GLOBAL ENTROPY SOLUTIONS TO MULTI-DIMENSIONAL ISENTROPIC GAS DYNAMICS WITH SPHERICAL SYMMETRY

FEIMIN HUANG, TIANHONG LI, AND DIFAN YUAN

ABSTRACT. We are concerned with spherically symmetric solutions to the Euler equations for the multi-dimensional compressible fluids, which have many applications in diverse real physical situations. The system can be reduced to one dimensional isentropic gas dynamics with geometric source terms. Due to the presence of the singularity at the origin, there are few papers devoted to this problem. The present paper proves two existence theorems of global entropy solutions. The first one focuses on the case excluding the origin in which the negative velocity is allowed, and the second one is corresponding to the case including the origin with non-negative velocity. The $L^\infty$ compensated compactness framework and vanishing viscosity method are applied to prove the convergence of approximate solutions. In the second case, we show that if the blast wave initially moves outwards and the initial densities and velocities decay to zero with certain rates near origin, then the densities and velocities tend to zero with the same rates near the origin for any positive time. In particular, the entropy solutions in two existence theorems are uniformly bounded with respect to time.

1. Introduction

In this paper, we consider the Euler equations for compressible isentropic fluids with spherical symmetry which read

\begin{equation}
\begin{cases}
\rho_t + \nabla \cdot \vec{m} = 0, \vec{x} \in \mathbb{R}^N, \\
\vec{m}_t + \nabla \cdot \left( \frac{\vec{m} \otimes \vec{m}}{\rho} \right) + \nabla p = 0, \vec{x} \in \mathbb{R}^N,
\end{cases}
\end{equation}

where $\rho, m$ and $p(\rho)$ denote the density, momentum and pressure of the gas respectively. The pressure takes the form of $p(\rho) = p_0 \rho^\gamma$, with $p_0 = \frac{\theta^2}{\gamma}, \theta = \frac{\gamma-1}{2}$ and $\gamma > 1$ being the adiabatic exponent.

We are interested in spherically symmetric solutions to system (1.1) with the form

\begin{equation}(\rho, \vec{m})(\vec{x}, t) = (\rho(x, t), m(x, t) \frac{\vec{x}}{|\vec{x}|}), x = |\vec{x}|.\end{equation}

Then $(\rho(x, t), m(x, t))$ in (1.2) is governed by the one-dimensional Euler equations with geometric source terms:

\begin{equation}
\begin{cases}
\rho_t + m_x = -\frac{N-1}{x}m, x \geq 0, t > 0, \\
m_t + \left( \frac{m^2}{\rho} + p(\rho) \right)_x = -\frac{N-1}{x} \frac{m^2}{\rho}, x \geq 0, t > 0.
\end{cases}
\end{equation}

Key words and phrases. isentropic gas, compensated compactness, uniform estimate.
For the system (1.3), the study of spherically symmetric motion originates from several important applications such as the theory of explosion waves in medium, and the stellar dynamics including gaseous star formation and supernova formation. Note that the geometric source terms of (1.3) are singular at the origin, i.e., $x = 0$. In the present paper, we first study the system (1.3) for the case that the origin is excluded. For simplicity, we consider (1.3) in the region outside the unit ball, that is,

$$
\begin{align*}
  v_t + F(v) &= G(x, v), x \in (1, +\infty), t \in [0, +\infty), \\
  v|_{t=0} &= v_0(x), x \in [1, +\infty), \\
  m|_{x=1} &= 0, t \in [0, +\infty),
\end{align*}
\tag{1.4}
$$

with initial data $v_0(x) \in L^\infty([1, +\infty))$, $v = (\rho, m)^\top$, $F(v) = (m, \frac{m^2}{\rho} + p(\rho))^\top$, $G(x, v) = (a(x)m, a(x)m^2)^\top$, where $a(x) = -\frac{N-1}{x}$. Then we consider the case that the origin is included, i.e., $x \geq 0$. Note that in this case, the initial boundary value problem is equivalent to the Cauchy problem of compressible Euler equations (1.1) with spherically initial data

$$
(\rho, m)|_{t=0} = (\rho_0(x), m_0(x)) \in L^\infty([0, +\infty)), x \geq 0. \tag{1.5}
$$

There has been considerable progress on the existence of global entropy solutions for one dimension. T. Nishida [25] first proved the existence of large BV solutions for isothermal gas (i.e., $\gamma = 1$) by Glimm Scheme. Nishida and Smoller [26] further studied the isentropic case (i.e., $\gamma > 1$) under some restrictions on the initial data. Note that both works are away from vacuum.

If the initial values contain vacuum, Diperna [11] first proved the global existence of $L^\infty$ entropy solutions with large initial data by the theory of compensated compactness for $\gamma = 1 + \frac{2}{2n+1}$, where $n \geq 2$ is any integer. Subsequently, Ding et al. [9] and Chen et al. [2] successfully extended the result to $\gamma \in (1, \frac{5}{3})$. Lions et al. [15] and [16] treated the case $\gamma > \frac{5}{3}$. Finally Huang et al. [12] solved the existence problem of $L^\infty$ entropy solutions for $\gamma = 1$ through compensated compactness and analytic extension method.

For the inhomogeneous case, that is, the right hand side of (1.1) is not zero, Ding et al. [10] established a general framework to investigate the global existence of $L^\infty$ entropy solutions through the fractional step Lax-Friedrichs scheme. It should be noted that in the framework of [10], the approximate solutions are only required to be uniformly bounded in the space $x$, but not in the time $t$. The $L^\infty$ norm of approximate solutions may increase with respect to time $t$. Later on, there have been extensive works on the inhomogeneous case, see [5,8,22,23] and the references therein. To study the large time behavior of entropy solution, it is important to show the uniform bound of solutions independent of time $t$.

As shown in (1.3), the multi-dimensional compressible Euler system with spherical symmetry can be reduced to one dimensional isentropic gas dynamics with geometric source terms, which may have singularity at $x = 0$. One of the main features is the resonance interaction among the characteristic mode and the geometrical source one. The local existence of spherically symmetric solutions outside a solid ball centered at the origin was discussed in Makino et al. [21] by the fractional step Lax-Friedrichs scheme. The global existence was first studied by Chen and Glimm [5], then by Tsuge [29]. For the domain including the origin, Chen et al. [3] proved a global existence theorem with large $L^\infty$ data having only non-negative initial velocity. More interesting works can be found in [3,6,14,20,30,32,33] and references therein. Recently Chen et al. [7] established $L^p$ global
finite-energy entropy solution of the isentropic Euler equations with spherical symmetry and large initial data.

Note that all of above works are based on numerical scheme and need laborious estimates. In this paper, we apply the vanishing viscosity method together with the invariant region of parabolic system with nonlinear source terms to obtain the a priori estimates of viscosity solutions. This approach is valid for both the Cauchy problem and initial boundary value problem. In the first part of present paper, we consider an initial boundary value problem outside a unit ball in which the origin is excluded. In the second part of present paper, we study the Cauchy problem so that the origin is included. In both cases, we obtain the uniform bound of viscosity solutions independent of space $x$ and time $t$, while the $L^\infty$ bound depends on time $t$ in almost all previous works. This marks an important step to investigate the large time behavior of entropy solutions. It worths to point out that a set of new delicate control functions are designed to obtain the uniform bound of approximate solutions. Moreover, a new approach is proposed in the proof of lower bound of density by using the appropriate decomposition of source terms of heat equation and corresponding solutions successively. Before formulating the main results, we define the entropy solutions of initial boundary value problem and Cauchy problem respectively as follows.

