Abstract

We show that the error probability of reconstructing kernel matrices from Random Fourier Features for the Gaussian kernel function is at most $O(R^2/3 \exp(-D))$, where $D$ is the number of random features and $R$ is the diameter of the data domain. We also provide an information-theoretic method-independent lower bound of $\Omega(\exp(-D))$ for $R > 2.1$. Compared to prior work, we are the first to show that the error probability for random Fourier features is independent of the dimensionality of data points. As applications of our theory, we obtain dimension-independent bounds for kernel ridge regression and support vector machines.

1 Introduction

Kernel methods are widely applied in many machine learning algorithms, including kernel perceptron, support vector machines, principal component analysis, and Gaussian processes. Kernels allow to convert problems that evaluate explicit feature mappings to problems that evaluate kernel functions, i.e., inner products of feature mappings. Kernel methods are efficient since computing inner products of feature mappings is often computationally cheaper than computing the feature mappings directly. To fully leverage the power of the kernel method, a $n \times n$ matrix called kernel matrix (Gram Matrix) must be computed, which does not scale when the number of data points $n$ is large. To cope with such problem, [Rahimi and Recht, 2007] proposed an algorithm called Random Fourier Features (RFF). RFF approximates the kernel evaluation by the average of Fourier Features (cosines of linear projections). This approach is theoretically motivated by Bochner’s theorem [Bochner, 1959], which states that any continuous, positive definite and shift-invariant function can be written as the Fourier transform of a nonnegative measure.

Though RFF is a successful method in practice, its theoretical performance is yet to be discovered. Along with the algorithm, Rahimi and Recht also analyzed the error probability of reconstructing kernel matrices, which is $O(dR^2 \exp(-D))$, for any compact data domain, where $R$ is the domain diameter, $D$ is the number of Fourier features, and $d$ is the dimensionality of the data points. Their approach is based on covering numbers. Following the work of [Rahimi and Recht, 2007], [Sutherland and Schneider, 2015] improved the constants in the previous covering-number upper bound and provided results which were
also $O(dR^2 \exp(-\frac{D}{d}))$. Later Sriperumbudur and Szabó [2015] proved an upper bound of $O(d^{512d} R^{1024d} \exp(-D))$, by using a Rademacher complexity approach.

In this paper, we remove the dependence on the dimensionality of the data points $d$ from the error probability, and show that the dependence on the domain diameter $R$ is sub-linear. That is, we show that the error probability depends only on the number of Fourier features $D$. More specifically, we show an upper bound on the error probability which is $O(R^{2/3} \exp(-D))$. In addition, we also reason about the lower bound, by showing that the minimax bound is $\Omega(\exp(-D))$ for $R > 2.1$.

2 Preliminaries

In this section, we introduce some definitions, notations and preliminaries that will be used in the following sections.

2.1 Definitions and Notations

For any vector we denote its $L^p$-norm by $\|\cdot\|_p$. We denote the compact ball centered at the origin and with radius $R$ by:

$$\mathbb{B}(R) = \{\Delta | \Delta \in \mathbb{R}^d, \|\Delta\|_2 \leq R\}$$

The above is the domain of the data points, considered throughout the paper. For a probability distribution $P$, denote its corresponding probability density function by $p$, any random vector from $P$ by $\omega$ and the expectation with respect to $\omega$ by $\mathbb{E}_{\omega \sim P}$. For any set $\Omega$ of $D$ i.i.d. samples from $P$, denote these samples by $\omega_1, \cdots, \omega_D$, its product distribution by $P^D$, and the expectation with respect to $\Omega$ by $\mathbb{E}_{\Omega \sim P^D}$. Finally denote any multivariate Gaussian distribution with mean $\mu$ and covariance $\Sigma$ by $\mathcal{N}(\mu, \Sigma)$, and denote the $d$-dimensional standard Gaussian distribution by $\mathcal{N}(0_d, I_d)$.

2.2 Random Fourier Features

Let $x, y \in \mathbb{R}^d$ be two data points, $\Delta = x - y$, and let $k$ be a nonnegative, continuous and shift-invariant function, that is

$$k(x, y) = k(x - y)$$

By Bochner’s theorem [Bochner, 1959], the Fourier transform of $k$ is a probability density function. We denote such probability density function by $p$ and its distribution by $P$. We have

$$k(x, y) = \int_{\mathbb{R}^d} p(\omega) e^{i\omega^\top (x-y)} d\omega$$

$$= \mathbb{E}_{\omega \sim P}[\cos(\omega^\top (x - y))]$$

since only the real part of the above integral is considered. Then RFF draws $D$ sample points from $P$, and approximates $k(x, y)$ by

$$s(x, y) = s(\Delta) := \frac{1}{D} \sum_{i=1}^{D} \cos(\omega_i^\top \Delta) = \langle z(x), z(y) \rangle$$
where
\[
\mathbf{z}(\mathbf{x}) = \frac{1}{\sqrt{D}} \left( \cos(\omega_1^\top \mathbf{x}), \sin(\omega_1^\top \mathbf{x}), \ldots, \cos(\omega_D^\top \mathbf{x}), \sin(\omega_D^\top \mathbf{x}) \right)
\]  

The above result enables us to draw a set of samples \(\{\omega_1, \ldots, \omega_D\}\) from \(P\) and approximates \(k(\mathbf{x}, \mathbf{y})\) for any \(\mathbf{x}, \mathbf{y} \in B(R)\), without computing the Gram matrix directly. For the performance analysis of RFF, \[\text{[Rahimi and Recht, 2007]}\] first provided a theoretical upper bound on the error probability for uniform convergence. Specifically, Claim 1 of \[\text{[Rahimi and Recht, 2007]}\] shows that the error probability behaves as follows

\[
\Pr \left[ \sup_{\mathbf{x}, \mathbf{y} \in B(R)} |k(\mathbf{x}, \mathbf{y}) - \langle \mathbf{z}(\mathbf{x}), \mathbf{z}(\mathbf{y}) \rangle| \geq \epsilon \right] \leq 256 \left( \frac{\sigma P R}{\epsilon} \right)^2 \exp \left( -\frac{D \epsilon^2}{4(d+2)} \right)
\]  

