \right) = \left( \mathrm{Ker} \ \mathrm{Ext}^1(\mathcal{F}', \mathcal{F}) \xrightarrow{p_1} \mathrm{Ext}^2(\mathbb{C}_{x_1}, \mathcal{F}), 0 \right)
$$

$$
\lambda \left( 0, 0, \mathrm{Ext}^1(\mathcal{F}'', \mathcal{F}'') \right) = \left( 0, \mathrm{Ker} \ \mathrm{Ext}^1(\mathcal{F}'', \mathcal{F}') \xrightarrow{p_2} \mathrm{Ext}^1(\mathcal{F}'', \mathbb{C}_{x_2}) \right)
$$

where $\mathbb{C}_{x_1}$ and $\mathbb{C}_{x_2}$ denote $\mathcal{F}/\mathcal{F}'$ and $\mathcal{F}'/\mathcal{F}''$, respectively. Therefore, the cokernel of the map $\lambda$ is isomorphic to the cokernel of the map:

$$
\mathrm{Ext}^1(\mathcal{F}', \mathcal{F}) \xrightarrow{(p_1, p_2)} \mathrm{Im} \ p_1 \oplus \mathrm{Im} \ p_2
$$

(4.39)
where the maps $\mu_1$ and $\mu_2$ are as in the diagrams below:

\[
\begin{align*}
\Hom(F', C_{x_1}) \rightarrow & \ Ext^1(F', F') \rightarrow Ext^1(F', F) \rightarrow Ext^1(F', C_{x_1}) \\
& \rightarrow Ext^2(C_{x_1}, F') \rightarrow Ext^2(C_{x_1}, F) \rightarrow Ext^2(C_{x_1}, C_{x_1}) \\
\Ext^1(C_{x_1}, C_{x_1}) \rightarrow & \ Ext^2(C_{x_1}, F') \rightarrow Ext^2(C_{x_1}, F) \rightarrow Ext^2(C_{x_1}, C_{x_1}) \\
& \rightarrow t_1, C^\varepsilon \\
\Ext^1(C_{x_2}, F') \rightarrow & \ Ext^1(F', F') \rightarrow Ext^1(F'', F') \rightarrow Ext^2(C_{x_2}, F') \\
& \rightarrow Ext^1(C_{x_2}, C_{x_2}) \rightarrow Ext^1(F', C_{x_2}) \rightarrow Ext^1(F'', C_{x_2}) \rightarrow Ext^2(C_{x_2}, C_{x_2}) \\
& \rightarrow t_2, C^\varepsilon
\end{align*}
\]

In each of the above diagrams, the space in the bottom right is $\cong C$.

- If $\varepsilon = 1$, it is easy to see that $\Ker s_i = \Ker t_i$ for both $i \in \{1, 2\}$. Therefore, we may rewrite (4.39) by saying that $\Coker \lambda$ is isomorphic to the cokernel of:

\[(4.40) \quad \Ext^1(F', F') \overset{(\mu_1, \mu_2)}{\rightarrow} \Im q_1 \oplus \Im q_2\]

We want to show that the cokernel of (4.40) has dimension 1 (respectively 0) in the first (respectively second) case of (4.38). Since $\mu_i = q_i \circ r_i$, we will solve this problem by noting that the following square commutes:

\[(4.41) \quad \Ext^1(F', F') \overset{r_1}{\rightarrow} \Ext^2(C_{x_1}, F') \overset{r_2}{\rightarrow} \Ext^1(F', C_{x_2}) \overset{y_2}{\rightarrow} \Ext^2(C_{x_1}, C_{x_2})\]

where the horizontal maps are induced by the sequence $0 \rightarrow F' \rightarrow F \rightarrow C_{x_1} \rightarrow 0$, and the vertical maps are induced by the sequence $0 \rightarrow F'' \rightarrow F' \rightarrow C_{x_2} \rightarrow 0$. By applying Serre duality to the square (4.41), it is easy to show that:

\[(4.42) \quad \Im (r_1, r_2) = \Ker (y_2, -y_1)\]

Therefore, the row and column of the following diagram are exact:

\[
\begin{align*}
\Ext^1(C_{x_1}, C_{x_1}) \oplus & \ Ext^1(C_{x_2}, C_{x_2}) \\
\Ext^1(F', F') \overset{(r_1, r_2)}{\rightarrow} & \ Ext^2(C_{x_1}, F') \oplus Ext^1(F', C_{x_2}) \overset{(y_2, -y_1)}{\rightarrow} Ext^2(C_{x_1}, C_{x_2}) \\
& \overset{(\mu_1, \mu_2)}{\rightarrow} \Im q_1 \oplus \Im q_2
\end{align*}
\]
If \( x_1 \neq x_2 \), then \( \text{Ext}^2(C_{x_1}, C_{x_2}) = 0 \), and the surjectivity of \( (r_1, r_2) \) implies
the surjectivity of \( (\mu_1, \mu_2) \), as required. If \( x_1 = x_2 \), then \( \text{Ext}^2(C_{x_1}, C_{x_2}) \cong \mathbb{C} \),
and the cokernel of \( (\mu_1, \mu_2) \) is isomorphic to the cokernel of \( \rho \). The latter is
1 or 0 dimensional depending on whether \( F/F'' \) is isomorphic to \( C_{x_1} \oplus C_{x_2} \) or not.

- If \( \varepsilon = 0 \), then \( \text{Im} \ q_1 \) has codimension 1 inside \( \text{Im} \ p_1 \), and so we may rewrite \( \text{Ext}^1(F', F'') \)
by saying that \( \text{Coker} \lambda \) is isomorphic to the cokernel of:

\[
\text{Ext}^1(F', F') \xrightarrow{(\mu_1, \mu_2)} \text{Im} \ q_1 \oplus \text{Im} \ q_2 \oplus \mathbb{C}^2
\]

where the right-hand side of \( \text{(4.43)} \) should more appropriately be called “a vector
space containing \( \text{Im} \ q_1 \oplus \text{Im} \ q_2 \) as a codimension 2 subspace”. One can repeat
the argument following equation \( \text{(4.40)} \) in the previous bullet to give us the desired
values \( \text{(4.35)} \) for the dimension of the cokernel of the map \( \text{(4.43)} \).

We must have \( x_1 = x_2 \) in order for \( (F \supset_{x_1} F' \supset_{x_2} F'') \) to lie in \( \mathfrak{S}_2 \), but we will use different
notations in order to not confuse the length 1 quotients \( F/F' \cong C_{x_1} \) and \( F'/F'' \cong C_{x_2} \).
However, in order to ensure that $(p_S^1 \times p_S^2)_*(w, w', w'') = (v, 0)$, both $w'$ and $w''$ must come from one and the same element of $\text{Ext}^1(F', F'')$. This is equivalent to requiring that in the diagram below with exact row and columns:

\[(4.49)\]

\[
\begin{array}{c}
\text{Ext}^1(F, F') \\ \downarrow \\
\text{Ext}^1(F', F') \\
\downarrow \quad \quad \downarrow \\
\text{Ext}^1(F', F') \\
\downarrow \\
\text{Ext}^1(F', C_{x_2}) \\
\end{array}
\]

we may choose $w' \in \text{Ext}^1(F', F')$ to map to 0 in $\text{Ext}^1(F', C_{x_2})$. But remember that $w'$ may only be changed by adding the image of an arbitrary element in $\text{Ext}^1(F, F')$, and so chasing through (4.49) implies that it is enough to show that $\phi(w') = 0$. To this end, recall that the extensions $w$ and $w'$ have the property that they map to one and the same element in $\text{Ext}^1(F', F)$. Consider the following diagram:

\[(4.50)\]

\[
\begin{array}{c}
\text{Ext}^1(F, F) \\
\downarrow \\
\text{Ext}^1(F', F') \\
\downarrow \\
\text{Ext}^1(F', F) \\
\downarrow \\
\text{Ext}^2(C_{x_1}, F') \\
\end{array}
\]

The map $\phi$ in diagram (4.49) is the composition of the two dotted maps in diagram (4.50), for the following reason: because we assumed that $F/F'' \cong C_{x_1} \oplus C_{x_2}$, we may extend the homomorphism $F' \to C_{x_2}$ to a homomorphism $F \to C_{x_2}$. But then the fact that $\phi(w') = 0$ is clear because $w$ and $w'$ map to the same element in $\text{Ext}^1(F', F)$ and the composition of the two vertical maps in (4.50) is zero.

Let us now treat the case in (4.48). We may ask for which $v \in \text{Tan}_{x_2} S = \text{Tan}_{x_2} S$ we may choose a tangent vector $(w, w', w'')$ to $\tilde{S}_2$ which maps to either $(v, 0)$ or $(0, v)$ under the map (4.49). Chasing through the proof on the previous page shows that such a tangent vector $(w, w', w'')$ can be chosen if and only if $\phi(w') = 0$, where $\phi$ is the diagonal arrow in (4.49). Since the image of $\phi$ is one-dimensional, this places a single linear condition on the vector $w'$, and therefore there exists a one-dimensional family of $v$'s such that $(v, 0)$ and $(0, v)$ lie in the image of $p_{S^*}^1 \times p_{S^*}^2$.

To prove (4.48), we must show that the image of $p_{S^*}^1 \times p_{S^*}^2$ is three-dimensional, and so we must show that there exists at least one more vector in the image. In fact, we will show that vectors of the form $(v, v)$ are always in the image of $p_{S^*}^1 \times p_{S^*}^2$. 
for any \( v \in \text{Tan}_{x_{1}}S \neq \text{Tan}_{x_{2}}S \). By (4.29), we may choose vectors:

\[
\begin{align*}
(4.51) & \quad \begin{pmatrix} w \\ w' \end{pmatrix} \in \text{Ker} \left( \begin{array}{c} \text{Ext}^{1}(F, F) \\ \oplus \rightarrow \text{Ext}^{1}(F', F) \end{array} \right) = \text{Tan}(F_{\triangleright}F_{\triangleright}F_{\triangleright}) S_{1} \\
(4.52) & \quad \begin{pmatrix} w'' \\ w'' \end{pmatrix} \in \text{Ker} \left( \begin{array}{c} \text{Ext}^{1}(F', F') \\ \oplus \rightarrow \text{Ext}^{1}(F''', F''') \end{array} \right) = \text{Tan}(F_{\triangleright}F_{\triangleright}F_{\triangleright}) S_{1}
\end{align*}
\]

which map to the same vector \( v \in \text{Tan}_{x_{1}}S = \text{Tan}_{x_{2}}S \) under the map \( p_{S_{1}} \). According to (4.30), we may modify the vectors \( w', w'' \) by arbitrary elements coming from \( \text{Ext}^{1}(F, F') \) and \( \text{Ext}^{1}(F', F'') \), respectively, without modifying the images of \( p_{S_{1}} \).

We claim that we can perform these modifications so as to ensure \( w' = \bar{w}' \), and in this case we are done, because the tangent vector \( (w, w', w'') \) will map to \( (v, v) \) under \( p_{S_{1}}^{1} \times p_{S_{2}}^{1} \). The elements \( w' = \bar{w}' \) lie in the space \( \text{Ext}^{1}(F', F') \) in the middle of the diagram (4.49). Chasing through the aforementioned diagram, we see that we can make \( w' = \bar{w}' \) upon modification by elements coming from \( \text{Ext}^{1}(F, F') \) and \( \text{Ext}^{1}(F', F'') \), respectively, if and only if:

\[
(4.53) \quad \phi(w') = \phi(\bar{w}')
\]

The fact that equality (4.53) holds is a direct consequence of the following claim:

**Claim 4.22.** The element \( \phi(w') \) coincides with the image of \( v \) under the map:

\[
(4.54) \quad \text{Ext}^{1}(C_{x_{1}}, C_{x_{2}}) \to \text{Ext}^{2}(C_{x_{1}}, C_{x_{2}})
\]

induced by the short exact sequence:

\[
0 \to F' / F'' \cong C_{x_{2}} \to F / F'' \to F / F' \cong C_{x_{1}} \to 0
\]

The analogous statement holds for \( \phi(\bar{w}') \), which implies equality (4.53).

We will prove the claim about \( \phi(w') \), and leave the analogous result for \( \phi(\bar{w}') \) as an exercise for the interested reader. Assume the pair \( (w, w') \) of (4.51) corresponds to a commutative diagram:

\[
\begin{CD}
0 @>>> F @>{\iota}>> S @>{\pi}>> F @>>> 0 \\
0 @>>> F' @>{\iota}>> S' @>{\pi'}>> F' @>>> 0
\end{CD}
\]

By a straightforward diagram chase, \( \phi(w') \) is given by the extension:

\[
(4.56) \quad 0 \to F' / F'' \cong C_{x_{2}} \xrightarrow{(1,0)} F' / F'' \oplus_{F'} S' \xrightarrow{(0, \pi')} F \oplus_{F'} F' \cong C_{x_{1}} \to 0
\]
and the notation $\oplus_{F'}$ denotes the push-out with respect to the standard projection map $F' \to F'/F''$ and the map $' : F' \to S'$. Because of the commutative diagram:

\[
\begin{array}{c}
\begin{array}{c}
0 \\
\end{array}
F' \to F'/F'' \xrightarrow{(0, \pi')} F \to F/F' \to 0
\end{array}
\end{array}
\]

(4.57)

\[
\begin{array}{c}
\begin{array}{c}
0 \\
\end{array}
F' \xrightarrow{(\ell', \text{projection})} S'/S'' \xrightarrow{\pi'} F/F' \to 0
\end{array}
\end{array}
\]

we infer that (4.56) is equal to the extension on the bottom row. However, the assumption that (4.51) and (4.52) map to the same tangent vector we infer that (4.56) is equal to the extension on the bottom row. However, the assumption that (4.51) and (4.52) map to the same tangent vector $v \in \text{Tan}_x S = \text{Tan}_{x_2} S$ implies that $S'/S'' \cong S'/S'$, hence the bottom row of (4.57) is equal to:

\[
\begin{array}{c}
\begin{array}{c}
0 \\
\end{array}
F'/F'' \to F/\to F'' \xrightarrow{\pi} F/F' \to 0
\end{array}
\]

(4.58)
in the 1-dimensional extension group $\text{Ext}^1(C_{x_2}, C_{x_2})$. Since (4.58) is nothing but the map (4.54) applied to the short exact sequence:

\[
0 \to F/\to F' \to C_{x_1} \to S/S' \to F/F' \to \mathbb{C}_{x_1} \to 0
\]

and this sequence represents the vector $v \in \text{Tan}_x S$, we are done.

\[\square\]

Corollary 4.23. The scheme $\bar{\mathcal{S}}_2$ is l.c.i. of dimension $\text{(4.34)}$.