**Definition 1.1.** A measurable function $v(x,t) \in L^\infty([1, +\infty) \times R_+)$ is called a global entropy solution of the initial boundary value problem (1.4) provided that

$$
\int_0^{+\infty} \int_1^{+\infty} (v \Phi_t + F(v) \Phi_x + G(x,v) \Phi) \, dx \, dt + \int_1^{+\infty} v_0(x) \Phi(x,0) \, dx = 0 \tag{1.6}
$$

holds for any function $\Phi \in C^1(1, +\infty) \times [0, +\infty)$ for $t \geq 0$ and for any weak convex entropy pair $(\eta, q)(v)$, the inequality

$$
\eta(v)_t + q(v)_x - \nabla \eta(v) \cdot G(x,v) \leq 0
$$

holds in the sense of distributions.

The weak convex entropy-flux pair will be defined in the next section. The precise statement of the first result is below.

**Theorem 1.1.** (Excluding the origin) Let $1 < \gamma \leq 3$. Assume that there are positive constants $M_1, M_2$ such that the initial data satisfy

$$
0 \leq \rho_0(x), \quad \frac{m_0}{\rho_0} + \rho_0^\theta \leq M_1 - M_2 x^{-\alpha}, \quad \frac{m_0}{\rho_0} - \rho_0^\theta \geq -M_2 x^{-\alpha}, \quad a.e.,
$$

$$
m(1,t) = 0, \quad t > 0, \tag{1.7}
$$

then there exists a global entropy solution of (1.4) satisfying

$$
0 \leq \rho(x,t), \quad \left(\frac{m}{\rho} + \rho^\theta\right)(x,t) \leq M_1 - M_2 x^{-\alpha}, \quad \left(\frac{m}{\rho} - \rho^\theta\right)(x,t) \geq -M_2 x^{-\alpha}, \quad a.e., \tag{1.8}
$$

where $\alpha$ is any constant satisfying $\alpha \geq \frac{(N-1)\theta}{(1+\sqrt{\theta})^2}$.
Remark 1.1. In Tsuge [28], the initial data satisfies \( \frac{m_0}{\rho_0} - \rho^\theta_0 \geq -M_2 x^{-\frac{(N-1)\theta}{1+\theta}} \). Since \( \frac{(N-1)\theta}{(1+\theta)^2} < \frac{(N-1)\theta}{1+\theta} \), the existence result of [28] is included in Theorem 1.1.

Remark 1.2. From (1.7) and (1.8), the negative velocity is allowed.

Definition 1.2. A measurable function \( v(x,t) \) is called a global entropy solution of the Cauchy problem (1.3) and (1.5) provided that
\[
\int_0^{+\infty} \int_0^{+\infty} (v \Phi_t + F(v) \Phi_x + G(x,t,v) \Phi) \, dx \, dt + \int_0^{+\infty} v_0(x) \Phi(x,0) \, dx = 0
\]
holds for any function \( \Phi \in C^1_0([0,\infty) \times [0,\infty)) \) and for any weak convex entropy pair \((\eta,q)\), the inequality
\[
\eta(v)_t + q(v)_x - \nabla \eta(v) \cdot G(x,t,v) \leq 0
\]
holds in the sense of distributions.

Remark 1.3. It is noted that the origin belongs to the support of \( \Phi(x,t) \) in (1.9). Thus, the origin is included. The precise statement of second result is stated as follows.

Theorem 1.2. (Including the origin) Let \( \gamma > 1 \). Assume that for any nonnegative constant \( c \), there exists a positive constant \( M \) such that
\[
0 \leq \rho_0(x), \quad \frac{m_0}{\rho_0} + \rho^\theta_0 \leq M x^c, \quad \frac{m_0}{\rho_0} - \rho^\theta_0 \geq 0, \quad a.e. \ x \in [0,\infty),
\]
then there exists a global entropy solution of (1.3) and (1.5) satisfying
\[
0 \leq \rho(x,t) \leq C x^c, \quad 0 \leq m(x,t) \leq C \rho(x,t) x^c \quad a.e. \ (x,t) \in [0,\infty) \times \mathbb{R}^+, \tag{1.11}
\]
where \( C \) depends on \( M \).

Remark 1.4. Theorem 1.2 means that if the blast wave initially moves outwards and \( \rho^\theta \) and \( u = \frac{m}{\rho} \) initially decay to zero with certain rates near origin, then they tend to zero with same rates near the origin for any positive time.

Remark 1.5. In Theorem 1.2 the initial data can be allowed to tend to infinity at far field.

Remark 1.6. The invariant region \( \frac{m}{\rho} + \rho^\theta \leq M, \frac{m}{\rho} - \rho^\theta \geq 0 \) was first observed in [3]. This corresponds to the case \( c = 0 \) in Theorem 1.2.

The main ingredient in proving Theorem 1.1 is how to get the uniform estimates of viscosity solutions independent of viscosity \( \varepsilon \) and time \( t \). In fact, the viscosity solutions are uniformly bounded through a maximum principle for parabolic system, see Lemma 2.1 below. Roughly speaking, we first add viscous perturbation on the system (1.3) and get a viscous system (3.1), which can be reduced into a decoupled system (3.3) of the Riemann invariants. Unfortunately Lemma 2.1 can not be directly applied since the coefficients \( a_{12} \) and \( a_{21} \) of Lemma 2.1 may not be negative in the system (3.3), while they have to be negative for the application of the lemma. The key point is to introduce modified Riemann invariants to derive a new system (3.6) in which the coefficients have desired sign. To prove Theorem 1.2, we first introduce a space scaling transformation for both variables \( \rho = \tilde{\rho} x^{c}, m = \tilde{m} x^{d} \) and space coordinate \( \xi = \frac{1}{c-d+1} x^{c-d+1} \) (if \( c - d + 1 \neq 0 \))
or \( \xi = \ln x, \) (if \( c - d + 1 = 0 \)), see section 4 below. Then we add viscous perturbations \( (\varepsilon \tilde{p}_\xi \xi, \varepsilon \tilde{m}_\xi \xi) \) on the new system for \((\tilde{p}, \tilde{m})\). Again using Lemma 2.1, we get desired uniform estimates of viscosity solutions in dependent of viscosity \( \varepsilon \) and time \( t \).

The present paper is organized as follows: In Section 2, we construct approximate solutions by adding viscosity and some preliminaries are given. In Section 3, we first obtain the uniform upper bounds independent of viscosity \( \varepsilon \) and time \( t \) for the viscosity solutions and then prove the \( H^{-1}_{loc} \) compactness for entropy-entropy flux pairs, and finally Theorem 1.1. Section 4 is devoted to Theorem 1.2, i.e., the existence of entropy solutions with spherical symmetry.