The above depends on \(d\) and \(\sigma^2_P = \mathbb{E}_{\omega \sim P} \|\omega\|^2 \in \mathcal{O}(d)\). Thus, the above bound is \(\mathcal{O}(d R^2 \exp(-\frac{D \epsilon^2}{d}))\). \[\text{[Sutherland and Schneider, 2015]}\] improved the upper bound of the error probability with the same features used in \[\text{[Rahimi and Recht, 2007]}\]. Their upper bound is given in Proposition 1 of \[\text{[Sutherland and Schneider, 2015]}\], which is

\[
\Pr \left[ \sup_{\mathbf{x}, \mathbf{y} \in B(R)} |k(\mathbf{x}, \mathbf{y}) - \langle \mathbf{z}(\mathbf{x}), \mathbf{z}(\mathbf{y}) \rangle| \geq \epsilon \right] \leq 66 \left( \frac{\sigma P R}{\epsilon} \right)^2 \exp \left( -\frac{D \epsilon^2}{8(d+2)} \right)
\]  

which has the same asymptotic upper bound as \[\text{[Rahimi and Recht, 2007]}\]. Later \[\text{[Sriperumbudur and Szabo, 2015]}\] proved the following upper bound (See Appendix A for more details):

\[
\Pr \left[ \sup_{\mathbf{x}, \mathbf{y} \in B(R)} |k(\mathbf{x}, \mathbf{y}) - \langle \mathbf{z}(\mathbf{x}), \mathbf{z}(\mathbf{y}) \rangle| \geq \epsilon \right] \leq (\sigma P + 1)(2R + 1)^{1024d} \exp \left( -\frac{D \epsilon^2}{2} + \frac{256d}{\log(2R + 1)} \right)
\]  

The above depends on \(d\) and \(\sigma^2_P = \mathbb{E}_{\omega \sim P} \|\omega\|^2 \in \mathcal{O}(d)\). Thus, the above bound is \(\mathcal{O}(d^{12d} R^{1024d} \exp(-D))\).

### 3 Sufficient Number of Samples

In this section we prove that the upper bound on the error probability for uniform convergence in RFF is independent of the dimensionality of the data points \(d\), and sub-linear with respect to the domain diameter \(R\).

**Theorem 1.** Let \(\Omega = \{\omega_1, \ldots, \omega_D\}\) be a set of i.i.d. \(d\)-dimensional random vectors from \(P = \mathcal{N}(0_d, I_d)\). Then:

\[
\Pr_{\Omega \sim P^D} \left[ \sup_{\Delta \in B(R)} \left| \frac{1}{D} \sum_{i=1}^{D} \cos(\omega_i^\top \Delta) - e^{-\frac{1}{2} \|\Delta\|^2} \right| \geq \epsilon \right] \leq 3 \frac{R^{2/3}}{D^{1/3} \epsilon^{2/3}} \exp \left( -\frac{D \epsilon^2}{12} \right)
\]  

\[\text{[Rahimi and Recht, 2007]}\] defines \(\mathbf{z}(\mathbf{x}) = \sqrt{2}(\cos(\omega_1^\top \mathbf{x} + b), \ldots, \cos(\omega_D^\top \mathbf{x} + b))\), where \(b\) is a random variable with uniform distribution in \([0, 2\pi)\).

\[\text{[Sutherland and Schneider, 2015]}\] uses the features in \(\mathbf{z}\), but the number of features is \(D/2\) instead.
Proof. Note $P = \mathcal{N}(0, I_d)$ and $\omega_i \sim P$ for all $i$. Note that since for every $i \neq j$, $\omega_i$ is independent of $\omega_j$ then $\omega_i^\top \Delta$ is independent of $\omega_j^\top \Delta$. Let $\alpha_i \sim \mathcal{N}(0, 1)$ for all $i$. Furthermore, $\alpha = (\alpha_1, \ldots, \alpha_D)$ is a random vector from $\mathcal{N}(0, I_d)$. Note that for $r = \|\Delta\|_2$, we have $\omega_i^\top \Delta \sim \mathcal{N}(0, r^2)$ and $\alpha_i r \sim \mathcal{N}(0, r^2)$. Given the above, we have:

$$
\mathbb{P}_{\Omega \sim PD} \left[ \sup_{\Delta \in \mathbb{B}(R)} \left| \frac{1}{D} \sum_{i=1}^{D} \cos(\omega_i^\top \Delta) - e^{-\frac{\|\Delta\|^2}{2}} \right| \geq \epsilon \right] = \mathbb{P}_{\alpha \sim \mathcal{N}(0, I_d)} \left[ \sup_{r \in [0, R]} |f(r)| \geq \epsilon \right]
$$

where $f(r) = s(r) - k(r)$, $s(r) = \frac{1}{D} \sum_{i=1}^{D} \cos(\alpha_i r)$ and $k(r) = \exp(-r^2/2)$. In order to proceed with a union bound for all $r \in [0, R]$, we divide the set $[0, R]$ into $T$ subsets $S_t = \left[ \frac{(t-1)R}{T}, \frac{tR}{T} \right]$ for all $t = 1, \ldots, T$, each of them with center $c_t = \frac{(t-1/2)R}{T}$. For a particular $t$ and $r \in S_t$, if $|f(c_t)| \leq \frac{\epsilon}{2}$ and if the Lipschitz constant $L$ of $f$ fulfills $L \leq \frac{R L}{1 - R}$, we have:

$$
|f(r)| = |f(c_t) + f(r) - f(c_t)| \\
\leq |f(c_t)| + |f(r) - f(c_t)| \\
\leq \frac{\epsilon}{2} + L|r - c_t| \\
\leq \frac{\epsilon}{2} + \frac{R L}{2T} \\
\leq \epsilon
$$

Next, we proceed to bound the expected value of the Lipschitz constant $L$ of $f$. By linearity of expectation, we have $\mathbb{E}_{\alpha \sim \mathcal{N}(0, I_d)}[\partial s(r)] = \partial k(r)$. Therefore:

$$
\mathbb{E}_{\alpha \sim \mathcal{N}(0, I_d)}[L^2] = \sup_{r \in [0, R]} \mathbb{E}_{\alpha \sim \mathcal{N}(0, I_d)}[(\partial f(r))^2] \\
= \sup_{r \in [0, R]} \mathbb{E}_{\alpha \sim \mathcal{N}(0, I_d)}[(\partial s(r) - \partial k(r))^2] \\
= \sup_{r \in [0, R]} \mathbb{E}_{\alpha \sim \mathcal{N}(0, I_d)}[(\partial s(r))^2 - (\partial k(r))^2] \\
= \sup_{r \in [0, R]} \mathbb{E}_{\alpha \sim \mathcal{N}(0, I_d)}[(\partial s(r))^2 - \mathbb{E}_{\alpha \sim \mathcal{N}(0, I_d)}[(\partial s(r))^2]] \\
= \sup_{r \in [0, R]} \mathbb{V} \mathbb{a} \alpha \sim \mathcal{N}(0, I_d)[\partial s(r)] \\
= \sup_{r \in [0, R]} \mathbb{V} \mathbb{a} \alpha \sim \mathcal{N}(0, I_d) \left[ \frac{1}{D} \sum_{i=1}^{D} \alpha_i \sin(\alpha_i r) \right] \\
\leq \sup_{r \in [0, R]} \frac{1}{D^2} \sum_{i=1}^{D} \mathbb{V} \mathbb{a} \alpha_i \sim \mathcal{N}(0, 1) \left[ \alpha_i^2 \sin^2(\alpha_i r) \right] \\
\leq \sup_{r \in [0, R]} \frac{1}{D^2} \sum_{i=1}^{D} \mathbb{E} \mathbb{a} \alpha_i \sim \mathcal{N}(0, 1) \left[ \alpha_i^2 \right] \\
= 1/D
$$

