Bell’s Inequality, Generalized Concurrence
and Entanglement in Qubits

Abstract

It is well known that the maximal violation of the Bell’s inequality for a two-qubit system is related to the entanglement formation in terms of a concurrence. However, a generalization of this relation to an n-qubit state has not been found. In the paper, we demonstrate some extensions of the relation between the upper bound of the Bell’s violation and a generalized concurrence in several n-qubit states. In particular, we show the upper bound of the Bell’s violation can be expressed as a function of the generalized concurrence, if a state can be expressed in terms of two variables. We apply the relation to the Wen-Plaquette model and show that the topological entanglement entropy can be extracted from the maximal Bell’s violation.
1 Introduction

Quantum entanglement is an essential concept in quantum systems that has no classical counterpart. In the past five decades, many developments including quantum information [1], quantum algorithm [2] and Bell’s inequality [3, 4], provide a deeper understanding of the quantum world. The basic concept of the quantum entanglement can be understood from the separability of a quantum state, which states if a state is inseparable, it is called an “entangled state”. The Bell state is the simplest example of an entanglement state $|\psi\rangle_{\text{Bell}} = \frac{1}{\sqrt{2}}(|0\rangle_A \otimes |1\rangle_B - |1\rangle_A \otimes |0\rangle_B)$, where the $|0(1)\rangle_{A(B)}$ represents a two level state in the subsystem $A(B)$.

Although the definition of an entangled state is clear, how to measure the ”entanglement” is rather subtle. On the one hand, the most common measure of entanglement is given by the entanglement entropy of a region $A, S_{\text{EE},A} = -\text{Tr} \rho_A \ln \rho_A$ with $\rho_A = \text{Tr}_B \rho$ being a reduced density matrix of a subsystem $A$ and $\rho$ being a density matrix of a Hilbert space $\mathbb{H} = \mathbb{H}_A \otimes \mathbb{H}_B$. When the entanglement entropy vanishes, the quantum entanglement between complementary subsystems $A$ and $B$ disappears. This measure of entanglement only requires the information of the local (reduced) density matrix $\rho_A$, which encodes its degree of entanglement with the complementary subsystem $B$. On the other hand, quantum entanglement is also encoded in the correlations between two local measurements on subsystems $A$ and $B$. The famous result of the violation of Bell’s inequality [3, 4] states that the correlations between different measurements of two separated particles of an entangled state must satisfy the inequality under the local realism. The violation of the constraints or Bell’s inequality indicates quantum entanglement in the system, which is demonstrated in two-qubit systems both theoretically [5] and experimentally [6, 7, 8].

Although the violation of the Bell’s inequality indicates quantum entanglement, how to quantify the ”entanglement” from the Bell’s correlators in many-body systems are not clear. In a two-qubit system, a relation between entanglement entropy, measured in terms of the concurrence [9], and violation of the Bell’s inequality is shown [10] through eigenvalues of an $R$-matrix [11]. An upper bound of Bell’s inequality for some three-qubit quantum states was also studied [12]. These studies show the entanglement, in terms of purity and concurrence, can be captured from the extremal Bell violations in few-body systems. In this paper, we extended this concept further to $n$-qubit systems. In particular, we consider an $n$-qubit state with two variables $(\lambda_+, \lambda_-)$ such that the concurrence can be expressed as $C(\psi(\lambda_+, \lambda_-))$. We show that if there exists an inverse mapping $(\lambda_+(C(\psi)), \lambda_-(C(\psi)))$, the upper bound of the violation of the Bell’s inequality

1
measured from an \( n \)-qubit Bell’s operator \([13, 14]\) can be expressed a function of a \textit{generalized} concurrence. In addition, we show in Theorem 2.1, this upper bound is the maximal violation of the Bell’s inequality for a specific \( n \)-qubit state.

The application of this relation in \( n \)-qubit systems is tremendous. In cutting edge experiments, quantum entanglement can be measured beyond a qubit system but is only accessible for few-body systems. This is because of the measures of entanglement requires probes with a single-site resolution such as a beam splitter operation in ultracold atoms \([15]\) or the nuclear magnetic resonance (NMR) quantum simulator on molecular \([16, 17, 18, 19, 20]\). On the other hand, the measure of Bell’s operators is accessible for many-body systems and is demonstrated experimentally for 480 atoms in a Bose-Einstein condensate\([21]\). The relation between the upper bound of the maximal violation of the Bell’s inequality and a generalized concurrence in \( n \)-qubit systems may provide an alternative measure of entanglement beyond few-body systems. The application of this generalization is the essential motivation presented in this paper.

Although we did not find a general relation for a generic \( n \)-qubit state, the examples that we demonstrated can apply to topological orders. Simple \( n \)-qubit models of topological orders are the toric code model \([22]\) and the Wen-Plaquette model \([23]\), which are constructed from stabilizer operators. It was shown that the topological entanglement entropy can detect the number of distinct quasi-particles when subregions are contractible \([24, 25]\). For a non-contractible region, one can also obtain the topological entanglement entropy, but it does not imply a number of distinct quasi-particles \([26]\). Hence, the entanglement measurement can be a direct probe of detecting topological orders. We show the topological entanglement entropy can be measured from the maximal violation of the Bell’s inequality in a Wen-Plaquette model \([23]\).

The structure of this paper is as follows. In Sec. 2 we study a relation between entanglement entropy and maximal violation of Bell’s inequality in the case that each quantum state is a linear combination of two product states. In Sec. 3 we demonstrate this relation in an XY model at zero and finite temperature and its application in the Wen-Plaquette model. We show the topological entanglement entropy in the Wen-Plaquette model can be computed from the relation of the maximal violation of the Bell’s inequality and the generalized concurrence. In Sec. 4 we demonstrate that this relation is also hold in a certain type of \( 2n \)-qubit states. Finally, we discuss and conclude in Sec. 5.
2 Entanglement and Maximal Violation

The Bell’s operator of $n$ qubits is defined iteratively as that [13]

$$\mathcal{B}_n = \mathcal{B}_{n-1} \otimes \frac{1}{2} \left( A_n + A'_n \right) + \mathcal{B}'_{n-1} \otimes \frac{1}{2} \left( A_n - A'_n \right), \quad (1)$$

where $A_n = a_n \cdot \sigma$, and $A'_n = a'_n \cdot \sigma$ are the operators in the $n$-th qubit with $a_n$ and $a'_n$ being unit vectors and $\sigma = (\sigma_x, \sigma_y, \sigma_z)$ being a vector of the Pauli matrices. The $(n-1)$-qubit operators $\frac{1}{2} \mathcal{B}_{n-1}$ and $\frac{1}{2} \mathcal{B}'_{n-1}$ act on the rest of the qubits. Note that we choose:

$$\frac{1}{2} \mathcal{B}_1 = b \cdot \sigma, \quad \frac{1}{2} \mathcal{B}'_1 = b' \cdot \sigma \quad (2)$$

with $b$ and $b'$ being unit vectors. It is known that for an $n$-qubit system, the upper bound of the expectation value of the Bell’s operator [13]

$$\text{Tr}(\rho \mathcal{B}_n) \leq 2^{\frac{n+1}{2}} \quad (3)$$

leads to violation of the Bell’s inequality [3].

For a given density matrix, the maximal expectation value of a Bell’s operator is called the maximal violation of Bell’s inequality. Here we prove a relation between maximal violation of the Bell’s inequality and a concurrence of a pure state or entanglement entropy in an $n$-qubit system [14] when the all $i$-th operators in the Bell’s operator are $A_i$ and $A'_i$ for $2 \leq i < n$

$$\tilde{\mathcal{B}}_n = \mathcal{B}_1 \otimes A_2 \otimes A_3 \otimes \cdots \otimes A_{n-2} \otimes A_{n-1} \otimes \frac{1}{2} \left( A_n + A'_n \right)$$

$$+ \mathcal{B}'_1 \otimes A'_2 \otimes A'_3 \otimes \cdots \otimes A'_{n-2} \otimes A'_{n-1} \otimes \frac{1}{2} \left( A_n - A'_n \right). \quad (4)$$

To proceed our derivation, we first introduce the generalized $R$-matrix:

$$R_{i_1 i_2 \cdots i_n} \equiv \text{Tr}(\rho \sigma_{i_1} \otimes \sigma_{i_2} \otimes \cdots \otimes \sigma_{i_n}) \equiv R_{I i_n}, \quad (5)$$

where $\rho$ is a density matrix, $\sigma_{i_\alpha}$ is the Pauli matrix labeled by $i_\alpha = x, y, z$ with site indices $\alpha = 1, 2, \cdots, n$. We express the generalized $R$-matrix as a $3^{n-1} \times 3$ matrix $R_{I i_n}$ with the first index being a multi-index $I = i_1 i_2 \cdots i_{n-1}$ and the second index being $i_n$. In a two-qubit system, maximal violation of the Bell’s inequality was computed from the $3 \times 3$ matrix $R_{ij}$ [11], which is a special case of the generalized $R$-matrix or the two-qubit system $n = 2$. Now we use the generalized $R$-matrix to generalize the maximal violation of the Bell’s inequality ($\tilde{\mathcal{B}}_n$) in an $n$-qubit system [14].
Lemma 1. The maximal violation of the Bell’s inequalities has the following relation:

$$\gamma \equiv \max_{\tilde{B}_n} \text{Tr}(\rho \tilde{B}_n) \leq 2\sqrt{u_1^2 + u_2^2},$$

(6)

where $u_1^2$ and $u_2^2$ are the first two largest eigenvalues of the matrix $R^\dagger R$ when a number of qubits larger than two, $n > 2$, and

$$\gamma = 2\sqrt{u_1^2 + u_2^2}$$

(7)

when a number of qubits is two, $n = 2$. Note that the matrix $R^\dagger R$ is contracted over the multi-index $I$.

Proof. We first introduce two three-dimensional orthonormal vectors $\hat{c}$ and $\hat{c}'$ such that:

$$\hat{a} + \hat{a}' = 2\hat{c}\cos \theta, \quad \hat{a} - \hat{a}' = 2\hat{c}'\sin \theta,$$

(8)

where $\theta \in [0, \frac{\pi}{2}]$, through three-dimensional unit vectors $\hat{a}$ and $\hat{a}'$. The maximal violation of the Bell’s inequality is defined as

$$\gamma \equiv \max_{\tilde{B}_n} \text{Tr}(\rho \tilde{B}_n)$$

(9)

with the Bell’s operator of $n$-qubit $\tilde{B}_n$ defined in (4). By using the generalized $R$-matrix and the unit vectors:

$$\hat{B} \equiv \hat{B}_I = \hat{B}_{i_1i_2\cdots i_{n-1}} \equiv \hat{a}_{1,i_1}\hat{a}_{2,i_2}\cdots \hat{a}_{n-1,i_{n-1}},$$

$$\hat{B}' \equiv \hat{B}'_I = \hat{B}'_{i_1i_2\cdots i_{n-1}} \equiv \hat{a}'_{1,i_1}\hat{a}'_{2,i_2}\cdots \hat{a}'_{n-1,i_{n-1}},$$

$$\tilde{\hat{a}} \equiv \hat{a}_{n,i_n}, \quad \tilde{\hat{a}'} \equiv \hat{a}'_{n,i_n},$$

(10)

in which $\hat{B}$ and $\hat{B}'$ are unit vectors in $3^{n-1}$ dimensions, we have:

$$\gamma = \max_{\hat{B},\hat{B}',\tilde{\hat{a}},\tilde{\hat{a}}'} \left( \langle \hat{B}, R(\tilde{\hat{a}} + \tilde{\hat{a}}') \rangle + \langle \hat{B}', R(\tilde{\hat{a}} - \tilde{\hat{a}}') \rangle \right)$$

$$\leq \max_{\hat{c},\hat{c}',\theta} \left( 2||R\hat{c}||\cos \theta + 2||R\hat{c}'||\sin \theta \right) = 2\sqrt{u_1^2 + u_2^2},$$

(11)

in which $u_1^2$ and $u_2^2$ are the first two largest eigenvalues of the matrix $R^\dagger R$. The inner product and the norm are defined as:

$$\langle P, Q \rangle \equiv P^\dagger Q, \quad ||U|| \equiv \sqrt{U^\dagger U}.$$  

(12)

Because $R(\tilde{\hat{a}} + \tilde{\hat{a}}')$ and $R(\tilde{\hat{a}} - \tilde{\hat{a}}')$ are defined in $3^{n-1}$ dimensions and each unit vector $\hat{B}$ and $\hat{B}'$ only contains $2(n-1)$ parameters, there is no guarantee for the below relations:

$$\hat{B} = k_1 R(\tilde{\hat{a}} + \tilde{\hat{a}}'), \quad \hat{B}' = k_2 R(\tilde{\hat{a}} - \tilde{\hat{a}}'),$$

(13)

except for $n = 2$, where $k_1$ and $k_2$ are two arbitrary constants. □
An earlier approach to relate the maximal violation of the Bell’s inequality and the concurrence of a pure state [9]

\[ C(\psi) \equiv \sqrt{2(1 - \text{Tr}\rho_A^2)} \] (14)

in a two-qubit system was discussed [10].