Proof. By Claim 4.21, we may stratify $\bar{\mathcal{S}}_2$ into two locally closed subsets: the locus $A$ of points where the tangent space has expected dimension $\text{(4.34)}$, and the locus $B$ of points where the tangent space has dimension 1 bigger than expected. It is clear that $\dim A$ is no greater than the right-hand side of (4.34), so it remains to show that the same is true of $B$. However, recall that Claim 4.21 implies:

\[
\begin{array}{c}
\begin{array}{c}
B \subset \bar{\mathcal{S}}_2 & \Rightarrow & \dim B \leq \dim \bar{\mathcal{S}} = \text{RHS of (4.44)} < \text{RHS of (4.34)}
\end{array}
\end{array}
\]

\[\square\]

5. The Double Shuffle Algebra Action

5.1. The correspondences $\mathcal{S}_1$ of (4.9) induce operators on the $K$-theory groups:

\[
K_{\mathcal{M}} = \bigoplus_{c_2 \in [\overline{2}, \overline{1}]} K_0(\mathcal{M}(r,c_1,c_2))
\]

explicitly by:

\[
K_{\mathcal{M}} \xrightarrow{e_d} K_{\mathcal{M}' \times S}, \quad e_d = (p_+ \times p_S)^* (L^d \cdot p_-^*)
\]

(5.1)

\[
K_{\mathcal{M}'} \xrightarrow{f_d} K_{\mathcal{M} \times S}, \quad f_d = \frac{(-1)^r}{\det U} \cdot (p_- \times p_S)^* (L^{d-r} \cdot p_+^*)
\]

(5.2)

\[\text{A non-split length 2 sheaf } A \text{ supported at a point } x \text{ of a smooth surface is an extension } 0 \to \mathbb{C}_x \to A \to \mathbb{C}_x \to 0, \text{ which is completely determined by how the two generators of } \mathfrak{m}_x / \mathfrak{m}_x^2 \text{ act on } A. \text{ If } A \text{ and } B \text{ are two such extensions, then we obtain two rank 1 maps } A \to B \text{ and } B \to A \text{ by projecting through the quotients } \mathbb{C}_x. \text{ It is easy to show that } 0 \to \mathbb{C}_x \to A \to B \to \mathbb{C}_x \to 0 \text{ and } 0 \to \mathbb{C}_x \to B \to A \to \mathbb{C}_x \to 0 \text{ are equal in the 1-dimensional extension group } \text{Ext}^2(\mathbb{C}_x, \mathbb{C}_x).\]
with the notations in \[4.13\]. Let us focus on the operators \( \{e_d\}_{d \in \mathbb{Z}} \). Compositions of \( k \) such operators can be described via the correspondence (fiber product is derived):

\[
\mathfrak{z}_k := \mathfrak{z}_1 \times \mathfrak{z}_1 \times \cdots \times \mathfrak{z}_1 \rightarrow \mathcal{M}_0 \times \cdots \times \mathcal{M}_k
\]

which is a dg scheme supported on:

\[
\mathfrak{z}_k = \left\{ \mathcal{F}_0, \ldots, \mathcal{F}_k \text{ sheaves}, \text{points } x_1, \ldots, x_k \in S \text{ s.t. } \mathcal{F}_0 \subset x_1 \cdots \subset x_k \mathcal{F}_k \right\}
\]

(the notation above is that \( \mathcal{M}_i \) denotes the moduli space that parametrizes the stable sheaf denoted by \( \mathcal{F} \)). Both \( \mathfrak{z}_k \) and \( \mathfrak{z}_k \) are endowed with line bundles \( \{L_i\}_{i \leq k} \), which parametrize the length 1 quotients \( \mathcal{F}_1/\mathcal{F}_{i-1} \). We have projection maps:

\[
\xymatrix{
\mathcal{M}_0 \ar[rr]^p_+ \ar[d]_{\bar{p}_+} & & \mathcal{M}_k \ar[d]_{\bar{p}_-} \\
S^k & & S^k
}
\]

where \( \bar{p}_+, \bar{p}_- \) send a flag of sheaves \( \mathfrak{z}_k \) to \( S^k \) and \( \bar{p}_- \) under the support map. Then we have:

\[
ed_1 \circ \cdots \circ e_d = (p_+ \times p_{S^k})_* \left( L_1^{d_1} \cdots L_k^{d_k} \cdot p_* \right) : K_{\mathcal{M}} \rightarrow K_{\mathcal{M} \times S^k}
\]

Certain quadratic relations (the case \( k = 2 \)) between these compositions were worked out in \[23\], but the full set of relations was conjectured in \textit{loc. cit.} to match those in the so-called universal shuffle algebra. However, we do not know how to describe the full ideal of relations explicitly. The situation is simplified if we compose \( \mathfrak{z}_k \) with restriction to the smallest diagonal \( \Delta : S \rightarrow S^k \):

\[
ed_1 \circ \cdots \circ e_d \big|_{\Delta} : K_{\mathcal{M}} \rightarrow K_{\mathcal{M} \times S}
\]

The idea that \( \mathfrak{z}_k \) is the “composition” of the operators \( \mathfrak{z}_1, \ldots, \mathfrak{z}_k : K_{\mathcal{M}} \rightarrow K_{\mathcal{M} \times S} \) leads to the following notion. Consider the ring homomorphism:

\[
K = \mathbb{Z}[q_1^{\pm 1}, q_2^{\pm 1}]^{\text{symmetric in } q_1, q_2} \xrightarrow{\phi} K_{S}
\]

given by sending \( q_1 \) and \( q_2 \) to the Chern roots of \( \Omega^1_S \). Let \( S \xrightarrow{\Delta} S \times S \) be the diagonal.

**Definition 5.2.** An “action” of the double shuffle algebra \( A \) from \( 3.1 \) on the abelian group \( K_{\mathcal{M}} \) is an abelian group homomorphism:

\[
A \big|_{c \rightarrow q} \xrightarrow{\phi} \text{Hom}(K_{\mathcal{M}}, K_{\mathcal{M} \times S})
\]

satisfying the following properties, for any \( x, y \in \text{Hom}(K_{\mathcal{M}}, K_{\mathcal{M} \times S}) \) and \( \gamma \in K \):

1. \( \Phi(1) = \text{proj}^1 \), where \( \text{proj}^1 : \mathcal{M} \times S \rightarrow \mathcal{M} \) is the natural projection map
2. \( \Phi(\gamma x) \) coincides with the composition:

\[
K_{\mathcal{M}} \xrightarrow{\Phi(x)} K_{\mathcal{M} \times S} \xrightarrow{\text{mult by } \phi(\gamma)} K_{\mathcal{M} \times S}
\]
3. \( \Phi(xy) \) coincides with the composition:

\[
K_{\mathcal{M}} \xrightarrow{\Phi(y)} K_{\mathcal{M} \times S} \xrightarrow{\Phi(x) \times \text{Id}_S} K_{\mathcal{M} \times S} \times S \xrightarrow{\text{Id}_S \times \Delta^*} K_{\mathcal{M} \times S}
\]
Conjecture 1.1 states that there exists a homomorphism (5.8) satisfying properties (1)–(4) above, and we will now show how to construct $\Phi(E_{n,k})$, $\forall (n, k) \in \mathbb{Z}^2 \setminus (0, 0)$.

Remark 5.3. There are general reasons why one expects the shuffle algebra to act on $K_\mathcal{M}$: as shown by Schiffmann-Vasserot in [29], their $K$–theoretic Hall algebra $\mathcal{H}$ naturally acts on groups akin to $K_\mathcal{M}$. There is a map $\Upsilon : \mathcal{H} \to S_{\text{big}}$ that arises from equivariant localization on the stack of finite length sheaves on $S$, and it is natural to conjecture that the image $\Upsilon(\mathcal{H})$ also acts on the groups $K_\mathcal{M}$ (see [19] for a detailed and rigorous treatment in a setup very close to ours, which results in a similar shuffle algebra). However, it is not clear how to prove that the map $\Upsilon$ is injective, or less ambitiously, that the kernel of this map acts trivially on $K_\mathcal{M}$.

5.4. As suggested in [23], we expect that the “action” $\Phi$ should be given by sending:

\begin{align}
\Phi (z^d_1) &= e_d \\
\Phi (z^d_\pm) &= f_d
\end{align}

\forall d \in \mathbb{Z}, \text{ where we implicitly use the isomorphism } \mathcal{A}^+ \cong S \text{ and } \mathcal{A}^- \cong S^{\text{op}}, \text{ and:}

\begin{align}
\Phi (E_{0,\pm k} \in \mathcal{A}^{\text{diag}}) &= \text{operator of multiplication by } \oint z^{\pm k} \Lambda \left( \frac{U^{\pm 1}}{z^{\pm 1} q^{-\delta_{\pm}}} \right)^{\pm 1} \\
\forall k \in \mathbb{N}. \text{ For example, when the sign is } \pm = + \text{ in the formula above, the contour integral just picks up the coefficient of } z^{-k} \text{ in the expansion of the rational function:}
\end{align}

\[
\Lambda \left( \frac{U}{z} \right) = \Lambda \left( \frac{\mathcal{V}}{\mathcal{W}} \right)
\]

where $\mathcal{V}, \mathcal{W}$ are the vector bundles of (4.3). Let us focus on the operators (5.11). By property (2) of Definition 5.2, the composition (5.6) should correspond to:

\[
\Phi \left( \text{Sym} \left[ z_{d_1} \ldots z_{d_k} \prod_{1 \leq i < j \leq k} \zeta \left( \frac{z_i}{z_j} \right) \right] \in \mathcal{A}^- \right) = e_{d_1} \circ \ldots \circ e_{d_k} |_{\Delta}
\]

However, to completely determine the action (5.8), we must conjecture how the generators $E_{d\pm}$ of (2.6) act. To do this, let us introduce some new correspondences:

**Definition 5.5.** Consider the following dg scheme, obtained by chains of derived fiber products of the dg scheme (4.19) via the maps (4.23) and (4.24):

\[
\mathcal{M}^\ast = \mathcal{M}_0^\ast \times \mathcal{M}_1^\ast \times \ldots \times \mathcal{M}_k^\ast \longrightarrow \mathcal{M}_0 \times \ldots \times \mathcal{M}_k
\]
which will be supported on the scheme:

\[(5.13) \bar{Z}^\bullet_k = \{ F_0, \ldots, F_k \text{ sheaves, } x \in S \text{ such that } F_0 \subset_x \cdots \subset_x F_k \}\]

There are line bundles \(L_1, \ldots, L_k\) on \(\bar{Z}^\bullet_k\) that correspond to the line bundles on \(\bar{Z}^\bullet_k\) that parametrize the quotients \(F_1/F_0, \ldots, F_k/F_{k-1}\), as well as projection maps:

\[(5.14) \]

\[\begin{array}{ccc}
\mathcal{M}_0 & \xleftarrow{p^+} & \mathcal{M}_k \\
\xrightarrow{p^+} & \bar{Z}^\bullet_k & \xrightarrow{\bar{p}^+} \mathcal{M}_k \,, \, S \\
& \xleftarrow{p^-} & \xrightarrow{\bar{p}^-} \end{array}\]

For any vector of integers \(d_\bullet = (d_1, \ldots, d_k)\), define the operators:

\[(5.15) K_M e^\bullet d \to K_{M \times S} \]

\[(5.16) K_M f^\bullet d \to K_{M \times S} \]

given by the following formulas:

\[(5.17) e^\bullet d = (p^+ \times p_S)_* \left( L_1^{d_1} \cdots L_k^{d_k} \cdot p^+_S \right) \]

\[(5.18) f^\bullet d = \frac{(-1)^{rk}}{(\det U)^{\otimes k}} \cdot (p^- \times p_S)_* \left( L_1^{d_1-r} \cdots L_k^{d_k-r} \cdot p^-_S \right) \]

For any \(d = (d_1, \ldots, d_k) \in \mathbb{Z}^k\), recall the elements \(E^\bullet d, F^\bullet d \in A\) from (3.13) and (3.14), respectively. We make Conjecture 1.1 more precise by stipulating that these elements should act on \(K\)-theory groups via the formulas:

\[(5.19) \Phi (E^\bullet d) = e^\bullet d \]

\[(5.20) \Phi (F^\bullet d) = f^\bullet d \]

for all \(d_\bullet = (d_1, \ldots, d_k) \in \mathbb{Z}^k\). Note that \(E^\bullet d\) and \(F^\bullet d\) generate the algebras \(A\to\) and \(A\leftarrow\), because these algebras are isomorphic to \(S\) and \(S^{op}\), respectively.

5.6. Consider the following particular cases of the operators (5.17) and (5.18):

\[(5.21) e_{-k,n} = q^{gcd(k,n)-1} e_{(d_1, \ldots, d_k)} \]

\[(5.22) e_{k,n} = q^{gcd(k,n)-1} f_{(d_1, \ldots, d_k)} \]

for all \(k > 0\) and \(n \in \mathbb{Z}\), where \(d_i = \left\lfloor \frac{ni}{k} \right\rfloor - \left\lfloor \frac{n(i-1)}{k} \right\rfloor + \delta_i^k - \delta_i^1\), together with:

\[(5.23) e_{0, \pm k} = \text{operator of multiplication by } \int z^{\pm k} \wedge \left( \frac{U^{\pm 1}}{z^{\pm 1}q^{-\delta_k^1}} \right)^{\pm 1} \]

By (5.19), (5.20), the operators \(e_{n,k}\) should correspond to the generators \(E_{n,k}\) (2.8) of the shuffle algebra. Recall from Theorem 3.3 that the relations in the algebra \(A\) are generated by the following commutation relation between the generators \(E_{n,k}\):

\[(5.24) [E_{n,k}, E_{n',k'}] = \Delta \sum_{v \text{ convex path}} p_{k,k_1,\ldots,k_t}^{n,n_1,\ldots,n_t,n'} (q_1, q_2) \cdot E_{n_1,k_1} \cdots E_{n_t,k_t} \]
for some Laurent polynomials \( p_{k_1, \ldots, k_t, k, k'}^{n_1, \ldots, n_t, n, n'}(q_1, q_2) \in \mathbb{K} \), where the sum in the right-hand side of (5.24) goes over all \( \sum n_i = n + n' \), \( \sum k_i = k + k' \) such that the path \( v = (n_1, k_1), \ldots, (n_t, k_t) \)

is sandwiched between the paths \( v_1 = (n + n', k + k') \) and \( v_2 = (n', k'), (n, k) \), and has the same convexity as the path \( v_2 \). Conjecture 1.1 implies that the analogous commutation relations hold between the operators (5.21)–(5.26).

**Conjecture 5.7.** For any lattice points \((n, k)\) and \((n', k')\), we have:

\[
(5.25) \quad [e_{n,k}, e_{n',k'}] = \Delta_\ast \left( \sum_{v \text{ convex path}} \phi(p_{k_1, \ldots, k_t, k, k'}^{n_1, \ldots, n_t, n, n'}(q_1, q_2)) \cdot e_{n_1,k_1} \ldots e_{n_t,k_t} \big|_\Delta \right)
\]

where \( \phi : \mathbb{K} \to \mathbb{K}_S \) is the map (5.7).

Let us explain the notation in (5.25). The LHS is an operator \( K_M \to K_{M \times S \times S} \), with \( e_{n,k} \) acting in the first factor of \( S \times S \) and \( e_{n',k'} \) acting in the second factor. Meanwhile, each summand in the RHS is the following composed operator:

\[
K_M \xrightarrow{e_{n_1,k_1}} K_{M \times S} \xrightarrow{e_{n_{t-1},k_{t-1}} \times \text{Id}_S} \ldots \xrightarrow{e_{n_1,k_1} \times \text{Id}_S^{k-1}} K_{M \times S \times \ldots \times S} \xrightarrow{\text{Id}_M \times \Delta'} K_{M \times S} \xrightarrow{\text{Id}_M \times \text{multiplication by } \phi(p_{k_1, \ldots, k_t, k, k'}^{n_1, \ldots, n_t, n, n'}(q_1, q_2))} K_{M \times S}
\]

and \( \Delta_\ast \) in (5.25) denotes the diagonal embedding \( K_{M \times S} \to K_{M \times S \times S} \).

