August 10, 2018

Abstract

This paper is focused on the double-grid integration with interpolation-projection (DoGIP), which is a novel discretisation approach of variational formulations. The method, introduced for Fourier-Galerkin method, is described here as a more general method and its application to the finite element method (FEM) on simplexes is investigated. The approach is based on treating the trial and a test functions in variational formulation together, which leads to the decomposition of a linear system into interpolation and (block) diagonal matrices. It usually leads to reduced memory demands, especially for higher-order basis functions, but with higher computational requirements. The numerical examples are studied here for two variational formulations: weighted projection and scalar elliptic problem modelling e.g. diffusion or stationary heat transfer. This paper also open a room for further investigations and applications, which is discussed in conclusion.

Keywords: discretisation; finite element method; computational requirements; interpolation; projection

1 Introduction

The numerical solution of a non-linear partial differential equations, after discretisation and linearisation, leads to the solution of linear systems. Often, they require excessive memory demands, especially when the system matrices are fully populated and no special structure is incorporated. In this paper, an alternative, matrix-decomposition approach, based on a double-grid integration with interpolation-projection operator (DoGIP) is described. This method, already used for numerical homogenisation with Fourier-Galerkin method [16, 15], belongs to more general framework with possible applicability to discretisation of variational problems with various approximation spaces. Here, the focus is aimed at the finite element method (FEM) on simplexes (triangles or tetrahedra).
**Introduction of the DoGIP idea**  As a model problem, an abstract variational setting discretised with Galerkin approximation is assumed: find trial function \( u \) from some finite dimensional vector space \( \mathcal{V} \) such that

\[
a(u, v) = F(v) \quad \forall v \in \mathcal{V}.
\]

This problem, which naturally arise in many engineering applications, is defined via a positive definite continuous bilinear form \( a : \mathcal{V} \times \mathcal{V} \to \mathbb{R} \) and linear functional \( F : \mathcal{V} \to \mathbb{R} \) representing a source term. The solution, which is expressed as a linear combination of basis functions \( u(x) = \sum_{i=1}^{V} u_i \phi_i(x) \) with \( V = \text{dim} \mathcal{V} \), is determined by the vector of coefficients \( u = (u_i)_{i=1}^{V} \) that can be calculated from a corresponding linear system

\[
Au = b, \quad \text{where } A = (a(\phi_j, \phi_i))_{i,j=1}^{V} \in \mathbb{R}^{V \times V} \text{ and } b = (F(\phi_i))_{i=1}^{V} \in \mathbb{R}^{V}.
\]

The properties of the matrix \( A \) are fundamental for the decision about a linear solver and consequently for computational and memory requirements. The FEM builds on the basis functions with a local support which result in a sparse matrix.

The idea in the DoGIP approach, first used for Fourier-Galerkin method \[19, 16\], is based on expressing the trial and test function as a product on a double-grid space, the space with doubled order of the polynomial basis functions in case of Fourier-Galerkin or FEM. It leads to a decomposed linear system

\[
A = C^*A_{\text{DoGIP}}B, \quad \text{where } A_{\text{DoGIP}} \in \mathbb{R}^{W \times W}, B, C \in \mathbb{R}^{W \times V} \text{ with } W > V.
\]

Here, the diagonal (or block-diagonal) matrix \( A_{\text{DoGIP}} \) expresses the weights obtained by integration of material-like coefficients with respect to a basis of a double-grid space. Despite its bigger size \( W > V \), the memory requirements to store \( A_{\text{DoGIP}} \) are typically reduced compared to the original matrix \( A \); the matrix-free variant avoiding assembling matrix \( A \) is usually unsuitable because of high number of integration points for general material coefficients; moreover their evaluation can be also computationally demanding for complex material laws.

Matrices \( B, C \) that can equal one another represents interpolation-projection operators from the original to the double-grid space and depend on the approximation spaces only. Those matrices are not stored because the required matrix-vector multiplication can be substituted with an efficient numerical routine. Particularly, the interpolation-projection matrix in Fourier-Galerkin method is evaluated very efficiently with fast Fourier transform in \( \mathcal{O}(N \log N) \) operations \[16, 15\]. In case of FEM, only the interpolation on reference element is needed.

**Applicability of the DoGIP.**  This paper shows that DoGIP is a promising approach with various applications. The method benefits from the fact that only the matrix \( A_{\text{DoGIP}} \) is stored, which can significantly reduce memory requirements especially for higher order basis functions, and that the interpolation-projection matrix \( B \) is independent of material coefficients or mesh distortion, which allows optimisation for fast matrix-vector multiplication.

There method is suitable for discretisation methods with higher order polynomial approximations (\( p \)-version of FEM, spectral methods \[4, 5\], finite cell method \[6\], etc.). Special benefits can be obtained for variational problems when the system matrix has to be solved many times such us in numerical homogenisation \[18\] in multiscale problems \[8, 10\], optimisation \[13\], uncertainty quantification \[7, 11, 12\], inverse problems \[14, 17\], non-linear or time-dependent problems \[2\].
Outline of the paper  In the section 2 the methodology of DoGIP is described for two problems: a weighted projection and a scalar elliptic problem modelling diffusion, stationary heat transfer, etc. Then in section 3 the numerical results are presented.