Now we generalize the relation of the maximal violation of the Bell’s inequality and the concurrence of a pure state in an \( n \)-qubit system, which still monotonically increases with respect to entanglement entropy, when a quantum state is a linear combination of two product states. The concurrence of the pure state is computed with respect to the bipartition with \((n - 1)\) qubits in a subsystem \(B\) and one qubit in a subsystem \(A\).

**Theorem 1.** We consider an \( n \)-qubit state

\[ |\psi\rangle = |u\rangle_B \otimes (\lambda_+ |v\rangle_B \otimes |1\rangle_A + \lambda_- |\bar{v}\rangle_B \otimes |0\rangle_A) \] (15)

with \( \lambda_+ |v\rangle_B \otimes |1\rangle_A + \lambda_- |\bar{v}\rangle_B \otimes |0\rangle_A \) being a non-biseparable, \( \alpha \)-qubit state, \(|u\rangle_B, |v\rangle_B, |\bar{v}\rangle_B \) being product states consisting of \( |0\rangle \)'s and \( |1\rangle \)'s. The state \(|v\rangle_B\) is orthogonal to the state \(|\bar{v}\rangle_B\) by choosing opposite bits on each site. Coefficients \( \lambda_+ \) and \( \lambda_- \) are real numbers and \( \lambda_+^2 + \lambda_-^2 = 1 \). The maximal violation of the Bell’s inequality in an \( n \)-qubit system is

\[ \gamma = 2f_\alpha(\psi), \] (16)

in which the function \( f_\alpha(\psi) \) is defined as:

1. \( \alpha \) is an even number:

\[ f_\alpha(\psi) \equiv \sqrt{1 + 2^{\alpha - 2} - 2C^2(\psi)}, \quad 2^{2-\alpha} \geq C^2(\psi), \]

\[ f_\alpha(\psi) \equiv 2^{\alpha - 1} C(\psi), \quad 2^{2-\alpha} \leq C^2(\psi). \] (17)

2. \( \alpha \) is an odd number:

\[ f_\alpha(\psi) \equiv \sqrt{1 + (2^{\alpha - 2} - 1)C^2(\psi)}, \quad \frac{1}{1 + 2^{\alpha - 2}} \geq C^2(\psi), \]

\[ f_\alpha(\psi) \equiv 2^{\alpha - 1} C(\psi), \quad \frac{1}{1 + 2^{\alpha - 2}} \leq C^2(\psi). \] (18)

Here \( C(\psi) \) is the concurrence of the pure state computed with respect to the bipartition that the subsystem \(B\) contains \((n - 1)\) qubits and the subsystem \(A\) contains one qubit.
Proof. The Hilbert space of an \( n \)-qubit system is bipartitioned as \( \mathbb{H} = \mathbb{H}_B \otimes \mathbb{H}_A \), in which dimensions of the sub-Hilbert spaces are \( \dim(\mathbb{H}_A) = 2 \) and \( \dim(\mathbb{H}_B) = 2^{n-1} \). We consider a quantum state with respect to this bipartition

\[
\ket{\psi} = |u\rangle_B \otimes (\lambda_+ |v\rangle_B \otimes |1\rangle_A + \lambda_- |\bar{v}\rangle_B \otimes |0\rangle_A),
\]

where \( |u\rangle_B \otimes |v\rangle_B \) and \( |u\rangle_B \otimes |\bar{v}\rangle_B \) are the product states in \( \mathbb{H}_B \) and \( |1\rangle_A \) and \( |0\rangle_A \) are the product states in \( \mathbb{H}_A \). By using the properties:

\[
\text{Tr}\rho_A = \lambda_+^2 + \lambda_-^2 = 1, \quad C(\psi) = \sqrt{2(1 - \lambda_+^4 - \lambda_-^4)},
\]

the coefficients \( \lambda_{\pm} \) can be expressed in terms of the concurrence

\[
\lambda_{\pm}^2 = \left( 1 \pm \sqrt{1 - C^2(\psi)} \right)/2.
\]

The generalized \( R \)-matrix is:

\[
egin{align*}
R_{I_x} &= \lambda_+ \lambda_- \text{Tr} [\sigma_{I_1} |u\rangle \langle u| \otimes \sigma_{I_2} (|v\rangle \langle \bar{v}| + |\bar{v}\rangle \langle v|)], \\
R_{I_y} &= -i \lambda_+ \lambda_- \text{Tr} [\sigma_{I_1} |u\rangle \langle u| \otimes \sigma_{I_2} (|v\rangle \langle \bar{v}| - |\bar{v}\rangle \langle v|)], \\
R_{I_z} &= -\lambda_+^2 \text{Tr} [\sigma_{I_1} |u\rangle \langle u| \otimes \sigma_{I_2} |v\rangle \langle v|] + \lambda_-^2 \text{Tr} [\sigma_{I_1} |u\rangle \langle u| \otimes \sigma_{I_2} |\bar{v}\rangle \langle \bar{v}|],
\end{align*}
\]

where \( I \equiv I_1 I_2 \) concatenating two strings of indices, \( I_1 \equiv i_1 \cdots i_{n-\alpha-1} \) and \( I_2 \equiv i_{n-\alpha} \cdots i_{n-1} \). We also define that \( \sigma_{I_1} \equiv \sigma_1 \otimes \cdots \otimes \sigma_{i_{n-\alpha-1}} \), \( \sigma_{I_2} \equiv \sigma_{i_{n-\alpha}} \otimes \cdots \otimes \sigma_{i_{n-1}} \).

Here we choose the basis, \( |0\rangle \equiv (1, 0)^T \) and \( |1\rangle \equiv (0, 1)^T \). One should notice that the dimensions of the matrix \( |u\rangle \langle u| \) is \( 2^{n-\alpha} \) and the dimensions of the matrices \( |v\rangle \langle \bar{v}| \), \( |\bar{v}\rangle \langle v| \) are \( 2^{n-1} \). The non-vanishing matrix elements of the generalized \( R \)-matrix \( R_{I\alpha}, \alpha = x, y, z \), come from the diagonal matrix elements of the below matrices:

\[
\begin{align*}
\sigma_{I_1} |u\rangle \langle u| \otimes \sigma_{I_2} |v\rangle \langle v|, & \quad \sigma_{I_1} |u\rangle \langle u| \otimes \sigma_{I_2} |\bar{v}\rangle \langle \bar{v}|, \\
\sigma_{I_1} |u\rangle \langle u| \otimes \sigma_{I_2} |\bar{v}\rangle \langle v|, & \quad \sigma_{I_1} |u\rangle \langle u| \otimes \sigma_{I_2} |v\rangle \langle \bar{v}|.
\end{align*}
\]

Then the conditions of non-vanishing matrix elements of the generalized \( R \)-matrix \( R_{I\alpha} \), where \( \alpha = x, y, z \), require the followings:

\[
\begin{align*}
\sigma_{I_1} |u\rangle &\rightarrow |u\rangle, \quad \sigma_{I_2} |\bar{v}\rangle &\rightarrow |v\rangle, \quad \sigma_{I_2} |v\rangle &\rightarrow |\bar{v}\rangle
\end{align*}
\]

for the generalized \( R \)-matrix \( R_{I\alpha(y)} \) and

\[
\begin{align*}
\sigma_{I_2} |u\rangle &\rightarrow |u\rangle, \quad \sigma_{I_2} |v\rangle &\rightarrow |v\rangle, \quad \sigma_{I_2} |\bar{v}\rangle &\rightarrow |\bar{v}\rangle
\end{align*}
\]

for the generalized \( R \)-matrix \( R_{Iz} \).
The conditions of the non-vanishing matrix elements $R_{Ix}$ are $(n - \alpha)$ number of the $\sigma_z$ matrices in the indices $I_1$, $(\alpha - 1 - j_1)$ number of the $\sigma_x$ matrices and $j_1$ number of the $\sigma_y$ matrices in the indices $I_2$ with $j_1$ being an even integer. The conditions of the non-vanishing matrix elements $R_{Iy}$ are $(n - \alpha)$ number of the $\sigma_z$ matrices in the indices $I_1$, $(\alpha - 1 - j_2)$ number of the $\sigma_x$ matrices and $j_2$ number of the $\sigma_y$ matrices in indices $I_2$ with $j_2$ being an odd integer. The conditions of the non-vanishing matrix elements $R_{Iz}$ are $(n - \alpha)$ number of the $\sigma_z$ matrices in the indices $I_1$, $(\alpha - 1)$ number of the $\sigma_z$ matrices in the indices $I_2$.

The above conditions lead to a diagonal form of the matrix $R^\dagger R$. In the case that $\alpha$ is an even integer, the eigenvalues of the matrix $R^\dagger R$ are:

$$
(1 + C_2^{n-1} + C_4^{n-1} + \cdots + C_{n-1}^{n-1})C^2(\psi_i) = 2^{n-1}C^2(\psi_i),
$$

$$
(1 + C_2^{n-1} + C_4^{n-1} + \cdots + C_{n-1}^{n-1})C^2(\psi_i) = 2^{n-2}C^2(\psi_i),
$$

1.

(26)

In the case that the integer $\alpha$ is an odd integer, the eigenvalues of the matrix $R^\dagger R$ are:

$$
(1 + C_2^{n-1} + C_4^{n-1} + \cdots + C_{n-1}^{n-1})C^2(\psi_i) = 2^{n-2}C^2(\psi_i),
$$

$$
(1 + C_2^{n-1} + C_4^{n-1} + \cdots + C_{n-1}^{n-1})C^2(\psi_i) = 2^{n-3}C^2(\psi_i),
$$

1 - C^2(\psi_i).

(27)

We used $C_k^n = C_{k-1}^{n-1} + C_{k-2}^{n-1}$, which comes from each coefficient of the equation $(1+x)^n = (1 + x)^{n-1}(1 + x)$, to compute the $xx$-component of the matrix $(R^\dagger R)_{x x}$ and the $yy$-component of the matrix $(R^\dagger R)_{y y}$.