**Proposition 5.8.** Conjectures 1.1 and 5.7 are equivalent.

**Proof.** It is clear that Conjecture 1.1 implies Conjecture 5.7 since formula (3.11), together with properties (2), (3), (4) of Definition 5.2, implies formula (5.25). Conversely, let us assume that (5.26) holds and prove Conjecture 1.1. By (5.3), any element of \( A_{\ell \to q} \) can be written as:

\[
(5.26) \quad x = \sum_{k_1, \ldots, k_t} p_{k_1, \ldots, k_t}^{n_1, \ldots, n_t}(q_1, q_2) \cdot E_{n_1,k_1} \ldots E_{n_t,k_t}
\]

for some \( p_{k_1, \ldots, k_t}^{n_1, \ldots, n_t}(q_1, q_2) \in \mathbb{K} \), where the vectors \((n_1, k_1), \ldots, (n_t, k_t)\) that appear in the right-hand side are ordered clockwise by slope. Properties (2) and (3) of Definition 5.2 completely determine the action of \( x \) on \( K_M \), since they force:

\[
(5.27) \quad \Phi(x) = \sum_{k_1, \ldots, k_t} \phi(p_{k_1, \ldots, k_t}^{n_1, \ldots, n_t}(q_1, q_2)) \cdot e_{n_1,k_1} \ldots e_{n_t,k_t} \big|_\Delta
\]

Property (1) of Definition 5.2 holds trivially. Since \( \phi \) is a ring homomorphism, \( \Phi \) defined by (5.27) satisfies property (2) of Definition 5.2. As for property (3), note

---

3The notation below means that \( v \) is the broken line between \((0,0)\) and \((n_1 + \ldots + n_t, k_1 + \ldots + k_t)\), formed out of the line segments \((n_1, k_1), \ldots, (n_t, k_t)\) in this order.
that restricting \((5.29)\) to the diagonal implies:

\[
e_{n,k}e_{n',k'}|_\Delta - e_{n',k'}e_{n,k}|_\Delta = \sum_{v \text{ convex path}} \phi((1 - q_1)(1 - q_2)p^{n,n_1,\ldots,n_t,n'_1}_{k,k_1,\ldots,k_t,k'_t}(q_1, q_2)) \cdot e_{n_1,k_1}\ldots e_{n_t,k_t}|_\Delta
\]

and relation \((5.28)\) allows us to iteratively transform any product \(e_{n_1,k_1}\ldots e_{n_t,k_t}|_\Delta\) into a linear combination of such products where the vectors \((n_1, k_1),\ldots, (n_t, k_t)\) are ordered by slope. Moreover, the specific coefficients that appear in the linear combination match the ones that transform the product \(E_{n_1,k_1}\ldots E_{n_t,k_t} \in \mathcal{A}\) into a linear combination of such products where the vectors \((n_1, k_1),\ldots, (n_t, k_t)\) are ordered by slope. This proves that \(\Phi(x)\Phi(y)|_\Delta = \Phi(xy)\) for any \(x, y\) of the form \((5.27)\), by showing that both \(\Phi(x)\Phi(y)|_\Delta\) and \(\Phi(xy)\) have the same expansion as in the right-hand side of \((5.27)\). Thus property \((3)\) of Definition \(5.2\) is established, and the only thing that we used was the associativity property:

\[
(\left(X \circ Y\right)|_\Delta \circ Z)|_\Delta = \left(X \circ \left( Y \circ Z\right)|_\Delta \right)
\]

for any \(K_{\mathcal{M}}^{X,Y,Z} \to K_{\mathcal{M} \times \mathcal{S}}\). The fact that assignment \((5.27)\) satisfies property \((4)\) of Definition \(5.2\) is proved analogously with the computation above, but instead of the associativity property \((5.29)\), one uses the following version of the Leibniz rule:

\[
\left[X, Y \circ Z\right]|_\Delta^{\text{red}} = \left[X, Y\right]^{\text{red}} \circ Z|_\Delta + Y \circ \left[X, Z\right]^{\text{red}}|_\Delta
\]

where if \([X, Y] = \Delta_\ast(A), we write \(A = [X, Y]^{\text{red}}\).

\[\square\]

**Remark 5.9.** In Conjecture \(\[5.7\] it suffices to assume that \(p^{n,n_1,\ldots,n_t,n'_1}_{k,k_1,\ldots,k_t,k'_t}(q_1, q_2)\) of \((5.25)\) are certain Laurent polynomials that do not depend on the surface \(S\), and one can deduce that they must coincide with the Laurent polynomials that appear in \((5.24)\). The argument for this claim is to consider \(S = \mathbb{A}^2\) and replace usual \(K\)-theory by equivariant \(K\)-theory with respect to the standard torus action \(\mathbb{C}^\ast \times \mathbb{C}^\ast \to \mathbb{A}^2\) \((q_1, q_2)\) correspond to the equivariant parameters) and replace \(\mathcal{M}\) by the moduli space of framed sheaves. If this is the case, we showed in \([24]\) that Conjecture \([1.1]\) holds and the generators \(E_{n,k}\) correspond to the operators \(e_{n,k}\), thus implying that the coefficients in \((5.24)\) match those in \((5.25)\).

5.10. If one is willing to accept the equivalent Conjectures \([1.1]\) and \(5.9\) one can skip to the next Section. The remainder of the current Section is devoted to the proof of both Conjectures subject to the following quite strong assumption:

**Assumption B:** The Kunneth decomposition \(K_{\mathcal{M} \times \mathcal{S}} \cong K_{\mathcal{M}} \boxtimes K_{\mathcal{S}}\), and the class of the diagonal splits up as:

\[
[O_\Delta] = \sum_c l_c \boxtimes l_c \in K_{\mathcal{M}} \boxtimes K_{\mathcal{S}}
\]

Following \([24]\) this implies \(K_{\mathcal{M} \times \mathcal{S}} \cong K_{\mathcal{M}} \boxtimes K_{\mathcal{S}}\), and so we may decompose the class of the universal sheaf as:

\[
[l] = \sum_c [T_c] \boxtimes l_c \in K_{\mathcal{M}} \boxtimes K_{\mathcal{S}}
\]
We assume that \( \{T_c\} \) are vector bundles on \( \mathcal{M} \) whose exterior powers generate \( K_\mathcal{M} \) as a ring.

Note that under assumption (5.31), the collections \( \{l_c\} \) and \( \{t^c\} \) yield dual \( \mathbb{Z} \)-bases of \( K_S \), with respect to the bilinear form:

\[
K_S \otimes K_S \to \mathbb{Z}, \quad ([V_1], [V_2]) = \chi(S, V_1 \otimes V_2)
\]

The last statement of Assumption B says that any element of \( K_\mathcal{M} \) is of the form:

(5.33) \[
\Psi(..., T_c, ...)
\]

where \( \Psi \) is a Laurent polynomial, symmetric in the Chern roots of each vector bundle \( T_c \) separately (if we weakened the assumption by dropping the condition that \( K_\mathcal{M} \) is generated by the \( T_c \), then we would be only constructing an action of \( \mathcal{A} \) on the subalgebra of \( K_\mathcal{M} \) generated by the \( T_c \)). Under Assumption B, [23] shows that the operators (5.11) and (5.2) act by:

(5.34) \[
ed_c \Psi(..., T_c, ...) = \int_{\infty}^{-\infty} z^d \Psi(..., T_c + z l_c, ...) \wedge^* \left( \frac{z q}{U} \right)
\]

(5.35) \[
f_d \Psi(..., T_c, ...) = \int_{\infty}^{-\infty} z^d \Psi(..., T_c - z l_c, ...) \wedge^* \left( -\frac{z}{U} \right)
\]

where:

(5.36) \[
\int_{\infty}^{-\infty} F(z) = \text{Res}_{z=\infty} F(z) - \text{Res}_{z=0} F(z)
\]

Iterating (5.34) and (5.35) yields:

(5.37) \[
ed_{d_1}...e_{d_k} \Psi(..., T_c, ...) = \\
= \int_{\infty}^{-\infty} \frac{z^{d_1}...z_k \Psi(..., T_c + \sum_{i=1}^{k} z_i l_c^{(i)}, ...)}{\prod_{1 \leq i < j \leq n} \zeta_{ij} \left( \frac{z_i}{z_j} \right)} \prod_{i=1}^{k} \wedge^* \left( \frac{z_i q^{(i)}}{U^{(i)}} \right)
\]

(5.38) \[
f_{d_k}...f_{d_1} \Psi(..., T_c, ...) = \\
= \int_{\infty}^{-\infty} \frac{z^{d_1}...z_k \Psi(..., T_c - \sum_{i=1}^{k} z_i l_c^{(i)}, ...)}{\prod_{1 \leq i < j \leq k} \zeta_{ij} \left( \frac{z_i}{z_j} \right)} \prod_{i=1}^{k} \wedge^* \left( -\frac{z_i}{U^{(i)}} \right)
\]

where \( z_i < z_j \) means that we first compute the residues at \( 0 \) and \( \infty \) in the variable \( z_j \) and then in \( z_i \) (more graphically, we thing of \( z_j \) as being “larger”, i.e. closer to the singularities at \( \infty \) and \( 0 \), than \( z_i \)). The RHS of expressions (5.37) and (5.38) are valued in:

(5.39) \[
K_{\mathcal{M} \times S \times ... \times S} \cong K_M \boxtimes K_S \boxtimes ... \boxtimes K_S
\]

and \( l_c^{(i)}, q^{(i)}, U^{(i)} \) refer to the elements of (5.39) obtained by pulling back \( l_c, q, U \) via the \( i \)-th projection \( S \times ... \times S \to S \). Finally, in formulas (5.37) and (5.38) we let:

\[
\zeta_{ij}(x) = \wedge^* (-x \cdot \mathcal{O}_{\Delta_{ij}}) \in K_{\mathcal{M} \times S \times ... \times S}(x)
\]

denote the pull-back of \( \wedge^* (-x \cdot \mathcal{O}_{\Delta}) \in K_{S \times S}(x) \) via the \( (i, j) \) projection.
5.11. Formulas \([5.37] - [5.38]\) are somewhat complicated, but they become simpler if one restricts the right-hand side to the smallest diagonal \(\Delta: S \hookrightarrow S \times \cdots \times S\):

\[
(5.40) \quad e_{d_1 \ldots d_k} \bigg|_{\Delta} \Psi(..., T_c, ...) = \int_{\infty - 0}^{\infty} \frac{z_1^{d_1} \ldots z_k^{d_k} \Psi(...) T_c + (z_1 + \ldots + z_k)l_c, \ldots)}{\prod_{1 \leq i < j \leq k} \zeta(z_i^\cdot)} \prod_{i=1}^k \zeta(z_i^\cdot) \left(\frac{z_i q}{U}\right)
\]

\[
(5.41) \quad f_{d_k \ldots d_1} \bigg|_{\Delta} \Psi(..., T_c, ...) = \int_{\infty - 0}^{\infty} \frac{z_1^{d_1} \ldots z_k^{d_k} \Psi(...) T_c - (z_1 + \ldots + z_k)l_c, \ldots)}{\prod_{1 \leq i < j \leq k} \zeta(z_i^\cdot)} \prod_{i=1}^k \zeta(z_i^\cdot) \left(\frac{z_i q}{U}\right)
\]

where:

\[
(5.42) \quad \zeta(x) = \&(-x \cdot O_\Delta) \bigg|_{\Delta} = \frac{\zeta(x \cdot \Omega^1_S)}{(1 - x)(1 - xq)} \in K_S(x)
\]

Note that the formula above matches \([2.3]\), as long as we set the Chern roots of \(\Omega^1_S\) equal to \(q_1\) and \(q_2\). By analogy with \((5.40)\) and \((5.41)\), we have the following:

**Proposition 5.12.** The operators of Definition \([5.3]\) act on tautological classes by:

\[
(5.43) \quad e_{(d_1, \ldots, d_k)} \Psi(..., T_c, ...) = \int_{\infty - 0}^{\infty} \frac{z_1^{d_1} \ldots z_k^{d_k} \Psi(...) T_c + (z_1 + \ldots + z_k)l_c, \ldots)}{\prod_{1 \leq i < j \leq k} \zeta(z_i^\cdot)} \prod_{i=1}^k \zeta(z_i^\cdot) \left(\frac{z_i q}{U}\right)
\]

\[
(5.44) \quad f_{(d_k, \ldots, d_1)} \Psi(..., T_c, ...) = \int_{\infty - 0}^{\infty} \frac{z_1^{d_1} \ldots z_k^{d_k} \Psi(...) T_c - (z_1 + \ldots + z_k)l_c, \ldots)}{\prod_{1 \leq i < j \leq k} \zeta(z_i^\cdot)} \prod_{i=1}^k \zeta(z_i^\cdot) \left(\frac{z_i q}{U}\right)
\]

for all \(d_1, \ldots, d_k \in \mathbb{Z}\).

**Proof.** We will prove \([5.43]\), and leave the analogous formula \([5.44]\) as an exercise for the interested reader. In virtue of the definition of the operator \(e_{(d_1, \ldots, d_k)}\) in \([5.17]\), the left-hand side of \([5.43]\) is given by:

\[
(5.45) \quad (p_+ \times p_S)^* \left(\mathcal{L}^{d_1}_1 \ldots \mathcal{L}^{d_k}_k \cdot \Psi(..., p_+^*(T_c), \ldots)\right)
\]

where the maps \(p_+, p_-, p_S\) are defined in \([5.14]\). However, note the equality:

\[
(5.46) \quad (p_+ \times \text{Id}_S)^*(U) = (p_+ \times \text{Id}_S)^*(U) + \Gamma_* (L_1) + \ldots + \Gamma_* (L_k)
\]

on \(3_k^* \times S\), where \(\Gamma\) denotes the graph of \(p_S: 3_k^* \rightarrow S\). From \([5.32]\), we have:

\[
(5.47) \quad T_c = \text{proj}_{1*} (U \otimes \text{proj}_{2*}^*(l_c))
\]
where $\text{proj}_1$ and $\text{proj}_2$ denote the projections from $\mathcal{M} \times S$ onto the two factors. Tensoring relation (5.46) with $l_c$ pulled back from the second factor of $\mathfrak{M}_k^* \times S$ and pushing forward to the first factor, we conclude that:

$$p_+^*(\mathcal{T}_c) = p_+^*(\mathcal{T}_c) + (\mathcal{L}_1 + ... + \mathcal{L}_k) \cdot p_+^*(l_c)$$

With this relation in hand, (5.45) equals:

$$(p_+ \times p_S)_* \left( \mathcal{L}_1^{d_1} ... \mathcal{L}_k^{d_k} \cdot \Psi(..., p_+^*(\mathcal{T}_c) + (\mathcal{L}_1 + ... + \mathcal{L}_k) p_+^*(l_c), ...) \right)$$

Now we need to recall the description of the map $p_+ \times p_S : \mathfrak{M}_0^* \rightarrow \mathcal{M}_0 \times S$, where $\mathcal{M}_0$ is the copy of the moduli space of stable sheaves that parametrizes the sheaf denoted by $\mathcal{F}_0$ in (5.13). By Definition 5.5, we have a derived fiber square:

\[
\begin{array}{ccc}
\mathfrak{M}_0^* & \longrightarrow & \mathfrak{M}_1^* \\
\downarrow p_+^{(k)} & & \downarrow \pi_+ \\
\mathfrak{M}_2^* & \longrightarrow & \mathfrak{M}_3^* \\
\end{array}
\]

where $p_+^{(k)}$ and $\pi_+$ are the obvious maps of dg schemes underlying the following map between their support schemes:

$$p_+^{(k)}(\mathcal{F}_0 \subset_x ... \subset_x \mathcal{F}_{k-2} \subset_x \mathcal{F}_{k-1} \subset_x \mathcal{F}_k) = (\mathcal{F}_0 \subset_x ... \subset_x \mathcal{F}_{k-2} \subset_x \mathcal{F}_{k-1})$$

and:

$$\pi_+(\mathcal{F}_{k-2} \subset_x \mathcal{F}_{k-1} \subset_x \mathcal{F}_k) = (\mathcal{F}_{k-2} \subset_x \mathcal{F}_{k-1})$$

Note that the line bundles $\mathcal{L}_1, ..., \mathcal{L}_{k-1}$ on $\mathfrak{M}_1^*$ are pulled back via $p_+^{(k)}$, while the line bundle $\mathcal{L}_k$ is pulled back from $\mathfrak{M}_3^*$ via the vertical map. We will use the notation $\mathcal{U}_0, ..., \mathcal{U}_k$ for the universal sheaves on $\mathfrak{M}_0^* \times S$ that correspond to $\mathcal{F}_0, ..., \mathcal{F}_k$. Since:

$$p_+ = p_+^{(1)} \circ ... \circ p_+^{(k)}$$

in order to prove that (5.48) equals the right-hand side of (5.43), it is enough to iterate the following equation $n$ times:

$$(5.50) \quad p_+^{(k)}(\mathcal{F}(\mathcal{L}_k)) = \int_{-\infty}^{\infty} F(z)^{\wedge^* \left( \frac{\pi q}{\mathcal{U}_{k-1}} \right)} = \int_{-\infty}^{\infty} \frac{F(z) \cdot \wedge^* \left( \frac{\pi q}{\mathcal{U}_{k-1}} \right)}{1 - \frac{\pi q}{\mathcal{L}_{k-1}}} \prod_{i=1}^{k-1} \zeta \left( \frac{\pi}{\mathcal{L}_{k-1}} \right)$$

where $F(z)$ is any function of $z$ with coefficients in $\text{Im} \ p_+^{(k)*}$. The first equality above is a direct application of Proposition 4.19 of [23], which describes the push-forward of tautological classes down projectivizations of coherent sheaves of projective dimension 1. Indeed, by (4.26), the bottom map $\pi_+$ of the derived fiber square (5.49) is the projectivization of a coherent sheaf of projective dimension 1, whose class in $\bar{K}$-theory is $-q[\mathcal{U}_{k-1}] + q[\mathcal{L}_{k-1}]$. By base change, so is the top map in (5.49). The second equality of (5.50) is a consequence of $\mathcal{U}_{k-1} = \mathcal{U}_0 + \sum_{i=1}^{k-1} \mathcal{L}_i \otimes (p_S \times \text{Id})^*(\mathcal{O}_\Delta)$. \hfill \square
5.13. As observed in Remark 2.19 of [23], one can redefine the integrals (5.37) and (5.38) in such a way that \(|z_1| = \ldots = |z_n|\). This is achieved by formally assuming that the Chern roots of \(\Omega^{1}_{S}\) are complex numbers of absolute value either < 1 or > 1, evaluating an \(n\)-fold integral by residues under this assumption, and acknowledging that the result is a Laurent polynomial in \(q_1\) and \(q_2\) and thus a well-defined \(K\)-theory class. The same definition applies to (5.40) and (5.41) by restriction, and also to (5.43) and (5.44) since the factors \(z_i - z_{i+1}q\) in the denominator of the latter expressions do not create any new poles (they are canceled by certain factors of \(\zeta\)).

