Abstract

We propose a general theory to construct functorial assignments

\[ \Sigma \mapsto \Omega_\Sigma \in E(\Sigma) \]

for a large class of functors \( E \) from a certain category of bordered surfaces to a suitable target category of topological vector spaces. The construction proceeds by successive excisions of homotopy classes of embedded pairs of pants, and thus by induction on the Euler characteristic. We provide sufficient conditions to guarantee the infinite sums appearing in this construction converge. In particular, we can generate mapping class group invariant vectors \( \Omega_\Sigma \in E(\Sigma) \). The initial data for the recursion encode the cases when \( \Sigma \) is a pair of pants or a torus with one boundary, as well as the “recursion kernels” used for gluing. We give this construction the name of Geometric Recursion.

As a first application, we demonstrate that our formalism produce a large class of measurable functions on the moduli space of bordered Riemann surfaces. Under certain conditions, the functions produced by the geometric recursion can be integrated with respect to the Weil–Petersson measure on moduli spaces with fixed boundary lengths, and we show that the integrals satisfy a topological recursion generalizing the one of Eynard and Orantin. We establish a generalization of Mirzakhani–McShane identities, namely that multiplicative statistics of hyperbolic lengths of multicurves can be computed by the geometric recursion, and thus their integrals satisfy the topological recursion. As a corollary, we find an interpretation of the intersection indices of the Chern character of bundles of conformal blocks in terms of the aforementioned statistics.

The theory has however a wider scope than functions on Teichmüller space, which will be explored in subsequent papers; one expects that many functorial objects in low-dimensional geometry could be constructed by variants of our new geometric recursion.

1 Introduction

This article grew out of the search for an intrinsic geometric meaning of the topological recursion of [15], inspired by the famous but isolated example of Mirzakhani–McShane identities and Mirzakhani’s recursion for the Weil–Petersson volume of the moduli spaces of bordered Riemann surfaces [20]. As an outcome, we devise a general formalism which constructs mapping class group invariant objects associated to surfaces of arbitrary topology. In order to speak of mapping class group invariant objects, we need to begin with spaces carrying actions of the mapping class groups. For the purposes of this article, this takes the form of a functor from a category of topological surfaces to a category of topological vector spaces. Our construction also demands functorial maps that realise the disjoint union and gluing of surfaces. The functor together with these maps is, roughly speaking, what we will call a “target theory”, and geometry provides a wide range of target theories. Given a target theory, and given initial data which are mapping class group invariant vectors attached to pairs of pants and tori with one boundary, our construction yields mapping class group invariant vectors for arbitrary topological surfaces by successive excisions of embedded pairs of pants, i.e. by induction on the Euler characteristic. In this text, we establish the foundations of this construction and explore its first applications.

1.1 Main construction

In the interest of keeping the introduction short, yet covering our main results, we provide sketches of definitions of needed concepts here and refer the reader to the main text for the precise definitions. We work in the category $\mathbb{B}_1$ whose

- objects are stable bordered topological surfaces $\Sigma$ with exactly one negatively oriented boundary component per connected component (denoted $\partial_-$), with non-empty boundary if the surface is non-empty. The stability condition means that the Euler characteristic of each connected component of $\Sigma$ must be negative (no disks or cylinders are allowed).

- morphisms are isotopy classes of diffeomorphisms of the surface preserving the orientation of the surface and the given orientations of the boundaries.

The automorphism group of an object $\Sigma$ is denoted $\Gamma_\Sigma$ and the subgroup consisting of mapping classes which induce the identity permutation on the set of boundary components is denoted $\Gamma^0_\Sigma$. We shall denote $\partial_-\Sigma$ and $\partial_+\Sigma$ the set of boundaries whose orientation (dis)agrees with the one of $\Sigma$. We will consider functors $E : \mathbb{B}_1 \to \mathcal{C}$ to the category $\mathcal{C} = \text{Pro-}\mathcal{V}$ of projective systems of objects in the category $\mathcal{V}$ of Hausdorff complete locally convex topological vector spaces over $\mathbb{K} = \mathbb{R}$ or $\mathbb{C}$ (Section 3.1). There is a particular subspace $\sharp E(\Sigma)$ of the projective limit in which our constructed mapping class group invariant vectors will be contained (see Equation 5).

In $\mathbb{B}_1$ we can take disjoint unions and we have the operations of cutting along primitive multicurves $\gamma$ with ordered boundary components $\gamma$ (see Section 2). We introduce the notion of target theory in Section 3.2: roughly speaking, it is the data of a functor $E : \mathbb{B}_1 \to \mathcal{C}$ together with multilinear morphisms $\cup$ and $\Theta$ representing the disjoint union and the cutting operations and a system of abstract “length functions” on the set of simple closed curves.

For connected $\Sigma$, we will be especially interested in sets $\mathcal{P}_\Sigma^\theta$ (resp. $\mathcal{P}_\Sigma^0$) of homotopy classes of embedded pairs of pants $[P \to \Sigma]$ such that $\partial P \cap \partial \Sigma$ is $\partial_- \Sigma$ (resp. $\partial_- \Sigma \cap b$ for some positively oriented boundary component $b$), see Section 2.3 for their definition. We shall denote $\Theta_P : E(P) \times E(\Sigma) \to E(\Sigma - P)$ the bilinear morphism that corresponds to cutting along $\partial P \cap \Sigma^0$ in the given target theory.
Our main result is the existence of the following construction.

**Theorem 1.1 (Definition)** Let $E : \mathcal{B}_1 \to \mathcal{E}$ be a target theory. Let $P$ (resp. $T$) be an object of $\mathcal{B}_1$ with the topology of a pair of pants (resp. a torus with one boundary), and $b$ be the choice of a positively oriented boundary of $P$. Assume we are given initial data

$$A_P \in E'(P)^{\Gamma_P}, \quad B_P^b \in E(P)^{\Gamma_P}, \quad C_P \in E(P)^{\Gamma_P}, \quad D_T \in E'(T)^{\Gamma_T}$$

which are admissible according to Definition 3.7. There exists a unique, well-defined, functorial assignment

$$\Sigma \mapsto \Omega_\Sigma \in E'(\Sigma)$$

specified by the formulas

$$\Omega_\emptyset = 1_{E(\emptyset)}, \quad \Omega_p = A_p, \quad \Omega_T = D_T, \quad \Omega_{\Sigma_1 \cup \Sigma_2} = \Omega_{\Sigma_1} \cup \Omega_{\Sigma_2}$$

and for any connected $\Sigma$ of Euler characteristic $\leq -2$

$$\Omega_\Sigma = \sum_{b \in \pi_0(\partial, \Sigma)} \sum_{[P] \in \mathcal{P}_E} \Theta_P(B_P^b, \Omega_{\Sigma,-}) + \sum_{[P] \in \mathcal{P}_E^T} \frac{1}{2} \Theta_P(C_P, \Omega_{\Sigma,-}) \quad (1)$$

The admissibility assumption of initial data includes decay in $B$ and $C$ with respect to the length functions provided by the target theory, which permits us to prove that the series (1) are absolutely convergent with respect to semi-norms provided and finally is contained in a smaller subspace $E(\Sigma)$. This implies functoriality, as the action of isotopy classes of diffeomorphisms merely permutes the terms in (1), in the strong sense below.

**Theorem 1.2 (Naturality)** Let $\eta : E \to \tilde{E}$ be a natural transformation between two target theories $E$ and $\tilde{E}$. Let $(A, B, C, D)$ be an admissible initial data for $E$, leading by the above construction to the functorial assignment $\Omega$. Then $(\eta(A), \eta(B), \eta(C), \eta(D))$ is an admissible data for $\tilde{E}$, and by the above construction it leads to a functorial assignment equal to $\eta(\Omega)$.

Notice that an $E$-valued functorial assignment is nothing but a natural transformation $E \to 1$ to the trivial functor $1 : \Sigma \to \mathbb{K}$, so that Theorem 1.2 expresses the compatibility of $\Omega : E \to 1$ with the pre-composition of natural transformations.

We give the name geometric recursion (GR) to our construction, because many of the target theories we have in mind come from spaces of geometric structures on surfaces. We refer to the $\Omega_\Sigma$’s as “GR amplitudes”.

### 1.2 Functions on Teichmüller spaces

A fundamental example of a target theory, which is developed in Section 8, is the space $E(\Sigma) = \mathrm{Mes}(\mathcal{T}_\Sigma)$ of measurable functions on the Teichmüller space $\mathcal{T}_\Sigma$ of the bordered surface $\Sigma$. We equip $\mathrm{Mes}(\mathcal{T}_\Sigma)$ with the topology of convergence on every compact subset, and this space is seen as the limit of a projective system $(\mathrm{Mes}(\mathcal{T}_E^\varepsilon))_{\varepsilon \in (0,1)}$ where $\mathcal{T}_E^\varepsilon \subset \mathcal{T}_E$ is the $\varepsilon$-thick part. In this case $E'(\Sigma)$ is the subspace of $E(\Sigma) = \mathrm{Mes}(\mathcal{T}_\Sigma)$ consisting of measurable functions which are uniformly bounded on each systole set $\mathcal{T}_E^\varepsilon$. The cutting morphism relies on the cutting of hyperbolic structures along geodesics, and the length functions in the target theory are given by hyperbolic lengths $\ell_\sigma$ for $\sigma \in \mathcal{T}_\Sigma$.