(3)
Since $E_{\alpha \sim \mathcal{N}(0,D,I_D)}[s(r)] = k(r)$ then $E_{\alpha \sim \mathcal{N}(0,D,I_D)}[f(r)] = 0$. Therefore, from (3), since $|f(r)| \leq 2$, and by Markov’s and Hoeffding’s inequalities and by the union bound, we have

$$
\Pr_{\alpha \sim \mathcal{N}(0,D,I_D)}\left[ \sup_{r \in [0,R]} |f(r)| \geq \epsilon \right] 
\leq \Pr_{\alpha \sim \mathcal{N}(0,D,I_D)}\left[ L \geq \frac{Te}{R} \right] + \Pr_{\alpha \sim \mathcal{N}(0,D,I_D)}\left[ \exists t \in \{1, \ldots, T\}, |f(c_t)| \geq \frac{\epsilon}{2} \right]
\leq \frac{R^2}{\epsilon^2 T^2} E_{\alpha \sim \mathcal{N}(0,D,I_D)}[L^2] + 2T \exp \left( -\frac{D\epsilon^2}{8} \right)
\leq \frac{R^2}{T^2 D\epsilon^2} + 2T \exp \left( -\frac{D\epsilon^2}{8} \right) \quad (4)
$$

By optimizing the above with respect to $T$, we obtain $T = \frac{R^{2/3}}{D^{1/3} \epsilon^{2/3}} \exp \left(\frac{D\epsilon^2}{24}\right)$. Finally, by replacing the optimal $T$ back in (4), and by (2) we prove our claim.

4 Necessary Number of Samples

In contrast to the relative popularity of the upper bound analysis on the error probability for RFF, lower bounds have not been analyzed before. In this section we try to shed light on the minimax bound of RFF by Le Cam’s Lemma \cite{Yu, Wasserman}. In the first part we introduce Le Cam’s Lemma for minimax bounds, then we use Le Cam’s Lemma to show the $\Omega(\exp(-D))$ minimax bound of the expected error for RFF. Finally we generalize our result in the last subsection and show that the supremum of the error probability is also bounded below by $\Omega(\exp(-D))$.

4.1 Le Cam’s Lemma

Recall that given any set of samples $X = \{X_1, \ldots, X_n\}$ from some distribution $P$ in a family of distributions $\mathcal{P}$, a function $\theta$ of $P$, and any estimator $\hat{\theta} = \hat{\theta}(X_1, \ldots, X_n)$ to $\theta$, the minimax risk is:

$$
\inf_{\theta} \sup_{P \in \mathcal{P}} \mathbb{E}_{X \sim P^n}[d(\hat{\theta}(X), \theta(P))]
$$

Minimax theory illustrates the lower bound of the estimation errors among all estimators. Le Cam’s Lemma is a method for providing a lower bound for the minimax risk. First we introduce Le Cam’s Lemma from Theorem 36.8 of \cite{Wasserman}, which is a revised version from the results in \cite{Yu}:

**Lemma 1** (Le Cam \cite{Yu, Wasserman}). Let $\mathcal{P}$ be a set of distributions over space $\mathcal{X}$, where every distribution $P \in \mathcal{P}$ corresponds to a parameter $\theta(P)$ in the parameter space $\Theta$. Let $\hat{\theta} : \mathcal{X}^D \rightarrow \Theta$ be any estimator, $X_P \in \mathcal{X}^D$ be any set of $D$ samples from $P,$
$d(\cdot, \cdot)$ be a metric in $\Theta$. Then for any pair of distributions $P_1, P_2 \in \mathcal{P}$
\[
\inf_{\hat{\theta}} \sup_{P \in \mathcal{P}} \mathbb{E}_{X_P \sim P}[d(\hat{\theta}(X_P), \theta(P))] \geq \frac{d(\theta(P_1), \theta(P_2))}{4} \int_{x \in \mathcal{X}} \min(p_1(x), p_2(x))dx
\]

where $p_1, p_2$ are the probability density functions of $P_1, P_2$, respectively.

(Detailed proof of Lemma 1 can be found in Appendix B.1)

Moreover, $d$ can be any semimetric or non-negative symmetric function satisfying the relaxed triangle inequality, that is,
\[
d(x, y) \leq A(d(x, z) + d(z, y))
\]

where $A \geq 1$. We generalize Le Cam’s Lemma as follows:

\textbf{Lemma 2}. Let $\mathcal{P}$ be a set of distributions over space $\mathcal{X}$, where every distribution $P \in \mathcal{P}$ corresponds to a parameter $\theta(P)$ in the space of parameter $\Theta$. Let $\theta : \mathcal{X}^D \rightarrow \Theta$ be any estimator from a set of estimators, $X_P \in \mathcal{X}^D$ be a set of $D$ samples from $P$, $d : \Theta \times \Theta \rightarrow \mathbb{R}$ be a non-negative symmetric function in $\Theta$ satisfying $d(x, y) \leq A(d(x, z) + d(z, y))$ whenever $d(x, y) > \epsilon > 0$ and $A \geq 1$. For any pair of distributions $P_1, P_2 \in \mathcal{P}$ satisfying $d(\theta(P_1), \theta(P_2)) > \epsilon$ we have:
\[
\inf_{\hat{\theta}} \sup_{P \in \mathcal{P}} \mathbb{E}_{X_P \sim P}[d(\hat{\theta}(X_P), \theta(P))] \geq \frac{d(\theta(P_1), \theta(P_2))}{4A} \int_{x \in \mathcal{X}} \min(p_1(x), p_2(x))dx
\]

where $p_1, p_2$ are the probability density functions of $P_1, P_2$, respectively.

(Detailed proof of Lemma 2 can be found in Appendix B.2)

Le Cam’s Lemma allows for analyzing the minimax bound of estimation errors, which gives us some insight of the lower bound on the estimator. In order to simplify our analysis with Le Cam’s Lemma, we also introduce the following result:

\textbf{Lemma 3} (Lemma 2.6 in [Tsybakov, 2009]). For any two distributions $P, Q$ with support $\mathcal{X}$, we have
\[
\int_{x \in \mathcal{X}} \min(p(x), q(x))dx \geq \frac{1}{2} e^{-KL(P \parallel Q)}
\]

where $KL(P \parallel Q)$ is the KL-divergence from $P$ to $Q$, and $p, q$ are the probability density functions of $P, Q$ respectively.

\textbf{4.2 Minimax Bound for the Expected Error}

In what follows, we prove that RFF has a $\Omega(\exp(-D))$ lower bound on the supremum of the expected error. In our proof, we regard the kernel as a parameter of its Fourier transform $P$. We then show by Le Cam’s Lemma that the minimax bound for such parameter estimation is $\Omega(\exp(-D))$ for $R > 2.1$. 