2. Preliminaries and Formulations

We first introduce some basic facts for the system (1.3). The eigenvalues are

\[
\lambda_1 = \frac{m}{\rho} - \theta \rho, \quad \lambda_2 = \frac{m}{\rho} + \theta \rho, \tag{2.1}
\]

where \( \theta = \frac{\gamma - 1}{2} \), and the corresponding right eigenvectors are

\[
r_1 = \begin{bmatrix} 1 \\ \lambda_1 \end{bmatrix}, \quad r_2 = \begin{bmatrix} 1 \\ \lambda_2 \end{bmatrix}. \tag{2.2}
\]

The Riemann invariants \((w, z)\) are given by

\[
w = \frac{m}{\rho} + \rho \theta, \quad z = \frac{m}{\rho} - \rho \theta, \tag{2.3}
\]

satisfying \( \nabla w \cdot r_1 = 0 \) and \( \nabla z \cdot r_2 = 0 \), where \( \nabla = (\partial_\rho, \partial_\eta) \) is the gradient with respect to \( U = (\rho, \eta) \). A pair of functions \((\eta, q) : \mathbb{R} \times \mathbb{R}^+ \mapsto \mathbb{R}^2 \) is defined to be an entropy-entropy flux pair of system (1.3) if it satisfies

\[
\nabla q(U) = \nabla \eta(U) \nabla \left[ \frac{m^2}{\rho} + p(\rho) \right]. \tag{2.4}
\]

When

\[
\eta \bigg|_{\rho=0, m \text{ fixed}} = 0,
\]

\( \eta(\rho, m) \) is called to be weak entropy. Moreover, an entropy \( \eta(\rho, m) \) is convex (strictly convex) if the Hessian matrix \( \nabla^2 \eta(\rho, m) \) is nonnegative (positive). For example,

\[
\eta^*(\rho, m) = \frac{m^2}{2\rho} + \frac{p_0 \rho^\gamma}{\gamma - 1}, \quad q^*(\rho, m) = \frac{m^3}{2\rho^2} + \frac{p_0 \rho^{\gamma - 1} m}{\gamma - 1}, \tag{2.5}
\]

is a strictly convex entropy pair. As shown in [15] and [16], any weak entropy for the system (1.3) is

\[
\eta = \rho \int_{-1}^{1} g(\frac{m}{\rho} + \rho \theta s)(1 - s^2)^\lambda ds, \quad q = \rho \int_{-1}^{1} (\frac{m}{\rho} + \rho \theta s) g(\frac{m}{\rho} + \rho \theta s)(1 - s^2)^\lambda ds, \tag{2.6}
\]

with \( \lambda = \frac{3 - \gamma}{2(\gamma - 1)} \) and \( g(\cdot) \in C^2(\mathbb{R}) \) is any function.

Now, we will introduce a revised version of the theory of invariant region which is essentially based on the maximum principle for parabolic equation, see [27].
Lemma 2.1. (Maximum principle on bounded domain) Let \( p(x,t), q(x,t), (x,t) \in [a,b] \times [0,T] \) be any bounded classical solutions of the following quasilinear parabolic system

\[
\begin{align*}
    p_t + \mu_1 p_x = p_{xx} + a_{11} p + a_{12} q + R_1, \\
    q_t + \mu_2 q_x = q_{xx} + a_{21} p + a_{22} q + R_2,
\end{align*}
\]

with

\[
\begin{align*}
    p(x,0) &\leq 0, \quad q(x,0) \geq 0, \quad \text{for} \quad x \in [a,b]. \\
    p(a,t) &\leq 0, \quad q(a,t) \geq 0, \quad \text{for} \quad t \in [0,T]. \\
    p(b,t) &\leq 0, \quad q(b,t) \geq 0, \quad \text{for} \quad t \in [0,T].
\end{align*}
\]

where

\[
\begin{align*}
    \mu_i = \mu_i(x,t,p(x,t),q(x,t)), \quad a_{ij} = a_{ij}(x,t,p(x,t),q(x,t)),
\end{align*}
\]

and the source terms

\[
R_i = R_i(x,t,p(x,t),q(x,t),p_x(x,t),q_x(x,t)), \quad i,j = 1,2, \forall (x,t) \in [a,b] \times [0,T].
\]

Here \( \mu_i, a_{ij} \) are bounded with respect to \( (x,t,p,q) \in [a,b] \times [0,T] \times K \), where \( K \) is an arbitrary compact subset in \( \mathbb{R}^2 \). \( a_{12}, a_{21}, R_1, R_2 \) are continuously differentiable with respect to \( p, q \). Assume that

(C1): \( a_{12} \leq 0 \) holds for \( p = 0 \) and \( q \geq 0 \); \( a_{21} \leq 0 \) holds for \( q = 0 \) and \( p \leq 0 \);

(C2): \( R_1 \leq 0 \) holds for \( p = 0 \) and \( q \geq 0 \); \( R_2 \geq 0 \) holds for \( q = 0 \) and \( p \leq 0 \).

Then for any \( (x,t) \in [a,b] \times [0,T] \),

\[
p(x,t) \leq 0, \quad q(x,t) \geq 0.
\]

3. Proof of Theorem 1.1

3.1. Uniform upper bound estimate. We approximate [13] by adding artificial viscosity as follows.

\[
\begin{align*}
    \rho_t + m_x &= -\frac{N-1}{x} m + \varepsilon \rho_{xx}, \\
    m_t + \left( \frac{m^2}{\rho} + p(\rho) \right)_x &= -\frac{N-1}{x} \frac{m^2}{\rho} + \varepsilon m_{xx} - \frac{2\varepsilon \alpha M_2}{x^{\alpha+1}} m_x,
\end{align*}
\]

where \( \alpha, M_2 \) are some positive constants, which will be determined later. We consider (3.1) on a cylinder \( (1,b) \times \mathbb{R}^+ \), with \( \mathbb{R}^+ = [0, +\infty), b := b(\varepsilon) \) satisfying \( \lim b(\varepsilon) = \infty \). The initial-boundary values are given by

\[
\begin{align*}
    (\rho, m)|_{t=0} &= (\rho_0(x), m_0(x)) = (\rho_0(x) + \varepsilon, m_0(x)) * j^\varepsilon, 1 \leq x \leq b, \\
    (\rho, m)|_{x=1} &= (\rho_0(1), 0), (\rho, m)|_{x=b} = (\rho_0(b), m_0(b)), t > 0,
\end{align*}
\]

where \( j^\varepsilon \) is the standard mollifier with small parameter \( \varepsilon > 0 \). Next we will derive the uniform bound of the viscosity solutions by the maximum principle, i.e., Lemma 2.1.
on the Riemann invariants \( w \) and \( z \), we transform (3.1) into the following form:

\[
\begin{align*}
  w_t + \lambda_2 w_x &= \varepsilon w_{xx} + 2\varepsilon (w_x - \alpha M_2 x^{-\alpha - 1}) \frac{p_x}{\rho} - \theta \frac{N - 1}{x} \rho^\theta z - \theta \frac{N - 1}{x} \rho^{2\theta}, \\
  z_t + \lambda_1 z_x &= \varepsilon z_{xx} + 2\varepsilon (z_x - \alpha M_2 x^{-\alpha - 1}) \frac{p_x}{\rho} + \theta \frac{N - 1}{x} \rho^\theta z + \theta \frac{N - 1}{x} \rho^{2\theta}.
\end{align*}
\] (3.3)

From the initial condition (1.7), we set the non-negative control functions \((\phi, \psi)\):

\[
\phi = \bar{M}_1 - M_2 x^{-\alpha} + \varepsilon e^{Ct}, \quad \psi = M_2 x^{-\alpha} + \varepsilon e^{Ct}, \quad \bar{M}_1 = M_1 - 1,
\]

where \( C \) is a positive constant, which will be determined later. Then a simple calculation shows that

\[
\begin{align*}
  \phi_t &= \varepsilon C e^{Ct}, \quad \phi_x = \alpha M_2 x^{-\alpha - 1}, \quad \phi_{xx} = -\alpha (\alpha + 1) M_2 x^{-\alpha - 2}; \\
  \psi_t &= \varepsilon C e^{Ct}, \quad \psi_x = -\alpha M_2 x^{-\alpha - 1}, \quad \psi_{xx} = \alpha (\alpha + 1) M_2 x^{-\alpha - 2}.
\end{align*}
\]

Define a modified Riemann invariants \((\bar{w}, \bar{z})\) as

\[
\bar{w} = w - \phi, \quad \bar{z} = z + \psi.
\] (3.4)