Notation  In the following text, \( L^2(\Omega) \) denotes the space of square Lebesgue-integrable functions \( f : \Omega \to \mathbb{R} \), where a computational domain \( \Omega \) is a bounded open set in \( \mathbb{R}^d \)-dimensional field (assuming \( d = 2 \) or \( 3 \)). The vector-valued and matrix-valued variants of \( L^2(\Omega) \) are denoted as \( L^2(\Omega; \mathbb{R}^d) \) and \( L^2(\Omega; \mathbb{R}^{d \times d}) \). A Sobolev space \( H^1(\Omega) \) is a subspace of \( L^2(\Omega; \mathbb{R}^d) \) with gradients in \( L^2(\Omega; \mathbb{R}^d) \). Vector and matrix-valued functions are denoted in bold with lower-case \( \mathbf{u} \) and upper-case letters \( A \). The vectors and matrices storing the coefficients of the discretised vectors are depicted with an upright font \( \mathbf{u} \), \( A \).

For vectors \( \mathbf{u}, \mathbf{v} \in \mathbb{R}^d \) and matrices \( A, B \in \mathbb{R}^{d \times d} \), we define inner product for vectors \( \mathbf{u} \cdot \mathbf{v} \in \mathbb{R} \) and matrices \( A : B \in \mathbb{R} \), and outer product of two vectors \( \mathbf{u} \otimes \mathbf{v} \in \mathbb{R}^{d \times d} \) as

\[
\mathbf{u} \cdot \mathbf{v} = u_i v_i, \quad A : B = A_{ij} B_{ij}, \quad \mathbf{u} \otimes \mathbf{v} = (u_i v_j)_{i,j=1}^d.
\]

2  DoGIP within finite element method

2.1  FEM on simplexes with Lagrange basis functions

The model problem is considered on a FEM mesh \( \mathcal{M}(\Omega) \) composed of simplexes (triangles or tetrahedra) with standard properties (non-overlapping elements, no hanging nodes, regular shapes). The vector \( \mathbf{N} \) denotes a discretisation parameter. The FEM spaces involves polynomials of order \( k \) (denoting the highest possible order)

\[
\mathcal{P}_k = \{ p : \mathbb{R}^d \to \mathbb{R} | p(\mathbf{x}) = \sum_{\alpha \in \mathbb{N}_0^d, \| \alpha \|_1 \leq k} a_\alpha x_1^{\alpha_1} x_2^{\alpha_2} \ldots x_d^{\alpha_d}, a_\alpha \in \mathbb{R} \}
\]

on each element. Depending on the trial and test spaces (e.g. \( H^1(\Omega) \), \( L^2(\Omega) \), etc.), the FEM spaces differ in the continuity requirement on the facets of the elements. Here, we take into account continuous and discontinuous finite element spaces

\[
\mathcal{C}_{N,k} = \{ v : \Omega \to \mathbb{R} | v|_T \in \mathcal{P}_k \ \forall T \in \mathcal{M}(\Omega) \text{ and } v \text{ is continuous} \},
\]

\[
\mathcal{D}_{N,k} = \{ v : \Omega \to \mathbb{R} | v|_T \in \mathcal{P}_k \ \forall T \in \mathcal{M}(\Omega) \}.
\]

Each approximation function \( v \in \mathcal{C}_{N,k} \) can be expressed as a linear combination

\[
v(\mathbf{x}) = \sum_{i=1}^{\dim \mathcal{C}_{N,k}} \mathbf{v}_i \phi^i(\mathbf{x})
\]

of the Lagrange basis functions (shape functions) \( \phi^i : \Omega \to \mathbb{R} \). The coefficients \( \mathbf{v}_i \), as the degrees of freedom, are the function values at the nodal points \( \mathbf{x}^i_{C_{N,k}} \), i.e. \( \mathbf{v}_i = v(\mathbf{x}^i_{C_{N,k}}) \). Those points are suitable for the interpolation of functions, thanks to the Dirac delta property of basis functions

\[
\phi^i(\mathbf{x}^j_{C_{N,k}}) = \delta_{ij}.
\]

A technical problem arises in the case of discontinuous approximation space \( \mathcal{D}_{N,k} \) because the function values have jumps at the boundary of the elements. Therefore, the
function values of \( v \in D_{N,k} \) at \( x^i_{D_{N,k}} \) are understood as a continuous prolongation from the element supporting the corresponding \( i \)-th basis function, i.e.

\[
v(x^i_{D_{N,k}}) = \lim_{x \to x^i_{D_{N,k}}} v(x) \quad \text{where } T_i \text{ is an element supporting } \phi^i.
\]

In the latter text, the function values at the nodal points will be used in the above sense.