6
Theorem 2. Let $\Omega = \{\omega_1, \cdots, \omega_D\}$ be a set of $D$ i.i.d. $d$-dimensional random vectors from $P = \mathcal{N}(0_d, I_d)$. Define

$$R^* = \sqrt{\frac{-2}{1 - \gamma}} \log \gamma < 2.1$$

and

$$g(R) = \begin{cases} e^{-\frac{R^2}{2}} - e^{-\frac{R^2}{2}} & \text{if } R < R^* \\ e^{-\frac{R^2}{2}} - e^{-\frac{R^2}{2}} & \text{otherwise} \end{cases}$$

where $\gamma = -W(-e^{-2})$ and $W$ is Lambert’s $W$ function. Then

$$\sup_{\Delta \in \mathbb{B}(R)} \mathbb{E}_{\Omega \sim P_D} \left[ \left| \frac{1}{D} \sum_{j=1}^{D} \cos(\omega_j^T \Delta) - e^{-\frac{||\Delta||_2^2}{2}} \right| \right] \geq \frac{g(R)}{8} e^{-\frac{D}{2}}$$

Proof. Note $P = \mathcal{N}(0_d, I_d)$ and $\omega_i \sim P$ for all $i$. Let $\alpha_i = \omega_i^T \Delta$ then $\{\alpha_1, \cdots, \alpha_D\}$ can be regarded as a set of $D$ i.i.d. samples from $\mathcal{N}(0, \|\Delta\|_2^2)$ and $\alpha = (\alpha_1, \cdots, \alpha_D)$ is a random vector from $\mathcal{N}(0_d, \|\Delta\|_2^2 I_d)$. The family of distributions $\mathcal{P}$ is defined as:

$$\mathcal{P} = \{\mathcal{N}(0_d, \|\Delta\|_2^2 I_d)\}_{\Delta \in \mathbb{B}(R)}$$

We let the parameter of $P_\Delta := \mathcal{N}(0_d, \|\Delta\|_2^2 I_d) \in \mathcal{P}$ be

$$\theta(P_\Delta) := \left( \int p_\Delta(\alpha)e^{i\alpha^T \|I_d\| \alpha} \right)^{1/2} = k(\Delta)$$

We also let

$$\hat{\theta}(\alpha_1, \cdots, \alpha_D) := \frac{1}{D} \sum_{j=1}^{D} \cos(\alpha_j) = \frac{1}{D} \sum_{j=1}^{D} \cos(\omega_j^T \Delta)$$

be the estimator of $\theta(P_\Delta)$. Then by Le Cam’s Lemma we have:

$$\sup_{\Delta \in \mathbb{B}(R)} \mathbb{E}_{\Omega \sim P_D} \left[ \left| \frac{1}{D} \sum_{j=1}^{D} \cos(\omega_j^T \Delta) - k(\Delta) \right| \right] \geq \inf_{\hat{\theta}} \sup_{P_\Delta \in \mathcal{P}} \mathbb{E}_{\alpha \sim P_\Delta} \left[ \left| \hat{\theta}(\alpha_1, \cdots, \alpha_D) - e^{-\frac{\|\Delta\|_2^2}{2}} \right| \right]$$

$$\geq \frac{1}{4} \left| e^{-\frac{\|\Delta\|_2^2}{2}} - e^{-\frac{\|\Delta_2\|_2^2}{2}} \right| \cdot \int_{\alpha} \min(p_{\Delta_1}(\alpha), p_{\Delta_2}(\alpha)) d\alpha$$

(5)

where $P_{\Delta_1}, P_{\Delta_2} \in \mathcal{P}$. By Lemma we can simplify (5) as

$$\sup_{\Delta \in \mathbb{B}(R)} \mathbb{E}_{\Omega \sim P_D} \left[ \left| \frac{1}{D} \sum_{j=1}^{D} \cos(\omega_j^T \Delta) - k(\Delta) \right| \right] \geq \frac{1}{8} \left| e^{-\frac{\|\Delta_1\|_2^2}{2}} - e^{-\frac{\|\Delta_2\|_2^2}{2}} \right| e^{-KL(P_{\Delta_1} \| P_{\Delta_2})}$$

(6)
Note that \( P_{\Delta_1} \) and \( P_{\Delta_2} \) are two multivariate normal distributions, which implies that their KL-divergence is
\[
KL(P_{\Delta_1} \parallel P_{\Delta_2}) = \frac{D}{2} \left( \frac{\|\Delta_1\|_2^2}{\|\Delta_2\|_2^2} - \log \frac{\|\Delta_1\|_2^2}{\|\Delta_2\|_2^2} - 1 \right)
\]  
(7)

By choosing \( \Delta_1, \Delta_2 \) such that \( \|\Delta_1\|^2 \|\Delta_2\|^2 = -W(-e^{-2}) \), we can make \( \|\Delta_1\|^2 \|\Delta_2\|^2 - \log \|\Delta_1\|^2 \|\Delta_2\|^2 - 1 = 1 \), then we get
\[
\sup_{\Delta \in \mathbb{R}^D} \mathbb{E}_{\Omega \sim P_D} \left[ \left| \frac{1}{D} \sum_{j=1}^D \cos(\omega_j^T \Delta) - k(\Delta) \right| \right] \geq \frac{1}{8}e^{-\|\Delta_1\|^2} - e^{-\|\Delta_2\|^2} \left| e^{-KL(P_{\Delta_1} \parallel P_{\Delta_2})} \right| 
\geq \frac{1}{8}e^{-\|\Delta_1\|^2} - e^{-\|\Delta_2\|^2} \left| e^{-\frac{D}{2}} \right|
\]
(8)

for any \( \Delta_1, \Delta_2 \) that satisfy the constraint \( \|\Delta_1\|^2 \|\Delta_2\|^2 = -W(-e^{-2}) \). Under this constraint, the solution to maximize
\[
|e^{-\|\Delta_1\|^2} - e^{-\|\Delta_2\|^2}|
\]
is
\[
\|\Delta_1\|^2 = \frac{-2\gamma}{1 - \gamma} \log \gamma = \gamma R^2
\]
\[
\|\Delta_2\|^2 = \frac{-2}{1 - \gamma} \log \gamma = R^2
\]
if \( R \geq R^* \), and
\[
\|\Delta_1\|^2 = \gamma R^2, \|\Delta_2\|^2 = R^2
\]
if \( R < R^* \). Thus we can maximize the right hand side of (8) and rewrite it as:

\[
\sup_{\Delta \in \mathbb{R}^D} \mathbb{E}_{\Omega \sim P_D} \left[ \left| \frac{1}{D} \sum_{j=1}^D \cos(\omega_j^T \Delta) - e^{-\|\Delta\|^2} \right| \right] \geq \frac{g(R)}{8}e^{-\frac{D}{2}}
\]

\[
\text{4.3 Minimax Bound for the Error Probability}
\]

In this part we generalize the results in the previous subsection and show that the supremum of the error probability is \( \Omega(\exp(-D)) \) for \( R > 2.1 \), by applying the generalized version of Le Cam’s Lemma. Here we introduce a generalization of Theorem 2 based on the generalized Le Cam’s Lemma.