In this context, mapping class group invariant measurable functions are simply just measurable functions defined on moduli spaces $\mathcal{M}_\Sigma = \mathcal{T}_\Sigma/\Gamma_\Sigma$ of bordered Riemann surfaces, and Theorem 1.1 specializes to the following result.
Corollary 1.3 Let \((A,B,C)\) be measurable functions on \(\mathbb{R}_+^3\) and \(D_T\) be a \(\Gamma_T\)-invariant measurable function on \(\mathbb{T}_T\). We assume that \(X(L_1,L_2,L_3) = X(L_1,L_3,L_2)\) for \(X \in \{A,C\}\), and the existence of \(t \geq 0\) and for any \(s,\varepsilon > 0\) the existence of \(M_{s,\varepsilon} > 0\) such that for any \(L_1,L_2,\ell,\ell' > \varepsilon\) and \(\sigma \in \mathbb{T}_T\)

\[
\begin{align*}
|A(L_1,L_2,L_3)| &= M_{s,1}(1 + L_1)^t(1 + L_2)^t(1 + L_3)^t \\
|B(L_1,L_2,\ell)| &\leq M_{s,\varepsilon}(1 + L_1)^t(1 + L_2)^t \left(1 + [\ell - L_1 - L_2]_+\right)^s \\
|C(L_1,\ell,\ell')| &\leq M_{s,\varepsilon}(1 + L_1)^t \left(1 + [\ell + \ell' - L_1]_+\right)^s \\
|D_T(\sigma)| &\leq M_{s,1}(1 + \ell_0(\partial T))^{t}
\end{align*}
\]

where \([x]_+ = \max(x,0)\). We have a well-defined functorial assignment \(\Sigma \mapsto \Omega_{\Sigma} \in \text{Mes}(\mathbb{T}_\Sigma)\) given by the formulas

\[
\Omega_P(\sigma) = A(\ell,\partial P), \quad \Omega_T(\sigma) = D_T(\sigma), \quad \Omega_{\Sigma_1 \cup \Sigma_2}(\sigma) = \Omega_{\Sigma_1}(\sigma_{\Sigma_1}) \Omega_{\Sigma_2}(\sigma_{\Sigma_2}),
\]

and for connected objects \(\Sigma\) of Euler characteristic \(\leq -2\)

\[
\Omega_{\Sigma}(\sigma) = \sum_{b \in \pi_0(\partial \Sigma)} \sum_{[P] \in \mathbb{P}_\Sigma} B(\ell,\partial P) \Omega_{\Sigma - P}(\sigma_{\Sigma - P}) + \frac{1}{2} \sum_{[P] \in \mathbb{P}_\Sigma} C(\ell,\partial P) \Omega_{\Sigma - P}(\sigma_{\Sigma - P})
\]

More precisely, the series (3) converges absolutely, uniformly for \(\sigma\) in any compact of \(\mathbb{T}_\Sigma\).

If \(\Omega\) is given by Corollary 1.3 and \(L \in \mathbb{R}_+^n\), we denote \(\Omega_{g,n}\) the function it induces on \(\mathcal{M}_{g,n}(L) \cong \mathcal{M}_g(L)\) where \(\Sigma\) is a bordered surface of genus \(g\) with \(n\) ordered boundary components such that \(\partial \Sigma\) is the first. The following result – stated with stronger assumptions than the result we prove in the text (Theorem 8.8) – provides sufficient conditions for the integrability of GR amplitudes with respect to the Weil–Petersson measure \(\mu_{WP}\) and computes these integrals

\[
V\Omega_{g,n}(L) := \int_{\mathcal{M}_{g,n}(L)} \Omega_{g,n} \, d\mu_{WP}
\]

Theorem 1.4 In the situation of Corollary 1.3, assume that one can choose \(M_{s,\varepsilon}\) independently of \(\varepsilon\). Then, for \(2g - 2 + n > 0\), the functions \(\Omega_{g,n}\) coming from Corollary 1.3 are integrable on \(\mathcal{M}_{g,n}(L)\), for each \(L \in \mathbb{R}_+^n\). They satisfy the topological recursion, for \(2g - 2 + n \geq 2\)

\[
\begin{align*}
V\Omega_{g,n}(L_1,\ldots,L_n) &= \sum_{m=2}^{n} \int_{\mathbb{R}_+^n} d\ell d\ell' \, B(L_1,\ell,m,\ell) V\Omega_{g,n-1}(\ell,L_2,\ldots,L_{m-1},L_m,\ldots,L_n) \\
&+ \frac{1}{2} \int_{\mathbb{R}_+^n} d\ell d\ell' d\ell'' \, C(L_1,\ell,\ell') \left(V\Omega_{g-1,n+1}(\ell,\ell',L_2,\ldots,L_n) + \sum_{J \cup J' = \{L_2,\ldots,L_n\}} V\Omega_{h,1+\#J}(\ell,J) V\Omega_{h',1+\#J'}(\ell',J')\right)
\end{align*}
\]

with the base cases

\[
V\Omega_{0,3}(L_1,L_2,L_3) = A(L_1,L_2,L_3), \quad V\Omega_{1,1} := VD(L_1) = \int_{\mathcal{M}_1(L_1)} D_T \, d\mu_{WP}
\]

The geometric recursion constructs a large class of functions on the moduli spaces \(\mathcal{M}_\Sigma\), namely those satisfying the “non-local gluing rule” (3) and they are designed such that their integrals against \(\mu_{WP}\) satisfies topological recursion. One may wonder if independently defined and geometrically meaningful functions on the moduli spaces belong to this class.

The first example, which in fact was an inspiration for the whole formalism, is the constant function 1 on \(\mathbb{T}_\Sigma\), as a result of Mirzakhani’s generalization of McShane identities.
The geometric recursion for the initial data $A^M = 1$, $D^M_T = 1$

\[ B^M(L_1, L_2, \ell) = 1 - \frac{1}{L_1} \ln \left( \frac{\cosh(L_2/2) + \cosh((L_1 + \ell)/2)}{\cosh(L_2/2) + \cosh((L_1 - \ell)/2)} \right) \]

\[ C^M(L_1, \ell, \ell') = \frac{2}{L_1} \ln \left( \frac{e^{L_1/2} + e^{(\ell + \ell')/2}}{e^{-L_1/2} + e^{(\ell + \ell')/2}} \right) \]
yields the function $\Omega_\Sigma = 1$ for all $\Sigma$.

We establish a generalization of Mirzakhani’s identities by showing that for a twist of the initial data, the GR amplitudes compute multiplicative statistics of the hyperbolic spectrum of multicurves.

**Theorem 1.6** Let $(A, B, C, D)$ satisfy the conditions of Corollary 1.3 and assume that the corresponding GR amplitudes $\Omega$ are invariant under braiding of all boundary components of $\Sigma$. Let $f$ be a measurable function on $\mathbb{R}_+$ such that $\sup_{\ell>0} (1 + \ell)^s |f(\ell)| < +\infty$ for any $s > 0$. Then, the series

\[ \Omega_{\Sigma}^{\prime}[f](\sigma) := \sum_{c \in \mathcal{M}_\Sigma^c} \Omega_{\Sigma^c}(\sigma_{|\Sigma^c}) \prod_{\gamma \in \pi_0(c)} f(\ell_\sigma(\gamma)) \]

converges absolutely, uniformly for $\sigma$ in any compact of $\mathcal{F}_\Sigma$, and it coincides with the GR amplitudes for the initial data

\[ A[f](L_1, L_2, L_3) = A(L_1, L_2, L_3) \]

\[ B[f](L_1, L_2, \ell) = B(L_1, L_2, \ell) + A(L_1, L_2, \ell) f(\ell) \]

\[ C[f](L_1, \ell, \ell') = C(L_1, \ell, \ell') + B(L_1, \ell, \ell') f(\ell) + B(L_1, \ell', \ell) f(\ell') + A(L_1, \ell, \ell') f(\ell) f(\ell') \]

\[ D_T[f](\sigma) = D_T(\sigma) + \frac{1}{2} \sum_{\gamma \in \mathcal{S}_T^\sigma} A(\ell_\sigma(\partial T), \ell_\sigma(\gamma), \ell_\sigma(\gamma)) f(\ell_\sigma(\gamma)) \]

where $\mathcal{S}_T^\sigma$ is the set of simple closed curves in $T$, non homotopic to $\partial T$.

The integrals of $\Omega_{g,n}[f]$ over $\mathcal{M}_{g,n}(L)$ against the Weil–Petersson measure can then be computed by the topological recursion from Theorem 1.4, or by direct integration as a sum over stable graphs $\mathcal{G}_{g,n} \cong M_\Sigma^c/\Gamma_\Sigma^c$ (see Lemma 10.4). After integration, the twisting has some relation with the Givental group action which we discuss in Section 10.3. We give in Section 10.4 an application of Theorem 1.6 that interprets the intersection indices of the Chern character of the bundle of conformal blocks of a 2d rational conformal field theories in terms of statistics of multicurves.

In particular, twisting the Mirzakhani initial data from Theorem 1.5 gives access to

\[ \Omega_{\Sigma}^{\prime}[f](\sigma) = \sum_{c \in \mathcal{M}_\Sigma^c} \prod_{\gamma \in \pi_0(c)} f(\ell_\sigma(\gamma)) \]

and its integrals. In [3], these results are used to prove that the Masur–Veech volumes of the (top) stratum of the moduli space of quadratic differentials $Q_{g,n}$ with $4g - 4 + n$ zeroes and $n$ poles, can be computed by topological recursion.

### 1.3 Comments and perspectives

**Generality** – Our construction has a much wider scope than the applications we have just presented and calls for the construction of many more target theories in which GR will then take its values. In
[4], we put a structure of target theory on the space of functions on the combinatorial Teichmüller space, address their integration against Kontsevich measure, and extend to statistics of combinatorial lengths of multicurves. To give more examples, one can contemplate putting a structure of target theory on

1. the space of smooth functions, of differential forms, (non necessarily even) cohomology classes, Radon measures, distributions on the Teichmüller space. In those case, the union and glueing morphisms can be constructed in a natural way via the geometry of the fibrations \( \mathcal{T}_{\Sigma_c} \to \mathcal{T}_{\Sigma} \) where \( c \in \mathcal{M}'_{\Sigma} \) and \( \mathcal{T}_{\Sigma_c} \) is the locus of hyperbolic metrics on the cut surface \( \Sigma_c \) assigning the same hyperbolic lengths to the two boundary components that project to \( \gamma \in \pi_0(c) \) after glueing along \( c \). The remaining difficulty in doing so consists in describing suitable topologies for which these morphisms are continuous.

2. similar spaces over Hitchin components of higher Teichmüller spaces.

3. similar spaces over the universal Teichmüller space of flat \( G \)-connections, where \( G \) is a compact Lie group, in order to study geometric quantization and applications to Chern–Simons theory.

4. similar spaces over the space of measured foliations.

5. the space of sections of the bundle of conformal blocks over the Teichmüller space of pointed bordered surfaces for a given 2d rational conformal field theory. It is then natural to ask if the conformal blocks themselves can be computed by GR, exploiting the sewing properties in conformal field theory.

In Proposition 8.7 we describe the behavior of GR functions close to the boundary of the Teichmüller space and show that for initial data with fast decay, a single term in the GR sum (3) yields an all-order perturbative expansion near the lowest boundary stratum (corresponding to a degeneration of hyperbolic surfaces to pair of pants glued along nodes). The role of GR in this case is to produce a function globally defined on the Teichmüller space which is mapping class group invariant from the sole knowledge of these boundary contributions. We see these type of results as a tool to study the possibility of constructing conformal blocks in the context of (5).