**Reference element.** It is assumed that all of the elements \( T \) are derived from a reference element \( \hat{T} \) using affine mapping \( F_T(\hat{x}) : \hat{T} \to T \) defined as \( F_T(\hat{x}) = R_T \hat{x} + S_T \) with invertible matrices \( R_T \in \mathbb{R}^{d \times d} \) and vectors \( S_T \in \mathbb{R}^d \). Consistently the objects on a reference element are denoted with a hat. Global basis functions \( \phi_i : T \to \mathbb{R} \) of a FEM space \( V \) are derived from a reference shape functions \( \hat{\phi}_i : \hat{T} \to \mathbb{R} \) by a composition with a mapping \( F_T \), i.e. \( \phi_i(x) = \hat{\phi}_i(F_T^{-1}(x)) \) for \( x \in T \). The relation between local \( \hat{i} \) and global index \( i = l_T(\hat{i}) \) is given with an injective map

\[
l_T : \{1, \ldots, V_T\} \to \{1, \ldots, V\} \quad \text{where } V = \dim V \text{ and } V_T = \dim V|_T = \dim P_k.
\]

The derivative of basis functions are related with the formula obtained by a chain rule

\[
\frac{\partial \phi(x)}{\partial x_i} = \frac{\partial \hat{\phi}(F^{-1}(x))}{\partial \hat{x}_i} = \sum_{p=1}^{d} \frac{\partial \hat{\phi}(F^{-1}(x))}{\partial \hat{x}_p} (R_T^{-1})_{pi}.
\]

Later, we also use a discretisation operator \( \mathcal{D}_V : V \to \mathbb{R}^V \) that assigns to each approximation function from space \( V \) a corresponding vector of coefficients, i.e. \( \mathcal{D}_V[v] = \mathbf{v} = (v(x^i_V))_{i=1}^{V_T} \) with vectors denoted with upright sans-serif font. Note that it is a one-to-one mapping between the space of functions \( V \) and the space of coefficients \( \mathbb{R}^V \). Similarly we will also use the local degrees of freedom on an element \( T \) as \( \mathbf{v}_T = (v_{l_T(i)})_{i=1}^{V_T} \in \mathbb{R}^{V_T} \).

### 2.2 Weighted projection

Here, the DoGIP is introduced for a a problem of the weighted projection.

**Definition 1** (Weighted projection). Let \( \mathcal{V} \) be a finite dimensional approximation space, \( m : \Omega \to \mathbb{R} \) be an uniformly positive integrable function representing e.g. material coefficient, and \( f \in L^2(\Omega) \) be a function representing e.g. a source term. Then we define bilinear form \( a : \mathcal{V} \times \mathcal{V} \to \mathbb{R} \) and linear functional \( F : \mathcal{V} \to \mathbb{R} \) as

\[
a(u, v) = \int_{\Omega} m(x) u(x) v(x) \, dx, \quad F(v) = \int_{\Omega} f(x) v(x) \, dx.
\]

The weighted projection represents the problem: Find trial function \( u \in \mathcal{V} \) such that

\[
a(u, v) = F(v) \quad \forall v \in \mathcal{V}.
\]

In the standard approach, the solution of weighted projection \( u = \sum_{i=1}^{V} u_i \phi^i \) with \( V = \dim \mathcal{V} \) is expressed as a linear combination with respect to the basis of the space \( \mathcal{V} \).
Then, the vector of coefficients \( \mathbf{u} = (u_i)_{i=1}^V \) is determined from the following square linear system

\[
\mathbf{A}\mathbf{u} = \mathbf{b} \in \mathbb{R}^V \quad \text{where } A_{ij} = \int_\Omega m(x) \phi^i_W(x) \phi^j_W(x) \, dx, \quad (3a)
\]

\[
b_i = \int_\Omega f(x) \phi^i_W(x) \, dx. \quad (3b)
\]

Alternative DoGIP approach relies on the incorporation of the double grid space.

**Lemma 2** (Double-grid space). Let a functions \( u, v \) be from a space \( \mathcal{V} = \mathcal{C}_N,k \) and let \( \mathcal{W} = \mathcal{C}_N,2k \). Then

\[
u \in \mathcal{W}, \quad \text{and} \quad uv \in \mathcal{W}.
\]

**Proof.** The product \( uv \) of two FEM functions is a continuous function and the polynomial order on each element is doubled. \( \square \)

**Theorem 3** (DoGIP for weighted projection). Let \( \mathcal{V} = \mathcal{C}_N,k \) be an approximation space and \( \mathcal{W} = \mathcal{C}_N,2k \) be a double-grid space. Then the standard linear system matrix (3) can be decomposed into

\[
\mathbf{A} \mathbf{u} \cdot \mathbf{v} = \mathbf{B} \star \mathbf{A}_{\text{DoGIP}} \mathbf{Bu} \cdot \mathbf{v}
\]

with \( \mathbf{A}_{\text{DoGIP}} \in \mathbb{R}^{W \times W} \) and \( \mathbf{B} \in \mathbb{R}^{W \times V} \) where \( V = \dim \mathcal{V}, \quad W = \dim \mathcal{W} \), and the components of matrices are

\[
A_{ij}^{\text{DoGIP}} = \delta_{ij} \int_\Omega m(x) \phi^i_W(x), \quad B_{ij} = \phi^i_W(x^j_W).
\]

**Remark 4.** In the case of continuous FEM space \( \mathcal{V} = \mathcal{C}_N,k \), the double-grid space is of the same type but with the doubled polynomial order \( \mathcal{W} = \mathcal{C}_N,2k \).