**Theorem 3.** Let \( \Omega = \{\omega_1, \cdots, \omega_D\} \) be a set of i.i.d. i.i.d. d-dimensional random vectors from \( P = N(0_d, I_d) \). Then
\[
\sup_{\Delta \in \mathbb{R}^D} \mathbb{P}_{\Omega \sim P_D} \left[ \left| \frac{1}{D} \sum_{j=1}^D \cos(\omega_j^T \Delta) - e^{-\|\Delta\|^2} \right| > \epsilon \right] \geq \frac{g(R)}{8}e^{-\frac{D}{2}}
\]
provided that \( g(R) \geq 3\epsilon \), where \( g(R) \) is defined as in Theorem 2.
Proof. The proof follows the proof of Theorem 2 at large. We can regard every \( \alpha_i = \omega_i^\top \Delta \) as a random variable from \( \mathcal{N}(0, \| \Delta \|_2^2) \) and regard \( \alpha = (\omega_1^\top \Delta, \ldots, \omega_D^\top \Delta) \) as a \( D \)-dimensional random vector from \( P_{\Delta} = \mathcal{N}(0_D, \| \Delta \|_2^2 I_D) \). Let

\[
P = \{ \mathcal{N}(0_D, \| \Delta \|_2^2 I_D) \}_{\Delta \in \mathbb{B}(R)}
\]

be the family of distributions,

\[
\theta(P_{\Delta}) := (\int p_{\Delta}(\alpha)e^{i \alpha^\top \mathbb{I} D} d\alpha)^{\frac{1}{D}} = k(\Delta)
\]

be the parameter of \( P_{\Delta} \in \mathcal{P} \), and

\[
\hat{\theta}(\alpha_1, \ldots, \alpha_D) := \frac{1}{D} \sum_{j=1}^{D} \cos(\alpha_j) = \frac{1}{D} \sum_{j=1}^{D} \cos(\omega_j^\top \Delta)
\]

be the estimator of \( \theta(P_{\Delta}) \). We also define a symmetric, nonnegative function

\[
d_\epsilon(x, y) = \frac{1}{2} \max(0, |x - y| - \epsilon)
\]

which satisfies

\[
d_\epsilon(x, y) \leq 3(d_\epsilon(x, z) + d_\epsilon(z, y))
\]

whenever \( |x - y| \geq 3\epsilon \). Now choose \( \Delta_1, \Delta_2 \in \mathbb{B}(R) \) such that

\[
\| \Delta_1 \|_2^2 = \frac{2W(-e^{-2})}{1 + W(-e^{-2}) \log(-W(-e^{-2}))}
\]

\[
\| \Delta_2 \|_2^2 = \frac{2}{1 + W(-e^{-2}) \log(-W(-e^{-2}))}
\]

which implies

\[
e^{-KL(P_{\Delta_1} \parallel P_{\Delta_2})} = e^{-\frac{D}{2}}
\]

and

\[
d_\epsilon(\theta(P_{\Delta_1}), \theta(P_{\Delta_2})) = d_\epsilon(e^{-\frac{\| \Delta_1 \|_2^2}{2}}, e^{-\frac{\| \Delta_2 \|_2^2}{2}})
\]

\[
= \frac{1}{2} \max(0, |e^{-\frac{\| \Delta_1 \|_2^2}{2}} - e^{-\frac{\| \Delta_2 \|_2^2}{2}}| - \epsilon)
\]

\[
= \frac{1}{2}(g(R) - \epsilon)
\]
by the fact that $3\epsilon \leq g(R)$. Then Lemma 2 implies

$$
\sup_{P_\Delta \in \mathcal{P}} \mathbb{E}_{\alpha \sim P_\Delta} \left[ d_\epsilon \left( \frac{1}{D} \sum_{j=1}^{D} \cos(\alpha_j), k(\Delta) \right) \right] \geq \inf_{\hat{\theta}} \sup_{P_\Delta \in \mathcal{P}} \mathbb{E}_{\alpha \sim P_\Delta} \left[ d_\epsilon (\hat{\theta}(\alpha), \theta(P_\Delta)) \right]
$$

$$
\geq \frac{1}{12} d_\epsilon (\theta(P_{\Delta_1}), \theta(P_{\Delta_2})) \int_{\alpha} \min(p_{\Delta_1}(\alpha), p_{\Delta_2}(\alpha)) d\alpha
$$

$$
\geq \frac{1}{24} d_\epsilon (\theta(P_{\Delta_1}), \theta(P_{\Delta_2})) e^{-\text{KL}(p_{\Delta_1} \parallel p_{\Delta_2})}
$$

$$
= \frac{1}{24} d_\epsilon (e^{-\frac{\|\Delta_1\|^2}{2}}, e^{-\frac{\|\Delta_2\|^2}{2}}) e^{-\text{KL}(p_{\Delta_1} \parallel p_{\Delta_2})}
$$

$$
= \frac{g(R) - \epsilon - \frac{D}{2}}{48} e^{-\frac{D}{2}}
$$

(9)

Observe that

$$
\sup_{\Delta \in \mathbb{B}(R)} \mathbb{P}_{\Omega \sim P_D} \left[ \left| \frac{1}{D} \sum_{j=1}^{D} \cos(\omega_j^\top \Delta) - e^{-\frac{\|\Delta\|^2}{2}} \right| > \epsilon \right] = \sup_{\Delta \in \mathbb{B}(R)} \mathbb{P}_{\Omega \sim P_D} (|\hat{\theta}(\omega_1^\top \Delta, \ldots, \omega_D^\top \Delta) - \theta(P_\Delta)| > \epsilon)
$$

$$
= \sup_{P_\Delta \in \mathcal{P}} \mathbb{P}_{\alpha \sim P_\Delta} (|\hat{\theta}(\alpha_1, \ldots, \alpha_D) - \theta(P_\Delta)| > \epsilon)
$$

$$
= \sup_{P_\Delta \in \mathcal{P}} \mathbb{E}_{\alpha \sim P_\Delta} [I_\epsilon(\hat{\theta}(\alpha_1, \ldots, \alpha_D), \theta(P_\Delta))]
$$

$$
\geq \sup_{P_\Delta \in \mathcal{P}} \mathbb{E}_{\alpha \sim P_\Delta} [d_\epsilon (\hat{\theta}(\alpha_1, \ldots, \alpha_D), \theta(P_\Delta))]
$$

$$
= \sup_{P_\Delta \in \mathcal{P}} \mathbb{E}_{\alpha \sim P_\Delta} [d_\epsilon (\frac{1}{D} \sum_{j=1}^{D} \cos(\alpha_j), k(\Delta))]
$$

(10)

for any $x, y$, where

$$
I_\epsilon(x, y) = \begin{cases} 
1 & \text{if } |x - y| > \epsilon \\
0 & \text{otherwise}
\end{cases}
$$