Relation to topological recursion – When the action of \( \Gamma_{\Sigma} \) factors through the action of the permutation group of (boundary) components of \( \Sigma \), the GR construction does not make sense as infinitely many terms in (3) are equal. In this case one can however make a much simpler construction, which we present in Section 4 under the name of “strict GR”. This construction only involves finite sums and the considerations of topology on the vector spaces \( E(\Sigma) \) can in principle be avoided. We explain in Section 6 that the original topological recursion of Eynard–Orantin [15] or Kontsevich–Soibelman [19] is an example of this construction. In a sense, the strict GR is a functorial setting generalizing TR so that the vector spaces to which the output of the construction belong can now depend on the topology of \( \Sigma \) – while for the original TR they only depend on \( \pi_0(\partial \Sigma) \).

Symmetry issues – The boundary component \( \partial_{-} \Sigma \) plays a special role in the construction, and therefore the GR amplitudes \( \Omega_{\Sigma} \in E(\Sigma) \) are a priori only invariant under the mapping classes preserving the choice of \( \partial_{-} \Sigma \). We present in Section 5 sufficient conditions on the initial data that guarantee the invariance of \( \Omega_{\Sigma} \) under the braiding of all boundary components, and call this construction “symmetric GR”. These conditions lift at the geometric level the conditions of symmetry known in the context of TR. However, these sufficient conditions are perhaps not optimal and the questions of symmetry deserve further investigations.

2 Two-dimensional geometry background

2.1 Categories of surfaces

Definition 2.1 A bordered surface $\Sigma$ is a smooth, oriented, compact 2-dimensional manifold with an orientation of its boundary. If $\Sigma$ is non-empty, we require that each connected component has a non-empty boundary.

We remark that a bordered surface has a decomposition of its boundary $\partial \Sigma$ into two subsets $\partial_+ \Sigma$ (resp. $\partial_- \Sigma$) consisting of those boundary components whose orientation agree (resp. disagree) with the orientation induced by $\Sigma$. The interior of $\Sigma$ is denoted $\Sigma^\circ$. We use the following notation for the components of $\Sigma$

$$\Sigma = \bigcup_{a \in \pi_0(\Sigma)} \Sigma(a).$$

The Euler characteristic is denoted $\chi_\Sigma$. We say that $\Sigma$ is of type $(g, n)$ if it is connected, has genus $g$ and $n$ boundary components.

Definition 2.2 A bordered surface $\Sigma$ is stable if $\Sigma = \emptyset$ or for any $a \in \pi_0(\Sigma)$ we have $\chi_{\Sigma(a)} < 0$. It is unstable otherwise.

Definition 2.3 Let $\mathcal{B}$ be the category whose objects are stable bordered surfaces, and morphisms are isotopy classes of orientation preserving diffeomorphisms, which also preserve the prescribed orientation of the boundary.

The mapping class group $\Gamma_\Sigma$ is the automorphism group (in the category $\mathcal{B}$) of a stable bordered surface $\Sigma$. We denote by $\Gamma^0_\Sigma$ the pure mapping class group, i.e. the subgroup consisting of the mapping classes inducing the identity permutation of $\pi_0(\partial \Sigma)$.

We shall often consider surfaces with a distinguished boundary component in each connected component. This can be achieved by requiring that the orientation of the distinguished boundary components disagrees with the orientation of the surface, while the orientation of the other boundary components agrees.

Definition 2.4 Let $\mathcal{B}_1$ be the full subcategory of $\mathcal{B}$ consisting of bordered surfaces for which the natural map $\pi_0(\partial_\Sigma) \to \pi_0(\Sigma)$ is a bijection.

If $\Sigma$ is a connected object in $\mathcal{B}_1$, we often denote by $b_1$ the boundary component with disagreeing orientation, i.e. $\partial_- \Sigma = b_1$. We remark that for a surface in $\mathcal{B}_1$, the mapping classes in $\Gamma_\Sigma$ must leave $b_1$ stable.

2.2 Multicurves and cutting

As the notions of homotopy and isotopy are the same for 1-dimensional submanifolds of bordered surfaces [12], we will not distinguish between them.

Definition 2.5 A multicurve is the homotopy class of a (possibly empty) one-dimensional compact submanifold $c$ of a bordered surface $\Sigma$, with no component null-homotopic or homotopic to a boundary component of $\Sigma$. A multicurve is primitive when we add the requirement that two components of $c$ cannot be homotopic to each other. A simple closed curve is a primitive multicurve with a single component.

We denote $M_\Sigma$ the set of multicurves, $M^\prime_\Sigma$ the set of primitive multicurves, $S^\circ_\Sigma$ the set of simple closed curves, and $S_\Sigma = S^\circ_\Sigma \cup \pi_0(\partial \Sigma)$. 

10
We have the operation of cutting a stable bordered surface $\Sigma$ along a primitive multicurve $\gamma$, producing a new stable bordered surface $\Sigma'$. If $c$ is a representative of $\gamma$, the new boundary components in the bordered surface $\Sigma \setminus c$ (where the closure is taken in $\Sigma$) receive the orientation induced from the orientation of the surface. If $c'$ is another representative of $\gamma$, a homotopy between $c$ and $c'$ determines a diffeomorphism between $\Sigma \setminus c$ and $\Sigma \setminus c'$, whose isotopy class is independent of the choice of the homotopy. To be precise, $\Sigma'$ will stand for any object in $\mathcal{B}$ of the form $\Sigma \setminus c$ previously described and we note that any two such objects are canonically isomorphic in $\mathcal{B}$.

2.3 Excising a pair of pants

The cutting operation which is particularly relevant for us is the excision of a pair of pants (i.e., a genus 0 surface with 3 boundary components) from a connected surface $\Sigma$ in $\mathcal{B}_1$ of type $(g, n)$. For this purpose we assume $2g + n \geq 0$.

Let us fix a connected bordered surface $P$ of genus 0 with 3 ordered boundary components, i.e., a fixed bijection between $\pi_0(\partial P)$ and $\{1, 2, 3\}$. We turn it into an object of $\mathcal{B}_1$ by declaring that the orientation on the first boundary component disagrees with the one of $P$ while the orientation of the second and the third boundary component agrees with the one of $P$. Equivalently, $P$ is a pair of pants in $\mathcal{B}_1$ together with an ordering of $\pi_0(\partial_1 \Sigma)$.

Let $f : P \to \Sigma$ be an embedding of a pair of pants with ordered boundary components such that $f(\partial P) = b_1 = \partial_1 \Sigma$ and for any $\beta \in \pi_0(\partial P)$ either $f(\beta)$ coincides with a boundary component of $\Sigma$ or $f(\beta)$ is neither null homotopic relative to $\partial \Sigma$ nor boundary parallel. Let us cut $\Sigma$ along the boundary components of $f(P)$ which are not boundaries of $\Sigma$, i.e., along the multicurve $\gamma_P = f(\partial P) \cap \Sigma^e$. This multicurve has either one or two components. In the latter case we denote $\gamma_P^1$ and $\gamma_P^2$, the two components respecting the order in which they appear in $\pi_0(\partial_1 P)$. There are finitely many possible topologies for

$$\Sigma' = P \cup \Sigma \setminus f(P).$$

I $(g, n) \neq (1, 1)$, $g \geq 1$, $\gamma_P$ has two components and $\Sigma \setminus f(P)$ is connected. Then $\Sigma \setminus f(P)$ must have type $(g - 1, n + 1)$.

$\mathbf{I'}$ $(g, n) \neq (0, 3)$, $f(P)$ has two boundary components in common with $\Sigma$, namely $b_1$ and some $b \in \partial_2 \Sigma$. In this case we require that $f$ is such that $b$ is the second boundary component of $f(P)$. Then $\Sigma \setminus f(P)$ has type $(g, n - 1)$.

$\mathbf{II}$ $\gamma_P$ has two components and $\Sigma \setminus f(P)$ is not connected. Then $\Sigma \setminus f(P)$ must have two ordered connected components. The $ith$ one has genus $g_i$, contains $\gamma_P^i$, and a subset $N_i \subseteq \partial_i \Sigma$ of other boundary components. We must have $g_1 + g_2 = g$ and $N_1 \cup N_2 = \pi_0(\partial_1 \Sigma)$ such that

$$\forall i \in \{1, 2\}, \quad (g_i, \#N_i) \neq (0, 1), (0, 2).$$

We change the choice of orientation of the boundary components in $\Sigma \setminus f(P)$ in the following way. In case $\mathbf{I}$, we reverse the orientation of $\gamma_P^1$ so that it disagrees with the orientation of the surface, while the orientation of $\gamma_P^2$ remains in agreement with the orientation of the surface. In case $\mathbf{I'}$, we reverse the orientation of $\gamma_P$ (which is a simple closed curve). In case $\mathbf{II}$, we reverse the orientation of $\gamma_P^1$ and of $\gamma_P^2$. In this way, $\Sigma \setminus f(P)$ becomes a surface in $\mathcal{B}_1$.

By an argument similar to our description of cutting, if $f' : P \to \Sigma$ belongs to the same homotopy class of embedding of pairs of pants as $f$, we have a canonical isomorphism in $\mathcal{B}_1$ between $\Sigma \setminus f(P)$ and $\Sigma \setminus f'(P)$.
Definition 2.6 We let \( \mathcal{P}_\Sigma \) be the set of homotopy classes, relative to the boundary, of embedded pairs of pants \( f : P \to \Sigma \) as described above. If \( d \in \{ \emptyset \} \cup \pi_0(\partial, \Sigma) \), \( \mathcal{P}_\Sigma^d \) is the subset of \( \{ f : P \to \Sigma \} \in \mathcal{P}_\Sigma \) such that \( f(\partial_1 P) \cap \partial_1 \Sigma = d \).

For conciseness, we use the notation \([P]\) for elements of \( \mathcal{P}_\Sigma \). We also write \( \Sigma - P \) for any object in \( \mathcal{B}_1 \) which is obtained by excision of a representative of the homotopy class \([P]\) from \( \Sigma \).

The mapping class group \( \Gamma_\Sigma \) acts on \( \mathcal{P}_\Sigma \), with a finite number of orbits partitioned according to the cases \( \text{I}, \text{I}' \) and \( \text{II} \). In particular, for each \( b \in \pi_0(\partial, \Sigma) \) the set \( \mathcal{P}_\Sigma^b \) is itself a \( \Gamma_\Sigma^b \)-orbit.