We shall use Lemma 2.1 to show \( \bar{w} \leq 0 \) and \( \bar{z} \geq 0 \) for any time. Inserting (3.4) into (3.3) yields the equations for \( \bar{w} \) and \( \bar{z} \):

\[
\begin{align*}
  \bar{w}_t + \lambda_2 \bar{w}_x &= \varepsilon \bar{w}_{xx} + 2\varepsilon \frac{p_x}{\rho} \bar{w}_x - \varepsilon \theta (\theta + 1) \rho^\theta - 2 \rho_x^2 \\
  \bar{z}_t + \lambda_1 \bar{z}_x &= \varepsilon \bar{z}_{xx} + 2\varepsilon \frac{p_x}{\rho} \bar{z}_x + \varepsilon \theta (\theta + 1) \rho^\theta - 2 \rho_x^2 \\
  &+ \psi_t + \lambda_1 \psi_x - \varepsilon \psi_{xx} + \theta \frac{N - 1}{x} \rho^\theta (\bar{z} - \psi) + \theta \frac{N - 1}{x} \rho^{2\theta}.
\end{align*}
\] (3.5)

Note that

\[
\lambda_1 = \bar{z} - \psi + (1 - \theta) \rho^\theta, \quad \lambda_2 = \bar{w} + \phi + (\theta - 1) \rho^\theta.
\]

The system (3.5) becomes

\[
\begin{align*}
  \bar{w}_t + (\lambda_2 - 2\varepsilon \frac{p_x}{\rho}) \bar{w}_x &= \varepsilon \bar{w}_{xx} + a_{11} \bar{w} + a_{12} \bar{z} + R_1, \\
  \bar{z}_t + (\lambda_1 - 2\varepsilon \frac{p_x}{\rho}) \bar{z}_x &= \varepsilon \bar{z}_{xx} + a_{21} \bar{w} + a_{22} \bar{z} + R_2,
\end{align*}
\] (3.6)

where

\[
\begin{align*}
  a_{11} &= -\phi_x, \quad a_{12} = -\theta \frac{N - 1}{x} \rho^\theta \leq 0, \quad a_{21} = 0, \quad a_{22} = \psi_x + \theta \frac{N - 1}{x} \rho^\theta, \\
  R_1 &= -\phi_t - [\phi + (\theta - 1) \rho^\theta] \phi_x + \varepsilon \phi_{xx} - \varepsilon \theta (\theta + 1) \rho^\theta - 2 \rho_x^2 + \theta \frac{N - 1}{x} \rho^\theta \psi - \theta \frac{N - 1}{x} \rho^{2\theta}, \\
  R_2 &= \psi_t + [-\psi + (1 - \theta) \rho^\theta] \psi_x - \varepsilon \psi_{xx} + \varepsilon \theta (\theta + 1) \rho^\theta - 2 \rho_x^2 - \theta \frac{N - 1}{x} \rho^\theta \psi + \theta \frac{N - 1}{x} \rho^{2\theta}.
\end{align*}
\]
A direct computation gives
\[
R_1 \leq (\tilde{M}_1 - M_2 x^{-\alpha} + 2\varepsilon C^t + (\theta - 1)\rho^\theta)\psi_x + \theta \frac{N - 1}{x} \rho^\theta \psi - \theta \frac{N - 1}{x} \rho^{2\theta} - \varepsilon C e^{C^t} \\
= - \alpha \tilde{M}_1 M_2 x^{-\alpha - 1} + \alpha M_2^2 x^{-2\alpha - 1} + \alpha M_2 (1 - \theta) \rho^\theta x^{-\alpha - 1} + \theta (N - 1) M_2 \rho^\theta x^{-\alpha - 1} \\
- \theta \frac{N - 1}{x} \rho^{2\theta} - 2\varepsilon C^t M_2 x^{-\alpha - 1} - \varepsilon C e^{C^t} + \theta \frac{N - 1}{x} \rho^\theta \varepsilon e^{C^t}.
\]

To ensure \( R_1 \leq 0 \), it is sufficient to show that
\[
\alpha M_2^2 x^{-\alpha} + M_2 [\alpha (1 - \theta) + \theta (N - 1)] \rho^\theta + \theta (N - 1) \rho^\theta \varepsilon e^{C^t} x^\alpha \\
\leq \theta (N - 1) \rho^\theta \varepsilon e^{C^t} x^\alpha + \alpha \tilde{M}_1 M_2 + 2\varepsilon e^{C^t} M_2 + \varepsilon C e^{C^t} x^{\alpha + 1}.
\]
(3.7)

By Cauchy-Schwartz inequality, we have
\[
M_2 [\alpha (1 - \theta) + \theta (N - 1)] \rho^\theta \leq \frac{1}{2} \theta (N - 1) \rho^{2\theta} + \frac{M_2^2 [\alpha (1 - \theta) + \theta (N - 1)]^2}{2\theta (N - 1)}.
\]

Since \( x \geq 1 \), choosing \( M_1 = \tilde{M}_1 + 1 \) and \( C \) large enough, (3.7) holds, thus \( R_1 \leq 0 \).

We now turn to the term \( R_2 \). Denote \( \beta = \frac{\alpha}{\theta (N - 1)} \). By a direct calculation, we have
\[
R_2 \geq \left[ -\psi + (1 - \theta)\rho^\theta \right] x \psi - \varepsilon x \psi_{xx} - (\theta N - 1) \frac{1}{x} \rho^\theta \psi + \theta N - 1 \frac{1}{x} \rho^{2\theta} + \psi_t \\
= \frac{\theta (N - 1)}{x} \left[ \rho^{2\theta} - \frac{\alpha (1 - \theta) + \theta (N - 1)}{\theta (N - 1)} \rho^\theta \psi + \frac{\alpha \psi^2}{\theta (N - 1)} \right] \\
- \varepsilon \alpha \psi e^{C^t} \frac{1}{x} + \varepsilon (1 - \theta) \rho^\theta \alpha e^{C^t} \frac{1}{x} + \varepsilon C e^{C^t} - \varepsilon \alpha (1 - 1) M_2 x^{-\alpha - 2} \\
= \frac{\theta (N - 1)}{x} \left[ \left( \rho^\theta - \frac{\beta (1 - \theta) + 1}{2} \psi \right)^2 - \frac{(\beta (1 - \theta) + 1)^2}{4} \psi^2 + \beta \psi^2 \right] \\
+ \varepsilon \left[ -\alpha (M_2 x^{-\alpha} + \varepsilon e^{C^t}) e^{C^t} \frac{1}{x} + C e^{C^t} - \alpha (\alpha + 1) M_2 x^{-\alpha - 2} + (1 - \theta) \rho^\theta \alpha e^{C^t} \frac{1}{x} \right].
\]
(3.8)

Choosing \( C \) sufficient large and \( \varepsilon \) small such that \( C > (\alpha^2 + 2\alpha) M_2 \) and using \( \theta \in (0, 1) \), we get that the second term of right hand side of (3.8) is non-negative. To ensure \( R_2 \geq 0 \), it remains to guarantee that
\[
\beta \psi^2 - \frac{(\beta (1 - \theta) + 1)^2}{4} \psi^2 \geq 0,
\]
i.e.,
\[
g(\beta) := \beta^2 (1 - \theta)^2 - 2\beta (1 + \theta) + 1 \leq 0,
\]
which holds for any
\[
\theta (N - 1) \beta_1 \leq \alpha \leq \theta (N - 1) \beta_2,
\]
where
\[
\beta_1 = \frac{1}{(1 + \sqrt{\theta})^2}, \quad \beta_2 = \frac{1}{(1 - \sqrt{\theta})^2}.
\]
\( \beta_1, \beta_2 \) are the roots of equation \( g(\beta) = 0 \). Note that if (1.7) holds for some \( \alpha_2 > 0 \), then (1.7) still holds for any \( \alpha_1 \) satisfying \( \alpha_1 > \alpha_2 \) with possible different constants \( M_1 \) and \( M_2 \). So we choose \( \alpha = \frac{(N-1)\theta}{2(1+\sqrt{\theta})^2} \) here. By the initial and boundary data (3.2), we obtain

\[
\dot{w}(x,0) = w(x,0) - \phi \leq 0, \quad \dot{z}(x,0) = z(x,0) + \psi \geq 0, \text{ for } x \geq 1;
\]
\[
\dot{w}(1,t) \leq 0, \quad \dot{z}(1,t) \geq 0, \text{ for } t > 0;
\]
\[
\dot{w}(b,t) \leq 0, \quad \dot{z}(b,t) \geq 0, \text{ for } t > 0.
\]