Combining (9) and (10) we have:

$$
\sup_{\Delta \in \mathbb{B}(R)} \mathbb{P}_{\Omega \sim P_D} \left[ \left| \frac{1}{D} \sum_{j=1}^{D} \cos(\omega_j^\top \Delta) - e^{-\frac{\|\Delta\|^2}{2}} \right| > \epsilon \right] \geq \frac{g(R) - \epsilon - \frac{D}{2}}{48} e^{-\frac{D}{2}}
$$

□

5 Applications

In this section, we provide examples of consequences of our theory. In particular, our theory allows for tighter results for the analysis of the expectation of the maximum error, and the sample complexity of kernel ridge regression and support vector machines.
5.1 Expectation of the Maximum Error

Proposition 3 of [Sutherland and Schneider, 2015] shows that when the kernel function $k$ is $L$-Lipschitz, the expected maximum error of approximation is bounded above by

$$
\mathbb{E}_{\Omega \sim P \mathcal{D}} \left[ \sup_{\Delta \in \mathbb{B}(R)} \left| \frac{1}{D} \sum_{i=1}^{D} \cos(\omega_i^\top \Delta) - k(\Delta) \right| \right] \in \mathcal{O}\left( \frac{\sqrt{dR}}{\sqrt{D}} \left( \mathbb{E}_{\Omega \sim P \mathcal{D}} \left[ \max_{i=1,\ldots,D} \|\omega_i\|_2 \right] + L \right) \right)
$$

We improve the above upper bound to be $\mathcal{O}(\frac{R^2}{D})$, by the following corollary:

**Corollary 1.** Let $k, P, \Omega$ be as in Theorem 1. We have that:

$$
\mathbb{E}_{\Omega \sim P \mathcal{D}} \left[ \sup_{\Delta \in \mathbb{B}(R)} \left| \frac{1}{D} \sum_{i=1}^{D} \cos(\omega_i^\top \Delta) - k(\Delta) \right| \right] \leq \frac{3^{1/6} \Gamma(1/6)}{\lambda^2 \epsilon} \frac{R^2}{\lambda + 1} m
$$

where $\Gamma$ is the Gamma function.

(Detailed proof of Corollary 1 can be found in Appendix B.3)

5.2 Kernel Ridge Regression

Given a training set of $n$ samples $\{(x_i, y_i)\}_{i=1}^{n}$, kernel matrix $K$, where $k_{ij} = k(x_i, x_j)$, and the vector $k_x = (k(x_1, x), \ldots, k(x_n, x))^\top$. As proved in Proposition 9 of [Sutherland and Schneider, 2015], the error probability for kernel ridge regression is bounded above by

$$
P\left[ |\hat{h}(x) - h(x)| \geq \epsilon \right] \leq \mathbb{P}_{\Omega \sim P \mathcal{D}} \left[ \sup_{\Delta} \left| \frac{1}{D} \sum_{i=1}^{D} \cos(\omega_i^\top \Delta) - k(\Delta) \right| \geq \frac{\lambda^2 \epsilon}{(\lambda + 1) m} \right]
$$

where

$$
h(x) = y^\top (K + \lambda I)^{-1} k_x
$$

$$
\hat{h}(x) = y^\top (\hat{K} + \lambda I)^{-1} \hat{k}_x
$$

$\hat{K}$ is the approximation of the kernel matrix $K$ using RFF, $\hat{k}_x = (\hat{k}(x_1, x), \ldots, \hat{k}(x_n, x))^\top$ is the approximation of $k_x$ from RFF, $\lambda$ is the regularization parameter and $m$ is the standard deviation of the values $y_1, \ldots, y_n$. With the upper bound of the error probability in [Sutherland and Schneider, 2015], the authors proved, by applying (11), that $|\hat{h}(x) - h(x)| \leq \epsilon$ with probability at least $1 - \delta$ if

$$
D \in \Omega\left( d \left( \frac{(\lambda + 1)m}{\lambda^2 \epsilon} \right)^2 \left( \log \frac{1}{\delta} + \log \frac{\sqrt{dR}((\lambda + 1)m)}{\lambda^2 \epsilon} \right) \right) = \Omega\left( \frac{d}{\epsilon^2} \left( \log \frac{1}{\delta} + \log \frac{\sqrt{dR}}{\epsilon} \right) \right)
$$

On the other hand, we reach the same result with less number of features. More specifically, from our result in Theorem II and (11), we obtain

$$
D \in \Omega\left( \left( \frac{(\lambda + 1)m}{\lambda^2 \epsilon} \right)^2 W(R^2/\delta^3) \right)
$$

where $W$ is Lambert’s W function.
5.3 Support Vector Machines

Now we consider support vector machine (SVM) classifiers. Given a training set of \( n \) samples \( \{(x_i, y_i)\}_{i=1}^{n} \) with \( y_i \in \{-1, +1\} \), the kernel embedding \( \Phi(x) : \mathcal{X} \rightarrow \mathcal{H} \), the SVM classifier \( h(x) = \eta^\top \Phi(x) \), where \( \eta \) is the parameter, and the optimization problem

\[
\arg \min_{\eta \in \mathcal{H}} \frac{1}{2} \|\eta\|^2 + \frac{C_0}{n} \sum_{i=1}^{n} \max(0, 1 - y_i \cdot \eta^\top \Phi(x_i))
\]

where \( C_0 \) is the regularization weight. As proved in Section 3.2 of [Sutherland and Schneider, 2015], if the RFF approximation of the kernel is controlled by \( \epsilon \), that is

\[
|k(x, y) - s(x, y)| \leq \epsilon
\]

then the approximation error \( |\hat{h}(x) - h(x)| \) of SVM is also controlled by

\[
|\hat{h}(x) - h(x)| \leq \sqrt{2} C_0 (n + \sqrt{n}) \frac{1}{4} \epsilon + C_0 (n + \sqrt{n}) \frac{1}{2} \epsilon
\]

\[
\in O(C_0 n \frac{1}{2} \epsilon \frac{1}{2})
\]

where \( \hat{h}(x) = \omega^\top \hat{\Phi}(x) \) and \( \hat{\Phi}(x) \) is the approximation of \( \Phi(x) \) using RFF. The results in [Sutherland and Schneider, 2015] show that if

\[
\epsilon \in \Theta\left(\sqrt{\frac{dW(D R^2 / \delta)}{D}}\right)
\]

\[
= \Theta\left(\sqrt{\frac{d}{D}} (\log D + \log R + \log \frac{1}{\delta})\right)
\]

where \( W \) is Lambert’s W function, then \( |\hat{h}(x) - h(x)| \leq O(C_0 n \frac{1}{2} \epsilon \frac{1}{2}) \) with probability at least \( 1 - \delta \). However, with our result in Theorem 1 we can control \( \epsilon \) to be

\[
\epsilon \in \Theta\left(\sqrt{\frac{W(R^2 / \delta^3)}{D}}\right)
\]

\[
= \Theta\left(\sqrt{\frac{1}{D}} (\log R + \log \frac{1}{\delta})\right)
\]

under which we also have \( |\hat{h}(x) - h(x)| \leq O(C_0 n \frac{1}{2} \epsilon \frac{1}{2}) \) with probability at least \( 1 - \delta \). (The dependence with respect to \( n \) can be customarily removed by using the weight \( C_0 \in \Omega(n^{-1/2}) \). This relates to scale the squared norm regularization as a function of the number of data points \( n \).)