Alternative description of \( \mathcal{P}_\Sigma \)

If \( b \) is a component in \( \partial, \Sigma \), the set \( \mathcal{P}_\Sigma^b \) is in bijection with the set of homotopy classes of simple curves \( c \in \Sigma \) from a point in \( b_1 \) to a point in \( b \). Given such a \( c \), we can indeed consider the free homotopy class \([\gamma]\) of a simple closed curve \( \gamma \) obtained by following \( c \), going around \( b \), following \( c \) in the opposite direction and going around \( b_1 \) (for the two boundary components we here used the orientation induced by the surface). We can always find a representative \( \gamma \) of this class which is simple. The component of \( \Sigma^\gamma \) which contains \( b_1 \) is a pair of pants, with its ordered boundary components \((b_1, b, \gamma)\). We therefore obtain an embedding \( f : P \to \Sigma \) such that \( f(P) \) contains \( c \) as shown in Fig. 1 and corresponding to case \( \text{I} \). The homotopy class of this embedding is independent of the choice of representatives of \([c]\), \([\gamma]\) and \( P \). The reciprocal bijection is obtained by associating to an embedding \( f : P \to \Sigma \) as in case \( \text{I} \) the homotopy class relative to the boundary of the curve \( c \) shown in Figure 1.

Likewise, \( \mathcal{P}_\Sigma^b \) is in bijection with the set of homotopy class of simple closed oriented curves \( c \) in \( \Sigma \) with one point in \( b_1 \), which are not homotopic to any composition of the form \( \tilde{c}^{-1} \cdot b \cdot \tilde{c} \) for some component \( b \) in \( \partial, \Sigma \) and some \( \tilde{c} \) in the equivalent description we just gave of \( \mathcal{P}_\Sigma^b \). Here we use \( \cdot \) for the composition of curves in the path groupoid of \( \Sigma \). The data of such a \([c]\) indeed determines two free homotopy class relative to the boundary of closed curves \([\gamma^1]\) and \([\gamma^2]\), where \([\gamma^1]\) is to the left of \( c \). After we pick simple representatives \( \gamma^1 \) and \( \gamma^2 \), we obtain an embedding \( f : P \to \Sigma \) (of the type \( \text{I} \) or \( \text{II} \)) of the component of \( \Sigma^{\gamma^1 \cup \gamma^2} \) which contains \( b_1 \). The curve \( c \) appears in the embedded pair of pants as it is shown in Figures 2 and 3.

3 The geometric recursion and its main properties

Our goal is to construct, by means of sums over pair of pants decompositions, for any surface \( \Sigma \) in \( \mathcal{B}_1 \) an element \( \Omega_\Sigma \) of a “space” \( E(\Sigma) \) attached to \( \Sigma \), which is a functorial assignment. First of all we need to specify what is the space \( E(\Sigma) \) to which \( \Omega_\Sigma \) will belong. For the construction to be meaningful, it should incorporate a compatible set of union and glueing maps, and a mechanism making sense of the countable sums over pair of pants decompositions. This data will be called a target theory. More precisely, it will be a functor \( E \) from \( \mathcal{B}_1 \) to some multicategory \( \mathcal{C} \), satisfying a list of axioms specified in Section 3.1. The definition of \( \Omega_\Sigma \) will depend on a small amount of initial data, specifying what happens for a pair of pants, for a torus with one boundary, and a way to inductively increase the complexity of the surfaces (Section 3.3). We call geometric recursion (valued in the chosen target theory \( E \)) the inductive process leading to \( \Omega_\Sigma \) from such initial data.

3.1 The category of projective systems of vector spaces

Let \( \mathbb{K} \) be \( \mathbb{R} \) or \( \mathbb{C} \). We will choose \( \mathcal{C} \) to be the category \( \text{Pro-} \mathcal{V} \), where \( \mathcal{V} \) be the category of Hausdorff, complete, locally convex topological vector spaces over \( \mathbb{K} \). Recall that an object \( V \in \mathcal{V} \) comes with a (possibly uncountable) family of seminorms \( (|\cdot|_\alpha)_{\alpha \in \mathcal{A}} \) which induces the topology of the vector space
V such that it is Hausdorff and complete as a locally convex topological vector space. We remark that V admits projective limits [26]. Pro-\(V\) is a category defined using projective families of objects in \(V\) which we now explain in detail.

**Definition 3.1** An object \(V\) of Pro-\(V\) is a directed set \(\mathcal{I}\) and an inverse system over \(\mathcal{I}\) of objects

\[ (V^i, (|i,\alpha|_{\alpha\in\mathcal{I}}))_{i\in\mathcal{I}} \]

of \(V\), together with an object \(V\) of \(V\) which is Hausdorff and complete as a locally convex topological vector space. We remark that an object \(V\) of Pro-\(V\) can be denoted \(\prod V\) or \(\prod_{i\in\mathcal{I}} V^i\), and the context will leave no room for confusion with the letter \(V\) also used for the projective limit of \((V^i)_{i\in\mathcal{I}}\).

The base field \(\mathbb{K}\) can be considered as an object in Pro-\(V\) with set of indices \(\mathcal{I} = \{1\}\) and \(\mathcal{A}^1 = \{1\}\) with single norm \(|\cdot|_{1,1} = |\cdot|\). By definition, for any \(i \in \mathcal{I}\) we have a restriction linear map \(\varrho^i : V \rightarrow V^i\) which is continuous. Using this map, elements of \(V\) can be silently considered as element of \(V^i\) for any \(i \in \mathcal{I}\).

**Definition 3.2** A morphism \(\Phi : V_1 \rightarrow V_2\) in Pro-\(V\) is an inverse system of continuous linear maps

\[ \Phi^{i,j} : V^i_1 \rightarrow V^j_2 \]

indexed by \((i,j) \in \mathcal{I}_1 \times \mathcal{I}_2\) such that \(i \geq h_j\) for some \(h_j \in \mathcal{I}_1\). This data determine continuous linear maps \(\Phi^i := \Phi^{i,j} \circ \varrho^i : V_1 \rightarrow V^i_2\) which do not depend on the choice of \(i \geq h_j\) by the very definition of an inverse system.

The category Pro-\(V\) can be considered as a multicategory using the cartesian product of objects of \(V\) and adopting the following definition.

**Definition 3.3** Given three objects \(V_1, V_2, V_3\) of Pro-\(V\), a bilinear morphism

\[ \Phi : V_1 \times V_2 \rightarrow V_3 \]

is an inverse system of continuous bilinear maps

\[ \Phi^{i,j,k} : V^i_1 \times V^j_2 \rightarrow V^k_3, \]

indexed by \((i,j,k) \in \mathcal{I}_1 \times \mathcal{I}_2 \times \mathcal{I}_3\) such that \((i,j) \geq h_k\) for some \(h_k \in \mathcal{I}_1 \times \mathcal{I}_2\) — where we use the lexicographic order on \(\mathcal{I}_1 \times \mathcal{I}_2\). This data determine continuous bilinear maps \(\Phi^k = \Phi^{i,j,k} \circ (\varrho^i \times \varrho^j) : V_1 \times V_2 \rightarrow V^k_3\) which do not depend on the choice of \((i,j) \geq h_k\).

Multilinear morphisms are defined in a similar fashion.

We do not consider tensor products of topological vector spaces, which usually turn bilinear maps into linear ones, since we want to (and we can) avoid discussing completions of the algebraic tensor product. This makes our setup more flexible.

This multicategory is suited to treat in a uniform way spaces of functions, forms, distributions, sections of vector bundles on many different topological spaces with various structures associated to surfaces, such as various moduli spaces of different kinds of structures on surfaces, possibly coupled to Teichmüller space, etc. It seems to contain the minimal structure needed to make sense of GR. Applications may justify other choices of categories. For instance, one could use the pro-category of the category of chain complexes of objects in \(V\).

Hereafter, we set once for all \(\mathcal{C} = \text{Pro-}V\). To keep lighter notations, we refrain the use of bold letters for objects and morphisms in \(\mathcal{C}\). For instance, an object \(V = (V^i, (|i,\alpha|_{\alpha\in\mathcal{I}}))_{i\in\mathcal{I}}\) will simply be denoted \(V\), and the context will leave no room for confusion with the letter \(V\) also used for the projective limit of \((V^i)_{i\in\mathcal{I}}\).
3.2 The notion of a target theory

Definition 3.4 A (\(C\)-valued) pre-target theory is a functor \(E\) from \(B_1\) to the category \(C\), together with functorial extra structures specified by the union and excision axioms below.

**Union** – For any two surfaces \(\Sigma_1\) and \(\Sigma_2\), we ask for a bilinear morphism in \(C\)

\[
\cup : E(\Sigma_1) \times E(\Sigma_2) \rightarrow E(\Sigma_1 \cup \Sigma_2)
\]

compatible with commutativity and associativity of cartesian products and of unions. We require \(E(\emptyset) = K\) and the union map \(\cup : E(\emptyset) \times E(\Sigma) \rightarrow E(\Sigma)\) is specified by \(1 \cup v = v\).

**Excision** – For any connected surface \(\Sigma\) with \(\chi_\Sigma \leq -2\) and \([P] \in P_\Sigma\), we ask for the data of a bilinear morphism in \(C\)

\[
\Theta_P : E(P) \times E(\Sigma - P) \rightarrow E(\Sigma)
\]

From the union axiom, one can define multilinear morphisms corresponding to any finite union of surfaces. It can be rephrased by saying that \(E\) is a multifunctor between the multicategories \((B_1, \cup)\) and \((C, \times)\). The morphisms \(\Theta_P\) in the excision axiom will be called the glueing morphisms.

Definition 3.5 A target theory is a pre-target theory \(E\) together with, for any surface \(\Sigma\) in \(B_1\), a functorial collection of functions on the set of simple closed curves or boundary components

\[
l_{i,\alpha} : S_\Sigma \rightarrow \mathbb{R}_{\geq 0}
\]

Here \(i \in A_\Sigma\) and \(\alpha \in A_i^\Sigma\) respectively index the spaces \(E^i(\Sigma)\) and their semi-norms \(\| \cdot \|_{i,\alpha}\) provided by the pre-target theory. We call \(l_{i,\alpha}\) length functions and we require that they satisfy the following four properties.

**Polynomial growth** – For any \(i \in A_\Sigma\), there exists functorial constants \(N_i, d_i > 0\) such that for any \(\alpha \in A_i^\Sigma\) and \(L > 0\),

\[
\# \{ \gamma \in M^i_\Sigma \mid l_{i,\alpha}(\gamma) \leq \lambda \} \leq N_i (1 + L)^{d_i}
\]

Here, we extended the definition of \(l_{i,\alpha}\) to primitive multicurves by setting setting

\[
l_{i,\alpha}(\gamma) = \sum_{\beta \in \pi_0(\gamma)} l_{i,\alpha}(\beta)
\]

**Small pair of pants** – For any \(i \in A_\Sigma\), there exists a functorial \(Q_i > 0\) such that for any \(\alpha \in A_i^\Sigma\) and \(b \in \pi_0(\partial_i \Sigma)\)

- the number of \([P] \in P_b^i\) such that \(l_{i,\alpha}(\gamma) \leq l_{i,\alpha}(b_1) + l_{i,\alpha}(b)\) is less than \(Q_i\);
- the number of \([P] \in P_{\gamma_1,\gamma_2}^i\) such that \(l_{i,\alpha}(\gamma_1) + l_{i,\alpha}(\gamma_2) \leq l_{i,\alpha}(b_1)\) is less than \(Q_i\);

with the notations introduced in Section 2.3.