**Proof.** Since both trial \( u \) and test function \( v \) belongs to the approximation space \( \mathcal{V} \), its product \( uv \) belongs to \( \mathcal{W} \) and can be represented with respect to the basis of \( \mathcal{W} \) as

\[
w(x) = u(x)v(x) = \sum_{i=1}^W u(x^i_W)v(x^i_W)\phi^i_W(x).
\]

The substitution of this formula into bilinear form (2) reveals an effective evaluation with respect to the basis of \( \mathcal{W} \)

\[
\int_\Omega m(x)u(x)v(x) \, dx = \sum_{j=1}^W u(x^j_W)v(x^j_W) \int_\Omega m(x) \phi^j_W(x) \, dx
\]

\[
= \sum_{i,j=1}^W \delta_{ij} \int_\Omega m(x) \phi^i_W(x) \, dx \, u^j_Wv^j_W = \left( A_{\text{DoGIP}} u^j_W, v^j_W \right)_{\mathbb{R}^M}
\]

where \( A_{\text{DoGIP}} \in \mathbb{R}^{W \times W} \) is a diagonal matrix and vectors \( \mathbf{u}_W = (u(x^i_W))_{i=1}^W \) and \( \mathbf{v}_W = (v(x^i_W))_{i=1}^W \) from \( \mathbb{R}^W \) stores the coefficients of functions \( u \) and \( v \) at DOFs of \( \mathcal{W} \).
Here one cannot arrive directly to linear system because the test vectors $v_W$ do not span the whole space $\mathbb{R}^W$. Therefore we express the coefficients $u_W$ and $v_W$ in terms of $u_k = u(x_k^i)$ and $v_k = v(x_k^i)$ for $k \in \{1, \ldots, V\}$.

The formula is based on the evaluation of the ansatz $u(x) = \sum_{j=1}^{V} u(x_j^i) \phi_W^j(x)$ at the DOFs of double-grid space $W$, which reveals the interpolation-projection matrix $B \in \mathbb{R}^{W \times V}$ as

$$u_W^i = u(x_W^i) = \sum_{j=1}^{V} u(x_j^i) \phi_W^j(x_W^i) = \sum_{j=1}^{V} B_{ij} u_j \quad \text{for } i = 1, \ldots, W.$$ 

The final formula in lemma is obtained by a substitution of interpolation-projection matrix $B$. \hfill \Box

A special version of DoGIP is obtained when the decomposition is provided on a level of elements.

**Theorem 5** (Element-wise DoGIP for weighted projection). Let $V = C_{N,k}$ be an approximation space and $W = D_{N,k}$ be a double-grid space. Then the quadratic form corresponding to the linear system matrix (6) can be decomposed as

$$Au \cdot v = \sum_{T \in \mathcal{M}} \hat{B}^s A_T^{\text{DoGIP}} \hat{B} u_T \cdot v_T = \sum_{T \in \mathcal{M}} \sum_{i,j=1}^{W_T} \sum_{k,l=1}^{V_T} A_{T,ij} \hat{B}_{jl} u_{T,k} \hat{B}_{ik} v_{T,l}$$

where $u_T = (u_T(i))_{i=1}^{V_T}$, $v_T = (v_T(k))_{k=1}^{V_T}$ stores the local DOFs on the element $T$. The arrays $A_T \in \mathbb{R}^{W_T \times W_T}$ and $\hat{B} \in \mathbb{R}^{W_T \times V_T}$ have the following components

$$A_{T,ij}^{\text{DoGIP}} = \delta_{ij} \int_{T} m(x) \phi_W^j(x) \, dx, \quad \hat{B}_{jl} = \phi_W^j(x_W^l).$$

**Proof.** The proof is analogical to the one of previous theorem. The main idea is to split the integral over domain $\Omega$ to integrals over elements, i.e.

$$\int_{\Omega} m(x) u(x) v(x) \, dx = \sum_{T \in \mathcal{M}} \sum_{i,j=1}^{W} \delta_{ij} \int_{T} m(x) \phi_W^j(x) \, dx \cdot u(x_W^i) v(x_W^i),$$

where the integrals are nonzero only when basis functions $\phi_W^j$ have support on $T$. Moreover, the interpolation

$$u(x_W^i) = \sum_{l=1}^{V} u(x_l^i) \phi_W^l(x_W^i) = \sum_{l=1}^{V} u_l \phi_W^l(F_T^{-1}(x_W^i)) = \sum_{l=1}^{V} u_l \phi_W^l(\hat{x_W^i}),$$

which is expressed with the reference basis, have nonzero coefficients only if $x_W^i$ is contained in the support of $\phi_W^j$. The substitution of the interpolation into (5) and reparametrisation of indices $i, j, k, l$ to local indices leads to the formulas stated in the theorem. \hfill \Box
2.3 Scalar elliptic equation

Here, the DoGIP is described for a scalar elliptic equation modelling e.g. diffusion or stationary heat transfer.