This procedure of moving the contours does not lead to more helpful formulas for the operators (5.37)–(5.44), but it does have the following important consequence: these operators vanish not only when the integrand vanishes as a function of \(z_1, \ldots, z_n\), but when the symmetrization of the integrand. In other words:

\[
(5.51) \quad \sum c_{d_1, \ldots, d_n} e_{(d_1, \ldots, d_n)} = 0 \iff \text{Sym} \left[ \sum c_{d_1, \ldots, d_n} z_1^{d_1} \ldots z_n^{d_n} \prod_{i=1}^{n-1} \left( 1 - \frac{z_i + 1}{z_i} \right) \prod_{i<j} \zeta \left( \frac{z_i}{z_j} \right) \right] = 0
\]

for any constants \(c_{d_1, \ldots, d_n}\), where Sym denotes averaging with respect to all \(n!\) permutations of the variables \(z_1, \ldots, z_n\). As a consequence of this fact, formulas (5.36), (5.39) imply the following equality of operators \(K_M \to K_{M \times S}\):

\[
(5.52) \quad e_{d_*} = \sum_{\frac{k}{n_1} \leq \ldots \leq \frac{k}{n_t}} \phi(s_{k_1, \ldots, k_t}(q_1, q_2)) \cdot e_{-n_1, k_1} \cdots e_{-n_t, k_t} \bigg|_{\Delta}
\]

and

\[
(5.53) \quad f_{d_*} = \sum_{\frac{k}{n_1} \geq \ldots \geq \frac{k}{n_t}} \phi(s_{k_1, \ldots, k_t}(q_1, q_2)) \cdot e_{n_1, k_1} \cdots e_{n_t, k_t} \bigg|_{\Delta}
\]

for any \(d_* = (d_1, \ldots, d_n) \in \mathbb{Z}^n\).

**Proof.** of Conjectures 1.1 and 5.7 subject to Assumption B: as shown in Proposition 5.8, the two conjectures are equivalent, so we only need to prove relation (5.22). To keep the subsequent notation simple, we will often ignore the homomorphism \(\phi\) of (5.7), and write \(q_1, q_2\) for the Chern roots of the cotangent bundle of \(S\). Therefore, symmetric polynomials in \(q_1, q_2\) will be elements of \(K_S\). We may assume \(n > 0\) without loss of generality, and then we have three cases to study:

**Case 1:** \(n' > 0\). By (5.22), we have \(e_{n,k} = f_{d_*}\) and \(e_{n',k'} = f_{d'_*}\) for certain vectors of integers \(d_*, d'_*\) (we ignore the powers of \(q\) that appear in (5.22), as they will play no role in what follows). Then (5.44) implies the following formula, for any \(\Psi\):

\[
\Psi(..., T_{c_1}, ...) \stackrel{e_{n,k}}{\longrightarrow} \int_{\infty}^{0} \int_{\infty}^{0} \frac{\prod_{i=1}^{n} \left( 1 - \frac{z_i}{w_i} \right)}{\prod_{i<j} \zeta \left( \frac{z_i}{z_j} \right)} \prod_{i=1}^{n} \left( 1 - \frac{z_i + 1}{z_i} \right) \prod_{i<j} \zeta \left( \frac{z_i}{z_j} \right) \left( 1 - \frac{z_i^k}{z_i} \right) \Psi(..., T_{c_1} - (z_1 + \ldots + z_n l_{c_1}, ...) \right) \prod_{i=1}^{n} \wedge^k \left( \frac{z_i}{w_i} \right)
\]

\[
\Psi(..., T_{c_1}, ...) \stackrel{e_{n',k'}}{\longrightarrow} \int_{\infty}^{0} \int_{\infty}^{0} \frac{\prod_{i=1}^{n'} \left( 1 - \frac{w_i}{w_i} \right)}{\prod_{i<j} \zeta \left( \frac{w_i}{w_j} \right)} \prod_{i=1}^{n'} \left( 1 - \frac{w_i^k}{w_i} \right) \Psi(..., T_{c_1} - (w_1 + \ldots + w_{n'} l_{c_1}, ...) \right) \prod_{i=1}^{n'} \wedge^k \left( -\frac{w_i}{w_i} \right)
\]
When composing two operators given by integral formulas as above, we obtain the following formulas (we henceforth write $l^{(1)}, l^{(2)} \in K_{S \times S}$ for the pull-backs of any class $l \in K_S$ via the first and second projections, respectively):

\[
e_{n,k}e_{n',k'}\Psi(\ldots, \mathcal{T}_c, \ldots) = \int_{\infty - 0}^{w_n < \ldots < z_1 < < z_1} z_1^{d_1} \ldots z_n^{d_n} w_1^{d'_1} \ldots w_n^{d'_n} \prod_{1 \leq i \leq n} \zeta_{12} \left( \frac{z_i}{w_i} \right)
\]

\[
\Psi(\ldots, \mathcal{T}_c - (z_1 + \ldots + z_n)^{l^{(1)}}, \ldots - (w_1 + \ldots + w_n)^{l^{(2)}}, \ldots, \prod_{i=1}^{n} \zeta_{i}^{\bullet} \left( - \frac{z_i}{w_i} \right) \prod_{i' = 1}^{n'} \zeta_{i'}^{\bullet} \left( - \frac{w_{i'}}{w_{i'}^{(2)}} \right)
\]

\[
\left( 1 - \frac{2z_{(1)}}{z_1} \right) \ldots \left( 1 - \frac{2z_{(2)}}{z_1} \right) \left( 1 - \frac{w_{n'}}{w_1} \right) \ldots \left( 1 - \frac{w_{n'}}{w_{n' - 1}} \right) \prod_{i < j} \zeta_{(1)} \left( \frac{z_i}{w_i} \right) \prod_{i' < j'} \zeta_{(2)} \left( \frac{w_{i'}}{w_{i'}} \right)
\]

where $\zeta_{12}(x) = \zeta^{\bullet}(x \cdot O_A)$ is a rational function with coefficients in $K_{S \times S}$, while $\zeta^{(1)}(x)$, $\zeta^{(2)}(x)$ denote the pull-backs to $S \times S$ of the rational functions $\zeta^{(1)}$, which have coefficients in $K_S$. The two expressions in the displays above differ in two ways: the rational function $\zeta_{12}$ has argument $w_{i'}/z_i$ in the first equation and $z_i/w_{i'}$ in the second equation, and the order of the contours is switched. However, because:

\[
\zeta_{12} \left( \frac{z}{w} \right) = 1 + \Delta \left[ \frac{zw}{(z - w)(zq - w)} \right]
\]

(see (3.6) of [29]) we conclude that:

\[
[e_{n,k}, e_{n',k'}]_\Psi(\ldots, \mathcal{T}_c, \ldots) = \Delta \left[ \text{residues of } \int \prod_i z_i^{d_i} \prod_{i'} w_{i'}^{d'_i} \prod_{i', i} \zeta \left( \frac{z_{i}}{w_{i'}} \right) \text{ or } \zeta \left( \frac{w_{i'}}{z_i} \right) \right]
\]

\[
\Psi(\ldots, \mathcal{T}_c - (z_1 + \ldots + z_n + w_1 + \ldots + w_n)^{l^{(1)}}, \ldots, \prod_{i=1}^{n} \zeta_{i}^{\bullet} \left( - \frac{z_i}{w_i} \right) \prod_{i' = 1}^{n'} \zeta_{i'}^{\bullet} \left( - \frac{w_{i'}}{w_{i'}} \right)
\]

\[
\left( 1 - \frac{2z_{(1)}}{z_1} \right) \ldots \left( 1 - \frac{2z_{(2)}}{z_1} \right) \left( 1 - \frac{w_{n'}}{w_1} \right) \ldots \left( 1 - \frac{w_{n'}}{w_{n' - 1}} \right) \prod_{i < j} \zeta_{(1)} \left( \frac{z_i}{w_i} \right) \prod_{i' < j'} \zeta_{(2)} \left( \frac{w_{i'}}{w_{i'}} \right)
\]

where the appropriate residues arise from one of the $z_i$ contours passing over one of the $w_{i'}$ contours. According to (5.54), such residues take the form $z_i = w_{i'}$, $z_i = w_{i'}q^{k_i}$. Regardless of what these residues are, it is clear that the right-hand side of the expression above is a $K_S$-linear combination of operators as (5.44):

\[
[e_{n,k}, e_{n',k'}] = \Delta \left[ \sum_{\delta} \phi(h_{\delta}(q_1, q_2)) : f_{\delta} \right]
\]

for various symmetric polynomials $h_{\delta}(q_1, q_2) \in K$. It is clear that these symmetric polynomials do not depend on the surface $S$ (in fact, the only dependence on $S$ is the fact that the ring homomorphism $\phi$ specializes $q_1, q_2$ to the Chern roots of the
cotangent bundle of $S$). As a consequence of (5.53), we conclude that:

$$
(5.56) \quad [e_{n,k}, e_{n',k'}] = \Delta \left( \sum_{n_1 + \ldots + n_k = n} \frac{n}{n_1} \geq \ldots \geq \frac{n}{n_k} \phi(P_{k_1, k_1', \ldots, k_r, k_r'}(q_1, q_2)) \cdot e_{n_1, k_1} \ldots e_{n_k, k_r} \right)
$$

for certain polynomials $P_{k_1, k_1', \ldots, k_r, k_r'}(q_1, q_2) \in \mathbb{K}$. These polynomials are completely determined by the case when $S = \mathbb{A}^2$ and $K$–theory is $\mathbb{C}^* \times \mathbb{C}^*$ equivariant, when \([26]\) implies that they coincide with the structure constants in the algebra $A$, i.e. the homonymous polynomials in the right-hand side of (3.11). This proves (5.25).

**Case 2:** $n' = 0$, and take $k' > 0$ without loss of generality. Consider the operators:

$$
p_{0,1}, p_{0,2}, \ldots : K_M \to K_M \times S
$$

which are to $e_{0,1}, e_{0,2}, \ldots$ as power-sum are to elementary symmetric functions, i.e.:

$$
p_{0,1} = e_{0,1}, \quad p_{0,2} = e_{0,1}e_{0,1} \Delta - 2e_{0,2}
$$

etc. It is elementary to show that formula (5.25) for the commutator $[e_{n,k}, e_{n,k'}]$ is equivalent to an analogous formula for the commutator $[e_{n,k}, p_{0,k'}]$, which in turn follows from the subsequent formula for any $d_1, \ldots, d_n \in \mathbb{Z}$:

$$
(5.57) \quad [f_{(d_1, \ldots, d_1)} \circ p_{0,k'}, \Psi(\ldots, T_c, \ldots)] = \int_{\infty - 0}^{z_1 \ldots z_n} \mathcal{P}_k \left( \left( T_c - (z_1 + \ldots + z_n)^{(1)} \right) \otimes l^{(2)} \right)
$$

Indeed, this mirrors the way formula (3.11) for $n' = 0$ follows from (3.10) and (3.10). In order to prove (5.57), one notices that the definition of $p_{0,k'}$ in relation to $e_{0,k'}$, as well as the definition of the operators $e_{0,k'}$ in (5.25), implies that:

$$
p_{0,k'} = \text{multiplication by } \mathcal{P}_k(U)
$$

where $\mathcal{P}_k$ is the additive functor on $K$–theory which takes the class of a bundle to the sum of the $t$-th powers of its Chern roots. Formulas (5.32) and (5.44) imply:

$$
\mathcal{P}_k \left( \left( T_c - (z_1 + \ldots + z_n)^{(1)} \right) \otimes l^{(2)} \right) = \mathcal{P}_k \left( \int_{\infty - 0}^{z_1 \ldots z_n} \mathcal{P}_k \left( \left( T_c - (z_1 + \ldots + z_n)^{(1)} \right) \otimes l^{(2)} \right) \right)
$$

where $l^{(1)}$ (respectively $l^{(2)}$) denotes the $K$–theory class $l$, pulled back from the first (respectively second) factor of $S \times S$. The composition $p_{0,k'} \circ f_{(d_1, \ldots, d_1)}$ is given by the same formula, but on the first line, one should replace:

$$
\mathcal{P}_k \left( \left( T_c - (z_1 + \ldots + z_n)^{(1)} \right) \otimes l^{(2)} \right) \to \mathcal{P}_k \left( \left( T_c \otimes l^{(2)} \right) \right)
$$

Since the functor $\mathcal{P}_k$ is additive and $\sum c l^{(1)} \otimes l^{(2)} = [O_D]$, we conclude that:

$$
(5.58) \quad \int_{\infty - 0}^{z_1 \ldots z_n} (z_1' + \ldots + z_n') \left( z_1^{d_1} \ldots z_n^{d_n} \Psi(\ldots, T_c, \ldots) \right) = -\mathcal{P}_k(\mathcal{O}_D) \cdot \int_{\infty - 0}^{z_1 \ldots z_n} \left( \left( T_c - (z_1 + \ldots + z_n)^{(1)} \right) \otimes l^{(2)} \right)
$$

where $\mathcal{P}_k$ is the additive functor on $K$–theory which takes the class of a bundle to the sum of the $t$-th powers of its Chern roots. Formulas (5.32) and (5.44) imply:
Now we will use the identity:

\[(5.59) \quad P_k(O_\Delta) = \Delta_* \left[ \frac{(1 - q_1^k)(1 - q_2^k)}{(1 - q_1)(1 - q_2)} \right] \]

which can be proved akin to (3.6) of [23] (specifically, one first proves \((5.59)\) directly when \([O_\Delta] = [O] - [V] + [\det V]\) for a rank 2 vector bundle \(V\), and then obtains the general formula by deformation to the normal bundle of \(\Delta \to S \times S\).