From the eigenvalues of the matrix $R^\dagger R$, we obtain the followings:

$$
f_\alpha(\psi) \equiv \sqrt{1 + 2^{n-2}C^2(\psi)},
$$

$$
f_\alpha(\psi) \equiv 2^{n-2}C(\psi),
$$

(28)

when $\alpha$ is an even number,

$$
f_\alpha(\psi) \equiv \sqrt{1 + 2^{n-2} - 1}C^2(\psi),
$$

$$
f_\alpha(\psi) \equiv 2^{n-3}C(\psi),
$$

(29)

when $n$ is an odd number and the inequality

$$
\gamma \leq 2f_\alpha(\psi).
$$

(30)
Now we want to show that the maximal violation of the Bell’s inequality should satisfy the below equations:

\[
\gamma = \max \langle \hat{B}, R(\hat{a} + \hat{a}') \rangle + \langle \hat{B}', R(\hat{a} - \hat{a}') \rangle = 2\sqrt{u_1^2 + u_2^2},
\]

in which \( u_1^2 \) and \( u_2^2 \) are the first two largest eigenvalues of the matrix \( R^t R \) and the variables are defined as the followings:

\[
\hat{B} \equiv \hat{a}_{1,i_1} \hat{a}_{2,i_2} \cdots \hat{a}_{n-1,i_{n-1}}, \quad \hat{B}' \equiv \hat{a}'_{1,i_1} \hat{a}'_{2,i_2} \cdots \hat{a}'_{n-1,i_{n-1}},
\]

\[
\hat{a} \equiv \hat{a}_{n,i_n}, \quad \hat{a}' \equiv \hat{a}'_{n,i_n},
\]

where

\[
\hat{a}_{n,i_n} + \hat{a}'_{n,i_n} \equiv 2 \hat{c}_{n,i_n} \cos \theta, \quad \hat{a}_{n,i_n} - \hat{a}'_{n,i_n} \equiv 2 \hat{c}'_{n,i_n} \sin \theta,
\]

with \( \theta \in [0, \pi/2] \). This equality holds when the below relations are satisfied:

\[
\hat{B} = k_1 R(\hat{a} + \hat{a}'), \quad \hat{B}' = k_2 R(\hat{a} - \hat{a}'),
\]

where \( k_1 \) and \( k_2 \) are constants. One natural choice of \( a_{\alpha,i_\alpha} \) and \( a'_{\alpha,i_\alpha} \) can be obtained by equating two ratios:

\[
\frac{|R_{I_2}(\hat{a}_x + \hat{a}'_x)|}{|R_{I'_2}(\hat{a}_y + \hat{a}'_y)|} = \frac{|B_I|}{|B'_I|}, \quad \frac{|R_{I_2}(\hat{a}_x - \hat{a}'_x)|}{|R_{I'_2}(\hat{a}_y - \hat{a}'_y)|} = \frac{|B'_I|}{|B'_I|},
\]

where the multi-index \( I \) and the multi-index \( I' \) are chosen in the way that one site of the index \( I_2 \) in the multi-index \( I \) is labeled by \( x \) and in the multi-index \( I' \) is labeled by \( y \), and other sites of the indices \( I_2 \) in the multi-index \( I \) and the multi-index \( I' \) are labeled by the same symbols. This leads to the following equations:

\[
\left| \frac{\hat{a}_{I_2,x}}{\hat{a}'_{I'_2,y}} \right| = \frac{\hat{c}_{n,x}}{\hat{c}'_{n,y}}, \quad \left| \frac{\hat{a}'_{I_2,x}}{\hat{a}'_{I'_2,y}} \right| = \frac{\hat{c}'_{n,x}}{\hat{c}'_{n,y}}.
\]

When the eigenvalues are

\[
u_1^2 = (R^t R)_{xx}, \quad u_2^2 = (R^t R)_{yy},
\]

we can choose the followings:

\[
(\hat{c}_{n,x}, \hat{c}_{n,y}, \hat{c}_{n,z})^T = \frac{1}{\sqrt{2}}(1, 1, 0), \quad (\hat{c}'_{n,x}, \hat{c}'_{n,y}, \hat{c}'_{n,z})^T = \frac{1}{\sqrt{2}}(1, -1, 0),
\]

\[
\cos(\theta) = \sin(\theta) = \frac{\sqrt{2}}{2},
\]

(38)
to show that the maximal violation of the Bell’s inequality saturates the upper bound
\[ \gamma = 2\sqrt{u_1^2 + u_2^2}. \]  

(39)

For the other case:
\[ u_1^2 = (R^d R)_{zz}, \quad u_2^2 = (R^d R)_{xx}, \]

(40)

we can choose the followings:
\[(\hat{c}_{n,x}, \hat{c}_{n,y}, \hat{c}_{n,z})^T = (0, 0, 1), \quad (\hat{c}'_{n,x}, \hat{c}'_{n,y}, \hat{c}'_{n,z})^T = \frac{1}{\sqrt{2}}(1, 1, 0), \]

(41)

\[ \cos(\theta) = \frac{u_1}{\sqrt{u_1^2 + u_2^2}}, \quad \sin(\theta) = \frac{u_2}{\sqrt{u_1^2 + u_2^2}} \]

to prove that the maximal violation of the Bell’s inequality saturates the upper bound
\[ \gamma = 2\sqrt{u_1^2 + u_2^2}. \]  

(42)

We prove that the maximal violation of the Bell’s inequality \((\tilde{B}_n)\) is directly related to the concurrence of the pure state when the subsystem \(A\) only contains one qubit and the quantum state is a linear combination of two product states. Because the concurrence of the pure state also monotonically increases with respect to entanglement entropy, the maximal violation of the Bell’s inequality is also related to entanglement entropy directly. For the maximally entangled state with the maximal concurrence of the pure state \(C(\psi) = 1\), the maximal violation of the Bell’s inequality is \(\gamma = 2^{n+1} \leq 2^{n+1}\) satisfies the upper bound of the Bell’s operator in an \(n\)-qubit system. Although we do not use the most generic form of the Bell’s operator, information of the quantum state is already contained in the \(n\)-th qubit operators. Thus, the computing of the generalized \(R\)-matrix should give the maximal violation of the Bell’s inequality \((\tilde{B}_n)\) directly when a quantum state is a linear superposition of two product states.

Now we discuss the maximal violation of the Bell’s inequality in a mixed state. The mixed state of a density matrix \(\rho\) is
\[ \rho = \sum_i p_i |\psi_i\rangle \langle \psi_i|, \]

(43)
in which the sum of $p_i$ is one. Because we have that:

$$
\gamma(\rho) := \max_{\mathcal{B}_n} \text{Tr}(\rho \mathcal{B}_n) = \max_{\mathcal{B}_n} \text{Tr}\left( \sum_i p_i |\psi_i\rangle \langle \psi_i| \mathcal{B}_n \right)
= \max_{\mathcal{B}_n} \sum_i p_i \langle \psi_i | \mathcal{B}_n | \psi_i \rangle \leq \sum_i p_i \cdot \max_{\mathcal{B}_n} \langle \psi_i | \mathcal{B}_n | \psi_i \rangle, \quad \text{(44)}
$$

We find the upper bound of the maximal violation of the Bell’s inequality of the mixed state is the sum of the maximal violation of the Bell’s inequality of the pure state with corresponding weight $p_i$.

Next, we want to relate this upper bound of the maximal violation of the Bell’s inequality of a mixed state to the concurrence of a mixed state. From Eq. (44), we have

$$
\gamma(\rho) \leq 2 \sum_i p_i f_\alpha(C(\psi_i)), \quad \text{(45)}
$$

where $f_\alpha(C(\psi_i))$ is defined in Eqs. (17) (18). The concurrence for mixed state is defined as [27]

$$
C(\rho) \equiv \min_{p_i, \psi_i} \sum_i p_i C(\psi_i), \quad \text{(46)}
$$

where $\{p_i, \psi_i\}$ is a chosen decomposition of $\rho$ such that minimize the right hand side of Eq. (46). When the function $f_\alpha$ is a linear function of the concurrence $C(\psi_i)$, $f_\alpha(C(\psi_i)) \propto C(\psi_i)$, we have the equality $\min_{p_i, \psi_i} \sum_i p_i f_\alpha(C(\psi_i)) = f_\alpha(\min_{p_i, \psi_i} \sum_i p_i C(\psi_i)) = f_\alpha(C(\rho))$. The maximal violation of the Bell’s inequality of a mixed state is bounded by the function of the concurrence of a mixed state, $\gamma(\rho) \leq 2 f_\alpha(C(\rho))$. On the other hand, in Eqs. (17) (18), we have the other form of the function $f_\alpha(C(\psi_i)) = \sqrt{1 + AC^2(\psi_i)}$ being a monotonously increasing convex function. Using the property of the monotonously increasing convex function, we have the inequality

$$
\min_{p_i, \psi_i} \sum_i p_i f_\alpha(C(\psi_i)) \geq f_\alpha(\min_{p_i, \psi_i} \sum_i p_i C(\psi_i)) = f_\alpha(C(\rho)). \quad \text{(47)}
$$

It was shown in Ref. [27] that there exists a decomposition of $\{p_i, \psi_i\}$ such that all the pure states $\psi_i$ have the same concurrence $C(\psi_i)$. This indicates the concurrence of a mixed state is exactly the same as the concurrence of pure states in this particular configuration, $C(\rho) = \min_{p_i, \psi_i} \sum_i p_i C(\psi_i) = C(\psi_i)$. Thus, the equality holds in Eq. (47), $\min_{p_i, \psi_i} \sum_i p_i f_\alpha(C(\psi_i)) = f_\alpha(C(\rho))$. Hence, we can conclude that the maximal violation
of the Bell’s inequality of a mixed state is bounded by the function of concurrence of a mixed state

\[ \gamma(\rho) \leq 2f_{\alpha}(C(\rho)) \]  

(48)

3  Applications of Theorem 2.1

We apply our results [Eqs. (16) and (48)] to two examples. The first one is an XY-model with a non-uniform magnetic field. As a demonstration, we only consider the two-qubit case at zero and finite temperature. The former one corresponds to a pure state and the later corresponds to a mixed state. The second example is the Wen-Plaquette model. In the case with only four sites, the ground state has the form as Eq. (15) and can be applied from Theorem 2.1. On the other hand, in the case with six sites, the ground state is not the form as Eq. (15) and Theorem 2.1 is not applicable. However, we can still relate the maximal violation of the Bell’s inequality and the generalized concurrence in this case. We then use this relation to extract the topological entanglement entropy \( S_{\text{TEE}} = \ln 2 \) in the Wen-Plaquette model.