**Definition 6** (Scalar elliptic problem). Let $\mathcal{V}$ be a finite dimensional approximation space, $f \in L^2(\Omega)$ be a function representing e.g. a source term, and $M : \Omega \rightarrow \mathbb{R}^{d \times d}$ be an integrable, uniformly positive definite and bounded matrix function, i.e.

$$\exists c, C \in \mathbb{R} \text{ such that } 0 < c \leq \frac{M(x)y \cdot y}{\|y\|} \leq C \quad \forall x \in \Omega \text{ and } \forall y \in \mathbb{R}^d.$$  

Then we define bilinear form $a : \mathcal{V} \times \mathcal{V} \rightarrow \mathbb{R}$ and linear functional $F : \mathcal{V} \rightarrow \mathbb{R}$ as

$$a(u,v) = \int_{\Omega} M(x) \nabla u(x) \cdot \nabla v(x) \, dx, \quad F(v) = \int_{\Omega} f(x) v(x) \, dx.$$  

The Galerkin approximation of the scalar elliptic problem stand for: find trial function $u \in \mathcal{V}$ such that

$$a(u,v) = F(v) \quad \forall v \in \mathcal{V}.$$  

Analogically to the case in previous section, the standard approach is based on expression of the approximate solution $u = \sum_{i=1}^{V} u_i \phi_i$ with $V = \text{dim} \mathcal{V}$ as a linear combination with respect to the basis of the space $\mathcal{V}$. The vector of coefficients $u = (u_i)_{i=1}^{V}$ is determined from the following square linear system

$$A u = b \in \mathbb{R}^V,$$

where

$$A_{ij} = \int_{\Omega} M(x) \nabla \phi_i(x) \cdot \nabla \phi_j(x) \, dx, \quad b_i = \int_{\Omega} f(x) \phi_i(x) \, dx.$$  

The DoGIP version builds on incorporation of double-grid space.

**Lemma 7** (Double-grid space). Let a functions $u, v$ be from a space $\mathcal{V} = \mathcal{C}_{N,k}$ and let $W = D_{N,2k-2}$. Then

$$\frac{\partial u}{\partial x_p} \in W, \quad \frac{\partial v}{\partial x_p} \in W \quad \text{for } p, q \in \{1, \ldots, d\}.$$  

**Proof.** The derivative of a function reduces the polynomial order by one while the continuity of the functions over facets (edges in 2D or faces in 3D) is lost. \qed \qed

Analogically to the weighted projection problem, there are two variants of DoGIP approach: the global and element-wise one. Since the double-grid space is discontinuous, the global variant has benefit only in special cases of regular grid and isotropic materials. Still both variants are presented here in following two theorems.

**Theorem 8** (DoGIP for elliptic problem). Let $\mathcal{V} = \mathcal{C}_{N,k}$ be an approximation space and $W = D_{N,2k-2}$ be a double-grid space. Then the standard linear system matrix (6) can be decomposed into

$$A u \cdot v = B^* A^{\text{DoGIP}} B u \cdot v = \sum_{k,l=1}^{V} \sum_{r,s=1}^{d} \sum_{i,j=1}^{W} A_{rsij}^{\text{DoGIP}} B_{sjl} u_l B_{rik} v_k$$  

7
where $V = \dim \mathcal{V}$, $W = \dim \mathcal{W}$, and the matrices $A_{\text{DoGIP}} \in \mathbb{R}^{d \times d \times W \times W}$ and $B \in \mathbb{R}^{d \times W \times V}$ have the following components

$$A_{rsij}^{\text{DoGIP}} = \delta_{ij} \int_{\Omega} M_{rs}(x) \phi_{ij}^{W}(x) \, dx \quad \text{for } r, s \in \{1, \ldots, d\}, i, j \in \{1, \ldots, W\},$$

$$B_{rik} = \frac{\partial \phi_{ik}^{W}(x)}{\partial x_r} \quad \text{for } r \in \{1, \ldots, d\}, i \in \{1, \ldots, W\}, k \in \{1, \ldots, V\}.$$

Proof. Now, we present method based on double-grid quadrature and interpolation operator. Albeit both trial $u$ and test function $v$ belongs to the approximation space $\mathcal{V}$, we express them on a double-grid space $u \otimes v \in \mathcal{W} \otimes \mathcal{W}$ as

$$w(x) = \nabla u(x) \otimes \nabla v(x) = \sum_{j=1}^{W} \nabla u(x_{W}^{j}) \otimes \nabla v(x_{W}^{j}) \phi_{ij}^{W}(x).$$

The substitution of this formula into bilinear form already reveals an effective evaluation of bilinear form

$$\int_{\Omega} M(x) \nabla u(x) \cdot \nabla v(x) \, dx = \int_{\Omega} M(x) : [\nabla u(x) \otimes \nabla v(x)] \, dx$$

$$= \sum_{j=1}^{W} \int_{\Omega} M(x) \phi_{ij}^{W}(x) \, dx : \nabla u(x_{W}^{j}) \otimes \nabla v(x_{W}^{j})$$

$$= (A_{\text{DoGIP}} u_{W}, v_{W})_{\mathbb{R}^{d \times W}}$$

where $u_{W} = (\nabla u(x_{W}^{j}))_{j=1}^{W}$, $v_{W} = (\nabla v(x_{W}^{j}))_{j=1}^{W} \in \mathbb{R}^{d \times W}$, the integral defines the coefficient of the block-diagonal matrix $A_{\text{DoGIP}}$, and the matrix vector multiplication is understood as

$$(A_{\text{DoGIP}} u_{W})_{ri} = \sum_{s=1}^{d} \sum_{j=1}^{W} A_{rsij}^{\text{DoGIP}} u_{W,sj} \quad \text{for } r \in \{1, \ldots, d\} \text{ and } i \in \{1, \ldots, W\}.$$