By Lemma 2.1

\[
w(x,t) \leq M_1 - M_2 x^{-\alpha}, \quad z(x,t) \geq -M_2 x^{-\alpha}.
\]

Hence we obtain

\[
0 \leq \rho(x,t) \leq \left( \frac{M_1}{2} \right)^{\frac{1}{\gamma}}, \quad -M_2 x^{-\alpha} \rho \leq m(x,t) \leq (M_1 - M_2 x^{-\alpha}) \rho(x,t).
\]

This gives the following Theorem 3.1.

**Theorem 3.1.** (L^\infty estimate: excluding the origin) Let \( 1 < \gamma \leq 3 \). Assume that there exist positive constants \( M_1, M_2 \) such that

\[
0 \leq \rho_0(x), \quad \frac{m_0}{\rho_0} + \rho_0^{\theta} \leq M_1 - M_2 x^{-\alpha}, \quad \frac{m_0}{\rho_0} - \rho_0^{\theta} \geq -M_2 x^{-\alpha}, \quad x \in [1,b],
\]

\[
\left( \frac{m}{\rho} + \rho^{\theta} \right)\big|_{x=1} \leq M_1 - M_2, \quad \left( \frac{m}{\rho} - \rho^{\theta} \right)\big|_{x=1} \geq -M_2,
\]

\[
\left( \frac{m}{\rho} + \rho^{\theta} \right)\big|_{x=b} \leq M_1 - M_2 b^{-\alpha}, \quad \left( \frac{m}{\rho} - \rho^{\theta} \right)\big|_{x=b} \geq -M_2 b^{-\alpha}, \quad t > 0,
\]

where \( \alpha \geq \frac{(N-1)\theta}{2(1+\sqrt{\theta})^2} \), then the solutions of (3.1) - (3.2) satisfy

\[
0 \leq \rho(x,t) \leq \left( \frac{M_1}{2} \right)^{\frac{1}{\gamma}}, \quad -M_2 x^{-\alpha} \rho \leq m(x,t) \leq (M_1 - M_2 x^{-\alpha}) \rho(x,t).
\]

### 3.2. Lower bound estimate of density.

From the above argument, we know that the velocity \( u = \frac{m}{\rho} \) is uniformly bounded, i.e., \(|u| \leq M_1\). The lower bound of density can be derived as in [18], but we introduce a different treatment for estimating a priori lower bound for solutions of heat equations with general source terms. Set \( e = \ln \rho \), and we can get a scalar equation for \( e \), that is,

\[
e_t + e_x u + u_x = e e_{xx} + \varepsilon e_x^2 - \frac{N-1}{x} u.
\]

From the initial-boundary value of (3.2), we have \( e|_{t=0} = \ln \rho_0^\varepsilon(x), e|_{x=1} = \ln \rho_0^\varepsilon(1), e|_{x=b} = \ln \rho_0^\varepsilon(b) \). Then it follows from (3.11) that

\[
e_t - e e_{xx} = e(e_x - \frac{u}{2\varepsilon})^2 - \frac{u^2}{4\varepsilon} - \frac{N-1}{x} u - u_x.
\]

To the best of our knowledge, we found no literature that ever stated the following Lemma to obtain the lower bound of density.
Lemma 3.1. Assume that $w$ is a classical solution of heat equation:
\[
\begin{cases}
w_t - \varepsilon w_{xx} = f_1(x,t) + f_2(x,t) + h(x,t), a < x < b, \\
w|_{t=0} = \varphi(x), a < x < b, \\
w|_{x=a} = \varphi(a), w|_{x=b} = \varphi(b),
\end{cases}
\]
where $f_1(x,t) \geq 0$, $f_2(x,t)$ and $h(x,t)$ are bounded smooth functions and $\varphi(x)$ is a bounded function. Then, there exits a positive constant $C(a,b,\varepsilon,t)$, s.t.,
\[
w \geq -C(a,b,\varepsilon,t).
\]
Proof: the proof is given in Appendix.

By applying Lemma 3.1 for
\[
w = e, f_1(x,t) = \varepsilon (v_x - \frac{u}{2\varepsilon})^2, f_2(x,t) = -\frac{u^2}{4\varepsilon} - \frac{N-1}{x} u, h(x,t) = u,
\]
it follows that
\[
\rho \geq e^{-C(a,b,\varepsilon,t)} > 0.
\]

From the local existence of solutions, the upper and the lower bound of density, we can conclude the following theorem.

Theorem 3.2. For any time $T > 0$, there exist positive constants $C, M_1, M_2$ and $\varepsilon_0$ such that for $0 < \varepsilon < \varepsilon_0$, the initial-boundary value problem (3.1)–(3.2) admits a unique classical solution satisfying
\[
e^{-C(\varepsilon,T)} \leq \rho^\varepsilon(x,t) \leq \left(\frac{M_1}{2}\right)^\frac{1}{\varepsilon}, -M_2 x^{-\alpha} \rho^\varepsilon(x,t) \leq m^\varepsilon(x,t) \leq (M_1 - M_2 x^{-\alpha}) \rho^\varepsilon(x,t).
\]

3.3. $H^{-1}_{loc}$ compactness of the entropy pair. For any $T \in (0, \infty)$, let $\Pi_T = (1, +\infty) \times (0, T)$. We consider the entropy dissipation measures
\[
(\eta(\rho^\varepsilon, m^\varepsilon)_t + q(\rho^\varepsilon, m^\varepsilon)_x),
\]
where $(\eta, q)$ is any weak entropy-entropy flux pair whose formula is given in (2.6). We will apply Murat Lemma to conclude that the entropy dissipation measures in (3.13) lie in a compact set of $H^{-1}_{loc}(\Pi_T)$.

Lemma 3.2. (Murat [24]) Let $\Omega \subseteq \mathbb{R}^n$ be an open set, then
\[
(\text{compact set of } W^{-1,q}_{loc}(\Omega)) \cap (\text{bounded set of } W^{-1,r}_{loc}(\Omega)) \subset (\text{compact set of } H^{-1}_{loc}(\Omega)),
\]
where $1 < q \leq 2 < r$.