The functoriality of the constants \(d_i, D_i, Q_i\) prosaically means that they only depend on the topology of \(\Sigma\) – taking into account that the ordered sets \(A_\Sigma\) to which \(i\) belongs are canonically isomorphic for surfaces \(\Sigma\) of the same topology.
Restriction – We assume that for any $k \in \mathcal{S}$, there exists $K_k > 0$ functorial, such that for any $[P] \in \mathcal{P}_\Sigma$, there exists $j_k \in \mathcal{S}_{P-P}$ functorial, such that for any $\alpha \in \mathcal{A}_\Sigma^k$ and $j \geq j_k$, there exists $\alpha' \in \mathcal{A}_{\Sigma-P}$ functorial such that for any $\gamma \in S_{\Sigma}$, we have

$$l_{j,\alpha'}(\gamma) \leq K_k l_{j,\alpha}(\iota \gamma),$$

where $\iota : (\Sigma - P) \to \Sigma$ is the natural inclusion.

This axiom means that we can control the lengths of a curve in an excised surface by the lengths of the same curve in the surface before excision.

We define pseudo-norms in $E(\Sigma)$, indexed by $i \in \mathcal{S}_\Sigma$ and $\varsigma > 0$

$$\|v\|_{i,\varsigma} = \sup_{\alpha \in \mathcal{A}_\Sigma} |v|_{i,\alpha} \prod_{\beta \pi_0(\partial \Sigma)} (1 + l_{\alpha}(\beta))^{-\varsigma},$$

and introduce the (not necessarily closed) subspace of bounded elements

$$\{v \in E(\Sigma) \mid \forall i \in \mathcal{S}_\Sigma \exists \varsigma_i \geq 0 \|v\|_{i,\varsigma_i} < +\infty\}.$$  \hfill (5)

### 3.3 Initial data

**Definition 3.6** Initial data for a given target theory $E$ are functorial assignments

- of $A_P, C_P \in E(P)^{\Gamma_T}$ for any pair of pants $P$,
- of $B^b_P \in E(P)$ for any pair of pants $P$ in which some $b \in \pi_0(\partial P)$ has been selected,
- of $D_T \in E(T)^{\Gamma_T}$ for any torus with one boundary $T$.

It is enough to make such choices $(A_P, B^b_P, C_P, D_T)$ for a reference $P$ and $T$ in such a way that

$$A_P, C_P \in E(P)^{\Gamma_T}, \quad D_T \in E(T)^{\Gamma_T}$$

If $P'$ is another pair of pants and $X \in E(P)^{\Gamma_T}$, we can use a morphism $f : P \to P'$ to transport $X' = E(f)(X) \in E(P')^{\Gamma_{T'}}$. As $X$ is invariant under the mapping class group, $X'$ is independent of the choice $f$. We can define uniquely $A_{P'}$ and $C_{P'}$ for all pair of pants $P'$ in $\mathcal{B}_1$. Likewise one defines unambiguously for any $b' \in \pi_0(\partial, \Sigma)$

$$B^b_{P'} = E(f)(B^b_P)^{-1}(b')$$

The same argument defines $D_{T'}$ for all tori $T'$ with one boundary in $\mathcal{B}_1$.

**Definition 3.7** An initial data is called admissible if $A_P$ and $D_T$ are bounded and $B^b_P$ and $C_P$ satisfy the decay properties stated below, where for $x \in \mathbb{R}$ we use the notation $[x]_+ = \max(x, 0)$.

**Decay** – For any connected surface $\Sigma$ in $\mathcal{B}_1$ and any $[P] \in \mathcal{P}_\Sigma$, we require that for any $k \in \mathcal{S}_\Sigma$, there exist $t_k \geq 0$ and $j_k \in \mathcal{S}_{\Sigma-P}$ functorial such that for any $s > 0$, there exists $M_{k,s} > 0$ functorial such that for any $\alpha \in \mathcal{A}_\Sigma^k$, any $j \geq j_k$ and any $\alpha' \in \mathcal{A}_{\Sigma-P}$, we have for any $v \in E(\Sigma-P)^{\Gamma_{T-P}}$

- if $b \in \pi_0(\partial, \Sigma)$ and $[P] \in \mathcal{P}_\Sigma$,

$$|\Theta^b_P(B^b_P, v)|_{k,\alpha} \leq M_{k,s} |v|_{j,\alpha'} \frac{\prod_{\beta \pi_0(\partial \Sigma)\alpha(\gamma)} (1 + l_{\alpha}(\beta))^{t_k}}{(1 + \pi_0(\partial \Sigma)(b) - l_{\alpha}(b))^{+}}.$$ \hfill (6)

- if $[P] \in \mathcal{P}_\Sigma$,

$$|\Theta^b_P(C_P, v)|_{k,\alpha} \leq M_{k,s} |v|_{j,\alpha'} \frac{\prod_{\beta \pi_0(\partial \Sigma)\alpha(\gamma_1,\gamma_2)} (1 + l_{\alpha}(\beta))^{t_k}}{(1 + \pi_0(\partial \Sigma)(\gamma_1,\gamma_2) - l_{\alpha}(b))^{+}}.$$ \hfill (7)
3.4 Definition of the geometric recursion

Let \((A, B, C, D)\) be admissible initial data for a target theory \(E\).

**Definition 3.8** We define the GR amplitudes as follows.

- We put \(\Omega_\emptyset := 1 \in E(\emptyset) = \mathbb{K}\).
- If \(P\) is a pair of pants in \(B_1\), we put \(\Omega_P = A_P\).
- If \(T\) is a torus with one boundary in \(B_1\), we put \(\Omega_T = D_T\).
- For disconnected surfaces \(\Sigma\) in \(B_1\), we declare \(\Omega_\Sigma := \bigsqcup_{a \in \pi_0(\Sigma)} \Omega_{\Sigma(a)}\).
- When \(\Sigma\) is a connected surface with \(\chi_\Sigma \leq -2\), we seek to inductively define
  \[
  \Omega_\Sigma := \sum_{b \in \pi_0(\Sigma)} \sum_{[P] \in \mathcal{P}_\Sigma^b} \Theta_P(B^b_P, \Omega_{\Sigma - P}) + \frac{1}{2} \sum_{[P] \in \mathcal{P}_\Sigma^b} \Theta_P(C_P, \Omega_{\Sigma - P})
  \]
  as an element of \(E(\Sigma)\).

![Figure 1: The B orbits (case I')](image1.png)

![Figure 2: The C orbits (case I)](image2.png)

**Theorem 3.9** The assignment \(\Sigma \mapsto \Omega_\Sigma\) is well-defined for any surface in \(B_1\). More precisely, the series (8) converges absolutely for any of the seminorms \(\cdot \mid_i, \alpha\) to a unique limit. This limit is an element of \(\mathbf{k}E(\Sigma)\) which is functorial. In particular, \(\Omega_\Sigma\) is mapping class group invariant.

**Proof.** The result holds true in the case \(\chi_\Sigma = -1\) by the assumptions on initial data. Assume it holds for all connected surfaces of Euler characteristic strictly smaller than some \(\chi_0 \leq -2\). Let \(\Sigma\) be a surface in \(B_1\) with Euler characteristic \(\chi_0\). For any \([P] \in \mathcal{P}_\Sigma\) the induction hypothesis applies to \(\Sigma - P\). In particular \(\Omega_{\Sigma - P}\) is functorial and belongs to \(\mathbf{k}E(\Sigma - P)\).
Since $\Theta_P$, $B_P^b$ and $\Omega_{\Sigma - P}$ are functorial, the value of $\Theta_P(B_P^b, \Omega_{\Sigma - P}) \in E(\Sigma)$ is independent of the embedding $f : P \to \Sigma$ representing a given class $[P] \in \mathcal{P}_\Sigma$. Likewise, $\Theta_P(C_P, \Omega_{\Sigma - P}) \in E(\Sigma)$ is independent of the embedding $f : P \to \Sigma$ representing a given class $[P] \in \mathcal{P}_\Sigma$ due to the functoriality of $C_P$.

Let us consider a $\Gamma^0_\Sigma$-orbit $\emptyset \in \mathcal{P}_\Sigma$. By functoriality of $E$ and the glueing morphisms we can find

- an ordered set $\mathcal{I}_{0,1}$, to which the ordered sets $\mathcal{I}_P$ for representatives of $[P] \in \emptyset$ are canonically identified.
- an ordered set $\mathcal{I}_{0,2}$, to which the ordered sets $\mathcal{I}_{\Sigma - P}$ for representatives of $[P] \in \emptyset$ are canonically identified.
- an object $E_{0,2}$ in $\mathcal{C}$, to which the objects $E(\Sigma - P)$ for representatives of $[P] \in \emptyset$ are (perhaps non-canonically) isomorphic to. However, the functorial elements $\Omega_{\Sigma - P}$ are all identified with a unique mapping class group invariant element $\Omega_\emptyset \in E_{0,2}$. We denote $\mathcal{A}_{0,2}$ the set indexing the semi-norms in $E_{0,2}$ for $j \in \mathcal{A}_{0,2}$.