Here, we cannot arrive directly to linear system because the test vectors $v$ do not span the whole space $\mathbb{R}^{d \times W}$. Therefore, we need interpolation-projection operator between $\mathcal{V}$ and $\mathcal{W}^{d}$, or rather between their corresponding spaces of coefficients $D_{\mathcal{V}}[\mathcal{V}]$ and $D_{\mathcal{W}}[\mathcal{W}]^{d}$. The derivation of the matrix is based on the evaluation of a gradient of a function $u(x) = \sum_{k=1}^{V} u(x_{W}^{k}) \phi_{W}^{k}(x)$ at the degrees of freedom of the double grid space, i.e. at $x = x_{W}^{j}$. It can be represented with an interpolation-projection operator $B \in \mathbb{R}^{d \times W \times V}$ as

$$\frac{\partial u(x_{W}^{j})}{\partial x_{s}} = \sum_{l=1}^{V} u(x_{W}^{l}) \frac{\partial \phi_{W}^{l}(x_{W}^{j})}{\partial x_{s}} B_{sij}$$

for $s \in \{1, \ldots, d\}$ and $j \in \{1, \ldots, W\}$.

To summarise, the bilinear form can be expressed using different vectors of coefficients

$$a(u, v) = (A_{\text{DoGIP}} u, v)_{\mathbb{R}^{d \times W}} = (A_{\text{DoGIP}}^{*} B_{W}, v)_{\mathbb{R}^{d \times W}} = (B^{*} A_{\text{DoGIP}} B_{W}, v)_{\mathbb{R}^{d \times W}},$$

where the transpose is understood as $B_{s}^{*} = B_{s}$. Since the last term holds for arbitrary vectors $u_{W}$ and $v_{W}$, the required decomposition is established. \qed
The special case of the theorem arise for isotropic material coefficients:

**Corollary 9.** Assume that \( M(x) = m(x)I \) is proportional to identity matrix \( I \) with some uniformly positive and bounded function \( m : \Omega \to \mathbb{R} \). Then, the coefficients of the block-diagonal matrix from previous theorem simplify to

\[
A_{rsij}^{\text{DoGIP}} = \delta_{rs} \delta_{ij} \int_{\Omega} m(x) \phi^j_W(x) \, dx.
\]

In particular for \( d = 2 \), the matrix \( A^{\text{DoGIP}} \) can be expressed as block-diagonal operator

\[
A^{\text{DoGIP}} = \begin{pmatrix}
a^{\text{DoGIP}} & 0 \\
0 & a^{\text{DoGIP}}
\end{pmatrix},
\]

where \( a^{\text{DoGIP}} = \left( \delta_{ij} \int_{\Omega} m(x) \phi^i_W(x) \, dx \right)^W_{i,j=1} \).

**Theorem 10** (Element-wise DoGIP for elliptic problem). Let \( V = C_{N,k} \) be an approximation space and \( W = D_{N,k} \) be a double-grid space. Then the quadratic form corresponding to the linear system (6) can be decomposed as

\[
Au \cdot v = \sum_{T \in \mathcal{M}} \hat{B}^* A^{\text{DoGIP}}_T \hat{B} u_T \cdot v_T
\]

where \( u_T,l = u_{T(t)} \), \( v_T,k = v_{T(k)} \) stores the local DOFs on the element \( T \). The quadratic forms on element level are evaluated as

\[
\hat{B}^* A^{\text{DoGIP}}_T \hat{B} u_T \cdot v_T = \sum_{r,s=1}^d \sum_{i,j=1}^W \sum_{k,l=1}^V A_{T,rsij}^{\text{DoGIP}} \hat{B}_{si}^{\text{DoGIP}} \hat{B}_{lj}^{\text{DoGIP}} u_{T,r} \hat{B}_{rk} \hat{B}_{lj}^{\text{DoGIP}} v_{T,k},
\]

where the arrays \( A_T \in \mathbb{R}^{d \times d \times W_T \times W_T} \) and \( \hat{B} \in \mathbb{R}^{d \times W_T \times V_T} \) have the following components

\[
A_{T,rsij}^{\text{DoGIP}} = \delta_{ij} \sum_{p,q=1}^d R^{-1}_{T,rp} R^{-1}_{T,sq} \int_T M_{pq}(x) \phi^i_W(x) \, dx,
\]

\[
\hat{B}_{rij}^{\text{DoGIP}} = \frac{\partial \phi^k_W(\hat{x}^j_W)}{\partial x_r}.
\]

**Proof.** Now, we present method based on double-grid quadrature and interpolation operator. Albeit both trial \( u \) and test function \( v \) belongs to the approximation space \( V \), we express them on a double-grid space \( u \otimes v \in W \otimes W \) as

\[
w(x) = \nabla u(x) \otimes \nabla v(x) = \sum_{j=1}^W \nabla u(x^j_W) \otimes \nabla v(x^j_W) \phi^j_W(x).
\]

The substitution of this formula into bilinear form reveals an effective evaluation of bilinear form

\[
\int_{\Omega} M(x) \nabla u(x) \cdot \nabla v(x) \, dx = \sum_{T \in \mathcal{M}} \int_T M(x) : [\nabla u(x) \otimes \nabla v(x)] \, dx
\]

\[
= \sum_{T \in \mathcal{M}} \sum_{j=1}^W \int_T M(x) \phi^j_W(x) \, dx : \nabla u(x^j_W) \otimes \nabla v(x^j_W)
\]

\[
= \sum_{T \in \mathcal{M}} \sum_{i,j=1}^d \sum_{p,q=1}^d \delta_{ij} \int_T M_{pq}(\hat{x}) \phi^i_W(x) \, dx : \frac{\partial u(x^j_W)}{\partial x_p} \frac{\partial v(x^j_W)}{\partial x_q},
\]
which is written here as a weighted scalar product between arrays \( (\nabla u(x_j^W))_{j=1}^W \) and \( (\nabla v(x_j^V))_{j=1}^W \).