3.1  Application in an XY-model

3.1.1  Zero Temperature

We consider the 2-qubit XY-model with the non-uniform magnetic field

\[ H_{\text{2qubits}} = -\frac{J}{2}(1 + \tilde{\gamma})\sigma_x \otimes \sigma_x + \frac{J}{2}(1 - \tilde{\gamma})\sigma_y \otimes \sigma_y \]

\[ -B(1 + \delta)\sigma_z \otimes I - B(1 - \delta)I \otimes \sigma_z, \]  

(49)

where

\[ 0 \leq \tilde{\gamma} \leq 1, \quad 0 \leq \delta \leq 1, \quad J \geq 0, \quad B \geq 0. \]  

(50)

Thus, the Hamiltonian is:

\[
H_{\text{2qubits}} = \begin{pmatrix}
-2B & 0 & 0 & -J\tilde{\gamma} \\
0 & 2B\delta & -J & 0 \\
0 & -J & -2B\delta & 0 \\
-J\tilde{\gamma} & 0 & 0 & 2B
\end{pmatrix}. \]  

(51)
The corresponding eigenvectors and eigenvalues are

\[ |\Psi_{1,\pm}\rangle = \begin{pmatrix} \mp \sqrt{\frac{\lambda_{1,\pm} \pm 2B}{2|\lambda_{1,\pm}|}} \\ 0 \\ 0 \\ \mp \sqrt{\frac{\lambda_{1,\pm} \pm 2B}{2|\lambda_{1,\pm}|}} \end{pmatrix} = \mp \sqrt{\frac{\lambda_{1,\pm} \pm 2B}{2|\lambda_{1,\pm}|}} |00\rangle + \sqrt{\frac{\lambda_{1,\pm} \pm 2B}{2|\lambda_{1,\pm}|}} |11\rangle, \]

\[ |\Psi_{2,\pm}\rangle = \begin{pmatrix} \mp \sqrt{\frac{\lambda_{2,\pm} \pm 2B\delta}{2|\lambda_{2,\pm}|}} \\ 0 \\ 0 \\ \pm \sqrt{\frac{\lambda_{2,\pm} \pm 2B\delta}{2|\lambda_{2,\pm}|}} \end{pmatrix} = \mp \sqrt{\frac{\lambda_{2,\pm} \pm 2B\delta}{2|\lambda_{2,\pm}|}} |10\rangle + \sqrt{\frac{\lambda_{2,\pm} \pm 2B\delta}{2|\lambda_{2,\pm}|}} |01\rangle, \]

(52)

where \( \lambda_{1,\pm} = \pm \sqrt{4B^2 + J^2G^2}, \lambda_{2,\pm} = \pm \sqrt{J^2 + 4B^2\delta^2}, \) and \(|00\rangle = (1, 0, 0, 0)^T, |11\rangle = (0, 0, 1, 0)^T, |10\rangle = (0, 1, 0, 0)^T, \) and \(|01\rangle = (0, 0, 1, 0)^T.\)

We first compute the R-matrices from Eq. (5) for these states which are all diagonal,

\[ R(\Psi_{1,\pm}) = \text{diag}(\mp \sqrt{\frac{\lambda_{1,\pm} \pm 4B^2}{2|\lambda_{1,\pm}|}}, \mp \sqrt{\frac{\lambda_{1,\pm} \pm 4B^2}{2|\lambda_{1,\pm}|}, 1}) \text{ and } R(\Psi_{2,\pm}) = \text{diag}(\mp \sqrt{\frac{\lambda_{2,\pm} \pm 4B^2}{2|\lambda_{2,\pm}|}}, \mp \sqrt{\frac{\lambda_{2,\pm} \pm 4B^2}{2|\lambda_{2,\pm}|}, -1}). \]

The maximal violation of the Bell’s inequality can be computed from the eigenvalues of \( R^\dagger R \) and is given in Eq. (7), \( \gamma(\Psi_{1,\pm}) = 2 \sqrt{1 + \frac{\lambda_{1,\pm} \pm 4B^2}{\lambda_{1,\pm}^2}} \) and \( \gamma(\Psi_{2,\pm}) = 2 \sqrt{1 + \frac{\lambda_{2,\pm} \pm 4B^2}{\lambda_{2,\pm}^2}}. \)

We can compute the concurrence direction from the pure states by Eq. (14),

\[ C(\Psi_{1,\pm}) = \frac{\lambda_{1,\pm} \pm 4B^2}{\lambda_{1,\pm}^2} \text{ and } C(\Psi_{2,\pm}) = \frac{\lambda_{2,\pm} \pm 4B^2}{\lambda_{2,\pm}^2}. \]

We can immediately see that Theorem 2.1 is held, \( \gamma(\Psi_{i,\pm}) = 2 \sqrt{1 + C(\Psi_{i,\pm})^2}, i = 1, 2. \) This relation demonstrates that we can extract the entanglement in terms of concurrence directly from the maximal violation of the Bell’s inequality.
### 3.1.2 Finite Temperature

To compute the density matrix at finite temperature, we first compute the following:

\[
\rho_{AB} = \exp \left( -\frac{1}{T} H_{2\text{qubits}} \right) \sum_{i=1,2;\alpha=\pm} |\Psi_{i,\alpha}\rangle \langle \Psi_{i,\alpha}| \]

\[
= \left( \cosh \left( \frac{|\lambda_{1,\pm}|}{T} \right) + 2 \frac{B}{|\lambda_{1,\pm}|} \sinh \left( \frac{|\lambda_{1,\pm}|}{T} \right) \right) |00\rangle \langle 00| \\
+ \left( \cosh \left( \frac{|\lambda_{1,\pm}|}{T} \right) - 2 \frac{B}{|\lambda_{1,\pm}|} \sinh \left( \frac{|\lambda_{1,\pm}|}{T} \right) \right) |11\rangle \langle 11| \\
+ \frac{\sinh \left( \frac{1}{T} \right)}{1 - \frac{4B^2}{\lambda_{1,\pm}^2}} \left( |00\rangle \langle 11| + |11\rangle \langle 00| \right) \\
+ \left( \cosh \left( \frac{|\lambda_{2,\pm}|}{T} \right) - 2 \frac{B\delta}{|\lambda_{2,\pm}|} \sinh \left( \frac{|\lambda_{2,\pm}|}{T} \right) \right) |10\rangle \langle 10| \\
+ \left( \cosh \left( \frac{|\lambda_{2,\pm}|}{T} \right) + 2 \frac{B\delta}{|\lambda_{2,\pm}|} \sinh \left( \frac{|\lambda_{2,\pm}|}{T} \right) \right) |01\rangle \langle 01| \\
+ \frac{\sinh \left( \frac{1}{T} \right)}{1 - \frac{4B^2\delta^2}{\lambda_{2,\pm}^2}} \left( |10\rangle \langle 01| + |01\rangle \langle 10| \right),
\]

(53)

where \( T \) is a temperature. We can use the density matrix at a finite temperature to compute the concurrence of the mixed state. We can determine a critical temperature \( T_c \) such that the concurrence of the mixed state vanishes.

The concurrence defined for a mixed state is given in Eq. (46). It is shown in Ref. [27] that Eq. (46) can be determined by \( C(\rho_{AB}) = \max(0, \xi_1 - \xi_2 - \xi_3 - \xi_4) \), where \( \xi_i \) are the eigenvalues, in decreasing order, of the quantity \( \sqrt{\rho_{AB}(\sigma_y \otimes \sigma_y)\rho_{AB}^*(\sigma_y \otimes \sigma_y)} \):

\[
\left\{ \xi_i \right\} = \left\{ \sqrt{\cosh^2 \left( \frac{|\lambda_{1,\pm}|}{T} \right) - \frac{4B^2}{|\lambda_{1,\pm}|^2} \sinh^2 \left( \frac{|\lambda_{1,\pm}|}{T} \right)} \pm \sinh \left( \frac{|\lambda_{1,\pm}|}{T} \right) \sqrt{1 - \frac{4B^2}{|\lambda_{1,\pm}|^2}} \right\}, \\
\left\{ \sqrt{\cosh^2 \left( \frac{|\lambda_{2,\pm}|}{T} \right) - \frac{4B^2\delta^2}{|\lambda_{2,\pm}|^2} \sinh^2 \left( \frac{|\lambda_{2,\pm}|}{T} \right)} \pm \sinh \left( \frac{|\lambda_{2,\pm}|}{T} \right) \sqrt{1 - \frac{4B^2\delta^2}{|\lambda_{2,\pm}|^2}} \right\}.
\]

(54)

The concurrence of the mixed state is

\[
\max \left( 2 \sinh \left( \frac{|\lambda_{1,\pm}|}{T} \right) \sqrt{1 - \frac{4B^2}{|\lambda_{1,\pm}|^2}} \right) - 2 \sqrt{\cosh^2 \left( \frac{|\lambda_{2,\pm}|}{T} \right) - \frac{4B^2\delta^2}{|\lambda_{2,\pm}|^2} \sinh^2 \left( \frac{|\lambda_{2,\pm}|}{T} \right)} , 0 \right)
\]

(55)
when
\[ \sqrt{\cosh^2\left(\frac{|\lambda_{1,\pm}|}{T}\right) - \frac{4B^2}{|\lambda_{1,\pm}|^2}\sinh^2\left(\frac{|\lambda_{1,\pm}|}{T}\right) + \sinh\left(\frac{|\lambda_{1,\pm}|}{T}\right)}\sqrt{1 - \frac{4B^2}{|\lambda_{1,\pm}|^2}} \geq \sqrt{\cosh^2\left(\frac{|\lambda_{2,\pm}|}{T}\right) - \frac{4B^2\delta^2}{|\lambda_{2,\pm}|^2}\sinh^2\left(\frac{|\lambda_{2,\pm}|}{T}\right) + \sinh\left(\frac{|\lambda_{2,\pm}|}{T}\right)}\sqrt{1 - \frac{4B^2\delta^2}{|\lambda_{2,\pm}|^2}}, \] (56)

and the concurrence of the mixed state is
\[ \max\left(2\sinh\left(\frac{|\lambda_{2,\pm}|}{T}\right)\sqrt{1 - \frac{4B^2\delta^2}{|\lambda_{2,\pm}|^2} - 2\cosh^2\left(\frac{|\lambda_{1,\pm}|}{T}\right) - \frac{4B^2}{|\lambda_{1,\pm}|^2}\sinh^2\left(\frac{|\lambda_{1,\pm}|}{T}\right)}, 0\right) \] (57)

when
\[ \sqrt{\cosh^2\left(\frac{|\lambda_{2,\pm}|}{T}\right) - \frac{4B^2\delta^2}{|\lambda_{2,\pm}|^2}\sinh^2\left(\frac{|\lambda_{2,\pm}|}{T}\right) + \sinh\left(\frac{|\lambda_{2,\pm}|}{T}\right)}\sqrt{1 - \frac{4B^2\delta^2}{|\lambda_{2,\pm}|^2}} \geq \sqrt{\cosh^2\left(\frac{|\lambda_{1,\pm}|}{T}\right) - \frac{4B^2}{|\lambda_{1,\pm}|^2}\sinh^2\left(\frac{|\lambda_{1,\pm}|}{T}\right) + \sinh\left(\frac{|\lambda_{1,\pm}|}{T}\right)}\sqrt{1 - \frac{4B^2}{|\lambda_{1,\pm}|^2}}, \] (58)

First, we consider when \( B = 0 \) which \( |\lambda_1| = J\tilde{\gamma} < J = |\lambda_2| \) and Eq. (58) hold. Hence the concurrence is given by Eq. (57)
\[ C(\rho_{AB}) = \max\left(2\sinh\left(\frac{|\lambda_{2,\pm}|}{T}\right) - 2\cosh\left(\frac{|\lambda_{1,\pm}|}{T}\right), 0\right). \] (59)

The critical temperature \( T_c \) can be found from the equation
\[ \sinh\left(\frac{J}{T_c}\right) = \cosh\left(\frac{J\gamma}{T_c}\right). \] (60)

Next, we consider \( \tilde{\gamma} = 0 \) and \( \delta = 1 \) case. In this case, \( |\lambda_1| < |\lambda_2| \) and the concurrence of the mixed state is given by Eq. (57)
\[ C(\rho_{AB}) = \max\left(2\sinh\left(\frac{\sqrt{J^2 + 4B^2}}{T}\right)\sqrt{1 - \frac{4B^2}{J^2 + 4B^2} - 2}, 0\right). \] (61)
The critical temperature is

$$T_c = \frac{\sqrt{J^2 + 4B^2}}{\sinh^{-1}\left(\sqrt{1 + \frac{4B^2}{J^2}}\right)}.$$  \hfill (62)

We observe that the critical temperature depends on the magnetic field $B$. When we take the limit $J \to \infty$, the critical temperature $T_c$ approaches to infinity. This is expected because the thermal state with infinite $J$ is still highly entangled. When we take another limit $J \to 0$, the concurrence of the mixed state approaches zero, since all spins are aligned along the direction of the magnetic field and will not be entangled. Thus, the mixed state approaches to a product state for each temperature in the limit. One interesting limit is taking the limit $B/J \to \infty$. The critical temperature approaches to $J$. These limits provide useful and interesting applications to entanglement from the concurrence of the mixed state at a finite temperature.