We first examine the case of $\emptyset \in \mathcal{P}_\Sigma^b$. Let $k \in \mathcal{I}_\Sigma$ and $\alpha \in \mathcal{A}^b_\Sigma$ and use the decay axiom for $B^b$. It ensures the existence of $t_k$ and $j_k \in \mathcal{I}_{0,2}$ such that, for any $s > 0$ there exists $M_{k,s} > 0$ satisfying for any $j \geq j_k$, any $[P] \in \mathcal{P}_\Sigma^b$ and $\alpha' \in \mathcal{A}^b_{0,2}$

$$
\left| \Theta^k_P(B^b_P, \Omega_{\Sigma - P}) \right|_{k,\alpha} \leq M_{k,s} |\Omega_\emptyset|_{j,\alpha'} \cdot \frac{(1 + l_{k,\alpha}(\gamma_P))^{t_k}}{(1 + [l_{k,\alpha}(\gamma_P) - l_{k,\alpha}(b) - l_{k,\alpha}(b_1)])^s} \prod_{\beta \in \pi_0(\partial \Sigma)} (1 + l_{k,\alpha}(\beta))^{t_k} \quad (9)
$$

By the induction hypothesis, $\Omega_\emptyset$ belongs to $^bE_{0,2}$, so there exists constants $\varsigma_0 > 0$ and $W_{0,j} > 0$ such that

$$
|\Omega_\emptyset|_{j,\alpha'} \leq W_{0,j} \prod_{\beta \in \pi_0(\partial \Sigma - P)} (1 + l_{j,\alpha'}(\beta))^\varsigma_0 \quad (10)
$$

We now pick $j$ large enough compared to $k$ and $\alpha'$ so that the restriction axiom on lengths function can be used, and deduce there exists a constant $K'_k > 0$ such that

$$
|\Omega_\emptyset|_{j,\alpha'} \leq W_0 K'_k (1 + l_{k,\alpha}(\gamma_P))^\varsigma_0 \prod_{\beta \in \pi_0(\partial \Sigma)} (1 + l_{k,\alpha}(\beta))^\varsigma_0 \quad (11)
$$

where we simply denoted $W_0 = W_{0,j}$ for the chosen $j$, and wrote down separately the contribution of $\gamma_P$ and the contribution of the other boundary components of $\Sigma - P$ to the product in (10). We
then insert this inequality in (9) and would like to perform the sum over all \([ P ] \) \( \in \mathcal{P}_\Sigma^b \). We distinguish the contribution of small pairs of pants, i.e. those satisfying \( l_{k,\alpha}(\gamma_P) \leq l_{k,\alpha}(b_1) + l_{k,\alpha}(b) \) from the non-small ones.

For small pairs of pants, we can bound

\[
| \Theta^k_P(\mathcal{P}_0, \Omega) |_{k,\alpha} \leq M^t_{k,s} W_{\Omega} K^t_k \prod_{\beta \in \pi_0(\partial \Sigma)} (1 + l_{k,\alpha}(\beta))^{t_k + \varsigma_0}
\]

and the eponymous axiom says there are less than \( Q_k \) such terms.

The set of non-small \([ P ] \) \( \in \mathcal{P}_\Sigma^b \) (with respect to \( l_{k,\alpha} \)) injects in the set of simple closed curves \( \gamma \) in the interior of \( \Sigma \) such that \( l_{k,\alpha}(\gamma_P) \geq l_{k,\alpha}(b_1) + l_{k,\alpha}(b) \). Setting \( M^t_{k,s,\Omega} = M_{k,s} K^t_k W_\Omega \), we deduce that the sum of \( | \Theta^k_P(\mathcal{P}_0, \Omega) |_{k,\alpha} \) over non-small pairs of pants admits for upper bound

\[
M^t_{k,s,\Omega} \left( \sum_{L \geq 0} \frac{(2 + L)^{t_k + \varsigma_0}}{\beta \in \pi_0(\partial \Sigma)} \prod_{\beta \in \pi_0(\partial \Sigma)} (1 + l_{k,\alpha}(\beta))^{t_k + \varsigma_0} \right) \leq N_k M^t_{k,s,\Omega} \left( \sum_{L \geq 0} \frac{(1 + L l_{k,\alpha}(b_1) + l_{k,\alpha}(b))^{t_k + \varsigma_0 + d_k}}{L^s} \prod_{\beta \in \pi_0(\partial \Sigma)} (1 + l_{k,\alpha}(\beta))^{t_k + \varsigma_0}, \right)
\]

where we have used the polynomial growth axiom between the second and third line. We can choose \( s = t_k + \varsigma_0 + d_k + 2 \) to make the series between the bracket convergent, and there is a constant \( M^t_{k,\Omega} > 0 \) such that the previous expression is bounded by

\[
M^t_{k,\Omega} \prod_{\beta \in \pi_0(\partial \Sigma)} (1 + l_{k,\alpha}(\beta))^{t_k + \varsigma_0 + d_k}.
\]

Therefore, there exists a constant \( M^t_{k,\Omega} > 0 \) such that

\[
\sum_{[ P ] \in \mathcal{P}_\Sigma^b} | \Theta^k_P(\mathcal{P}_0, \Omega) |_{k,\alpha} \leq M^t_{k,\Omega} \prod_{\beta \in \pi_0(\partial \Sigma)} (1 + l_{k,\alpha}(\beta))^{t_k + \varsigma_0 + d_k}.
\]

The other \( \Gamma^3_\Sigma \)-orbits \( \Omega \) \( \in \mathcal{P}_\Sigma^b \) can be treated in a similar fashion, replacing \( \mathcal{P}_0^b \) with \( C_P \) and using the second part of the small pair of pants axiom and the decay assumption (7). The result is

\[
\sum_{[ P ] \in \mathcal{P}_\Sigma^b} | \Theta^k_P(\mathcal{P}_0, \Omega) |_{k,\alpha} \leq M^t_{k,\Omega} \prod_{\beta \in \pi_0(\partial \Sigma)} (1 + l_{k,\alpha}(\beta))^{t_k + \varsigma_0 + d_k}
\]

for some constant \( M^t_{k,\Omega} > 0 \).

In particular, for any orbit \( \Omega \) \( \in \mathcal{P}_\Sigma^b \), the series \( \sum_{[ P ] \in \mathcal{P}_\Sigma^b} \Theta^k_P(X^\Omega_P, \Omega) \) (where \( X \) is \( B^b \) or \( C \) depending on the orbit \( \Omega \)), is absolutely convergent in \( E^k(\Sigma) \). Let us denote \( w_\Omega \) the limit. Since the maps we have used are compatible with the restriction morphisms over \( k \in \mathcal{A}_\Sigma \), there exists a unique \( w_\Omega \in E(\Sigma) \) such that \( w^k_\Omega = \theta^k(w_\Omega) \). The inequalities (12)-(13) imply that

\[
| w_\Omega |_{k, t_k + \varsigma_0 + d_k} < +\infty,
\]

thus \( w_\Omega \in \mathcal{P}_\Sigma \). Summing over the finitely many \( \Gamma^3_\Sigma \)-orbits we have a well-defined element

\[
\Omega = \left( \sum_{\Omega \in \mathcal{P}_\Sigma^b} w_\Omega \right) \in \mathcal{P}_\Sigma, \quad \Omega \in \mathcal{P}_\Sigma,
\]

which is by definition the limit of the series in (8).

Let \( \varphi : \Sigma \to \Sigma' \) be a morphism in \( \mathcal{B}_1 \). Since the linear map \( E(\varphi) \) is continuous, \( E(\varphi)(\Omega) \) coincides with the series (8) to which one applies \( E(\varphi) \) term by term. For \( [ P ] = [ f : P \to \Sigma ] \) \( \in \mathcal{P}_\Sigma \), \( \varphi \) induces
a morphism $\hat{\varphi}$ in $\mathcal{B}_1$ between $P \cup \Sigma \ast f(P)$ and $P \cup \Sigma \ast \varphi \circ f(P)$. We denote $[\hat{\varphi}(P)]$ the class of $[\varphi \circ f: P \to \Sigma'] \in \mathcal{P}_{\Sigma'}$. The functoriality of the glueing morphisms implies that

$$E(\varphi)(\Theta_P(X_P, \Omega_{\Sigma'-P})) = \Theta_{\hat{\varphi}(P)}(E(\varphi)(X_P, \Omega_{\Sigma'-P})).$$

We apply this formula to $X_P = B^b_P$ or $C_P$ which are functorially attached to pairs of pants. The induction hypothesis guarantees that $\Omega_{\Sigma'-P}$ is also functorial. Therefore,

$$E(\varphi)(\Theta_P(X_P, \Omega_{\Sigma'-P})) = \Theta_{\hat{\varphi}(P)}(X_{\hat{\varphi}(P)}, \Omega_{\Sigma'-\hat{\varphi}(P)})$$  \hspace{1cm} (15)

Note that if $X = B^b$, by $X_{\hat{\varphi}(P)}$ we actually mean $B^\hat{\varphi}_2\hat{b}(P)$ taking into account that the mapping class $\varphi$ can permute the components in $\partial_r \Sigma$.

Through (15) we observe a bijection between the terms in $E(\varphi)(\Omega_{\Sigma})$ and the terms in $\Omega_{\Sigma'}$. Thanks to absolute convergence of the series for each seminorm, we deduce that

$$E(\varphi)(\Omega_{\Sigma}) = \Omega_{\Sigma'},$$

and thus we have proved functoriality. In particular, taking $\Sigma' = \Sigma$ gives the property of mapping class group invariance $E(\varphi)(\Omega_{\Sigma}) = \Omega_{\Sigma}$. We conclude the proof by induction. \hfill \Box

### 3.5 Natural transformations of target theories

Let $\mathbf{1}: \mathcal{B}_1 \to \mathcal{C}$ be the symmetric monoidal functor which assigns $\mathbb{K}$ to any surface in $\mathcal{B}_1$. A functorial assignment in $E$ is equivalent to the data of a natural transformation from the functor $\mathbf{1}$ to the functor $E$. For any admissible data, the GR amplitudes provide such a natural transformation.

More generally, let $E$ and $\tilde{E}$ be two target theories, and $\eta: E \Rightarrow \tilde{E}$ be a natural transformation compatible with the union morphisms, the glueing morphisms and the length functions. If

$$\mathcal{J} := (A_P, B^b_P, C_P, D_T)$$

is an admissible initial data for $E$, it is clear that

$$\eta(\mathcal{J}) := (\eta_P(A_P), \eta_P(B^b_P), \eta_P(C_P), \eta_T(D_T))$$

are admissible initial data for $\tilde{E}$. Denote $\Omega^\eta$ and $\tilde{\Omega}^\eta(\mathcal{J})$ the $E$-valued (respectively $\tilde{E}$-valued) outcome of GR from these two set of initial data.

**Proposition 3.10** For any surface $\Sigma$ in $\mathcal{B}_1$, we have $\tilde{\Omega}^\eta(\mathcal{J}) = \eta_{\Sigma}(\Omega^\eta_{\Sigma})$.