We write $U = -\frac{N-1}{x} m, V = -\frac{N-1}{x} m^2 \rho$ for simplicity. Let $K \subseteq \Pi_T$ be any compact set and choose $\varphi \in C^\infty(\Pi_T)$ such that $\varphi|_K = 1$ and $0 \leq \varphi \leq 1$. When $\varepsilon$ is small, $K \subseteq (1, b(\varepsilon)) \times (0, T)$. Multiplying (3.1) by $\nabla \eta^* \varphi$ with $\eta^*$ being the mechanical entropy in (2.3), we obtain
\[
\varepsilon \int_{\Pi_T} (\rho_x, m_x) \nabla^2 \eta^* (\rho_x, m_x)^T \varphi dx dt = \int_{\Pi_T} [(V \phi - 2\varepsilon \phi_x \rho_x) \eta_{\phi m}^* + U \eta_{\rho}^* \varphi + \eta^* \varphi_t + q^* \varphi_x + \varepsilon \eta^* \varphi_{xx}] dx dt.
\]
Note that
\[(\rho_x, m_x)\nabla^2 \eta^*(\rho_x, m_x) = p_0 \gamma \rho^{-2} \rho_x^2 + \rho u_x^2,
\]
and
\[|(V \varphi - 2\varepsilon \phi_x \rho_x)\eta_m^*| \leq \frac{\varepsilon p_0 \gamma}{2} \rho^{-2} \rho_x^2 + \varepsilon C \phi_x^2 \rho^{-\gamma} + C \|V\|_{L^\infty},\]
we get
\[
\frac{\varepsilon}{2} \int \int_{\Pi_T} \varphi(\rho_x, m_x) \nabla^2 \eta^*(\rho_x, m_x) d\gamma d\rho_x d\rho
\]
\[
\leq \int \int_{\Pi_T} C(\varepsilon \phi_x^2 \rho^{-\gamma} + \|V\|_{L^\infty}) d\gamma d\rho_x d\rho
\]
\[
+ \int \int_{\Pi_T} \left[ \eta^* \varphi_t + q^* \varphi_x + \varepsilon \eta^* \varphi_{xx} + \left( \frac{m_3}{2\rho^2} + \frac{\gamma}{\gamma - 1} m \rho^{-1} \right) \|U\|_{L^\infty} \right] d\gamma d\rho_x d\rho
\]
\[
\leq C(\varphi).
\]
Thus we have arrived that
\[
\varepsilon \rho^{-2} \rho_x^2 + \varepsilon \rho u_x^2 \in L_{loc}^{1}(\Pi_T).
\]
(3.15)
Note that when \(\gamma > 2, \rho^{-2} \rho_x^2\) is degenerate near \(\rho = 0\). For simplicity, we assume that \(1 < \gamma \leq 2\). For any weak entropy-entropy flux pairs given in (2.6), as in (3.14), we have
\[
\eta_t + q_x = \varepsilon \eta_{xx} - \varepsilon (\rho_x, m_x) \nabla^2 \eta(\rho_x, m_x)^T + (\eta \rho U + \eta_m V) - 2\varepsilon \eta_m \rho_x \phi_x =: \sum_{i=1}^4 J_i.
\]
(3.16)
From (3.15), it is obvious that \(J_i\) is compact in \(H_{loc}^{-1}(\Pi_T)\). Note that for any weak entropy, the Hessian matrix \(\nabla^2 \eta\) is controlled by \(\nabla^2 \eta^*\) (see [15]), i.e.,
\[
(\rho_x, m_x) \nabla^2 \eta(\rho_x, m_x)^T \leq (\rho_x, m_x) \nabla^2 \eta^*(\rho_x, m_x)^T,
\]
(3.17)
then \(J_2\) is bounded in \(L_{loc}^{1}(\Pi_T)\) and then compact in \(W_{loc}^{-1,\nu}(\Pi_T)\) by the embedding theorem, for some \(1 < \nu < 2\). Similarly, \(J_3\) and \(J_4\) are bounded in \(L_{loc}^{4}(\Pi_T)\). Thus
\[
\eta_t + q_x\]
is compact in \(W_{loc}^{-1,\alpha}(\Pi_T)\) for some \(1 < \nu < 2\).
On the other hand, \(\eta_t + q_x\) is bounded in \(W_{loc}^{-1,\infty}(\Pi_T)\). With the help of Lemma 3.2 we conclude that
\[
\eta_t + q_x\]
is compact in \(H_{loc}^{-1}(\Pi_T)\)
(3.18)
for all weak entropy-entropy flux pairs.

Remark 3.1. We are focusing on the uniform bound of \(\rho\) and \(m\). In the above argument, (3.18) still holds for the case that \(2 < \gamma \leq 3\) by a similar argument of [31]. See also [18]. We assume \(1 < \gamma \leq 2\) for simplicity.

3.4. Entropy solution. By (3.18) and the compactness framework established in [9],[11],[15], we can prove that there exists a subsequence of \((\rho^\varepsilon, m^\varepsilon)\) (still denoted by \((\rho^\varepsilon, m^\varepsilon)\)) such that
\[
(\rho^\varepsilon, m^\varepsilon) \rightarrow (\rho, m) \quad \text{in} \quad L_{loc}^p(\Pi_T), \quad p \geq 1.
\]
(3.19)
As in [30],[28],[29], we can prove that \((\rho, m)\) is an entropy solution to the initial-boundary value problem (1.4) and \(m_{|x=1} = 0\) in the sense of the divergence-measure fields introduced in [4]. Therefore Theorem 1.1 is completed.
Remark 3.2. The approach can also be applied to the Euler-Poisson system with spherical symmetry.

4. Proof of Theorem 1.2

4.1. Uniform upper bound estimate. Consider the system \((1.3)\) on a cylinder \((a, b) \times \mathbb{R}^+\), with \(\mathbb{R}^+ = [0, +\infty)\), \(a := a(\varepsilon), b := b(\varepsilon) > 1\), and \(\lim_{\varepsilon \to 0} \varepsilon a(\varepsilon)^d = 0\) for any \(\delta \in \mathbb{R}\) and \(\lim_{\varepsilon \to 0} b(\varepsilon) = \infty\). For example, \(a(\varepsilon)\) can be taken as \(-\frac{1}{m\varepsilon}\). We make a scaling transformation

\[
\rho = \tilde{\rho} x^c, m = \tilde{m} x^d.
\]

Take \(d = (\theta + 1)c > 0\), the system \((1.3)\) can be rewritten as

\[
\begin{aligned}
\partial_t \tilde{\rho} + x^{d-c} \tilde{m}_x &= - (N - 1 + d)x^{d-c-1}\tilde{m}, \\
\tilde{m}_t + x^{d-c} \left( \frac{\tilde{m}_x^2}{\tilde{\rho}} + p(\tilde{\rho}) \right) &= - [-(2d - c + N - 1)\frac{\tilde{m}_x^2}{\tilde{\rho}} - (2d - c)p(\tilde{\rho})] x^{d-c-1}.
\end{aligned}
\]

(4.1)

If \(c - d + 1 \neq 0\), let \(\xi = \frac{1}{c-d+1} x^{c-d+1}\). If \(c - d + 1 = 0\), let \(\xi = \ln x\). Then (4.1) becomes

\[
\begin{aligned}
\partial_t \tilde{\rho} + \tilde{m}_t + \tilde{m}_x &= - (N - 1 + d)x^{d-c-1}\tilde{m}, \\
\tilde{m}_t + \tilde{m}_x &= - [-(2d - c + N - 1)\frac{\tilde{m}_x^2}{\tilde{\rho}} - (2d - c)p(\tilde{\rho})] x^{d-c-1}.
\end{aligned}
\]

(4.2)

We approximate (4.2) by adding artificial viscosity as follows:

\[
\begin{aligned}
\partial_t \tilde{\rho} + \tilde{m}_t + \tilde{m}_x &= - (N - 1 + d)x^{d-c-1}\tilde{m} + \varepsilon \tilde{\rho}_\xi, \\
\tilde{m}_t + \tilde{m}_x &= - [-(2d - c + N - 1)\frac{\tilde{m}_x^2}{\tilde{\rho}} - (2d - c)p(\tilde{\rho})] x^{d-c-1} + \varepsilon \tilde{m}_\xi.
\end{aligned}
\]

(4.3)