Now, those components will be expressed in terms of nodal values \( u_k = v(x_k^V) \) of space \( V \). The formula is based on the interpolation of a gradient of a function \( u(x) = \sum_{k=1}^V u_k \phi_k^V(x) \) at a degree of freedom of the double grid space \( W \) (i.e. at \( x = x_j^W \) with basis \( \phi_k^V \) supported at the element \( T \))

\[
\frac{\partial u(x_j^V)}{\partial x_q} = \sum_{l=1}^V u_l \frac{\partial \phi_l^V(x_j^V)}{\partial x_q} = \sum_{l=1}^V u_l \sum_{s=1}^d \frac{\partial \hat{\phi}_l^V(x_j^V)}{\partial \hat{x}_s} (R_T^{-1})_{sq},
\]

where the derivatives of basis function are expressed with respect to the reference basis function, see (1), and \( \hat{x}_j^V = F_T^{-1}(x_j^V) \).

The substitution into the integral provides the DoGIP evaluation over elements

\[
\int_{\Omega} M(x) \nabla u(x) \cdot \nabla v(x) \, dx =
\]

\[
= \sum_{T \in \mathcal{M}, \, j=1}^W \sum_{r=1}^d \left( \delta_{ij} \sum_{p,q=1}^d R_{r,p} R_{s,q} \int_T M_{pq}(x) \phi_j^V(x) \, dx \right) \cdot \sum_{k,l=1}^V u_{lk} \frac{\partial \hat{\phi}_l^V(x_j^V)}{\partial \hat{x}_s} \frac{\partial \hat{\phi}_k^V(x_i^V)}{\partial \hat{x}_r}.
\]

The interpolation coefficients \( \hat{\phi}_k^V(\hat{x}_i^W) \) as well as the integral over \( T \) are nonzero only if the support of \( \phi_k^V \) and \( \phi_i^W \) is on \( T \). Therefore, we can reparametrisate the sums over \( i, j, k, \) and \( l \) to local indices in order to obtain the final formula stated in theorem. \( \square \)

The actual matrix-vector multiplication can be provided by a following Algorithm 1.

---

**Algorithm 1** Matrix-vector multiplication for element-wise DoGIP

**Require:** \( A_T \in \mathbb{R}^{d \times W_T \times V_T} \) for all \( T \in \mathcal{M}, \ B \in \mathbb{R}^{W_T \times V_T} \)

1: function multiplication(\( A, u \))
2: allocate \( v \) of size like \( u \)
3: for \( T \) in \( \mathcal{M} \) do
4: \hspace{1em} get local DOFs \( u_T \) from \( u \)
5: \hspace{1em} calculate sequentially from right \( BA_T^{\text{DoGIP}} B_T \) \hspace{1em} \( \triangleright \) Eq. (4) or (7)
6: \hspace{1em} add \( BA_T^{\text{DoGIP}} B_T \) to \( v \)
7: end for
8: return \( v \)
9: end function
3 Numerical results

Here the memory and computational requirements are compared for the DoGIP and the standard discretisation approach. The two variational problems presented in sections 2.2 and 2.3 were implemented in an open-source FEM software FEmiCS [3]; the self-contained scripts are freely available on https://github.com/vondrejc/DoGIP.

The irregular meshes $\mathcal{M}_N$, with an example depicted in Figure 1, are described with the parameter $N = (N, N, N)$ corresponding to the number of elements in each spatial direction; for simplicity the mesh will be denoted as $\mathcal{M}$.

Now the memory and computational demands are discussed. To store sparse matrices obtained from FEM formulations, compressed sparse row (CSR) format is considered; it requires the storage of all the elements, all the indices in each row, and the number of rows, i.e.

$$\text{mem} \, \mathbf{A} = 2 \, \text{nnz} \, \mathbf{A} + \text{nrows} \, \mathbf{A},$$

where nnz is a number of non-zero elements and nrows number of rows. It is also noted that the values below the threshold $10^{-14}$ are consistently considered as zeros and therefore do not affect the memory requirements.

The following ratio provides

$$\text{memory efficiency} = \frac{\text{nnz} \, \mathbf{A}_{\text{DoGIP}}^T \cdot \dim \mathcal{M}}{\text{mem} \, \mathbf{A}}$$

between DoGIP and standard approach, where $\text{nnz} \, \mathbf{A}_{\text{DoGIP}}^T$ are non-zero elements of dense matrices $\mathbf{A}_{\text{DoGIP}}^T$ for each element $T$ and $\dim \mathcal{M}$ corresponds to the number of elements ($2N^2$ in 2D and $6N^3$ in 3D).