According to Eq. (48), if one measures the extremal Bell’s violation, it will be bounded by the function of the concurrence of the mixed states,

$$\max_{\mathcal{B}_n} \text{Tr}(\rho B_n) \leq 2f_2(\rho_{AB}) = 2\sqrt{1 + C^2(\rho_{AB})}.$$  \hfill (63)

### 3.2 Applications to the Wen-Plaquette Model

Next example we considered is the Wen-Plaquette model, which is a two-dimensional spin (qubit) model with the following interactions,

$$H_{WP} = \sum_i \sigma_i^x \sigma_y^{i+\hat{x}} \sigma_x^{i+\hat{y}} \sigma_y^{i+\hat{y}}.$$  \hfill (64)

Here qubits live on vertices with a four-spin interaction on each plaquette. A quantum state of the Hamiltonian is an $n$-qubit quantum state with $n$ being a number of vertices. First, we apply our Theorem 2.1 to a four-qubit quantum state, with the geometry of the system containing four vertices, eight edges, and four faces, in which the Euler number of the torus is zero [see Fig. 1(a)], $\chi = V - E + F = 0$ with $V$, $E$, and $F$ being a number of vertices, edges, and faces, respectively. There are four degenerate ground states $|G\rangle_{4\text{-qubit}}$:

$$\frac{1}{\sqrt{2}}(|0000\rangle + |1111\rangle), \quad \frac{1}{\sqrt{2}}(|1010\rangle + |0101\rangle),$$

$$\frac{1}{\sqrt{2}}(|0011\rangle - |1100\rangle), \quad \frac{1}{\sqrt{2}}(|1001\rangle - |0110\rangle).$$  \hfill (65)
We define the order of each site in these four-qubit states in the Fig. 1(a). We first compute the \( R \)-matrices from Eq. (5) for these states which are \( 27 \times 3 \) matrices. The \( R^\dagger R \) of different states have same diagonal form, \( R^\dagger R = \text{diag}(4, 4, 1) \), which lead to the maximal violation of Bell’s inequality \( \gamma = 4\sqrt{2} \) from the Lemma 2.1 (Eq. (7)).

Next we compute the concurrence directly from these ground state, \( C(|G\rangle_{4\text{-qubit}}) = 1 \). We immediately see that Theorem 2.1 [ Eq. (16)] still holds. The maximal violation of the Bell’s inequality is \( \gamma = 2 \times 2^{4-1} = 4\sqrt{2} \). Here we demonstrate that the maximal violation of the Bell’s inequality can be directly computed from the concurrence in the 4-qubit Wen-Plaquette model.

Next, we would like to consider a six-qubit states. The ground state of the Wen-Plaquette model are

\[
|G_1\rangle_{6\text{-qubit}} = \frac{1}{2} (- |111000\rangle + |001110\rangle + |100011\rangle + |010101\rangle),
\]

\[
|G_2\rangle_{6\text{-qubit}} = \frac{1}{2} (- |000111\rangle + |110001\rangle + |011100\rangle + |101010\rangle),
\]

with the site labels shown in Fig. 1(b). Obvious these states do not have the form of Theorem 2.1 and thus Theorem 2.1 is not applicable.

To relate the upper bound of the maximal violation of the Bell’s inequality and the \textit{generalized} concurrence (which we will define later), we need to rewrite the ground states in terms of two parameters \((\lambda_+, \lambda_-)\). Without loss of generality, we choose

\[
|\psi_1\rangle_{6\text{-qubit}} = \frac{\lambda_+}{\sqrt{2}} (- |111000\rangle + |001110\rangle) + \frac{\lambda_-}{\sqrt{2}} (|100011\rangle + |010101\rangle),
\]

\[
|\psi_2\rangle_{6\text{-qubit}} = \frac{\lambda_+}{\sqrt{2}} (- |000111\rangle + |110001\rangle) + \frac{\lambda_-}{\sqrt{2}} (|011100\rangle + |101010\rangle).
\]
When $\lambda_+ = \lambda_- = \frac{1}{\sqrt{2}}$, the above states are the ground states of the six-site Wen-Plaquette model.

Now we can relate the upper bound of the maximal violation of the Bell’s inequality to the generalized concurrence of the pure states given in Eq. (68). Two different bipartitions are considered: (1) subsystem $A$ contains a site number six, and (2) subsystem $A$ contains a site number five and a site number six. Here we use $\delta = 1$ or $2$ as an indicator for the case one and case two. According to the Lemma, we find that the upper bound of the maximal violation of the Bell’s inequality can be expressed by the eigenvalues of the $R^TR$ and will be a function of $(\lambda_+, \lambda_-)$. We then find the inverse mapping of the generalized concurrence such that these two parameters can be expressed in terms of the generalized concurrence $(C)$, $(\lambda_+(C), \lambda_-(C))$. Thus, the maximal Bell’s violation can be written as a function of the generalized concurrence $\gamma(C)$.

One should notice that the maximal Bell’s violation is bipartition independent but measures of entanglement are not, i.e., the concurrence, the entanglement entropy, or the purity may depend on how we bipartition the system. Here we define the generalized concurrence as following,

$$C(\delta) \equiv \sqrt{2 \left( 1 - 2^{\delta-1} \text{Tr} \rho^2_{A(\delta)} \right)},$$

which $\delta$ indicates different bipartitions. In we show that the above definition keeps the relation of the concurrence and entanglement entropy be independent on the bipartition $\delta$ in the toric code model. However, the purity $\text{Tr} \rho^2_{A(\delta)}$ still depends on the bipartition. We find that the relation of the generalized concurrence and entanglement entropy is also independent on the bipartitions in the 6-site Wen-Plaquette model as well. Hence the maximal violation of the Bell’s inequality will be the same functional form of the generalized concurrence as we will demonstrate in the follows.

Without repeating the similar calculation, we only give the computation of the quantum state $|G_1\rangle_{6\text{-qubit}}$. To obtain the upper bound of the maximal violation of the Bell’s inequality, we first compute the density matrix

$$\rho_{6\text{-qubit},1} = \frac{\lambda_+^2}{2} (|111000\rangle\langle 111000| + |001110\rangle\langle 001110| - |111000\rangle\langle 001110| - |001110\rangle\langle 111000|)
+ \frac{\lambda_-^2}{2} (|100011\rangle\langle 100011| + |010101\rangle\langle 010101| + |100011\rangle\langle 010101| + |010101\rangle\langle 100011|)
+ \frac{\lambda_+\lambda_-}{2} (- |111000\rangle\langle 100011| - |111000\rangle\langle 010101| + |001110\rangle\langle 100011| + |001110\rangle\langle 010101|
- |100011\rangle\langle 111000| - |010101\rangle\langle 111000| + |100011\rangle\langle 001110| + |010101\rangle\langle 001110|).
$$

(70)
The non-vanishing matrix elements of the generalized \( R \)-matrix are:

\[
R_{zzzzzz} = R_{yyzxx} = R_{xxzyyz} = -1,
\]
\[
R_{xzzxxz} = R_{yxzyxz} = R_{xyzxyz} = R_{yyzyyz} = \lambda^2 - \lambda^2, 
\]
\[
R_{yxzxyz} = R_{xyzyxz} = 1,
\]
\[
R_{zyyzxx} = -2\lambda_+\lambda_-,
R_{zxyzyx} = 2\lambda_+\lambda_-,
\]
\[
R_{zyxyzy} = 2\lambda_+\lambda_-,
R_{xzyyzx} = 2\lambda_+\lambda_-,
\]
\[
R_{zyxzxy} = 2\lambda_+\lambda_-,
R_{zxxzyy} = -2\lambda_+\lambda_-,
\]
\[
R_{yzxxzy} = 2\lambda_+\lambda_-,
R_{xzxyzy} = -2\lambda_+\lambda_-.
\]

(71)

The eigenvalues of the matrix \( R^\dagger R \) are \((5 + 4(\lambda^2_+ - \lambda^2_+))^2, 16\lambda^2_+\lambda^2_-, 16\lambda^2_+\lambda^2_+ \)).

Now we want to compute the concurrence of these states. If we denote the last qubit as the region \( A \) and the complementary region as the region \( B \), the concurrence is \( C(\lambda_+ + \lambda_-) = 2|\lambda_+\lambda_-| \). We also have the normalization condition of the state \( 1 = \lambda^2_+ + \lambda^2_- \). Therefore, we can invert the function of the concurrence and have

\[
\lambda^2_+ = \frac{1 \pm \sqrt{1 - C^2(1, \psi)}}{2}, \quad \lambda^2_- = \frac{1 \mp \sqrt{1 - C^2(1, \psi)}}{2}.
\]

(72)

Now the eigenvalues of the matrix \( R^\dagger R \) can be expressed as \( (9 - 4C^2(1, \psi), 4C^2(1, \psi), 4C^2(1, \psi)) \).

The upper bound of maximal violation of the Bell’s inequality from the eigenvalues of the matrix \( R^\dagger R \) [Eq. (7)] is a function of the concurrence

\[
\gamma(C) \leq \begin{cases} 
6, & C^2(1, \psi) \leq \frac{9}{8} \\
2\sqrt{8C^2(1, \psi)}, & C^2(1, \psi) > \frac{9}{8}.
\end{cases}
\]

(73)

Next, we consider difference bipartition of computing the generalized concurrence defined in Eq. (69). If we denote the last two qubits as the region \( A \) and the complementary region as the region \( B \), the generalized concurrence is \( C(2, \psi) = 2|\lambda_+\lambda_-| \) and its inverse mapping gives the same form as Eq. (72). The above result shows that the upper bound of the maximal violation of Bell’s inequality has the same functional form for the generalized concurrence with different bipartitions.

One should be noticed that the generalized concurrence we defined is always less or equal then one, \( C(\delta, \psi) \leq 1 \). This indicates the upper bound of the maximal violation of the Bell’s inequality is always six which is independent on the states and bipartitions. This independency is purely an artifact from the choice of the Bell’s operator [Eq. (4)]. We can find another Bell’s operator to have a better upper bound. This choice
is switching site-1 and site-6 from the original Bell’s operator defined in Eq. (4). We recompute the upper bound of the maximal violation of the Bell’s inequality for this choice of the Bell’s operator. The non-vanishing elements of the $R$-matrix in this Bell’s operator are switching the first and six indices of the $R$-matrix in Eq. (71). The corresponding eigenvalues of the matrix $R^\dagger R$ are $(4, 4, 1 + 16\lambda_+^2\lambda_-^2)$. The generalized concurrence under redefinition of the site-1 and site-6 are the same as the original one. Hence the eigenvalues of the matrix $R^\dagger R$ are $(4, 4, 1 + 4C_2(\delta, \psi))$, $\delta = 1, 2$.