The initial-boundary value conditions are given as follows:

\[
\begin{aligned}
(\tilde{\rho}, \tilde{m})|_{t=0} &= (\tilde{\rho}_0(x), \tilde{m}_0(x)) = (\tilde{\rho}_0(x) + \varepsilon, \tilde{m}_0(x)\chi_{|2a(\varepsilon), b(\varepsilon)|}) * j^\varepsilon, x \in [a(\varepsilon), b(\varepsilon)], \\
(\tilde{\rho}, \tilde{m})|_{x=a(\varepsilon)} &= (\tilde{\rho}_0(a(\varepsilon)), \tilde{m}_0(a(\varepsilon))) = (\tilde{\rho}_0(a(\varepsilon)), 0), \\
(\tilde{\rho}, \tilde{m})|_{x=b(\varepsilon)} &= (\tilde{\rho}_0(b(\varepsilon)), \tilde{m}_0(b(\varepsilon))), t > 0,
\end{aligned}
\]

(4.4)

where \(j^\varepsilon\) is the standard mollifier and \(\chi\) is the characteristic function. As in the proof of Theorem 1.1, the key point is to derive the uniform upper bound of the approximate solution \(\tilde{\rho}\) and \(\tilde{m}\). By the definition of Riemann invariants, we have

\[
w = \frac{m}{\rho} + \rho^\theta = \left( \frac{\tilde{m}}{\tilde{\rho}} + \rho^\theta \right) = \tilde{w} x^c, z = \frac{m}{\rho} - \rho^\theta = \left( \frac{\tilde{m}}{\tilde{\rho}} - \rho^\theta \right) x^c := \tilde{z} x^c.
\]

Similarly, we have

\[
\lambda_1 = \frac{m}{\rho} - \theta \rho^\theta = \left( \frac{\tilde{m}}{\tilde{\rho}} - \theta \rho^\theta \right) x^c := \tilde{\lambda}_1 x^c, \lambda_2 = \frac{m}{\rho} + \theta \rho^\theta = \left( \frac{\tilde{m}}{\tilde{\rho}} + \theta \rho^\theta \right) x^c := \tilde{\lambda}_2 x^c.
\]
It is obvious that the system (4.3) is equivalent to the following system

\[ \begin{align*}
\rho_t + m_x &= -\frac{N-1}{x}m + \varepsilon \left[ \rho_{xx}x^{2(d-c)} + (d-3c)\rho x^{2(d-c)-1} \right. \\
&\quad + c(2c+1-d)\rho x^{2(d-c)-2} \bigg] , \\
\frac{m_t}{\rho} + p(\rho) &= -\frac{N-1}{x}m + \varepsilon \left[ m_{xx}x^{2(d-c)} - (c+d)m_x x^{2(d-c)-1} \right. \\
&\quad + d(c+1)m x^{2(d-c)-2} \bigg], x \in [a(\varepsilon), b(\varepsilon)], t > 0.
\end{align*} \]

(4.5)

By the rescaled Riemann invariants \( \tilde{w} \) and \( \tilde{z} \), we have

\[ \begin{align*}
\tilde{w}_t + \tilde{\lambda}_2 \tilde{w}_\xi &= \varepsilon \tilde{w}_{\xi\xi} + 2\varepsilon \tilde{\rho}_\xi \tilde{w}_\xi - \varepsilon \theta(\theta+1)\tilde{\rho}^{\theta-2} \tilde{\rho}_\xi^2 \\
&\quad + \left[ (c-d)\frac{m}{\rho} + \theta(N-1+d)\rho^{\theta-1}\tilde{m} - (2d-c)\frac{\rho}{\gamma} \tilde{\rho}^{2\theta} \right] x^{d-c-1}, \\
\tilde{z}_t + \tilde{\lambda}_1 \tilde{z}_\xi &= \varepsilon \tilde{z}_{\xi\xi} + 2\varepsilon \tilde{\rho}_\xi \tilde{z}_\xi + \varepsilon \theta(\theta+1)\tilde{\rho}^{\theta-2} \tilde{\rho}_\xi^2 \\
&\quad + \left[ (c-d)\frac{m}{\rho} + \theta(N-1+d)\rho^{\theta-1}\tilde{m} - (2d-c)\frac{\rho}{\gamma} \tilde{\rho}^{2\theta} \right] x^{d-c-1}.
\end{align*} \]

(4.6)

Set the control functions \( (\phi, \psi) = (M_3, 0) \) and assume that

\[ \frac{m_0}{\rho_0} + \rho_0^\theta \leq M_3x^{c\theta}, \left( \frac{m}{\rho} + \rho^\theta \right) \bigg|_{x=a(\varepsilon)} \leq M_3 a(\varepsilon)^{c\theta}, \left( \frac{m}{\rho} + \rho^\theta \right) \bigg|_{x=b(\varepsilon)} \leq M_3 b(\varepsilon)^{c\theta}. \]

(4.7)

Define the modified Riemann invariants \( (\tilde{w}, \tilde{z}) \) as

\[ \tilde{w} = \tilde{w} - \phi, \quad \tilde{z} = \tilde{z} + \psi. \]

(4.8)

The system (4.6) becomes

\[ \begin{align*}
\tilde{w}_t + \left( \tilde{\lambda}_2 - 2\varepsilon \tilde{\rho}_\xi \right) \tilde{w}_\xi &= \varepsilon \tilde{w}_{\xi\xi} + a_{11} \tilde{w} + a_{12} \tilde{z} + R_1, \\
\tilde{z}_t + \left( \tilde{\lambda}_1 - 2\varepsilon \tilde{\rho}_\xi \right) \tilde{z}_\xi &= \varepsilon \tilde{z}_{\xi\xi} + a_{21} \tilde{w} + a_{22} \tilde{z} + R_2,
\end{align*} \]

(4.9)

where

\[ a_{11} = 0, \quad a_{12} = -\theta(N-1+d)\tilde{\rho}^{\theta} x^{d-c-1} \leq 0, \]

\[ a_{21} = 0, \quad a_{22} = \left[ \frac{1}{4} [(c-d) - \theta(N-1+d) - \theta^2c] \right] \tilde{z} + \frac{1}{2} \left[ (c-d) + \theta^2c \right] \tilde{w} x^{d-c-1}, \]

\[ R_1 = \left[ (c-d)\frac{m}{\rho} - \theta(N-1+d)\rho^{\theta-2} - \theta^2c \tilde{\rho}^{2\theta} \right] x^{d-c-1} - \varepsilon \theta(\theta+1)\tilde{\rho}^{\theta-2} \tilde{\rho}_\xi^2 \leq 0, \]

\[ R_2 = \frac{1}{4} [(c-d) + \theta(N-1+d) - \theta^2c] \tilde{w}^2 x^{d-c-1} + \varepsilon \theta(\theta+1)\tilde{\rho}^{\theta-2} \tilde{\rho}_\xi^2 \]

\[ \geq \frac{1}{4} \theta(N-1)\tilde{w}^2 x^{d-c-1} \geq 0. \]
By the initial and boundary data (4.4) and maximum principle Lemma 2.1, we have
\[ \tilde{w}(\xi, t) \leq C, \tilde{z}(\xi, t) \geq 0, \]
which implies that
\[ 0 \leq \tilde{\rho}(x, t) \leq C, 0 \leq \tilde{m}(x, t) \leq C\tilde{\rho}(x, t). \]
i.e.
\[ 0 \leq \rho(x, t) \leq Cx^c, 0 \leq m(x, t) \leq C\rho(x, t)x^\theta, (x, t) \in [a(\varepsilon), b(\varepsilon)] \times \mathbb{R}^+, \]
where \( C \) depends on \( M_3 \), but not on \( T \). Thus we have