6 Concluding Remarks

There are several ways of extending our work. For instance, note that [Rahimi and Recht, 2007, Sutherland and Schneider, 2015, Sriperumbudur and Szabó, 2015] focus on more general shift-invariant kernel functions. In this paper, all results are based on the assumption that the kernel function is Gaussian. Extensions to more general kernel functions can be of interest.
References

A Regarding the Bound in [Sriperumbudur and Szabó, 2015]

Theorem 1 of [Sriperumbudur and Szabó, 2015] proved the following upper bound:

\[
\mathbb{P}\left[ \sup_{x,y \in \mathbb{B}(R)} |k(x, y) - \langle z(x), z(y) \rangle| \geq \sqrt{2048 \log(2R+1) + 512d \log(2R+1) + 2 \log \frac{1}{\delta}} \leq \delta \right]
\]

If we rewrite the error threshold to be \( \epsilon \), by the fact that \( \sqrt{x} + \sqrt{y} = \Theta(\sqrt{x+y}) \) since \( \sqrt{x+y} \leq \sqrt{x} + \sqrt{y} \leq \sqrt{2(x+y)} \), we can rewrite (12) as:

\[
\mathbb{P}\left[ \sup_{x,y \in \mathbb{B}(R)} |k(x, y) - \langle z(x), z(y) \rangle| \geq \epsilon \right] \leq ((\sigma_p + 1)(2R+1))^{1024d} \exp\left(- \frac{D\epsilon^2}{2} + \frac{256d}{\log(2R+1)} \right)
\]

B Detailed Proofs

We state the proofs of all theorems and lemmas here.

B.1 Proof of Lemma 1

All statements and proofs in this section come from [Wasserman, 2010]. We reproduce the proof here in order to gain intuition and later generalize the proof, for the result shown in Lemma 2. First, we introduce an auxiliary lemma:

Lemma 4. [Wasserman, 2010] Let \( \Psi^* \) be Neyman-Pearson test, that is,

\[
\Psi^*(x) = \begin{cases} 
0 & \text{if } p_1(x) \geq p_2(x) \\
1 & \text{if } p_1(x) < p_2(x)
\end{cases}
\]

Then for any test function \( \Psi \)

\[
\mathbb{P}_1(\Psi(x) = 1) + \mathbb{P}_2(\Psi(x) = 0) \geq \mathbb{P}_1(\Psi(x)^* = 1) + \mathbb{P}_2(\Psi(x)^* = 0)
\]

in other words,

\[
\mathbb{P}_1(\Psi(x)^* = 1) + \mathbb{P}_2(\Psi(x)^* = 0) = \inf_{\Psi} [\mathbb{P}_1(\Psi(x) = 1) + \mathbb{P}_2(\Psi(x) = 0)]
\]
Proof. Note that \( p_1(x) \geq p_2(x) \) when \( \Psi(x) = 0 \) and \( p_1(x) < p_2(x) \) when \( \Psi(x) = 1 \), therefore

\[
\mathbb{P}_1(\Psi(x) = 1) + \mathbb{P}_2(\Psi(x) = 0) = \int_{\Psi(x)=1} p_1(x)dx + \int_{\Psi(x)=0} p_2(x)dx
\]

\[
\geq \int_{\Psi(x)=1} p_1(x)dx + \int_{\Psi(x)=0} p_2(x)dx
\]

\[
= \mathbb{P}_1(\Psi(x)^* = 1) + \mathbb{P}_2(\Psi(x)^* = 0)
\]

With the help of the auxiliary lemma above, we turn our attention to the proof of the main lemma.

Proof of Lemma. For simplicity, denote \( \theta(P_1) \) by \( \theta_1 \) and \( \theta(P_2) \) by \( \theta_2 \), and any \( E_x \sim P[x] \) by \( E_P[x] \). For any observation \( X \sim P^D \), define the test function \( \Psi \):

\[
\Psi(X) = \begin{cases} 
1 & \text{if } d(\hat{\theta}(X), \theta_2) \leq d(\hat{\theta}(X), \theta_1) \\
0 & \text{if } d(\hat{\theta}(X), \theta_2) > d(\hat{\theta}(X), \theta_1)
\end{cases}
\]

Note that if the true distribution \( P = P_1 \) and \( \Psi(X) = 1 \), then

\[
d(\theta_1, \theta_2) \leq d(\hat{\theta}(X), \theta_1) + d(\hat{\theta}(X), \theta_2) \leq d(\hat{\theta}(X), \theta_1) + d(\hat{\theta}(X), \theta_1) = 2d(\hat{\theta}(X), \theta_1)
\]

which implies

\[
d(\hat{\theta}(X), \theta_1) \geq \frac{d(\theta_1, \theta_2)}{2}
\]

We have

\[
\mathbb{E}_{P_1}[d(\hat{\theta}(X), \theta_1)] \geq \mathbb{E}_{P_1}[d(\hat{\theta}(X), \theta_1)1(\Psi(X) = 1)] \geq \frac{d(\theta_1, \theta_2)}{2} \mathbb{P}_1(\Psi(X) = 1)
\]

By an argument analogous to the above, we also have

\[
\mathbb{E}_{P_2}[d(\hat{\theta}(X), \theta_2)] \geq \frac{d(\theta_1, \theta_2)}{2} \mathbb{P}_2(\Psi(X) = 0)
\]
Thus we have
\[
\sup_{P \in \mathcal{P}} \mathbb{E}_P[d(\hat{\theta}(X_P), \theta(P))] \geq \max_{P \in \{P_1, P_2\}} \mathbb{E}_P[d(\hat{\theta}(X_P), \theta(P))]
\geq \frac{d(\theta_1, \theta_2)}{2} \max(\mathbb{P}_1(\Psi(X_P) = 1), \mathbb{P}_2(\Psi(X_P) = 0))
\geq \frac{d(\theta_1, \theta_2)}{2} \mathbb{P}_1(\Psi(X_P) = 1) + \mathbb{P}_2(\Psi(X_P) = 0)
\]
(Since the maximum is greater than or equal to the average)
\[
\geq \frac{d(\theta_1, \theta_2)}{2} \inf_{\Psi} \mathbb{P}_1(\Psi(X_P) = 1) + \mathbb{P}_2(\Psi(X_P) = 0)
\]

By taking the infimum on the left hand side, we have
\[
\inf_{\hat{\theta}} \max_{P \in \mathcal{P}} \mathbb{E}_P[d(\hat{\theta}(X_P), \theta(P))] \geq \frac{d(\theta_1, \theta_2)}{4} \int \min(p_1(x), p_2(x))dx
\]  \hspace{1cm} (13)