The upper bound of the maximal violation of the Bell’s inequality as a function of the generalized concurrence is

$$\gamma(C) \leq \begin{cases} 
2\sqrt{5} + 4C_2(\delta, \psi), & C_2(\delta, \psi) \geq \frac{3}{4} \\
4\sqrt{2}, & C_2(\delta, \psi) < \frac{3}{4}, \quad \delta = 1, 2.
\end{cases}$$

(74)

One can find the ground state of the six-site Wen-Plaquette model ($\lambda_+ = \lambda_- = 1/\sqrt{2}$) has the upper bound of the Bell’s inequality equal to 6 and the concurrence $C = 1$.

Here we give a brief comment on the choice of Bell’s operators. The essential idea of using the upper bound of the maximal Bell’s violation as a measure of entanglement is to express the upper bound of the maximal Bell’s violation as a function of the concurrence. The functional form of the upper bound of the maximal Bell’s violation strongly depends on the choice of the Bell’s operators. If it is a constant for a given region of the concurrence, e.g. $C_2 \geq 3/4$ for the first choice of the Bell’s operator and $C_2 < 3/4$ for the second choice of the Bell’s operator, we cannot extract the entanglement information form the upper bound of the maximal Bell’s inequality. This is different from Theorem 2.1 where the maximal violation of the Bell’s inequality is always a function of the concurrence with the particular form of the wavefunction.

Now let us suppose that we choose the first Bell’s operator and we know that the generalized concurrence is always greater than $\sqrt{3}/2$. Can we extract the topological entanglement entropy from measuring the upper bound of the maximal violation of the Bell’s inequality? The answer is yes. First we write down the entanglement entropy

$$S_{EE,A(\delta)} = -\text{Tr} \rho_{A(\delta)} \ln \rho_{A(\delta)}$$

for different bipartitions,

$$S_{EE,A(1)} = -\lambda_+^2 \ln \lambda_+^2 - \lambda_-^2 \ln \lambda_-^2, \quad S_{EE,A(2)} = \ln 2 - \lambda_+^2 \ln \lambda_+^2 - \lambda_-^2 \ln \lambda_-^2.$$

(75)

Next we express $\lambda_\pm^2$ in term of the upper bound of the maximal violation of the
Bell’s inequality $\gamma_M$,
\[
\lambda_+^2 = \frac{1}{2} \left( 1 \pm \sqrt{\frac{9}{4} - \frac{\gamma_M^2}{16}} \right),
\]
(76)

Thus the entanglement entropy can be written as the function of the concurrence,
\[
S_{EE,A(1)} = -\frac{1}{2} \ln \left( \frac{\gamma_M^2}{4^3} - \frac{5}{4^2} \right) - \frac{1}{2} \sqrt{\frac{9}{4} - \frac{\gamma_M^2}{16}} \ln \left( \frac{1 + \sqrt{\frac{9}{4} - \frac{\gamma_M^2}{16}}}{1 - \sqrt{\frac{9}{4} - \frac{\gamma_M^2}{16}}} \right),
\]
\[
S_{EE,A(2)} = S_{EE,A(1)} + \ln 2.
\]
(77)

For the ground state of the six-site Wen-Plaquette model, $\gamma_M = 6$ leads to $S_{EE,A(1)} = \ln 2$ and $S_{EE,A(2)} = 2 \ln 2$.

In general, the entanglement entropy has the form
\[
S_{EE,A(L)} = \alpha L - S_{TEE},
\]
(78)
in which the first term indicates the area law with $L$ being the length of an entangling boundary, $\alpha$ being a constant, and $S_{TEE}$ is called topological entanglement entropy [24]. In the Wen-Plaquette model, the length of an entangling boundary $L$ is a number of bonds that connect the subsystem $A$ and the subsystem $B$. We consider the following number of bonds:
\[
L(\delta = 1) = 4, \quad L(\delta = 2) = 6
\]
(79)
to extract the area law of entanglement entropy and obtain the topological entanglement entropy:
\[
S_{TEE} = \ln 2 = \ln \sqrt{D},
\]
(80)
where $D = 4$ is the number of distinct quasiparticles [24]. In the case that the subsystem $A$ contains one site corresponds to the four bonds $L = 4$. In the case that subsystem $A$ contains two adjacent sites along a vertical direction corresponds to the four bonds $L = 4$. In the case that the subsystem $A$ contains two adjacent sites along a horizontal direction corresponds to the six bonds $L = 6$. In the case that the subsystem $A$ contains two disjointed sites corresponds to the six bonds $L = 6$. In the case that the subsystem $A$ contains three adjacent sites corresponds to the six bonds $L = 6$. In the case that the subsystem $A$ contains two adjacent sites and one disjointed site corresponds to the six bonds $L = 6$. Thus, we use the maximal Bell’s violation from the generalized $R$-matrix constructing from the first Bell’s operator to demonstrate an indirect measure of the topological entanglement entropy.
4 Generalized Concurrence, Entanglement Entropy and 2n Qubits

The last example we would like to demonstrate the relation between the upper bound of the maximal Bell’s violation and the generalized concurrence is a 2\(^n\) qubits with the following form

\[
|\psi\rangle = \frac{\lambda_+}{\sqrt{2^n}} \left( |00\cdots0\rangle_A |00\cdots0\rangle_B + |00\cdots01\rangle_A |00\cdots01\rangle_B \right)
+ \cdots + \frac{\lambda_-}{\sqrt{2^n}} \left( |00\cdots0\rangle_A |00\cdots0\rangle_B + |00\cdots01\rangle_A |00\cdots01\rangle_B \right)
+ \cdots + \frac{\lambda_+}{\sqrt{2^n}} \left( |11\cdots1\rangle_A |11\cdots1\rangle_B \right),
\]

in which each region \(A\) and region \(B\) contains \(n\) qubits. For each region, apart from the last qubit, we consider a linear superposition of all possible configurations in the first \(n-1\) qubits. The generalized concurrence of the pure state is defined as before [Eq. (69)]

\[
The entanglement entropy of the region \(A\) is
\[
S_{EE,A} = (n - 1) \ln 2 - \frac{\lambda_+^2}{2} \ln \left( \frac{\lambda_+^2}{2} \right) - \frac{\lambda_-^2}{2} \ln \left( \frac{\lambda_-^2}{2} \right).
\]

The coefficients, \(\lambda_+\) and \(\lambda_-\), for 2\(^n\) qubits also satisfy the following equations:

\[
\frac{\lambda_+^2}{2} = 1 \pm \sqrt{1 - C(n,\psi)^2}, \quad \frac{\lambda_-^2}{2} = 1 \mp \sqrt{1 - C(n,\psi)^2}.
\]

The entanglement entropy of the region \(A\) also monotonically increases with respect to concurrence of the pure state \(C(n,\psi)\).

Now we first compute and discuss the maximal violation of the Bell’s inequality for \(n = 2\). We use the identities given in [B] to compute the non-vanishing elements of the generalized \(R\)-matrix

\[
R_{xxxx} = R_{yyyy} = R_{xyyx} = R_{zzzz} = \lambda_+\lambda_-,
R_{xyxy} = R_{zyzy} = -\lambda_+\lambda_-,
R_{zzxx} = R_{zzzz} = -R_{yzyz} = 1.
\]

Thus, the eigenvalues of the matrix \(R^\dagger R\) are \((3C(2,\psi)^2, 3C(2,\psi)^2, 3)\).
Now we can obtain the upper bound of the maximal violation of the Bell’s inequality
\[ \gamma \leq 2\sqrt{3}\sqrt{1 + C(2, \psi)^2}. \] (85)

We consider different bipartitions, the quantum state can be rewritten as
\[ |\psi\rangle = \frac{\lambda_+}{2} (|000_A\rangle + |101_A\rangle)|0_B\rangle + \frac{\lambda_-}{2} (\alpha_0 - \alpha_1)(|010_A\rangle + |111_A\rangle)|1_B\rangle. \] (86)

the entanglement entropy of the region \(A\) is
\[ S_{EE,A} = -\frac{\lambda_+^2}{2} \ln \left( \frac{\lambda_+^2}{2} \right) - \frac{\lambda_-^2}{2} \ln \left( \frac{\lambda_-^2}{2} \right), \] (87)

and the upper bound of the maximal violation of the Bell’s inequality is
\[ \gamma \leq 2\sqrt{3}\sqrt{1 + C(1, \psi)^2}. \] (88)

The entanglement entropy of the region \(A\) also monotonically increases with respect to the concurrence of the pure state \(C(1, \psi)\). Although the bipartition does not affect the maximal violation of the Bell’s inequality, we can use the concurrence of the pure state to express the intensity of entanglement entropy or how large of entanglement entropy for the corresponding bipartition from the upper bound of the maximal violation of the Bell’s inequality.

This example also shows that even if a quantum state is not just a linear combination of two product states, the upper bound of the maximal violation of the Bell’s inequality can relate to the value of entanglement entropy.

For a generalization of an arbitrary number of \(n\), the upper bound of the maximal violation of the Bell’s inequality
\[ \gamma \leq 2\sqrt{3}^{n-1}\sqrt{1 + C(n, \psi)^2}. \] (89)

5 Discussion and Outlook

We demonstrated the relations between the upper bound of the maximal violation of the Bell’s inequality and the generalized concurrence of \(n\)-qubit pure states in several examples. In particular, we show the this upper is equal to the maximal Bell’s violation for an \(n\)-qubit state which has the form in Eq. [15]. We emphasize that the maximal violation of the Bell’s inequality is a measure of the Bell’s operator in a full system, while the computation of the generalized concurrence only involves a reduced density.
matrix in a subsystem. The relation that we showed in the paper can provide an alternative measure of entanglement, from the inverse mapping of the upper bound of the Bell’s operator to the generalized concurrence.

We applied our results to the various models. We first considered the two-qubit system with the non-uniform magnetic field at a finite temperature. We also studied the maximal violation of the Bell’s inequality in the Wen-Plaquette model [23] for four sites and six sites on a torus manifold. Our computation of the generalized $R$-matrix in the Wen-Plaquette model reveals that the ground states are maximally entangled or the generalized concurrence of the pure state is one. We also provided a possible detection of topological entanglement entropy [24] through the upper bound of the maximal violation of the Bell’s inequality by using different bipartitions of the concurrence of the pure state.

The studies of the upper bound of the maximal violation of the Bell’s inequality can shed the light to understand an alternative detection of entanglement beyond using the reduced density matrix. Extracting the information of the reduced density matrix form the local probe requires single-site resolution which is very restricted in experiments and is very hard to apply to many-body systems. On the other hand, the measure of the Bell’s operator, in principle, does not require single-site resolution and can be performed to a large system. It was shown that Bell’s operators have been measured in a Bose-Einstein condensate with about 480 atoms [21].

A Generalized Concurrence, Entanglement Entropy
and the Toric Code Model

We compute Rényi entropy [28] in a toric code model [22] on a disk manifold, which
can have an arbitrary number of holes, and a cylinder manifold [29] with boundary
conditions. From our result of the Rényi entropy, we can obtain a relation between a
generalized concurrence of a pure state and entanglement entropy. For the case of a disk
manifold, we find that the Rényi entropy always equals to entanglement entropy for any
bipartition. For the case of a cylinder manifold, we consider a non-contractible region.
The Rényi entropy can be different from the entanglement entropy [29]. The result is
interesting because we can find that a choice of a ”generalized concurrence” depends on
boundary degrees of freedom of a Hilbert space in a toric code model. We first review a
toric code model on a torus manifold, then compute the Rényi entropy in a toric code
model on a disk manifold and on a cylinder manifold. The generalized concurrence is
useful for us to demonstrate a relationship between the maximal violation of the Bell’s
inequality and entanglement entropy in the $2^{2n}$-qubit quantum state.