**Theorem 4.1.** (L\(^\infty\) estimate: including the origin) Let \( \gamma > 1 \). Assume that for any positive constant \( c \), there exists a positive constant \( M_3 \) such that the initial and boundary data satisfy
\[
0 \leq \rho_0(x), \quad \frac{m_0}{\rho_0} + \rho_0^\theta \leq M_3x^c, \quad \frac{m_0}{\rho_0} - \rho_0^\theta \geq 0, \quad a.e. \quad x \in [a(\varepsilon), b(\varepsilon)],
\]
\[
\left( \frac{m}{\rho} + \rho^\theta \right)_{|x=a(\varepsilon)} \leq M_3a(\varepsilon)^c, \quad \left( \frac{m}{\rho} - \rho^\theta \right)_{|x=a(\varepsilon)} \geq 0,
\]
\[
\left( \frac{m}{\rho} + \rho^\theta \right)_{|x=b(\varepsilon)} \leq M_3b(\varepsilon)^c, \quad \left( \frac{m}{\rho} - \rho^\theta \right)_{|x=b(\varepsilon)} \geq 0, \quad t > 0,
\]
then the solution of (4.5) and (4.7) satisfies
\[ 0 \leq \rho(x, t) \leq Cx^c, 0 \leq m(x, t) \leq C\rho(x, t)x^\theta, (x, t) \in [a(\varepsilon), b(\varepsilon)] \times \mathbb{R}^+, \]
where \( C \) depends on \( M_3 \), but not on \( T \).

4.2. **Lower bound estimate.** When \( c - d + 1 \neq 0 \), set \( \tilde{\nu} = \ln \tilde{\rho} \), then we get a scalar equation for \( \tilde{\nu} \),
\[
\tilde{\nu}_t + \tilde{\nu}_\xi \tilde{u} + \tilde{u}_\xi = \varepsilon \tilde{\nu}_\xi \xi + \varepsilon \tilde{\nu}_\xi^2 - \frac{N - 1 + b}{(c - d + 1)} \tilde{\nu}.
\]
Note that the velocity \( \tilde{u} = \frac{\tilde{m}}{\rho} \) is uniformly bounded, i.e., \( |\tilde{u}| \leq C \), and
\[
\tilde{\nu}(\xi, 0) = \tilde{\nu}_0(\xi), \quad \frac{1}{c - d + 1}(a(\varepsilon))^{c-d+1} \leq \xi \leq \frac{1}{c - d + 1}(b(\varepsilon))^{c-d+1},
\]
following the same way in Subsection 3.2, we can show that \( \tilde{\rho} \geq e^{-C(\varepsilon, t)} \). A similar argument can be applied to the case when \( c - d + 1 = 0 \). Consequently, we conclude that

**Theorem 4.2.** For any time \( T > 0 \), there exist positive constants \( C \) and \( \varepsilon_0 \) such that for \( 0 < \varepsilon < \varepsilon_0 \), the initial-boundary value problem (4.3) - (4.4) admits a unique classical solution satisfying
\[ e^{-C(\varepsilon, T)} x^c \leq \rho^\varepsilon(x, t) \leq Cx^c, 0 \leq m^\varepsilon(x, t) \leq C\rho^\varepsilon(x, t)x^\theta, \]
where \( C \) is independent of \( x \) and \( T \).
4.3. $H^{-1}_{loc}$ compactness of entropy pair. For any $T \in (0, \infty)$, let $\Pi_T = (0, +\infty) \times (0, T)$. Let $K \subset \Pi_T$ be any compact set, and choose $\varphi \in C^\infty_c(\Pi_T)$ such that $\varphi|_K = 1$, and $0 \leq \varphi \leq 1$. When $\varepsilon$ is small, $K \subset (a(\varepsilon), b(\varepsilon)) \times (0, T)$. Similarly as in subsection 3.3, we omit it here.

4.4. Entropy solution. By (4.15) and the compactness framework established in [9,11,15], we can prove that there exists a subsequence of $(\rho^\varepsilon, m^\varepsilon)$ (still denoted by $(\rho^\varepsilon, m^\varepsilon)$) such that

$$ (\rho^\varepsilon, m^\varepsilon) \to (\rho, m) \quad \text{in } L^p_{loc}(\Pi_T), \quad p \geq 1. \quad (4.16) $$

Note that $\rho = O(1)x^c$ and $m = O(1)x^d$ so that the right hand sides of (4.3), that is, $\frac{1}{\varepsilon}m$ and $\frac{1}{\varepsilon^2}m^2$, are integrable near the origin with respect to $x$. As in [5,6,28,29], we can prove that $(\rho, m)$ is an entropy solution to the problem (1.3) and the test function $\Phi(x,t)$ can contain the origin. Therefore, Theorem 1.2 is completed. It is remarked that the entropy solution obtained above is exactly the entropy solution to the Cauchy problem of isentropic gas dynamics system with spherical symmetry.

5. Appendix

Proof of Lemma 3.1: We decompose $w$ into $w = \sum_{i=0}^{3} w_i$, where $w_2$ and $w_3$ are

$$ w_2(x,t) = \int_{0}^{t} \int_{a}^{b} \Gamma(x - \xi, t - \tau) f_2(\xi, \tau) d\xi d\tau, $$

$$ w_3(x,t) = \int_{0}^{t} \int_{a}^{b} \Gamma(x - \xi, t - \tau) h(\xi, \tau) d\xi d\tau, $$

and $\Gamma$ is the heat kernel:

$$ \Gamma(x - \xi, t - \tau) = \begin{cases} 
1 / (4\pi \varepsilon(t-\tau))^{1/2} e^{-|x-\xi|^2 / 4\varepsilon(t-\tau)}, & t > \tau; \\
0, & t \leq \tau.
\end{cases} \quad (5.2) $$

and $w_0$ and $w_1$ are the solutions of the following problems respectively:

$$(P_0): \begin{cases} 
w_0 - \varepsilon w_{0xx} = 0, a < x < b, \\
w_0|_{t=0} = \varphi(x), a < x < b, \\
w_0|_{x=a} = \varphi(a) - w_2(a,t) - w_3(a,t), w_0|_{x=b} = \varphi(b) - w_2(b,t) - w_3(b,t), \end{cases} \quad (5.3)$$

$$(P_1): \begin{cases} 
w_{1t} - \varepsilon w_{1xx} = f_1(x,t), a < x < b, \\
w_{1t}|_{t=0} = 0, a < x < b, \\
w_{1}|_{x=a} = 0, w_{1}|_{x=b} = 0. \end{cases} \quad (5.4)$$
It is obvious that \(w_{2t} - \varepsilon w_{2xx} = f_2(x, t)\) and \(w_{3t} - \varepsilon w_{3xx} = h_{x}(x, t)\). Thus \(w = \sum_{i=0}^{3} w_i\) is the unique solution of the equation (3.12). Note that

\[
0 \leq \Gamma(x - \xi, t - \tau) \leq \frac{C}{(t - \tau)^{\frac{1}{2}}},
\]

\[
|\Gamma_{x}(x - \xi, t - \tau)| \leq \frac{C}{(t - \tau)^{\frac{1}{2} - \alpha}|x - \xi|^{2\alpha - 1}},
\]

(5.5)

for any \(\frac{1}{2} < \alpha < 1\). For example \(\alpha = \frac{2}{3}\), then \(\Gamma_{x}\) is integrable with respect to \(\xi\) and \(\tau\) up to time \(T > 0\). From (5.5), we obtain that \(w_2\) and \(w_3\) are bounded. Moreover, they are also bounded on the boundary \(x = a, b\). We then turn to the problem \((P_0)\) and find that its solution \(w_0\) is bounded. For the problem \((P_1)\), the solution \(w_1 \geq 0\) due to \(f_1(x, t) \geq 0\).

Therefore, the proof of Lemma 3.1 is completed.