If we use \((5.44)\) and \((5.59)\), we transform relation \((5.58)\) into \((5.57)\), as desired.

**Case 3:** \(n' < 0\). We will show that for any \(d = (d_1, \ldots, d_n)\) and \(d' = (d'_1, \ldots, d'_{n'})\), we have the following a priori weaker version of Conjecture 5.7:

\[(5.60) \quad \left[ e_d, f_d' \right] = \Delta_* \left( \sum_{d_*,k,d_*'} \phi(p_{d_*,k,d_*'}(q_1, q_2)) \cdot e_{d_*} h^\pm_{k_0} f_{d_*'} \right) \]

where the coefficients \(p_{d_*,k,d_*'}(q_1, q_2) \in K\) that appear in the right-hand side do not depend on the surface \(S\). In the formula above:

\[h^\pm_k : K_M \to K_{M \times S}\]

are the coefficients of \(h^\pm(z) = \sum_{k=0}^\infty h^\pm_k \frac{z^k}{k!}\), which acts on \(K_M\) as multiplication by:

\[h^\pm \left( \frac{z}{w} \right) = \Delta_* \left( \frac{h^\pm(z) - h^\pm(w)}{1 - q} \right)\]

Its relevance to our purposes is the following simple formula for the \(n = -n' = 1\) case of \((5.60)\), which follows immediately from \((5.43)\) and \((5.44)\), and was proved in [23] even in the absence of Assumption B:

\[\left[ \sum_{d \in \mathbb{Z}} e_d \frac{z^d}{d!} \sum_{d' \in \mathbb{Z}} f_{d'} \frac{w^{d'}}{d'!} \right] = \delta \left( \frac{z}{w} \right) \Delta_* \left( \frac{h^+(z) - h^-(w)}{1 - q} \right) \]

Let us show that \((5.60)\) implies \((5.25)\). By \((5.13)\) and \((3.16)\), the right-hand side of \((5.60)\) can be written as a product of generators \(e_{n,k}\) in increasing order of the slope \(n/k\). Since the coefficients of the resulting decomposition do not depend on the surface \(S\), and since for equivariant \(S = A^2\) the coefficients match those that occur in the algebra \(A\) (as shown in [24], [26]), relation \((5.25)\) follows.

Therefore, it remains to prove \((5.60)\), which will occupy the remainder of the present Section. We will use a residue computation, which will require us to assume that:

\[(5.61) \quad 1 - q^a\text{ is invertible in the ring } K_S \]

for all \(a \in \mathbb{N}\). Since this never happens in the algebraic \(K\)-theory of a smooth projective surface (as \(q\) is unipotent), we must argue for why this assumption is allowed. By Assumption B, in order to prove \((5.60)\), it is enough to show that:

\[(5.62) \quad \left| e_{d_*}, f_{d_*'} \right| \Psi(\ldots, T_c, \ldots) = \Delta_* \left( \sum_{d_*,k,d_*'} \phi(p_{d_*,k,d_*'}(q_1, q_2)) \cdot e_{d_*} h^\pm_{k_0} f_{d_*'} \right) \Psi(\ldots, T_c, \ldots) \]
for all symmetric Laurent polynomials $\Psi$ as in (5.33). Because of (5.43) and (5.44), both sides of relation (5.62) will be Laurent polynomials in the tautological classes, with coefficients which are Laurent polynomials in $q_1, q_2 \in K_S$. To prove that a certain identity between such polynomials holds, it is enough to do it for a choice of $M$ and $S$ for which there do not exist any relations between the $K$-theory classes $q_1, q_2$ and the various tautological classes $T_c$. To this end:

- choose $S = \mathbb{A}^2$
- replace $K$–theory by the $\mathbb{C}^* \times \mathbb{C}^*$ equivariant $K$–theory of $S$ (which is the ring $\mathbb{K}$ of (2.21)), localized with respect to the elements $1 - q^a$ of (5.61)
- consider the moduli space $M$ of rank $R$ sheaves on $\mathbb{P}^2$, for a sufficiently large natural number $R$, framed along the divisor $\infty \subset \mathbb{P}^2$: 

\[
\mathcal{F}|_\infty \cong \mathcal{C}_\infty^{\oplus R}
\]

(see [24], [26] for a version of our treatment in the setting of framed sheaves).

Moreover, let any torus $T \subset GL_R$ act on $M$ by left multiplication of the isomorphism (5.63). Therefore, in $\mathbb{C}^* \times \mathbb{C}^* \times T$ equivariant $K$–theory, the universal sheaf $U$ on $M \times S$ splits up as a direct sum $\oplus_c U_c \cdot t^c$, where $\{t^c\}$ goes over the elementary characters of the torus $T$. If one chooses $R \in \mathbb{N}$ large enough, then there will be no relations between the tautological bundles $T_c = \text{proj}_1(U_c)$, hence there are no algebraic relations between $\{\Psi(\ldots, T_c, \ldots)\}$. Therefore, it remains to prove formula (5.62) subject to assumption (5.61). We start by invoking (5.43) and (5.44):

\[
e_{d^*} f_d^* \Psi(\ldots, T_c, \ldots) = \int_{-\infty}^{z_1 < \ldots < z_n < \omega_{n'} < \ldots < \omega_1} R(z_1, \ldots, z_n, w_1, \ldots, w_{n'})
\]

where:

\[
R(z_1, \ldots, z_n, w_1, \ldots, w_{n'}) = z_1^{d_1} \ldots z_n^{d_n} w_1^{d_1'} \ldots w_{n'}^{d_{n'}} \prod_{1 \leq i \leq n}^{1 \leq j \leq -n'} \zeta_{12} \left( \frac{z_i}{w_j} \right)
\]

\[
\zeta(\ldots, T_c + (z_1 + \ldots + z_n)l^{(1)}_c - (w_1 + \ldots + w_{n'})l^{(2)}_c, \ldots) \prod_{i=1}^{n} \left( 1 - \frac{z_{i+1}q_i^{(1)}}{z_i} \right) \prod_{j=1}^{n'} \left( 1 - \frac{w_{j+1}q_j^{(2)}}{w_j} \right) \prod_{1 \leq i < i' \leq n} \left( \frac{z_i}{z_{i'}} \right) \prod_{1 \leq j < j' \leq -n'} \left( \frac{w_j}{w_{j'}} \right)
\]

where $\zeta_{12}$ is defined in (5.54). The composition $f_d^* e_{d^*}$ is given by the same formula as (5.64), but the order of the contours of integration is now $w_{n'} \prec \ldots \prec w_1 \prec \ldots \prec z_1 \prec \ldots \prec z_n$. Therefore, the commutator is given by taking residues when the contour of some variable $z_a$ passes over the contour of some other variable $w_b$:

\[
[e_{d^*}, f_d^*] \Psi(\ldots, T_c, \ldots) = \sum_{a=1}^{n} \sum_{b=1}^{-n'} \int_{-\infty}^{w_{n'} < \ldots < w_{b+1} < z_1 < \ldots < z_{a-1} < z_a < w_b < z_a+1 < \ldots < z_n < w_{b-1} < \ldots < w_1} \left[ \text{Res}_{z_a, w_b} R'' \right]
\]
where "\[ \sum \text{Res}_{z_a} w_R \]" is shorthand for the sum of residues at all poles of the form \( z_a = \alpha w_b \), as \( \alpha \) ranges over all possible constants \( \notin \{0, \infty\} \). From now on, we will often write expressions such as \( \text{Res}_{z_a = \alpha s} R \), which mean “take the residue at \( z_a = \alpha w_b \) and then relabel the variable \( w_b = s \).” Since \( \zeta_{12} \) is given by formula (5.64), the poles that appear in the right-hand side of (5.66) are \( z_a = w_b \) and \( z_a = w_b g^{-1} \). Moreover, the corresponding residues are both multiples of \( [O_\Delta] \). We may therefore use the projection formula in the guise of the identity:

\[ [O_\Delta] \cdot \gamma = \Delta_\gamma(\gamma) \quad \forall \gamma \in KS \times S \]

and conclude that:

\[ [e_{d_*}, f_{d_*}] \Psi(\ldots, T_c, \ldots) = \sum_{a=1}^n \sum_{k=1}^{n'} \frac{1}{\zeta(z_i/w_j)} \]

\[ \int_{\infty=0}^{\infty} \left[ \text{Res}_{z_a = \alpha s} (R|\Delta) - \frac{\text{Res}_{z_a = \alpha s} (R|\Delta)}{(1 - q_1)(1 - q_2)} \right] \]

where \( R|\Delta \) refers to the restriction of the coefficients of the rational function \( R \), which are a priori elements in \( KS \times S \), to the diagonal \( \Delta : S \to S \times S \). In practice, this involves setting in (5.65) \( \iota_{e(1)} \to \iota_c, \quad q^{(1)} \to q, \quad U^{(1)} \to U \) and:

\[ \zeta_{12}(x) \to \zeta(x) = \frac{\Lambda^*(\Omega_b^i \cdot x)}{1 - x} \in KS(x) \]

Explicitly, we have:

\[ R|\Delta(z_1, \ldots, z_n, w_1, \ldots, w_{n'}) = z_1^{d_1} \ldots z_n^{d_n} w_1^{d_1} \ldots w_{n'}^{d_{n'}} \prod_{1 \leq i \leq n} \frac{1}{\zeta(z_i/w_j)} \]

\[ \Psi(\ldots, T_c + (z_1 + \ldots + z_n - w_1 - \ldots - w_{n'})(c_1, \ldots) \prod_{i=1}^{n-1} \Lambda^* \left( \frac{z_i}{w_j} \right) \prod_{j=1}^{n'} \Lambda^* \left( -\frac{w_j}{z_i} \right) \]

\[ \prod_{i=1}^{n-1} \left( 1 - \frac{z_i^{a+1}q}{z_i} \right) \prod_{j=1}^{n'} \left( 1 - \frac{w_j^{a+1}q}{w_j} \right) \prod_{1 \leq i < j \leq n} \frac{\zeta(z_i/w_j)}{\zeta(z_j/w_i)} \prod_{1 \leq j < j' \leq n'} \frac{\zeta(w_j/w_i)}{\zeta(w_{j'}/w_i)} \]

Let us take the residue at \( z_a = w_b \) in (5.68) and call the resulting variable \( s \):

\[ \text{Res}_{z_a = \alpha s} (R|\Delta) = \frac{1}{\Delta^*(\Omega_b^i \cdot x)} \prod_{i < a} \frac{\zeta(s/z_i)}{\zeta(s/w_i)} \prod_{j > b} \frac{\zeta(w_j/s)}{\zeta(w_j/w_i)} \]

\[ \prod_{i, i+1 \neq a} \left( 1 - \frac{z_i^{a+1}q}{z_i} \right) \prod_{j, j+1 \neq b} \left( 1 - \frac{w_j^{a+1}q}{w_j} \right) \prod_{i < j} \frac{\zeta(z_i/w_j)}{\zeta(w_j/w_i)} \]

and when we take the residue at \( z_a = s/q \) and \( w_b = s \) in (5.68), we obtain:

\[ \text{Res}_{w_b = s} \frac{R|\Delta}{\text{Res}_{z_a = \alpha s} R} = \frac{1}{1 - q} \prod_{i > a} \frac{\zeta(s/w_i)}{\zeta(s/q)} \prod_{j < b} \frac{\zeta(w_j/s)}{\zeta(w_j/w_i)} \]

\[ \prod_{i, i+1 \neq a} \left( 1 - \frac{z_i^{a+1}q}{z_i} \right) \prod_{j, j+1 \neq b} \left( 1 - \frac{w_j^{a+1}q}{w_j} \right) \prod_{i < j} \frac{\zeta(z_i/w_j)}{\zeta(w_j/w_i)} \]

\[ \prod_{i < j} \frac{\zeta(w_j/w_i)}{\zeta(w_j/w_i)} \]

\[ \prod_{i, i+1 \neq a} \left( 1 - \frac{z_i^{a+1}q}{z_i} \right) \prod_{j, j+1 \neq b} \left( 1 - \frac{w_j^{a+1}q}{w_j} \right) \prod_{i < j} \frac{\zeta(z_i/w_j)}{\zeta(w_j/w_i)} \]

\[ \prod_{i < j} \frac{\zeta(w_j/w_i)}{\zeta(w_j/w_i)} \]

\[ \prod_{i, i+1 \neq a} \left( 1 - \frac{z_i^{a+1}q}{z_i} \right) \prod_{j, j+1 \neq b} \left( 1 - \frac{w_j^{a+1}q}{w_j} \right) \prod_{i < j} \frac{\zeta(z_i/w_j)}{\zeta(w_j/w_i)} \]

\[ \prod_{i < j} \frac{\zeta(w_j/w_i)}{\zeta(w_j/w_i)} \]

\[ \prod_{i, i+1 \neq a} \left( 1 - \frac{z_i^{a+1}q}{z_i} \right) \prod_{j, j+1 \neq b} \left( 1 - \frac{w_j^{a+1}q}{w_j} \right) \prod_{i < j} \frac{\zeta(z_i/w_j)}{\zeta(w_j/w_i)} \]

\[ \prod_{i < j} \frac{\zeta(w_j/w_i)}{\zeta(w_j/w_i)} \]
Putting all the residues together, we conclude that the RHS of (5.67) equals:

\[ \text{In the case of } (5.69), \text{ we can move the variable } a \text{ to the left of the chain of variables } \ldots < w_{b+1} < \ldots < z_{a-1} < s < z_{a+1} < \ldots < w_{b-1} < \ldots \text{ and the only poles we would encounter are } z_{a-1} = s \text{ (with sign +) and } w_{b+1} = \frac{s}{q} \text{ (with sign –), because } \Psi \text{ has no poles in } s \text{ other than 0 and } \infty. \]

\[ \text{In the case of } (5.70), \text{ we can move the variable } s \text{ to the right of the chain of variables } \ldots < w_{b+1} < \ldots < z_{a-1} < s < z_{a+1} < \ldots < w_{b-1} < \ldots \text{ and the only poles we would encounter are } z_{a+1} = \frac{s}{q} \text{ (with sign –) and } w_{b-1} = sq \text{ (with sign +), together with 0 and } \infty. \]

\[ \text{However, note that the residues at 0 and } \infty \text{ in } s \text{ can be computed by expanding } (5.69) \text{ in powers of } s, \text{ which yields some Laurent polynomial in the variables } \{z_i\}_{i \neq a}, \{w_j\}_{j \neq b} \text{ and some series coefficient of the ratio:} \]

\[ \frac{\wedge^\bullet \left( \frac{s}{q} \right)}{\wedge^\bullet \left( \frac{1}{q} \right)} \]

\[ \text{expanded in either positive or negative powers of } s. \text{ In virtue of the induction hypothesis, the corresponding residue will be a nice summand, which for the remainder of this proof will refer to a summand as in the right hand side of (5.62).} \]