By Lemma 4, if we define
\[
\Psi^s(x) = \begin{cases} 
0 & \text{if } p_1(x) \geq p_2(x) \\
1 & \text{if } p_1(x) < p_2(x)
\end{cases}
\]
Then \(\Psi^s\) is the minimizer of \(\inf_{\Psi} \mathbb{P}_1(\Psi'(x) = 1) + \mathbb{P}_1(\Psi'(x) = 0)\) and
\[
\mathbb{P}_1(\Psi(X_P)^s \neq 0) + \mathbb{P}_2(\Psi(X_P)^s \neq 1) = \int_{p_2 > p_1} p_1(x)dx + \int_{p_2 \leq p_1} p_2(x)dx = \int \min(p_1(x), p_2(x))dx
\]  \hspace{1cm} (14)

Combining (13) and (14), we have
\[
\inf_{\hat{\theta}} \max_{P \in \mathcal{P}} \mathbb{E}_P[d(\hat{\theta}(X_P), \theta(P))] \geq \frac{d(\theta_1, \theta_2)}{4} \int \min(p_1(x), p_2(x))dx
\]

\[\square\]

**B.2 Proof of Lemma 2**

Note that in the above proof, we have used triangle inequality of norms. This implies that we can generalize Le Cam’s Lemma by considering any semimetric with relaxed triangle inequality. Moreover, since Le Cam’s Lemma holds for any \(\theta_1, \theta_2\), we can further generalize it by considering any nonnegative and symmetric function which has triangle inequality locally.

**Proof.** Here we follow the same notations as above. For any observation \(X_P \sim P^D\), define the test function \(\Psi\)
\[
\Psi(X_P) = \begin{cases} 
1 & \text{if } d(\hat{\theta}(X_P), \theta_2) \leq d(\hat{\theta}(X_P), \theta_1) \\
0 & \text{if } d(\hat{\theta}(X_P), \theta_2) > d(\hat{\theta}(X_P), \theta_1)
\end{cases}
\]
Note that if the true distribution $P = P_1$ and $\Psi(X) = 1$ and $\epsilon < d(\theta_1, \theta_2)$, then by relaxed triangle inequality

\[ d(\theta_1, \theta_2) \leq A(d(\hat{\theta}(X_P), \theta_1) + d(\hat{\theta}(X_P), \theta_2)) \leq A(d(\hat{\theta}(X_P), \theta_1) + d(\hat{\theta}(X_P), \theta_1)) = 2Ad(\hat{\theta}(X_P), \theta_1) \]

which implies

\[ d(\hat{\theta}(X_P), \theta_1) \geq \frac{d(\theta_1, \theta_2)}{2A} \]

We have

\[ \mathbb{E}_{P_1}[d(\hat{\theta}(X_P), \theta_1)] \geq \mathbb{E}_{P_1}[d(\hat{\theta}(X_P), \theta_1)\mathbb{1}(\Psi(X_P) = 1)] \geq \frac{d(\theta_1, \theta_2)}{2A} \mathbb{P}_1(\Psi(X_P) = 1) \]

By an argument analogous to the above, we also have

\[ \mathbb{E}_{P_2}[d(\hat{\theta}(X_P), \theta_2)] \geq \frac{d(\theta_1, \theta_2)}{2A} \mathbb{P}_2(\Psi(X_P) = 0) \]

Thus we have

\[
\sup_{P \in \mathcal{P}} \mathbb{E}_P[d(\hat{\theta}(X_P), \theta(P))] \geq \max_{P \in \{P_1, P_2\}} \mathbb{E}_P[d(\hat{\theta}(X_P), \theta(P))] \\
\geq \frac{d(\theta_1, \theta_2)}{2A} \max(\mathbb{P}_1(\Psi(X_P) = 1), \mathbb{P}_2(\Psi(X_P) = 0)) \\
\geq \frac{d(\theta_1, \theta_2)}{2A} (\mathbb{P}_1(\Psi(X_P) = 1) + \mathbb{P}_2(\Psi(X_P) = 0)) \\
\geq \frac{d(\theta_1, \theta_2)}{2A} \inf_{\Psi} \frac{\mathbb{P}_1(\Psi(X_P) = 1) + \mathbb{P}_2(\Psi(X_P) = 0)}{2}
\]

By taking the infimum on the left hand side, we have

\[
\inf_{\hat{\theta}} \sup_{P \in \mathcal{P}} \mathbb{E}_P[d(\hat{\theta}(X_P), \theta(P))] \geq \frac{d(\theta_1, \theta_2)}{2A} \inf_{\Psi} \frac{\mathbb{P}_1(\Psi(X_P) = 1) + \mathbb{P}_2(\Psi(X_P) = 0)}{2} \tag{15}
\]

By Lemma 3, if we define

\[ \Psi^*(x) = \begin{cases} 
0 & \text{if } p_1(x) \geq p_2(x) \\
1 & \text{if } p_1(x) < p_2(x)
\end{cases} \]

Then $\Psi^*$ is the minimizer of $\inf_{\Psi'} \mathbb{P}_1(\Psi'(x) = 1) + \mathbb{P}_1(\Psi'(x) = 0)$ and

\[ \mathbb{P}_1(\Psi(X_P)^* \neq 0) + \mathbb{P}_2(\Psi(X_P)^* \neq 1) = \int_{p_2 > p_1} p_1(x) dx + \int_{p_2 \leq p_1} p_2(x) dx = \int \min(p_1(x), p_2(x)) dx \tag{16} \]

Combining (15) and (16), we have

\[ \inf_{\hat{\theta}} \sup_{P \in \mathcal{P}} \mathbb{E}_P[d(\hat{\theta}(X_P), \theta(P))] \geq \frac{d(\theta_1, \theta_2)}{4A} \int \min(p_1(x), p_2(x)) dx \]

\[ \square \]
B.3 Proof of Corollary

Proof. By the layer cake representation and Theorem, we have:

$$E_{\Omega \sim P^D} \left[ \sup_{\Delta \in \mathbb{B}(R)} \left| \frac{1}{D} \sum_{i=1}^{D} \cos(\omega_i^\top \Delta) - k(\Delta) \right| \right] = \int_0^\infty \mathbb{P}_{\Omega \sim P^D} \left[ \sup_{\Delta \in \mathbb{B}(R)} \left| \frac{1}{D} \sum_{i=1}^{D} \cos(\omega_i^\top \Delta) - k(\Delta) \right| \geq \epsilon \right] d\epsilon$$

$$\leq \int_0^\infty 3 \frac{R^{2/3}}{D^{1/3} \epsilon^{2/3}} \exp \left( - \frac{D\epsilon^2}{16} \right) d\epsilon$$

$$= \frac{3^{1/6} \Gamma(1/6) R^{2/3}}{2^{2/3} \sqrt{D}}$$