**Proof.** This is directly implied by the fact that $\eta_{\Sigma}: E(\Sigma) \to \tilde{E}(\Sigma)$ is continuous, linear, and that the assignment $\Sigma \mapsto \eta_{\Sigma}$ is compatible with union and glueing morphisms and with the length functions. \hfill \Box

### 3.6 Sums over embedded fatgraphs

In this paragraph, we show that the geometric recursion can be repackaged as a finite sum over fatgraphs of the appropriate topology with no reference to embeddings. The contribution of each fatgraph also satisfy a recursion under removal of the first vertex, albeit of non local nature. The similarity but also important differences with the topological recursion of [15] will be spelled out in Section 4.
Preliminary: fatgraphs and their doubled surface

In this paragraph we assume $2g - 2 + n > 1$. We consider the set $G_{g,n}$ of connected uni-trivalent fatgraphs with exactly $n$ univalent vertices and genus $g$. We denote by $G_{1}^{g,n}$ the set of graphs $G$ in $G_{g,n}$ equipped with a distinguished univalent vertex, called the root.

We recall the construction of the canonical spanning tree $t(G)$ for any element $G \in G_{1}^{g,n}$ [2] (see Figure 4 for an example). We inductively define $t(G)$ by starting at the root in the direction of its incident edge, traveling on the edges of $G$ respecting the cyclic order of the half-edges at vertices, adding at each step to $t(G)$ the edge we encounter along the face we are traveling on, whenever it has not already been added and it does not create a loop. Once we come back to the root, we restart the same travel until we get to the first edge $e$, for which the face on the other side of the edge is different from the one we are traveling on currently. We then jump to this next face and continue the travel along this component, adding edges to $t(G)$ with the same rules. When we come back to the starting point of travel for this face next to the edge $e$, we iterate the process (travel till we can jump to an unexplored opposite face), until we cannot add more edges without creating a loop. The outcome is a rooted tree $t(G)$, which spans all the vertices of $G$.

![Figure 4](image1.png)

Figure 4: The exploration on a fatgraph $G \in G_{1}^{2,6}$. We start from the root 1, and the numbers indicate in which order we then meet the (unoriented) edges. The spanning tree $t(G)$ is in black.

![Figure 5](image2.png)

Figure 5: Hexagon attached to a trivalent vertex.

To any $G \in G_{g,n}$ one can associate a bordered surface $\Sigma(G)$ of genus $g$ with $n$ boundary components, called the double (Figure 6). Let us briefly recall this construction. For each vertex of $v$, we take two copies $H_{v}^{+}$ and $H_{v}^{-}$ of a closed hexagon in which $v$ and its incident half-edges are embedded such that they end on three (alternating) sides of the hexagon (Figure 5). If there is an edge from a univalent vertex $u$ to $v$, we ask that the edge from $u$ to $v$ is embedded in $H_{v}^{+}$ such that $u$ maps to a point in the interior of a side of the hexagon. We orient $H_{v}^{+}$ (respectively $H_{v}^{-}$) so as to agree (respectively disagree) with the cyclic order of half-edges around $v$. We then glue together $H_{v}^{+}$ and $H_{v}^{-}$ into a pair
of pants \( P_v \) by identifying pairs \((s_-, s_+)\) of sides with opposite orientation in \((H^-_v, H^+_v)\) which are not crossed by edges incident to \( v \). The surface \( \Sigma(G) \) is then obtained by the quotient of \( \bigcup_v P_v \), where we for each edge in \( G \), say between the vertices \( v \) and \( v' \), identify the boundary components of \( P_v \) and \( P_{v'} \) corresponding to the edge. In particular, two copies of \( G \) are embedded in \( \Sigma(G) \), and the image \( \Sigma^+(G) \) of \( \bigcup_v H^+_v \) in \( \Sigma(G) \) deformation retracts onto \( G \).

Since two different ways of choosing the topological spaces \( H^-_v \) and the glueing are related by diffeomorphisms in a unique orientation-preserving isotopy class, \( \Sigma(G) \) can be considered as a single object in \( \mathcal{B} \) up to canonical isomorphisms.

If \( G \in \mathcal{G}^{g,n}_1 \), reversing the orientation of the boundary component of \( \Sigma(G) \) containing the root gives an object in \( \mathcal{B}_1 \) which is uniquely defined up to canonical isomorphisms. From here on \( G \) always stands for a graph in \( \mathcal{G}^{g,n}_1 \) and \( \Sigma(G) \) the associated object in \( \mathcal{B}_1 \).

Let \( \tilde{M}^G(\Sigma) \) be the set of morphisms in \( \mathcal{B}_1 \) from \( \Sigma(G) \) to \( \Sigma \). We observe that an element of \( \tilde{M}^G(\Sigma) \) induces a pair of pants decomposition of \( \Sigma \), up to ambient isotopy. Thus there is a well-defined subgroup \( \Gamma^G \) associated to each \( G \), which is the subgroup of \( \Gamma \) preserving each pair of pants as well as each boundary component of a pair of pants in this decomposition. We denote the quotient by

\[
\tilde{M}^G(\Sigma) = \tilde{M}^G(\Sigma)/\Gamma^G,
\]

and we will write

\[
\tilde{M}(\Sigma) = \bigcup_{G \in \mathcal{G}^{g,n}_1} \tilde{M}^G(\Sigma), \quad M(\Sigma) = \bigcup_{G \in \mathcal{G}^{g,n}_1} M^G(\Sigma).
\]

**GR as a sum over fatgraphs**

The spanning tree \( \mathcal{I}(G) \) of \( G \) allows us to determine an ordering on the embedded pair of pants \( (P_1, \ldots, P_{2g-2+n}) \) as well as an ordering of the set of boundary component of each \( P_i \). We can therefore consider each \( P_i \) as an object in \( \mathcal{B}_1 \), by declaring the orientation of its first boundary to disagree with the orientation of the surface. We put \( \Sigma(G)_1 = \Sigma(G) \), and successively excise the pair of pants \( P_i \), for \( i = 1, 2, \ldots \) to obtain a sequence of surfaces inductively defined by \( \Sigma(G)_{i+1} = \Sigma(G)_i - P_i \). When excising \( P_i \), we can distinguish the following four mutually exclusive cases.

**A –** \( \partial P_i \notin \partial \Sigma(G)_i \).
B – Exactly two of the boundary components of $P_i$ are boundary components of $\Sigma(G)_i$.

C – Exactly one of the boundary components of $P_i$ is a boundary component of $\Sigma(G)_i$, and the two other boundary components of $P_i$ are disjointly embedded in $\Sigma(G)_i$.

D – Two of the boundary components of $P_i$ are glued together under the embedding into $\Sigma(G)_i$. In this case, by gluing these two boundary components we replace $P_i$ by a torus with one boundary component (which we keep denoting $P_i$ for convenience).

This defines for us a type map $X : \left[ [1, 2g-2+n] \rightarrow \{A, C, D\} \cup \bigcup_{b \in \pi_0(\partial \Sigma)} \{B^b\} \right]$. In the B situation, the type also records the second boundary of the corresponding pair of pants with the letter $b$. We denote

$$\#\text{Aut}(G) = 2^{X^{-1}(C)} \quad (16)$$

In a given target theory $E$, we introduce the composed gluing morphism

$$\Theta^G = \Theta_{P_{2g-2+n}} \circ \cdots \circ \Theta_{P_1} : \prod_{i=1}^{2g-2+n} E(P_i) \longrightarrow E(\Sigma(G)).$$

For given admissible initial data, we define $\omega^G \in E(\Sigma(G))$ by

$$\omega^G = \Theta^G((X_P(i))_{i=1}^{2g-2+n}).$$

For a $\hat{\varphi} \in \tilde{M}(\Sigma)$ we have of course a morphism $E(\hat{\varphi}) : E(\Sigma(G)) \rightarrow E(\Sigma)$. Since the mapping classes in $\Gamma^G(\Sigma)$ leave stable each boundary component of the $P_i$s, $\omega^G$ is $\Gamma^G(\Sigma)$-invariant. Therefore $E(\hat{\varphi})(\omega^G) \in E(\Sigma)$ only depends on the projection $\varphi \in M(\Sigma)$ of $\hat{\varphi}$ and can be denoted $E(\varphi)(\omega^G)$.

**Proposition 3.11** For any surface $\Sigma$ in $B_1$, the GR amplitudes satisfy

$$\Omega_{\Sigma} = \sum_{G \in G^{\Sigma}_{g,n}} \frac{\Omega^G_{\Sigma}}{\#\text{Aut}(G)}, \quad \Omega^G_{\Sigma} = \sum_{\varphi \in M(\Sigma)} E(\varphi)(\omega^G).$$

**Proof.** Unfolding the recursive definition (8) and thanks to the property of absolute convergence from Theorem 3.9, we can apply the Fubini theorem and obtain a sum over sequences $([P_1], \ldots, [P_m])$ where $[P_i] \in P_{\Sigma(i)}$, with $\Sigma^{(0)} = \Sigma$ and $\Sigma^{(i)} = \Sigma^{(i-1)} - P_i$. At each step, the excision of a pair of pants produces the isotopy class of embeddings $[P_i] = [f_i : P_i \rightarrow \Sigma^{(i-1)}]$ of a pair of pants with ordered boundary components. What is left, when no more excisions are possible (recall we stop before getting the empty surface), are connected components which are either pairs of pants (an $A$ factor) or tori with one boundary component (a $D$ factor). Tracking the ordering of boundary component of the $P_i$ in this nested structure reveals that this set of sequences is in bijection with $M(\Sigma)$. For each $\varphi \in M(\Sigma)$, we can then rearrange the nested application of gluing maps into the composite gluing map $E(\varphi) \circ \Theta^G$. It should be applied to a tuple formed by the factors contributing to each embedded piece $P_i$, either an $A$, $B$, $C$ or $D$, depending only on the abstract fatgraph $G$ as specified by the type map. The automorphism factor (16) takes into account the conventional power of 1/2 attached to each $C$ in (3.8). $\square$

**Fatgraph recursion**

We can also write a fatgraph recursion, but we stress that the gluing maps will be non local, i.e. they *a priori* not only depend on the excision of a trivalent vertex, but on the full structure of the fatgraph. This makes our recursion quite different from usual fatgraph recursions encountered in enumerative geometry, as we will comment on in Section 4.
Let us define $E_G = E(\Sigma(G))$ and let

$$\Omega^G = \Omega^G_{\Sigma(G)} = \sum_{\varphi \in M^G(\Sigma(G))} E(\varphi)(\omega^G) \in E_G. \quad (17)$$

Let $t_1 \in \mathfrak{t}(G)$ be the union of the univalent vertex $u$, the trivalent vertex $v$ incident to it, and the half edges attached to these two vertices. $G - t_1$ may or may not be a connected graph. If it is connected we put $\tilde{E}_{G-t_1} := E_{G-t_1}$. If it is not connected, $G - t_1$ will consist of an ordered (by cyclic order at $v$ starting with $u \to v$) pair of connected components $(G', G'')$, and we define $\tilde{E}_{G-t_1} := E_{G'} \times E_{G''}$. In both cases, we construct a fatgraph glueing map

$$\Theta^{G, t_1} : E_{t_1} \times \tilde{E}_{G-t_1} \longrightarrow E_G$$

as follows. Let $\mathcal{P}(G, t_1)$ be the set of isotopy classes of all embeddings of the pair of pants $\Sigma(t_1)$ into $\Sigma(G)$ preserving the orientation of the surfaces and of their boundary components. For each $[p] \in \mathcal{P}(G, t_1)$ we choose an orientation-preserving identification $\varphi_p$ of the complement of $p$ with $\Sigma(G - t_1)$. This way we obtain glueing map $\Theta_p : E_{t_1} \times \tilde{E}_{G-t_1} \rightarrow E_G$, which does not depend on the choice of $\varphi_p$, and we define

$$\Theta^{G, t_1} := \sum_{[p] \in \mathcal{P}(G, t_1)} \Theta_p. \quad (18)$$

The right-hand side is only defined when evaluated on certain elements of $E_{t_1} \times \tilde{E}_G$ making the series absolutely convergent.