Putting all the residues together, we conclude that the RHS of (5.67) equals:

\[ \sum_{a=1}^{n} \sum_{b=1}^{n'} \int_{\infty}^{0} \ldots < w_{a+2} < s < z_{1} < \ldots < z_{a-1} < z_{a+1} < \ldots < z_{n} < w_{b-1} < \ldots - \sum_{a=2}^{n} \sum_{b=1}^{n'} \int_{\infty}^{0} \ldots < w_{a+1} < z_{1} < \ldots < z_{a-1} < z_{a+1} < \ldots < z_{n} < w_{b-1} < \ldots + \sum_{a=1}^{n} \sum_{b=1}^{n'} \int_{\infty}^{0} \ldots < w_{b+1} < z_{1} < \ldots < z_{a-1} < z_{a+1} < \ldots < z_{n} < w_{b-1} < \ldots - \sum_{a=1}^{n} \sum_{b=2}^{n'} \int_{\infty}^{0} \ldots < w_{a+1} < z_{1} < \ldots < z_{a-1} < z_{a+1} < \ldots < z_{n} < s < w_{b-2} < \ldots \]

\[ \Delta_s \left[ \text{Res}_{z_{a+1}=s} \frac{z_{a+1}^{\frac{s}{q}}}{(1 - q_1)(1 - q_2)} \right] - \Delta_s \left[ \text{Res}_{w_{a+1}=s, w_{a+2}=w_{b-1}} \frac{z_{a+1}^{\frac{s}{q}}}{(1 - q_1)(1 - q_2)} \right] + \Delta_s \left[ \text{Res}_{w_{a+1}=s} \frac{z_{a+1}^{\frac{s}{q}}}{(1 - q_1)(1 - q_2)} \right] - \Delta_s \left[ \text{Res}_{z_{a+1}=s, z_{a+2}=w} \frac{z_{a+1}^{\frac{s}{q}}}{(1 - q_1)(1 - q_2)} \right] \]

plus nice summands. Note that the second and third rows cancel out, because they give the same residues with opposite signs (upon relabeling a \(\mapsto a - 1\)). The first and fourth rows consist of the same integrand (upon relabeling b \(\mapsto b - 1\) and \(s \mapsto sq\)), but the contours of integration have s to the left/right of chain of variables in the case of the first/fourth rows. Therefore, we conclude that the formula above is simply the base case (namely \(k = 1\)) of the following result:
Claim 5.14. For any $k \geq 1$, the RHS of (5.67) equals the sum over all $A, B$ of:

$$\int_{\infty}^{-\infty} \cdots (z_i \text{ for } i \not\in A) (z_i^* \text{ for } i \not\in A) (z_{i-1}^* \cdots z_{k-1}^*) \Delta_* \left[ \frac{\text{Res}_{w_k=s, \ldots, w_k=sq^k} (R|\Delta)}{(1-q_1)(1-q_2)} \right] -$$

(5.71)

$$- \int_{\infty}^{-\infty} \cdots (z_i \text{ for } i \not\in A) (z_i^* \text{ for } i \not\in A) (z_{i-1}^* \cdots z_{k-1}^*) \Delta_* \left[ \frac{\text{Res}_{w_k=s, \ldots, w_k=sq^k} (R|\Delta)}{(1-q_1)(1-q_2)} \right] -$$

plus nice summands, as $A$ ranges over the following $k$-element subsets of $\{1, ..., n\}$:

$$A = \left\{ a_1, ..., c_k - 1, ..., a_t, ..., c_t - 1 \right\} \text{ for } a_1 < c_1 \leq a_2 < c_2 \leq ... \leq a_t < c_t$$

and $B = \{b - k, ..., b\}$ ranges over $(k+1)$-element subsets of $\{1, ..., -n'\}$ consisting of consecutive elements. The contours of the variables $z_i$ in the two integrals are ordered in increasing order of $i$. The residues that appear in (5.71) have denominators $1 - q^a$, for various $a \in \mathbb{N}$, but these are acceptable due to (5.61).

To make the subsequent explanation more vivid, we will think of $A$ as a disjoint union of strings, each string consisting of consecutive numbers $a_i, ..., c_i - 1$. In (5.71), the variables $z_j$ for $a_i \leq j < c_i$ are specialized to $sq^e$ where $e \in \{0, ..., k-1\}$ increases from one string to the next, but decreases with step 1 within a given string. First of all, let us note that Claim completes the proof of the Conjecture subject to Assumption B, because as soon as $k > \min(n, -n')$, the sum of integrals above is vacuous, and all we are left with are nice summands.

We now prove Claim 5.14. For fixed sets $A$ and $B$, the integrand of the two integrals of (5.71) is one and the same rational function in $s, \{z_i\}_{i \not\in A}, \{w_j\}_{j \not\in B}$, namely:

$$\text{Res}_{w_k=s, ..., w_{k-1}=sq^k} (R|\Delta) = \frac{1^{1 \leq i \leq t} (\sum_{j \leq c_i - 1} (s q^{e - 1 + \sum_j c_j - a_j} a_j) \Delta_1, b-k (s q^e - 1) a_j d_j \psi)}{1 - sq^{k+1}} (w_{k-1}) \prod_{j \not\in B} (1 - sq^e - 1 + \sum_{j \leq c_j - a_j} a_j) \Delta_1, b-k \Psi(\cdots, T_c + (\sum_{i \not\in A} z_i - \sum_{j \not\in B} w_j - sq^e) T_c, ...)$$

$$\prod_{i \not\in A} (1 - sq^{k+1}) \prod_{j \not\in B} (1 - sq^{e - 1 + \sum_j c_j - a_j}) \prod_{i \not\in A} (1 - sq^{e - 1 + \sum_j c_j - a_j}) \Psi(\cdots, T_c + (\sum_{i \not\in A} z_i - \sum_{j \not\in B} w_j - sq^e) T_c, ...)$$

$$\prod_{i \not\in A} \Delta_1, b-k \Psi(\cdots, T_c + (\sum_{i \not\in A} z_i - \sum_{j \not\in B} w_j - sq^e) T_c, ...)$$

where we set $c_0 = 1$ and $a_{t+1} = n + 1$. The term labeled “constant” is an element of $\mathbb{K}$ divided by various factors $\{1 - q^a\}_{a \in \mathbb{N}}$. The difference between the integrals in Claim 5.14 has to do with the contour of the variable $s$ passing over the $z$ variables, and the only poles this picks up are those of the form $s = z_i a$ for some $i \not\in A$ and
some α ∈ 𝕂. Explicitly from the 3-row expression above, these are all of the form:

\[ z_{a_i-1} = sq^{\sum_{j \leq i} c_j - a_j} \quad \text{if } a_i \neq c_i-1 \]

\[ z_{c_i} = sq^{-1+\sum_{j < i} c_j - a_j} \quad \text{if } c_i \neq a_i+1 \]

\[ z_{c} = sq^{\sum_{j \leq i} c_j - a_j} \quad \text{for some } c_i \leq e < a_{i+1} \]

\[ z_{e} = sq^{-1+\sum_{j < i} c_j - a_j} \quad \text{for some } c_{i-1} \leq e < a_i \]

In terms of the interpretation of the set \( A \) as a union of strings of consecutive numbers in \{1, ..., n\}, where the index \( i \) corresponds to the variable \( z_i \), these four specializations mean the following: the first refers to adding the number \( a_i - 1 \) to the left of the string \{\( a_i, ..., c_i - 1 \)\}, the second refers to adding the number \( c_i \) to the right of the string \{\( a_i, ..., c_i - 1 \)\}, while the last two specializations correspond to creating the one-element string \{\( e \)\}. We will refer to either of these four situations as extending the string by the index \( a_i - 1, c_i \) or \( e \), respectively.

Let us now consider the powers \( sq^* \) to which the variables \( z_i \) are specialized in the extended string (specifically, the powers of \( q \) which appear in \( \text{(5.72)}-\text{(5.75)} \)). There are only four types of extended strings where the powers never repeat, namely:

\[ z_{a_i-1} = sq^{\sum_{j \leq i} c_j - a_j} \quad \text{for } i = t \]

\[ z_{c_i} = sq^{-1+\sum_{j < i} c_j - a_j} \quad \text{for } i = 1 \]

\[ z_{e} = sq^{\sum_{j \leq i} c_j - a_j} \quad \text{for } i = t \text{ for some } e \geq c_t \]

\[ z_{e} = sq^{-1+\sum_{j < i} c_j - a_j} \quad \text{for } i = 1 \text{ for some } e < a_1 \]

All other extended strings are repeated, which means that the particular power of \( q \) in \( sq^* \) that appears in the right-hand side of \( \text{(5.72)}-\text{(5.75)} \) will appear again somewhere in the string. However, any repeated string arises twice in this way, since either of the two equal powers \( sq^* \) can play the role of the one which was last added to yield the extended string. We leave it as an exercise to the interested reader to show that the corresponding residues of the two occurrences of any repeated string cancel each other out. We conclude that \( \text{(5.71)} \) consists of nice summands plus the residues corresponding to the extended strings \( \text{(5.76)}-\text{(5.79)} \), which are:

\[
\int_{-\infty}^{\ldots}<w_{b+1}<z_i \text{ for } i < a_i-1><s<z_i \text{ for } i \geq c_i><w_{b-k-1}<\ldots
\]

\[-\int_{-\infty}^{\ldots}<w_{b+1}<z_i \text{ for } i < a_1><s<z_i \text{ for } i > c_1><w_{b-k-1}<\ldots
\]

\[+ \sum_{c_i \geq e} \int_{-\infty}^{\ldots}<w_{b+1}<z_i \text{ for } i < e><s<z_i \text{ for } i > e><w_{b-k-1}<\ldots
\]

\[-\sum_{e < a_1} \int_{-\infty}^{\ldots}<w_{b+1}<z_i \text{ for } i < e><s<z_i \text{ for } i > e><w_{b-k-1}<\ldots
\]

\[\Delta_* \left[ \frac{\text{Res}^{(1)}(R|\Delta)}{(1-q_1)(1-q_2)} \right] - \]

\[\Delta_* \left[ \frac{\text{Res}^{(2)}(R|\Delta)}{(1-q_1)(1-q_2)} \right] + \]

\[\Delta_* \left[ \frac{\text{Res}^{(3)}(R|\Delta)}{(1-q_1)(1-q_2)} \right] - \]

\[\Delta_* \left[ \frac{\text{Res}^{(4)}(R|\Delta)}{(1-q_1)(1-q_2)} \right] \]
where $\text{Res}(1), \ldots, \text{Res}(4)$ denote the residues at:

\begin{align*}
(5.80) & \quad \left\{ z_{a_{1}+\varepsilon} = sq^{-\varepsilon_1+\sum_{j \leq i} \epsilon_j-a_j}, z_{a_{i}-1} = sq^k, w_b = s, \ldots, w_{b-k} = sq^k \right\} \\
(5.81) & \quad \left\{ z_{a_{i}+\varepsilon} = sq^{-\varepsilon_1+\sum_{j \leq i} \epsilon_j-a_j}, z_{c_{1}} = \frac{s}{q}, w_b = s, \ldots, w_{b-k} = sq^k \right\} \\
(5.82) & \quad \left\{ z_{a_{i}+\varepsilon} = sq^{-\varepsilon_1+\sum_{j \leq i} \epsilon_j-a_j}, z_{e} = sq^k, w_b = s, \ldots, w_{b-k} = sq^k \right\} \\
(5.83) & \quad \left\{ z_{a_{i}+\varepsilon} = sq^{-\varepsilon_1+\sum_{j \leq i} \epsilon_j-a_j}, z_{e} = \frac{s}{q}, w_b = s, \ldots, w_{b-k} = sq^k \right\}
\end{align*}

respectively. In each of the four integrands, the set of indices of the $z$ variables form a string of total size $k + 1$ (henceforth called \textbf{long string}), since the string of size $k$ (henceforth called \textbf{short string}) in the statement of Claim 5.14 has been extended by an extra index. However, this extra index can be placed either at the end of the short string (as in (5.80) and (5.82), a placement we will call \textbf{posterior}) or at the beginning of the short string (as in (5.81) and (5.83), a placement we will call \textbf{anterior}). So we conclude that every long string appears twice in the sum of four integrals: once in (5.80) or (5.82) and once in (5.81) or (5.83). For example, (5.69)/(5.70) are the posterior/anterior situations when $k = 0$.

\begin{itemize}
  \item For the integrals corresponding to \textbf{anterior} placement, namely the residues at (5.81) and (5.83), we move the $s$ variable to the very left of the chain of variables, and the only pole we encounter is $w_{b+1} = \frac{s}{q}$. The value of the corresponding integral is exactly equal to the first line of (5.71) for $k$ replaced by $k + 1$, $s$ replaced by $\frac{s}{q}$, the short string replaced by the long string, and $b$ replaced by $b+1$.

  \item For the integrals corresponding to \textbf{posterior} placement, namely the residues at (5.80) and (5.82), we move the $s$ variable to the very right, and the only poles we encounter are $w_{b-k-1} = sq^{k+1}$, as well as $s = 0$ and $\infty$.

  \begin{itemize}
    \item The value of the corresponding residue at the pole $s = w_{b-k-1}q^{-k-1}$ is exactly equal to the second line of (5.71) for $k$ replaced by $k + 1$ and the short string replaced by the long string.
    \item The value of the corresponding residue at $s \in \{0, \infty\}$ is a nice summand. This is proved similarly to the case $k = 1$ in the third bullet preceding Claim 5.14.
  \end{itemize}
\end{itemize}

6. \textbf{The $A_r$-action}

6.1. The dg scheme $\mathcal{Z}_r^\bullet$ of Definition 4.16 has the following very interesting intersection theoretic property, which will later be recognized as the reason why the higher $W$-algebra currents vanish for the moduli space of stable sheaves on $S$. 

\hfill \Box
Lemma 6.2. Consider the following diagram:

\[(6.1)\]

\[
\begin{array}{ccc}
\mathcal{Z}_1 \times \mathcal{Z}_1' & \xrightarrow{\delta} & \mathcal{Z}_1 \\
\varepsilon & & \\
\end{array}
\]

with maps given in terms of closed points by:

\[(6.2)\]

\[
\begin{array}{ccc}
(F_1 \subset \mathcal{F} \subset \tilde{\mathcal{F}}) \times (F_2 \subset \mathcal{F} \subset \tilde{\mathcal{F}}) & \xrightarrow{\varepsilon} & \{F_1 = F_2\} \\
\end{array}
\]

Note that \(\mathcal{Z}_1 = \mathcal{Z}_1'\) are denoted differently in (6.1) to emphasize the fact that the former has \(\mathcal{F}\) as the bigger sheaf, while the latter has \(\mathcal{F}\) as the smaller sheaf:

\[
\mathcal{Z}_1 = \{\mathcal{F}' \subset \mathcal{F}\} \quad \text{and} \quad \mathcal{Z}_1' = \{\mathcal{F} \subset \tilde{\mathcal{F}}\}
\]

Consider the line bundles \(L, L_1, L_2, \tilde{L}\) on the spaces in (6.1) whose fibers over the closed points (6.2) are given by the one-dimensional quotients:

\[
L_1 = \mathcal{F}/\mathcal{F}_1, \quad L_2 = \mathcal{F}/\mathcal{F}_2, \quad \tilde{L} = \tilde{\mathcal{F}}/\mathcal{F}_x \quad \text{and} \quad \mathcal{L} = \delta^*(L_1) = \delta^*(L_2)
\]

Consider also the universal sheaf \(U\) that parametrizes sheaves denoted \(\mathcal{F}\) in the diagram above. Then we have the following equality in the \(K\)-theory of \(\mathcal{Z}_1 \times \mathcal{Z}_1\):

\[(6.3)\]

\[
\delta_* [L^k] - \varepsilon_* [\tilde{L}^{k-r}] (-1)^r q^{k-r} (\det U) = \int_{\infty}^{-\infty} \left( \frac{z^k}{1 - \frac{z}{\xi_1}} \right) \left( \frac{1 - \frac{z}{\xi_2}}{1 - \frac{z}{\xi_2}} \right)
\]

for all \(k \in \mathbb{Z}\). Recall that the notation \(\int_{\infty}^{-\infty}\) was introduced in (5.36).