A.1 Review of a Toric Code Model on a Torus Manifold

We consider a lattice, which can be embedded on an arbitrary two-dimensional surface.
The simplest case is an $L \times L$ square lattice with a periodic boundary condition which
forms a torus. The Hilbert space of each edge $\mathcal{H}_i$ consists of a spin one-half degree of
freedom and the total Hilbert space of a toric code model is a tensor product of the
Hilbert space of each edge as the Hilbert space $\mathcal{H} = \bigotimes_i \mathcal{H}_i$. The lattice model on a
torus has $L^2$ vertices and $L^2$ plaquettes. Since the dimensions of the Hilbert space of
each spin is two and the number of links on a square lattice is $2L^2$, the total dimensions
of the Hilbert space are $2^{2L^2}$. The Hamiltonian of the toric code model is

$$H = - \sum_v U_v A_v - \sum_p J_p B_p$$

(90)
with $U_v \geq 0$ and $J_p \geq 0$, where:

$$A_v = \bigotimes_{i \in \text{star}(v)} \sigma_i^z = \sigma_{i_1}^z \otimes \sigma_{i_2}^z \otimes \sigma_{i_3}^z \otimes \sigma_{i_4}^z,$$

$$B_p = \bigotimes_{j \in \partial p} \sigma_j^x = \sigma_{j_1}^x \otimes \sigma_{j_2}^x \otimes \sigma_{j_3}^x \otimes \sigma_{j_4}^x,$$

in which the index $i \in \text{star}(v)$ runs over all four edges around an vertex $v$ and $j \in \partial p$ goes around four edges on a boundary of a plaquette $p$. We also remind that the operators $A_v$ (vertex operators), and $B_p$ (plaquette operators) act on the Hilbert space $\mathcal{H}$ rather than acting on some local Hilbert spaces so the operators are trivial operators or the identity operators on the edges, which are not in the vertex $v$ and the plaquette $p$.

To have a complete set of observables on a torus, it turns out that we also need two loop operators of two non-contractible cycles on a torus:

$$Z(C_1) \equiv \bigotimes_{i \in C_1} \sigma_i^z, \quad X(C_2) = \bigotimes_{j \in C_2} \sigma_j^x,$$

in which $C_1$ and $C_2$ are loops.

### A.2 A Disk Manifold with Holes

We compute entanglement entropy in the toric code model on a disk manifold with an arbitrary number of holes. A non-zero number of holes on a disk manifold can increase ground state energy of the toric code model compared to ground state energy of the toric code model on the disk manifold without holes. This could be seen as a generation of anyons on a disk manifold through increasing the number of holes. Note that we pick boundary conditions, from which an upper edge of the disk manifold and a right edge of the disk manifold are smooth boundary conditions and a lower edge of the disk manifold and the left edge of the disk manifold are rough boundary conditions. A vertex operator at a smooth boundary only acts on three qubits on the three links meeting at a vertex. A plaquette operator at a rough boundary lacks a qubit so it only acts on three qubits on the three links nearby.

When we do a bipartition, there are $(n_{L,v}, n_{L,c}, n_{R,v}, n_{R,c})$ anyons, in which the label $L$ stands for a left region in the system and the label $R$ stands for a right region in the system and the label $v$ represents vortex particles and the label $c$ represents charged

---

4It is also referred to a surface code model if a manifold is not a torus.
particles. In our convention, the vortex particles are generated by the $X$ operators acting on links and the charge particles are generated by the $Z$ operators acting on a dual lattice. For the convenience, we remove the vertex operators and plaquette operators corresponding to a position of the anyons so that the quantum state is, in fact, a ground state of the Hamiltonian. We also find that entanglement entropy of the disk manifold with a number of holes is independent of cutting because we can use vertex or the plaquette operators to deform the $X$ and $Z$ operators, as shown in Fig. 2 and Fig. 3. The other decomposition method can be implemented by putting boundary conditions on the entangling surface. We can set the rough boundary condition on the left side of an entangling surface and set the smooth boundary condition on the right side of the entangling surface. A form of the entanglement entropy is not modified.

We define a group $G$ as the group generated by all the plaquette operators, including those sitting at an edge and those at a position of anyons. Hence, the quantum state $|\Omega\rangle$ or the ground state of the Hamiltonian without quasiparticles can be written as the following:

$$|\Omega\rangle \equiv \frac{1}{\sqrt{|G|}} \sum_{g \in G} g|0\rangle = \frac{1}{\sqrt{|G|}} \sum_{g \in G} g|0_L\rangle \otimes |0_R\rangle,$$

where $|0_L\rangle$ and $|0_R\rangle$ are just shorthand expressions representing qubits live in a left region and a right region. Therefore, the quantum state $|\psi\rangle$ on a disk manifold with

---

5 Now the quantum states with the presence and the absence of anyons are all ground states of the Hamiltonian, we have a larger ground state degeneracy than a toric code model on a disk manifold without any hole.
Figure 3: We can move the line operator creating vortex anyons by applying vertex operators on the
edge as shown in Figure (a) or in the bulk as shown in Figure (b).

holes can be written as the following:

$$|\psi\rangle = \prod_{i_{L,v}} X_{i_{L,v}} \prod_{i_{L,c}} Z_{i_{L,c}} \prod_{i_{R,v}} X_{i_{R,v}} \prod_{i_{R,c}} Z_{i_{R,c}} |\Omega\rangle$$

$$= \frac{1}{\sqrt{|G|}} \prod_{i_{L,v}} X_{i_{L,v}} \prod_{i_{L,c}} Z_{i_{L,c}} \prod_{i_{R,v}} X_{i_{R,v}} \prod_{i_{R,c}} Z_{i_{R,c}}$$

$$\times \sum_{g \in G} g |0_L\rangle \otimes |0_R\rangle.$$  

For convenience, we define the operators as the followings:

$$E_L \equiv \prod_{i_{L,v}} X_{i_{L,v}} \prod_{i_{L,c}} Z_{i_{L,c}}, \quad E_R \equiv \prod_{i_{R,v}} X_{i_{R,v}} \prod_{i_{R,c}} Z_{i_{R,c}},$$  

$$E_L^2 = 1, \quad E_R^2 = 1,$$  

and write the element of the group $G$ as that $g \equiv g_L \otimes g_R$ and the wavefunction as that

$$|\psi\rangle = \frac{1}{\sqrt{|G|}} \sum_{g \in G} E_L g_L |0_L\rangle \otimes E_R g_R |0_R\rangle.$$  

The operator $g_L$ and the operator $g_R$ do not contain a complete plaquette operators on
an entangling surface. The operator $g_L$ only acts on one qubit for each plaquette oper-
ator and the action acts on three qubits for each plaquette operator on the entangling
surface.
Figure 4: Condensation of each type of anyons is generated on the corresponding boundary, costing no energy to produce anyon at the boundary. The anyon in the bulk can be generated by a string operator with one end attached to a suitable edge. Each blue line consists of a string of the $X$ operators, which generates vortex particle pairs. The orange lines are strings of the $Z$ operators, which generates charge particle pairs. Vortex particles condense at the rough boundary while charge particles condensed at the smooth boundary. By using the operation in Fig. 2 and Fig. 3, we can move any configuration of blue lines and orange lines with a bulk end fixed and boundary ends at their proper boundary to the configuration shown in this Figure. Note that qubits live on links.

Each $X$ and $Z$ operator has one ending point attached to an edge and the other ending point fixed at where the corresponding anyon sits as in Fig. 4.

Now we have the reduced density matrix of the $L$ system (the notations we use here are summarized in the Table. 1 and the Table. 2):

$$\rho_L = \sum_{g,g' \in G} E_L g_L |0_L\rangle \langle 0_L| g_L' E_L |0_R\rangle \langle 0_R| g_R' E_R g_R |0_R\rangle$$

$$= \sum_{g,g' \in G} E_L g_L |0_L\rangle \langle 0_L| g_L' E_L \cdot |0_R\rangle \langle 0_R| g_R' g_R |0_R\rangle$$

$$= \sum_{g \in G, \tilde{g} \in G} E_L g_L |0_L\rangle \langle 0_L| g_L \tilde{g}_L E_L \cdot |0_R\rangle \langle 0_R| \tilde{g}_R |0_R\rangle$$

$$= \frac{|G_R|}{|G|} \sum_{h \in G/G_R, \tilde{g} \in G_L} E_L h_L |0_L\rangle \langle 0_L| h_L \tilde{g}_L E_L,$$

where

$$\tilde{g}_L \equiv g_L' g_L, \quad \tilde{g}_R \equiv g_R' g_R.$$

Because the operator $g_L$ and the operator $g_R$ do not contain complete plaquette operators on the entangling surface, we remind our reader: $g_L \notin G_L$ and $g_R \notin G_R$, in which

$$\begin{align*}
\tilde{g}_L \equiv g_L' g_L, \\
\tilde{g}_R \equiv g_R' g_R.
\end{align*}$$
$G_L$ is a group generated by all the plaquette operators fully supported on a left region and $G_R$ is a group generated by all the plaquette operators fully supported on a right region. We also remind that the operator $\tilde{g}_L$ and the operator $\tilde{g}_R$ do not contain any plaquette operator on an entangling surface.

in the third equality. Then we can obtain:

$$\rho_L^2 = \frac{|G_R|^2}{|G|^2} \sum_{h,h' \in G/G_R, \tilde{g}, \tilde{g}' \in G_L} E_L h |0_L\rangle \langle 0_L | h \tilde{g} L h' \tilde{g}' L |0_L\rangle \langle 0_L | h' \tilde{g}' L E_L$$

$$= \frac{|G_R|^2}{|G|^2} \sum_{h \in G/G_R, \tilde{g} \in G_L} E_L h |0_L\rangle \langle 0_L | h \tilde{g} L \tilde{g} E_L$$

$$= \frac{|G_R|^2 |G_L|}{|G|^2} \sum_{h \in G/G_R, \tilde{g} \in G_L} E_L h |0_L\rangle \langle 0_L | h \tilde{g} L E_L$$

$$= \frac{|G_L||G_R|}{|G|} \rho_L$$

$$\equiv \lambda \rho_L,$$  \hfill (100)

where

$$\lambda \equiv \frac{|G_L||G_R|}{|G|} = 2^{-n_L}. \hfill (101)$$

We used the relation

$$\langle 0_L | h \tilde{g} L h' |0_L\rangle = \delta_{h', h} \tilde{g} L$$  \hfill (102)

in the second equality. Thus, it is also easy to use the same way to obtain the equality

$$\rho_L^n \equiv \lambda^n \left( \frac{\rho_L}{\lambda} \right). \hfill (103)$$

The Rényi entropy of the order $\alpha$ in the toric code model on a disk manifold with any number of holes is:

$$S_\alpha \equiv \frac{1}{1 - \alpha} \ln \text{Tr} \rho_L^\alpha = n_L \ln 2, \hfill (104)$$
where \( n_L \) is a number of plaquettes on the entangling surface between the region \( L \) and the region \( R \). In summary, entanglement entropy of the system with an arbitrary number of holes is:

\[
S_{EE,L} = S_\alpha = n_L \ln 2.
\]  

(105)

Note that at each hole, we can have two possibilities: presence and absence of an anyon. In this section, we consider the case where anyons are present at each hole. It turns out that all the other cases actually give the same Rényi entropy expression. Hence, the result does not give any constraint to a generalized concurrence.