The computational requirements are directed by the number of operations (real multiplications) for matrix-vector multiplication which is directed by number of nonzero elements of the system matrix $\mathbf{A}$ or item-by-item of matrices $\mathbf{B} \cdot \mathbf{A}_{\text{DoGIP}}^T \mathbf{B}$ for each element $T$ of mesh $\mathcal{M}$. The following ratio provides

$$\text{computational eff.} = \frac{[2(\text{nnz} \, \mathbf{B} - \text{nnz}_{\pm 1} \, \mathbf{B}) + \text{nnz} \, \mathbf{A}_{\text{DoGIP}}^T] \cdot \dim \mathcal{M}}{\text{nnz} \, \mathbf{A}}.$$

Figure 1: Finite element mesh $\mathcal{M}_N$ of size $N = (5, 5)$ and characteristic mesh size $\frac{1}{5}$. 
Additional costs that are attributed to the multiplication of non-structured sparse matrices is not considered here. For both memory and computational efficiency the DoGIP approach is advantageous, compared to standard approach, when the ratio is below one.

### 3.1 Weighted projection

In the weighted projection, the basis space $V$ is considered to be the space of continuous piecewise-polynomials $C_{N,p}$. Then the double-grid space can be considered again as a space of continuous piecewise-polynomials but with the doubled polynomial order, i.e.

\[ V = \mathcal{C}_{N,p}, \quad W = \mathcal{C}_{N,2p}. \]

**Table 1:** Comparison of DoGIP and standard approach for weighted projection in 2D. Here $1/N$ is the characteristic mesh size, $p$ is a polynomial order, and memory and computational efficiency are defined in (8) and (9).

In the numerical test summarised in Tables 1 and 2 the characteristic mesh size $1/N$ and polynomial order $p$ have been considered as parameters. They are chosen such that it provides the same dimension of the original space $V$ as well as of double grid space $W$. One directly observes that the sparsity of the original systems $A$ is significantly reduced with the growing polynomial order $p$. On other side, the dimension of diagonal matrix $A_T^{\text{DoGIP}}$ remains the same which makes the DoGIP approach efficient especially for higher order polynomials. This reaches the value of 0.04 in 2D for $p = 8$ and the value of 0.10 in 3D for $p = 4$. On other side the computational demands are increased for DoGIP approach but decrease with increasing polynomial order $p$. The values of computational efficiency, see (9), reach 2.81 for $p = 8$ in 2D and 4.25 for $p = 4$ in 3D.
Both tables show the results for a element-wise variant of DoGIP approach however better results can be achieved for variant in Theorem 8 because the continuity of the double grid space can be used.

### 3.2 Scalar elliptic equation

In the case of scalar elliptic equation, the initial approximation space is again considered as a space of continuous piece-wise polynomials, however, the double-grid space consists of discontinuous piece-wise polynomials with reduced polynomial order $2(p - 1)$ because of the gradient, i.e.

$$V = C_{N,p}, \quad W = D_{N,2(p-1)}.$$ 

**Table 3**: Comparison of DoGIP and standard approach for scalar elliptic equation with isotropic material coefficients in 2D. Here $1/N$ is the characteristic mesh size, $p$ is a polynomial order, and memory and computational efficiency are defined in (8) and (9).

</tbody>
</table>

The numerical results are summarised in the Tables 3 and 4 again for two parameters (the characteristic mesh size $1/N$ and polynomial order $p$) which are chosen in a way to provide the same dimension of the original space $V$. Contrary to the weighted projection in previous subsection, the size of the double-grid space $W$ and thus the size of block-diagonal matrix $\mathbf{A}_{DoGIP}$ grows with polynomial order $p$ but slower that the memory requirements on the original matrix $\mathbf{A}$ which can be seen from memory effectiveness. Particularly the memory effectiveness reaches 0.12 for $p = 8$ in 2D and 0.45 for $p = 4$ in 3D. Still the memory requirements fail to be beneficial for polynomial order 1 and 2 in 3D. The memory requirements grows with polynomial order $p$ reaching the factor of 10.
4 Conclusion and discussion

In this paper, the double-grid integration with interpolation-projection (DoGIP) is introduced and compared to the standard Galerkin discretisation of variational formulations. This novel discretisation approach introduced for Fourier-Galerkin method in [19, 16] is here recognised to be more general framework. Here, it is investigated within finite element method (FEM) on simplexes for weighted projection and scalar elliptic equation.

The main results and observations are summarised:

- The DoGIP method is based on a decomposition of the original system matrix into a (block) diagonal $A^{\text{DoGIP}}$ and an interpolation-projection matrices $B$ evaluated only on a reference element; interpolation is thus independent of the material coefficients or mesh distortions.

- The DoGIP approach is typically memory efficient compared to the original system, however the computational demands for FEM on simplexes are higher.

The proposed DoGIP approach has a several possibilities for future research, which is discussed here:

- Reducing the complexity of the interpolation-projection operators $B$ by a special choice of the basis functions for a primal as well as a double-grid space.

- Reducing the memory requirements on $A_T$ by using orthogonality of material coefficients and double-grid basis functions.

- Application of the method to different discretisations and approximations such as FEM on quadrilaterals, spectral methods, or wavelets.

- Effective evaluation of interpolation-projection operator $B$ using e.g. low-rank approximations or incorporating parallel algorithms with an emphasis on GPU.

- Investigation of special linear solvers such as the multigrid that could fit to the structure of DoGIP systems.