6.3. Before proving Lemma 6.2, we need to set up certain concepts and notation from homological algebra. Given a space \(X\) (which for us will be a dg scheme supported over a Noetherian scheme) with structure sheaf \(\mathcal{O}\), and a locally free sheaf \(\mathcal{E}\) endowed with a co-section \(s: \mathcal{E} \to \mathcal{O}\), one may define the Koszul complex:

\[
\Lambda^\bullet (\mathcal{E}, s) = \left[ \cdots \xrightarrow{d_{-2}} \Lambda^2 \mathcal{E} \xrightarrow{d_{-1}} \mathcal{E} \xrightarrow{d_0} \mathcal{O} \right]
\]

where we define:

\[(6.4)\]

\[
\Lambda^k \mathcal{E} \xrightarrow{d_k} \Lambda^{k-1} \mathcal{E}
\]

\[
e_1 \wedge \cdots \wedge e_k \sim \sum_{i=1}^{k} (-1)^{i-1} s(e_i) \cdot e_1 \wedge \cdots \wedge \hat{e}_i \wedge \cdots \wedge e_k
\]

The Koszul complex is a dg algebra, which can be best seen by packaging it as:

\[(6.5)\]

\[
\Lambda^\bullet (\mathcal{E}, s) = \bigoplus_{a=0}^{\infty} \Lambda^a \mathcal{E}[-a], d_s
\]

where the differential \(d_s\) is the direct sum of the maps (6.4), and the grading is marked by the number inside the square brackets (so an element \(v \in \Lambda^a \mathcal{E}\) has...
degree $|v| = -a)$. The multiplication in the dg algebra \((6.4)\) is given by wedge product, and it is commutative (in the dg sense) since:

$$v \wedge w = (-1)^{|v||w|} w \wedge v$$

More generally, if $\iota : E' \to E$ is a map of locally free sheaves on the space $X$ such that $s \circ \iota = 0$, then we consider the commutative dg algebra:

\begin{equation}
\wedge^\bullet \left( E' \xrightarrow{\iota} E, s \right) = \left( \bigoplus_{a, b = 0} \bigoplus_{a, b = 0} S^a E' \otimes \wedge^b E \right)
\end{equation}

where the differential is given by summing up the maps:

\begin{equation}
\delta_a E' \otimes \wedge^b E \xrightarrow{\delta_a} \bigoplus_{a, b = 0} S^{a-1} E' \otimes \wedge^{b+1} E
\end{equation}

with the maps $d_a : S^a E' \otimes \wedge^b E \to S^a E' \otimes \wedge^{b-1} E$ given by the same formula as \((6.4)\).

**Proposition 6.4.** Consider a map of locally free sheaves $\iota : E' \to E$ and a cosection $s : E \to O$ on a space $X$, and let $s' = s \circ \iota : E' \to O$. The natural map of dg algebras:

$$O_{Z'} := \wedge^\bullet (E', s') \to \wedge^\bullet (E, s) =: O_{Z}$$

induced by $\iota$ gives rise to a map of dg schemes $Z \to Z'$. Moreover, we have:

\begin{equation}
O_Z q_{Z.} \cong \wedge^\bullet_{Z'} \left( E'|_{Z}, \iota \right) \to E|_{Z'}, s) \right)
\end{equation}

as dg modules over $O_{Z'}$.

**Proof.** Note that in order for \((6.6)\) to be complex, one needs the composition of $s$ and $\iota$ to vanish. In the case at hand, this does not hold over $X$ by assumption, but it does hold over the dg scheme $Z'$ on account of the latter being the derived zero locus of the cosection $s' = s \circ \iota$. Explicitly, for all $a \geq 0$, the map:

$$S^a E' \xrightarrow{\gamma} S^{a-1} E'$$

$$e_1' \ldots e_a' \mapsto \sum_{i=1}^a s'(e_i') \cdot e_1' \ldots \hat{e_i'} \ldots e_a'$$

is null-homotopic over the dg scheme $Z'$. To see this, we observe that “restricting” to the dg scheme $Z'$ is the same thing as tensoring with the Koszul complex $\wedge^\bullet (E', s')$, and therefore the induced map:

$$S^a E' \otimes \wedge^\bullet (E', s') \xrightarrow{\gamma \otimes \text{Id} \ldots \text{Id}} S^{a-1} E' \otimes \wedge^\bullet (E', s')$$

has the property that $\gamma \otimes \text{Id} \ldots \text{Id} (e_i, s') = [h, d_v]$, where the homotopy is:

$$S^a E' \otimes \wedge^\bullet E' \xrightarrow{\delta_a} \bigoplus_{a, b = 0} S^{a-1} E' \otimes \wedge^{b+1} E'$$

$$e_1' \ldots e_a' \otimes e_1 \ldots \wedge e_c \mapsto \sum_{i=1}^a e_1' \ldots \hat{e_i'} \ldots e_a' \otimes e_i \wedge e_1 \ldots \wedge e_c$$
Therefore, the right-hand side of (6.8) can be presented as a complex over $X$ as:

$$(6.9) \left( \bigoplus_{a,b,c=0}^{\infty} S^a \mathcal{E}'[-2a] \otimes \wedge^b \mathcal{E}[-b] \otimes \wedge^c \mathcal{E}'[-c], d_i + d_s + d_{s'} - (-1)^c h \right)$$

(the fact that this is a chain complex is a consequence of the equality $(d_i + d_s)^2 = \gamma \otimes \text{Id}_{\wedge^*(\mathcal{E}'_s, s')} \otimes \text{Id}_{\wedge^*(\mathcal{E}, s)} = [h, d_s] \otimes \text{Id}_{\wedge^*(\mathcal{E}, s)},$ which is straightforward). However, the complex above can be filtered according to $n = a + c,$ with associated graded:

$$\bigoplus_{n=0}^{\infty} \left( \bigoplus_{a=0}^{n} S^a \mathcal{E}'[-a] \otimes \wedge^{n-a} \mathcal{E}', h \right) [-n] \otimes \wedge^*(\mathcal{E}, s)$$

It is well-known that the underlined complex is acyclic unless $n = 0,$ so therefore (6.9) is quasi-isomorphic to $\wedge^*(\mathcal{E}, s) = O_Z.$ Hence (6.8) holds in the derived category of coherent sheaves on $X.$ However, it also holds in the derived category of coherent sheaves on $Z'$ because all complexes involved (including (6.9)) are dg algebras which receive a natural map from $O_{Z'} = \wedge^*(\mathcal{E}', s').$

□

6.5. We will now use Proposition 6.4 to prove Lemma 6.2. To keep the notation easily legible, throughout the proof below we will use the notation $\times$ (with no further subscript) for derived fiber product over the scheme $M \times S,$ where $M$ parametrizes the sheaves denoted by $F$ in the statement of Lemma 6.2. Similarly, we will write $P(\mathcal{E})$ for the projectivization of the locally free sheaf $\mathcal{E}$ on $M \times S.$

Proof. of Lemma 6.2: We will compute $\delta_*(\mathcal{L}^k)$ and $\varepsilon_*(\mathcal{L}^k)$ as complexes in:

$$D^- (\text{Coh} (Z_1 \times Z_1))$$

and we will show that the complexes are identical, except for finitely many terms at the right of the complex. These terms will be expressed in terms of $U, L_1, L_2$ and their powers, and the resulting expression will be shown to match the right-hand side of (6.3), thus concluding the proof of the Lemma. We recall that $U = V/W$ where $W \hookrightarrow V$ are vector bundles on $M \times S,$ which leads to the presentation (4.9) of the map of dg schemes $Z_1 \to M \times S,$ $(F' \subset F) \mapsto (F, x)$:

$$(6.10) \quad Z_1 \hookrightarrow P(V)$$

where the embedding is the derived zero locus of the co-section:

$$W \otimes O(-1) \to V \otimes O(-1) \to O$$

(we write $O(1)$ for the tautological line bundle on the projectivization in (6.10), and abuse notation by writing $V, W$ for the aforementioned vector bundles on $M \times S,$ as well as their pull-backs to the projectivization). With this in mind, let us consider the following diagram of derived fiber products:

$$(6.11) \quad Z_1 \xrightarrow{\delta} Z_1 \times Z_1 \xrightarrow{p} P(V) \times Z_1$$
By definition, the embedding $q$ is cut out by the composition $W \otimes \mathcal{O}_1(-1) \to V \otimes \mathcal{O}_1(-1) \to \mathcal{O}$ (where we use the notation $\mathcal{O}_1(1)$ and $\mathcal{O}_2(1)$ to denote the tautological line bundles on the first and second factors in the fiber products (6.11), respectively). Meanwhile, because $p$ is obtained from the diagonal embedding:

$$P(V) \hookrightarrow P(V) \times P(V)$$

by derived base change, then Beilinson’s resolution implies that the embedding $p$ is cut out by the composition $\sigma: N_2 \otimes \mathcal{O}_1(-1) \to V \otimes \mathcal{O}_1(-1) \to \mathcal{O}$, where:

$$N_1 = \text{Ker } \nu \mapsto \mathcal{O}_1(1)$$

$$N_2 = \text{Ker } \nu \mapsto \mathcal{O}_2(1)$$

We may then invoke Proposition 6.4 to conclude that the embedding $\delta$ is cut out by the induced map of complexes $[W \otimes \mathcal{O}_1(-1) \to N_2 \otimes \mathcal{O}_1(-1)] \to \mathcal{O}$, i.e.:

$$\delta \cong \bigoplus_{a,b=0}^\infty S^a W \otimes \land^b N_2 \otimes L^{-1}_{-a-b} \nu_{\delta} + d_{\sigma}$$

where $d_{\sigma}$ and $d_{\nu}$ are the differentials (6.4) and (6.7) associated to the maps $\sigma: N_2 \otimes L^{-1}_{-1} \to \mathcal{O}$ and $\nu: W \to N_2 = \text{Ker } \nu \mapsto \mathcal{O}_2(1)$. Since $L = \delta^*(L_1) = \delta^*(L_2)$:

$$\delta^*(L) = \bigoplus_{a,b=0}^\infty S^a W \otimes \land^b N_2 \otimes L^{-1}_{-a-b} \nu_{\delta} + d_{\sigma}$$

(6.12)

Formula (6.12) gives the first summand in the left-hand side of (6.3), and now we must obtain a similar expression for the second summand. We have the diagram:

$$\begin{array}{ccc}
Z_1 \times Z_1 & \xrightarrow{\gamma} & P_3 \times (W^* \otimes \omega_S) \\
\downarrow \rho & & \downarrow \pi \\
\rho \downarrow \nu & & \delta \downarrow \\
\mathbf{P}(V) \times \mathbf{P}(V) \times \mathbf{P}(W^* \otimes \omega_S)
\end{array}$$

By Definition 4.16 the closed embedding $Z_1 \hookrightarrow \mathbf{P}(V) \times \mathbf{P}(W^* \otimes \omega_S)$ is cut out by:

$$\text{Coker } \left( \mathcal{O}_1(-1) \otimes \mathcal{O}_2(-1) \otimes \omega_S \to W \otimes \mathcal{O}_1(-1) \oplus V^* \otimes \mathcal{O}_2(-1) \otimes \omega_S \right) \to \mathcal{O}$$

where the arrows are the tautological maps on $\mathbf{P}(V)$ and $\mathbf{P}(W^* \otimes \omega_S)$. Since:

$$Z_1 \hookrightarrow \mathbf{P}(W^* \otimes \omega_S)$$
is cut out by the natural map $\mathcal{V}^\vee \otimes \mathcal{O}(-1) \otimes \omega_S \to \mathcal{O}$ on $\mathbb{P}(\mathcal{V}^\vee \otimes \omega_S)$ in virtue of (6.12), we conclude that the embedding \( \nu \) in diagram (6.13) is cut out by:

\[
(6.14) \quad \text{Coker } \begin{pmatrix}
\mathcal{O}_1(-1) \otimes \mathcal{O}(-1) \otimes \omega_S \\
\mathcal{O}_2(-1) \otimes \mathcal{O}(-1) \otimes \omega_S \\
\mathcal{V}^\vee \otimes \mathcal{O}(-1) \otimes \omega_S
\end{pmatrix}
\begin{array}{c}
\oplus \\
\oplus \\
\to
\end{array}
\begin{pmatrix}
W \otimes \mathcal{O}_1(-1) \\
W \otimes \mathcal{O}_2(-1) \\
\mathcal{V}^\vee \otimes \mathcal{O}(-1) \otimes \omega_S
\end{pmatrix}
\to \mathcal{O}
\]

on $\mathbb{P}(\mathcal{V}) \times \mathbb{P}(\mathcal{V}) \times \mathbb{P}(\mathcal{V}^\vee \otimes \omega_S)$, where \( \mathcal{O}_1(1), \mathcal{O}_2(1), \mathcal{O}(1) \) denote the tautological line bundles on the three projectivizations, and all arrows in (6.14) are the tautological maps. Similarly, according to Proposition 6.11, the closed embedding \( \rho \) in diagram (6.13) is cut out by the co-section:

\[
\begin{align*}
W \otimes \mathcal{O}_1(-1) & \oplus W \otimes \mathcal{O}_2(-1) \\
\to & \mathcal{O}
\end{align*}
\]

Combining this fact with (6.14) allows us to apply Proposition 6.4 to the setting of (6.13). We thus conclude that the closed embedding \( \eta \) has the property that:

\[
\mathcal{O}_\eta \cong \bigwedge \cdot (\mathcal{O}_1(-1) \otimes \mathcal{O}(-1) \otimes \omega_S \to \mathcal{V}^\vee \otimes \mathcal{O}(-1) \otimes \omega_S, \sigma')
\]

where the Koszul complex is computed on $\mathbb{P}_3(\mathcal{V}^\vee \otimes \omega_S)$. Since the kernel bundle of \( \mathcal{O}_2(-1) \to \mathcal{V}^\vee \) is the vector bundle \( \mathcal{N}_2' \), we may simplify the complex above to:

\[
\mathcal{O}_\eta \cong \bigwedge \cdot (\mathcal{O}_1(-1) \otimes \mathcal{O}(-1) \otimes \omega_S \to \mathcal{N}_2' \otimes \mathcal{O}(-1) \otimes \omega_S, \sigma')
\]

\[
= \bigoplus_{a,b=0}^{\infty} \bigwedge^b \mathcal{N}_2' \otimes \mathcal{O}(-a - b) \otimes \omega_S^{a+b}[-2a - b], d_{\sigma^\vee} + d_{\sigma'}
\]

where we recall the section \( \sigma : \mathcal{N}_2 \to \mathcal{O}_1(1) \). Recall that $\mathcal{O}_1(1)|_3 = \mathcal{L}_1$, hence:

\[
(6.15) \quad \varepsilon_*(\mathcal{L}_k) = \eta_* \circ \pi_*(\mathcal{O}(-k)) = \pi_*(\mathcal{O}(-k) \otimes \mathcal{O}_\eta) = \pi_* \left( \bigoplus_{a,b=0}^{\infty} \bigwedge^b \mathcal{N}_2' \otimes \mathcal{O}(-a - b - k) \otimes \mathcal{L}_1^{-a} \otimes \omega_S^{a+b}[-2a - b], d_{\sigma^\vee} + d_{\sigma'} \right)
\]

The push-forward \( \pi_* \) does not affect \( \mathcal{N}_2, \mathcal{L}_1 \) or \( \omega_S \), which are pulled back from the base $3_1 \times 3_1$, but it has the following well-known effect on powers of $\mathcal{O}(-1)$:

\[
(6.16) \quad \pi_*(\mathcal{O}(l)) = \begin{cases} 
S^l \mathcal{V}^\vee \otimes \omega_S^l & \text{if } l \geq 0 \\
S^{-l-w} \mathcal{V} \otimes \det \mathcal{V} \otimes \omega_S^l[w-1] & \text{if } l \leq -w \\
0 & \text{otherwise}
\end{cases}
\]

where $w = \text{rank } \mathcal{V}$. For simplicity, let us assume we are dealing with $k > 0$ in (6.15), so that we uniformly plug in the second formula in (6.16):

\[
\varepsilon_*(\mathcal{L}_k) = \bigoplus_{a,b=0}^{\infty} \bigwedge^b \mathcal{N}_2' \otimes S^{a+b+k-w} \mathcal{V} \otimes \mathcal{L}_1^{-a} \otimes \omega_S^{-k} \otimes \det \mathcal{V}[-2a - b + w - 1]
\]
(we will not write down the differential explicitly anymore, but note that it matches the one in the complex (6.12), because applying \( \pi_* \) to the tautological map \( \sigma' : \mathcal{N}_2^\vee \otimes \omega_S \to \mathcal{O}(1) \) yields precisely the map \( \iota \)). We may use the natural isomorphism
\[ \Lambda^k \mathcal{N}_2^\vee \cong (\det \mathcal{N}_2)^\vee \otimes \Lambda^{v-1-b} \mathcal{N}_2, \]
where \( v = \text{rank } \mathcal{V} = w + r \), to obtain the formula:
\[
\varepsilon_*(\tilde{L}^k) = \left( \bigoplus_{a,b=0}^\infty \Lambda^{v-1-b} \mathcal{N}_2 \otimes \mathcal{S}^{a+b+k-w} \mathcal{W} \otimes \mathcal{L}_1^{-a} \omega_S^{-k} \frac{\det \mathcal{W}}{\det \mathcal{N}_2} [-2a - b + w - 1] \right)
\]