### A.3 A Cylinder Manifold

We consider the toric code model on a cylinder manifold, cutting it into two non-contractible sub-cylinders, region \( A \) and region \( B \). The operators on a boundary of the cylinder manifold satisfy the periodic boundary conditions for the upper and lower sides of the cylinder manifold. We also set the rough (smooth) boundary conditions for other two sides and put boundary conditions on an entangling surface to decompose a region \[30\]. When we cut the cylinder manifold into two sub-cylinder manifolds, the operators on an entangling surface between the region \( A \) and the region \( B \) in the sub-cylinder manifolds satisfy the rough (smooth) boundary condition.

The toric code model on a cylinder manifold has two ground states \[29\]:

\[
|\psi_{00}\rangle = \frac{1}{\sqrt{2N_q}} \sum_{l=1}^{N_q} (|q_l = 0, 0_A\rangle|q_l = 0, 0_B\rangle + |q_l = 0, 1_A\rangle|q_l = 0, 1_B\rangle),
\]

\[
|\psi_{01}\rangle = \frac{1}{\sqrt{2N_q}} \sum_{l=1}^{N_q} (|q_l = 0, 0_A\rangle|q_l = 0, 1_B\rangle + |q_l = 0, 1_A\rangle|q_l = 0, 0_B\rangle),
\]

(106)

in which a crossing number to an entangling surface is always an even number, which is labeled by 0 at the first index of \( q_l \), a winding number around the sub-cylinders \( A \) or \( B \) can be an even number, which is labeled by 0 at the second index of \( q_l \), or an odd number, which is labeled by 0 at the second index of \( q_l \), and \( N_q = 2^{n_L - 1} \), where \( n_L \) is a number of plaquettes on an entangling surface. A generic ground state is

\[
|\psi\rangle = \alpha_{00}|\psi_{00}\rangle + \alpha_{01}|\psi_{01}\rangle.
\]

(107)
Thus, the reduced density matrix in the region $A$ is

$$\rho_A = \frac{1}{2N_q} \sum_{i=1}^{N_q} \left( |\alpha_{00}|^2 + |\alpha_{01}|^2 \right) \times (|q_i = 0, 0_A\rangle \langle q_i = 0, 0_A| + |q_i = 0, 1_A\rangle \langle q_i = 0, 1_A|) + \left( \alpha_{00}^* \alpha_{01} + \alpha_{00} \alpha_{01}^* \right) \times (|q_i = 0, 0_A\rangle \langle q_i = 0, 1_A| + |q_i = 0, 1_A\rangle \langle q_i = 0, 0_A|).$$

(108)

We can diagonalize the reduced density matrix of the region $A$ to obtain the eigenvalues of the reduced density matrix of the region $A$:

$$\frac{1}{2N_q} |\alpha_{00} + \alpha_{01}|^2, \quad \frac{1}{2N_q} |\alpha_{00} - \alpha_{01}|^2,$$

(109)

and the Rényi entropy of the order $n$ is:

$$S_n = \frac{1}{1 - n} \ln \left( \frac{1}{2N_q} \right)^n N_q \left( \sum_{i=1}^{2} (2p_i)^n \right)$$

$$= \ln N_q + \frac{1}{1 - n} \ln \left( \sum_{i=1}^{2} p_i^n \right)$$

$$= n_L \ln 2 - \left( \ln 2 - \frac{1}{1 - n} \ln \left( \sum_{i=1}^{2} p_i^n \right) \right),$$

(110)

where:

$$p_1 \equiv \frac{1}{2} |\alpha_{00} + \alpha_{01}|^2, \quad p_2 \equiv \frac{1}{2} |\alpha_{00} - \alpha_{01}|^2, \quad p_1 + p_2 = 1.$$

(111)

Topological entanglement entropy is defined as a boundary independent part of entanglement entropy and from (110), the topological entanglement entropy is $\ln 2 + \sum_{i=1}^{2} p_i \ln p_i$. The maximal topological entanglement entropy is $\ln 2$. When $p_i = 1/2$ for each index $i$ we can get the vanishing topological entanglement entropy:

$$\ln 2 - \sum_{i} p_i \ln p_i = \ln 2 - \frac{1}{2} \ln 2 - \frac{1}{2} \ln 2 \ln 2 = \ln 2 - \ln 2 = 0.$$

(112)

Since we only have one independent parameter for $p_i$ from the second Rényi entropy in (110), we have the following equations:

$$(n_L - 1) \ln 2 + \ln \text{Tr} \rho_A^2 = \ln \left( 2p_1^2 - 2p_1 + 1 \right),$$

(113)
\begin{align}
2p_1^2 - 2p_1 + \left(1 - 2^{n_L-1}\text{Tr}\rho_A^2\right) &= 0, \\
p_1 &= \frac{1 \pm \sqrt{1 - 2(1 - 2^{n_L-1}\text{Tr}\rho_A^2)}}{2}, \\
p_2 &= \frac{1 \mp \sqrt{1 - 2(1 - 2^{n_L-1}\text{Tr}\rho_A^2)}}{2}.
\end{align}

By comparing (21) and (115), we find the entanglement entropy is quite similar to the entanglement entropy of the two qubits [9]. We can know that the entanglement entropy should monotonically increase by decreasing \(\text{Tr}\rho_A^2\) and also find that the generalized concurrence of the pure state in a toric code model on a cylinder manifold should be defined by

\[C(n_A, \psi) \equiv \sqrt{2\left(1 - 2^{n_A-1}\text{Tr}\rho_A^2\right)}.
\]

If \(n_A = 1\), a definition of the generalized concurrence of the pure state goes back to the concurrence of two qubits [9]. Even if \(n_A = 1\), the entanglement entropy of the toric model on the cylinder manifold does not vanish and has the contribution from classical Shannon entropy because the region \(A\) is non-contractible. Hence, it is interesting to obtain the generalized concurrence of the pure state between different regions in the toric code model. We also find that the factor \(2^{n_A-1}\) in the concurrence of the pure state depends on boundary degrees of freedom of the Hilbert space. Thus, a relation between the maximal violation of Bell’s inequality and entanglement entropy possibly be expressed in terms of the generalized concurrence \(C(n_A, \psi)\) with corresponding boundary degrees of freedom of the Hilbert space in the toric code model. This also motivates us to use the definition of the generalized concurrence.

**B Some identities for computing the R-matrix**

To compute the upper bound of the maximal violation of the Bell’s inequality for the 2n-qubit states in Sec. 4, we need to compute elements of the R-matrix, which have
the form,

\[
\text{Tr} \left( \left( (a_1 \otimes a_2 \otimes \cdots \otimes a_n) \otimes (a_1 \otimes a_2 \otimes \cdots \otimes a_n) \right) \times ((b_1^T \otimes b_2^T \otimes \cdots \otimes b_n^T) \otimes (b_1^T \otimes b_2^T \otimes \cdots \otimes b_n^T)) \times (\sigma_{i_1} \otimes \sigma_{i_2}) \otimes (\sigma_{i_3} \otimes \sigma_{i_4}) \otimes \cdots \otimes (\sigma_{i_{2n-1}} \otimes \sigma_{i_{2n}}) \right)
\]

\[
= \text{Tr} \left( ((a_1 b_1^T) \otimes (a_2 b_2^T) \otimes \cdots \otimes (a_n b_n^T)) \otimes ((a_1 b_1^T) \otimes (a_2 b_2^T) \otimes \cdots \otimes (a_n b_n^T)) \times (\sigma_{i_1} \otimes \sigma_{i_2}) \otimes (\sigma_{i_3} \otimes \sigma_{i_4}) \otimes \cdots \otimes (\sigma_{i_{2n-1}} \otimes \sigma_{i_{2n}}) \right)
\]

\[
= \text{Tr} \left( ((a_1 b_1^T) \otimes (a_2 b_2^T)) \cdot (\sigma_{i_1} \otimes \sigma_{i_2}) \otimes ((a_3 b_3^T) \otimes (a_4 b_4^T)) \cdot (\sigma_{i_3} \otimes \sigma_{i_4}) \otimes \cdots \otimes (\sigma_{i_{2n-1}} \otimes \sigma_{i_{2n}}) \right)
\]

\[
= \text{Tr} \left( ((a_1 b_1^T) \otimes (a_2 b_2^T)) \cdot (\sigma_{i_1} \otimes \sigma_{i_2}) \right) \times \text{Tr} \left( ((a_3 b_3^T) \otimes (a_4 b_4^T)) \cdot (\sigma_{i_3} \otimes \sigma_{i_4}) \right) \times \cdots \times \text{Tr} \left( ((a_{n-1} b_{n-1}^T) \otimes (a_n b_n^T)) \cdot (\sigma_{i_{2n-1}} \otimes \sigma_{i_{2n}}) \right)
\]

\[
= \text{Tr} \left( (\sigma_{i_1} \otimes \sigma_{i_2}) \cdot ((a_1 b_1^T) \otimes (a_2 b_2^T)) \right) \times \text{Tr} \left( (\sigma_{i_3} \otimes \sigma_{i_4}) \cdot ((a_3 b_3^T) \otimes (a_4 b_4^T)) \right) \times \cdots \times \text{Tr} \left( (\sigma_{i_{2n-1}} \otimes \sigma_{i_{2n}}) \cdot ((a_{n-1} b_{n-1}^T) \otimes (a_n b_n^T)) \right)
\]

\[
= \text{Tr} \left( (\sigma_{i_1} a_1 b_1^T) \otimes (\sigma_{i_2} a_2 b_2^T) \right) \times \text{Tr} \left( (\sigma_{i_3} a_3 b_3^T) \otimes (\sigma_{i_4} a_4 b_4^T) \right) \times \cdots \times \text{Tr} \left( (\sigma_{i_{2n-1}} a_{n-1} b_{n-1}^T) \otimes (\sigma_{i_{2n}} a_n b_n^T) \right)
\]

\[
= \text{Tr} \left( (\sigma_{i_1} a_1 b_1^T) \right) \times \text{Tr} \left( (\sigma_{i_2} a_2 b_2^T) \right) \times \cdots \times \text{Tr} \left( (\sigma_{i_{2n}} a_{2n} b_{2n}^T) \right)
\]

(117)

in which the notation \( \otimes \) represents a tensor product of matrices while \( \times \) and \( \cdot \) stand for a matrix multiplication, a scalar multiplication or a dyad product, depending on
the context. The two-component vectors \( a_i \) and \( b_j \) can be the following

\[
\begin{bmatrix}
1 \\
0
\end{bmatrix} \quad \text{or} \quad \begin{bmatrix}
0 \\
1
\end{bmatrix}.
\]

To obtain the eigenvalues of the matrix \( R^\dagger R \), we list the following useful identities:

\[
\begin{align*}
\text{Tr} & \left[ \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right] = 1, & \text{Tr} & \left[ \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} \right] = 1, \\
\text{Tr} & \left[ \begin{bmatrix} 0 & -i \\ i & 0 \end{bmatrix} \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right] = i, & \text{Tr} & \left[ \begin{bmatrix} 0 & -i \\ i & 0 \end{bmatrix} \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} \right] = -i, \\
\text{Tr} & \left[ \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right] = 1, & \text{Tr} & \left[ \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} \right] = -1.
\end{align*}
\]