Let us relabel indices \( a' = a + b + k - w \) and \( b' = v - 1 - b \), and thus:
\[
\varepsilon_*(\tilde{L}^k) = \left( \bigoplus_{0 \leq b' \leq v-1} \mathcal{S}^{a'} \mathcal{W} \otimes \Lambda^{b'} \mathcal{N}_2 \otimes \mathcal{L}_1^{k+r-1-a'-b'} \mathcal{L}_2 \omega_S^{-k} \frac{\det \mathcal{W}}{\det \mathcal{V}} [-2a' - b' + 2k + r - 2] \right)
\]

Once again relabeling \( k \sim k - r, a' \sim a, b' \sim b \) gives us:
\[
\varepsilon_*(\tilde{L}^{k-r}) = \left( \bigoplus_{0 \leq b \leq v-1} \mathcal{S}^{a+b} \mathcal{W} \otimes \Lambda^b \mathcal{N}_2 \otimes \mathcal{L}_1^{k-1-a-b} \mathcal{L}_2 \omega_S^{-k} \frac{\det \mathcal{W}}{\det \mathcal{U}} [-2a - b + 2k - r - 2] \right) \Rightarrow
\]

\[
\Rightarrow \varepsilon_*(\tilde{L}^{k-r}) \otimes (\det \mathcal{U}) \otimes \omega_S^{-k-r} [-2k + r + 2] =
\]

\[
\left( \bigoplus_{0 \leq b \leq v-1} \mathcal{S}^{a+b} \mathcal{W} \otimes \Lambda^b \mathcal{N}_2 \otimes \mathcal{L}_1^{k-1-a-b} \mathcal{L}_2 [-2a - b] \right)
\]

Comparing the right-hand side of the relation above with (6.12) implies that there is a map in \( D^- (\operatorname{Coh}(\mathcal{Z}_1 \times \mathcal{Z}_1)) \):
\[
\delta_*(\tilde{L}^k) \longrightarrow \varepsilon_*(\tilde{L}^{k-r}) \otimes (\det \mathcal{U}) \otimes \omega_S^{-k-r} [-2k + r + 2]
\]
whose cone is the finite complex:
\[
\left( \bigoplus_{0 \leq a+b \leq k-2} \mathcal{S}^{a+b} \mathcal{W} \otimes \Lambda^b \mathcal{N}_2 \otimes \mathcal{L}_1^{k-1-a-b} \mathcal{L}_2 [-2a - b], d_i + d_\sigma \right)
\]

The class of this complex in \( K^- \) theory is precisely the right-hand side of (6.13), as a consequence of \( [\mathcal{N}_2] = [\mathcal{V}] - [\mathcal{L}_2], \ [\mathcal{U}] = [\mathcal{V}] - [\mathcal{W}] \) and the additivity of \( \Lambda^* \).

\[ \square \]

6.6. Armed with Lemma 6.2 it is now time to prove Theorem 1.2. We assume Conjecture 5.1, namely the existence of an “action” (in the sense of Definition 5.2):
(6.17) \( \mathcal{A} \curvearrowleft K_M \) i.e. an assignment \( \mathcal{A} \to \operatorname{Hom}(K_M, K_{M \times S}) \)
which sends:

\[
E_{d_\bullet} \in \mathcal{A}^r \subset \mathcal{A} \quad \text{to the operator } \quad e_{d_\bullet} \text{ of (5.17)}
\]
\[
F_{d_\bullet} \in \mathcal{A}^r \subset \mathcal{A} \quad \text{to the operator } \quad f_{d_\bullet} \text{ of (5.18)}
\]

for all \( d_\bullet = (d_1, \ldots, d_k) \). Moreover, we recall that \( K_M \) is a good module of \( \mathcal{A} \), since the grading on \( K_M \) by second Chern class is bounded below in virtue of the Bogomolov inequality. This implies that \( f_{(d_1, \ldots, d_k)} \) annihilates any given element of \( K_M \) if \( k \) is large enough, hence the conjectural action (6.17) induces an action of:
\[
\hat{\mathcal{A}}^r \curvearrowleft K_M \quad \text{and hence an action } \quad \mathcal{A}_\infty \curvearrowleft K_M
\]
(by the definition of $A_\infty$ in (3.37), there exists a homomorphism $A_\infty \to \tilde{A}$). The extended algebra $A_{\text{ext}}^\text{diag}$ of (3.12) also acts on $K_\mathcal{M}$ by the same reasons.

6.7. It would be rather difficult to prove that relations (3.45) and (3.46) hold in $K$ based on the definition (3.27) of the generating currents of the deformed W-algebra, so we appeal to a different formula that was worked out in (3.20) of [24]:

$$W_{d,k} = \sum_{k_0+k_1+k_2=k}^{d_2-d_1=d} T_{d_1,k_1}^r E_{0,k_0} T_{d_2,k_2}^r \cdot q^{(k-1)d_2}$$

where $k_1, k_2$ go over the natural numbers, and $k_0, d_1, d_2$ go over the non-negative integers. The elements $E_{0,k_0}$ in (6.18) are simply the standard generators of $A_{\text{diag}} \subset A$ (see Proposition 3.3), while:

$$T_{n,k}^+ \in A^+ \cong \mathcal{S} \quad \text{and} \quad T_{n,k}^- \in A^- \cong S^\text{op}$$

correspond to the following elements of the shuffle algebra:

$$T_{n,k}(z_1, \ldots, z_n) = \text{Sym} \left[ \frac{(-1)^{k-1} z_n^k}{\prod_{i=1}^{n-1} (1 - \frac{z_i + iz_{i+1}}{z_i})} \prod_{1 \leq i < j \leq n} \zeta \left( \frac{z_i}{z_j} \right) \right]$$

Formula (6.18) was derived in [24] by showing that $T_{n,k}^+$ and $T_{n,k}^-$ are equal to the sums of $E_{n,k_1} \ldots E_{n,k_i}$, as in (3.27), but the sums only run over $n_i < 0$ and $n_i > 0$, respectively. By Conjecture 6.1 the shuffle element:

$$T_{n,k}^+ \text{ acts on } K \text{ as } (-1)^{n+k-1} (p_+ \times p_\mathcal{S}) \cdot \left( \mathcal{L}_n^k \cdot p_+^* \right) \quad \text{and}$$

$$T_{n,k}^- \text{ acts on } K \text{ as } (-1)^{n+k-1} (\det \mathcal{U})^{\otimes n} (p_- \times p_\mathcal{S}) \cdot \left( \frac{\mathcal{L}_n^k}{Q} \cdot p_-^* \right)$$

where $Q = \mathcal{L}_1 \ldots \mathcal{L}_n$ and the maps $p_+, p_-, p_\mathcal{S}$ are as in diagram (5.14).

6.8. Finally, recall that $E_{0,k}$ acts on $K_\mathcal{M}$ as multiplication by the coefficient of $z^{-k}$ in $\wedge^* (\mathcal{U}/z)$. Therefore, (6.18) implies that $W_{d,k} : K_\mathcal{M} \to K_\mathcal{M} \times S$ is given by:

$$\sum_{k_0+k_1+k_2=k}^{d_2-d_1=d} q^{(k-r)d_2} (\pi_1 \times \pi_\mathcal{S}) \left[ (-1)^{k_1-1} \mathcal{L}_1^{k_1} \cdot \wedge_0 (\tilde{\mathcal{U}}) \cdot (-1)^{r_{d_2}+k_2-1} (\det \tilde{\mathcal{U}})^{d_2} \mathcal{L}_2^{k_2} \pi_2^* \right]$$

where $k_1, k_2 \in \mathbb{N}$, $k_0, d_1, d_2 \in \mathbb{N} \cup \{0\}$, and the maps are given by:

$$\mathfrak{B}_{d_1,d_2} := \{ F_1 \subset_x \ldots \subset_x F \subset_x \bar{F} \supset_x F' \supset_x \ldots \supset_x F_2 \}$$

Here, $\mathcal{L}_1, \mathcal{L}_2$ parametrize the length 1 sheaves $\bar{F}_x/F_x$ and $\bar{F}_x/F'_x$, respectively, and $Q$ is the determinant of the rank $d_2$ vector bundle $\bar{F}_x/F_{2x}$. The number of inclusion signs $\subset_x, \supset_x$ in (6.23) is $d_1, d_2$, respectively, and the dg scheme structure is:

$$\mathfrak{B}_{d_1,d_2} = \mathfrak{B}_{d_1-1} \times \mathfrak{B}_\mathcal{M} \times \mathfrak{B}_\mathcal{S} \times \mathfrak{B}_{d_2-1}$$
where \( \hat{M} \) is the moduli space that parametrizes the sheaves denoted by \( \tilde{F} \) in (6.23). Note that we may rewrite (6.22) as a residue, namely:

\[
W_{d,k} = (-1)^k \sum_{d_2 - d_1 = d} q^{(k-r)d_2} (\pi_1 \times \pi_S)_* \left[ z^k \, dz \wedge ^* \left( \frac{\tilde{U}}{z} \right) \frac{(-1)^r d_2 (\det \tilde{U})^{d_2}}{Q^r} \cdot \pi_2^* \right]
\]

Theorem 1.2 reduces to the following, which we prove regardless of Conjecture 1.1.

**Theorem 6.9.** The RHS of (6.24) vanishes if \( k > r \), while for \( k = r \) it equals:

\[
\sum_{d_1 - d_2 = d} (\pi_1 \times \pi_S)_* \left[ \frac{(-1)^r d_2 (\det \tilde{U})^{d_2}}{Q^r} \cdot \det \tilde{U} \cdot \pi_2^* \right]
\]

We observe that the operator (6.25) precisely matches the action on \( K_{M} \) of:

\[
u_{d_1, d_2} \geq 0 \sum_{d_2 - d_1 = d} h_{-d_1} h_{d_2} \in A
\]

where \( u = \det \tilde{U} \), and \( h_{\pm k} \) are to the elements \( p_{\pm k} \) of (3.38) as complete symmetric polynomials are to power-sum functions. Indeed, as shown in [24], the elements:

\[
h_{-k} = H_{-k, 0} \in A^- \quad \text{and} \quad h_k = q^{(k-1)r} H_{k, 0} \in A^+
\]

 correspond to setting \( d_1 = \ldots = d_k = 0 \) in (5.17) and (5.18), respectively (the fact that this statement also holds in the module \( K_{M} \) requires assuming Conjecture 1.1).

**Proof. of Theorem 6.9.** We claim that both cases \( k > r \) and \( k = r \) boil down to:

\[
0 = \sum_{d_2 - d_1 = d} q^{(k-r)d_2} (\pi_1 \times \pi_S)_* \left[ \frac{(-1)^r d_2 (\det \tilde{U})^{d_2}}{Q^r} \int_{-\infty}^0 \frac{z^k \, dz \wedge ^* \left( \frac{\tilde{U}}{z} \right) \cdot \pi_2^*}{\left( 1 - \frac{z}{z_1} \right) \left( 1 - \frac{z}{z_2} \right)} \right]
\]

for all \( k \geq r \). This is a consequence of the fact that the integrand in the right-hand side of (6.26) is \( z^{k-r} \) times a rational function which is regular at 0. The value of this rational function at \( z = 0 \) is equal to the right-hand side of (6.25).

Therefore, the task has become to prove (6.26). Let us consider the space \( \mathcal{M}_{d_1, d_2} \) which parametrizes flags:

\[
\tilde{F} \to x
\]

\[
\mathcal{F}_1 \subset \ldots \subset x \mathcal{F}_1 \subset_x \mathcal{F} \supset x \mathcal{F}_2 \supset \ldots \supset x \mathcal{F}_2'
\]

where the total number of inclusions in the horizontal row is \( d_1 \) and \( d_2 \), respectively. As a dg scheme, \( \mathcal{M}_{d_1, d_2} \) is defined as the derived fiber product:
where the vertical maps remember \( \{ F_1, F_2 \subset_x F \subset_x \tilde{F} \} \) and \( \{ F_1, F_2 \subset_x \tilde{F} \} \), respectively, and the horizontal maps forget \( \tilde{F} \). We also have a derived fiber square:

\[
\begin{array}{ccc}
\mathcal{M}_{d_1, d_2} & \xrightarrow{b^{(d_1, d_2)}} & \mathcal{M}_{d_1, d_2} \\
\downarrow & & \downarrow \\
\mathcal{M}_{d_1-1, d_2-1} & \xrightarrow{\delta} & \mathcal{M}_{d_1, d_2}
\end{array}
\]

where the vertical projection maps remember \( \{ F \subset_x \tilde{F} \} \) and \( \{ F \subset_x \tilde{F} \supset_x F' \} \), respectively. Because both squares are Cartesian, we may invoke Lemma 6.2

\[
b^{(d_1, d_2)} \left[ \mathcal{L}^k \right] - a^{(d_1, d_2)} \left( \mathcal{L}^{k-r} \right) (-1)^r q^{k-r} \det U = \int_{\infty-0} \frac{z^k \wedge^r \left( \frac{U}{z} \right)}{\left( 1 - \frac{z}{d_1} \right) \left( 1 - \frac{z}{d_2} \right)}
\]

where \( \tilde{L} \) parametrizes the one-dimensional vector space \( \tilde{F}_x/F_x \). As we sum the formula above over all non-negative integers \( d_1, d_2 \) such that \( d_2 - d_1 = d \), we obtain:

\[
\sum_{d_2-d_1=d} (\pi_1 \times \pi_S)_* \left[ \left( -1 \right)^r q^{(k-r)d_2} (-1)^{d_1-1} \left( \frac{det U}{Q^r} \right) \right] \cdot \pi_2^* -
\]

\[
\sum_{d_2-d_1=d} (\pi_1 \times \pi_S)_* \left[ \left( -1 \right)^r (d_2+1) q^{(k-r)(d_2+1)} \left( \frac{det \tilde{U}}{Q} \right) \right] \cdot \pi_2^* =
\]

\[
\sum_{d_2-d_1=d} (\pi_1 \times \pi_S)_* \left[ q^{(k-r)d_2-1} \left( \frac{det \tilde{U}}{Q^r} \right) \int_{\infty-0} \frac{z^k \wedge^r \left( \frac{U}{z} \right)}{\left( 1 - \frac{z}{d_1} \right) \left( 1 - \frac{z}{d_2} \right)} \cdot \pi_2^* \right]
\]

The equality above uses the identity \( Q_{d_2-1} \tilde{L} = Q_{d_2} \), where we write \( Q_d \) for the line bundle parametrizing \( \tilde{F}_x/F_{2,x}^{*} \) in the diagram (6.27) with \( d_2 \) symbols \( \supset_x \).

Moreover, in (6.28) we used the equality of line bundles \( \det U = \det \tilde{U} \), which holds because the determinants of all possible universal bundles on the correspondences \( 3_1 \) and \( 3_2^* \) are canonically isomorphic. The LHS of (6.28) vanishes because the first term for a pair \((d_1, d_2)\) precisely cancels out the second term for \((d_1 - 1, d_2 - 1)\). Therefore, the RHS of (6.28) also vanishes, thus establishing (6.20).