**Proposition 3.12** For any $G \in \mathbb{G}_1^{2n}$ with $2g - 2 + n \geq 2$, we have $\Omega^G = \Theta^{G, t_1}(\Omega^{t_1}, \Omega^{G-t_1})$.

**Proof.** As the series (17) is absolutely convergent, it can be repackaged as

$$\Omega^G = \sum_{[p] \in \mathcal{P}(G, t_1)} \sum_{\varphi \in M^G(\Sigma(G))} E(\varphi)(\omega^G).$$

By the definition of $\Theta^{G, t_1}$, $\Omega^{G-t_1}$ and $\Omega^G$, this sum may be rewritten as $\Omega^G = \Theta^{G, t_1}(\Omega^{t_1}, \Omega^{G-t_1})$. \qed

### 3.7 Inducing initial data for tori with one boundary

In quantum field theories, defining correlation functions for tori with one boundary by a cutting procedure often involves a renormalisation procedure to get rid of infinities. We avoid addressing these potential problems in the construction of target theories since we did not include self-glueings in our axioms.

Imagine that we are nevertheless given a functorial morphism,

$$\Xi : E(P) \longrightarrow E(T) \quad (19)$$

where $P$ is a pair of pants seen as an object in $\mathcal{B}_1$, and $T$ is the torus with one boundary obtained by glueing the two boundary components in $\partial P$.

If $T$ is now an arbitrary object in $\mathcal{B}_1$ which is a torus with one boundary, for any simple closed curve $\gamma \in S^1_T$, we obtain a homotopy class of pairs of pants $[P_{\gamma}]$ by cutting $T$ along $\gamma$. By definition of cutting/glueing, this $T$ is obtained by self-glueing on $P_{\gamma}$, and we denote by $\Xi_{\gamma}$ the self-glueing morphism coming from (19).

Assume that we are given a functorial assignment $P \mapsto C_P \in E(P)$, in particular $C_P$ must be $\Gamma_P$-invariant. We remark that, due to the assumed invariance of $C_P$ under braiding of the two boundary
components of $\partial_s P$, and the assumed functoriality of the self-glueing morphism, $\Xi_\gamma(C_{P_\gamma})$ does not depend on an ordering of the two last boundary components. We may seek to define

$$\Omega_T := \sum_{\gamma \in S_T^0} \Xi_\gamma(C_{P_\gamma}) \in E(T).$$

For this purpose, we introduce an additional axiom for $C$.

**Decay for self-glueing.** Assume that we are given a functorial self-glueing morphism for pairs of pants as above. For any object $T$ in $B_1$ which is a torus with one boundary component, for any $\gamma \in S_T^0$, for any $k \in \mathcal{I}_T$, there exists $t_k \geq 0$ and $j_k \in \mathcal{I}_P^{\gamma}$ functorial such that for any $s > 0$, there exists $M_{k,s} > 0$ functorial such that for any $\alpha \in \mathcal{A}_k^T$, we have

$$|\Xi_\gamma^k(C_{P_\gamma})|_{k,\alpha} \leq M_{k,s} \left(1 + l_{k,\alpha}(\gamma)\right)^{2t_k} \left(1 + \left[2l_{k,\alpha}(\gamma) - l_{k,\alpha}(\partial T)\right]\right)^{s}. \quad (20)$$

By an argument of convergence similar to the one detailed in the proof of Theorem 3.9, we find

**Lemma 3.13** Assume $(A,B,C)$ satisfy the properties listed in Definition 3.7 and the axiom of decay for self-glueing. Then

$$D_T = \sum_{\gamma \in S_T^0} \Xi_\gamma(C_{P_\gamma}) \quad (21)$$

is a well-defined, functorial assignment for any object $T$ in $B_1$ which is a torus with one boundary component, and $(A,B,C,D)$ is an admissible initial data.

Note that the $(A,B,C)$ parts of the initial data are sufficient to define the GR amplitudes $\Omega_\Sigma$ for surfaces $\Sigma$ of genus 0. The $D$ part is necessary to extend this definition to positive genus. Lemma 3.13 gives a way to induce a $D$ if we have self-glueing morphisms for pairs of pants and if $C$ satisfying the self-glueing decay axiom. Note that we could replace $C$ by $A$ in the discussion. Note that $B_P$ does not a priori have the invariance under braiding of the two boundary components of $\partial_s P$. If we insist in using a $B$ to induce a $D$, we should replace (21) with the formula

$$\sum_{\gamma \in S_T^{0,\alpha}} \Xi_\gamma(B_{P_\gamma}^\alpha),$$

where $S_T^{0,\alpha}$ now enumerates oriented simple closed curves and $\gamma_\alpha$ is the boundary component of $P_\gamma$ created to the left of $\gamma$ when we cut $T$.

## 4 The strict geometric recursion

Suppose we have chosen for a single reference object $\Sigma_{g,n}$ for each type $(g,n)$ in $B_1$ or $B_s$. In the geometric recursion, the functoriality of $\Sigma \mapsto \Omega_\Sigma$ allows a non-ambiguous definition of

$$w_{g,n} := \Omega_{\Sigma_{g,n}} \quad (22)$$

by induction on $2g - 2 + n > 0$. Namely, it is possible to work solely with reference surfaces for each $g$ and $n$ all the way through the recursion. Passing from $\Omega_\Sigma$ to $w_{g,n}$, we have lost the memory of the structure of $B_1$, and therefore a lot of topological (and interesting) information and naturality of the construction.

In this section, we want to formalise the type of recursion satisfied by $(w_{g,n})_{g,n}$, which we call strict geometric recursion. The assignment (22) will be a special case of this strict GR. It is a kind
of generalisation of the topological recursion of [15, 19, 5], and is only based on finitely many gluing maps (Section 4.1). This construction contains less information than GR, but it can also be induced from the richer context of GR when the gluing maps are assembled from a converging series of isotopy class-dependent glueing maps as in (18) (see Section 4.3).

4.1 Definition

We form a category \( \overline{B}_1 \) which is a kind of strictification of \( B_1 \). Its objects are finite (possibly empty) sequences \((g_i, N_i)_{i \in I}\) where \( g_i \in \mathbb{N} \) and \( N_i \) is a pointed finite set such that \( 2 - 2g_i - \#N_i < 0 \) for all \( i \in I \). We denote \( 1 \) the distinguished element of \( N_i \). Concatenation \( \cup \) of such sequences gives \( \overline{B}_1 \) a monoidal structure, of which we only retain the structure of multicategory. A morphism from \((g_i, N_i)_{i \in I}\) to \((g'_i, N'_i)_{i \in I'}\) are tuples \((\varphi, (\sigma_i)_{i \in I})\) where \( \varphi : I \to I' \) is a bijection such that for any \( i \in I \), \( g'_{\varphi(i)} = g_i \) and \( \sigma_i : N_i \to N'_{\varphi(i)} \) is an isomorphism of pointed sets. We say that an object \((g_i, N_i)_{i \in I}\) is connected if \( \#I = 1 \); in that case it is simply denoted \((g, N)\), the distinguished element is denoted 1, and an automorphism is characterized by an element \( \sigma \in \mathfrak{S}_{N\setminus\{1\}} \).

**Definition 4.1** A strict target theory is a functor \( e : \overline{B}_1 \to \mathcal{C} \) together with functorial extra data satisfying the union and excision axioms below.

**Union Axiom.** For any objects \( s \) and \( s' \), we ask for the data of a continuous bilinear map

\[
\cup : e(s) \times e(s) \rightarrow e(s \cup s'),
\]

compatible with commutativity and associativity of cartesian products. We require that \( e(\emptyset) = \mathbb{K} \) and the union morphism \( \cup : e(\emptyset) \times e(s) \rightarrow e(s) \) is specified by \( 1 \cup v = v \).

To present the excision axiom, we need a few more notations. If \((g, N)\) is a connected object in \( \overline{B}_1 \), we introduce the set \( \mathcal{K}_{g,N} \) contains the following objects of \( \overline{B}_1 \):

1. \((g - 1, N \cup \{\ast\})\), meaning that we added an extra element \( \ast \) to the pointed set \( N \).
2. \( I' \) for each \( b \in N \setminus \{1\} \), the object \((g, N^{[b]}\)\), where \( N^{[b]} \) is the set \( \{\ast\} \cup N \setminus \{1, b\} \) with the new distinguished element \( \ast \).
3. \( II \) for each ordered partition \( J \cup J' = N \setminus \{1\} \) and ordered pair \((h, h')\) such that \( h + h' = g \) with \( 2 - 2h - \#J < 0 \) and \( 2 - 2h' - \#J' < 0 \), the object \(( (h, \{1\} \cup J), (h', \{1\} \cup J') \)\), where \( 1 \) and \( 1' \) are the new distinguished elements.

**Excision Axiom.** For any connected object \((g, N)\) and \( \kappa \in \mathcal{K}_{g,N} \), we ask for the data of functorial continuous multilinear morphisms

\[
\theta_\kappa : e(0, 3) \times e(\kappa) \rightarrow e(g, n)
\]

**Definition 4.2** A strict initial data is a quadruple \((A, B, C, D)\) such that

\[
A, C \in e(0, \{1, 2, 3\})^{E(1,3)}, \quad B^2 \in e(0, \{1, 2, 3\}), \quad D \in e(1, \{1\}).
\]

Let \((A, B, C, D)\) be strict initial data for a strict target theory \( e : \overline{B}_1 \to \mathcal{C} \).

**Definition 4.3** We define the strict GR amplitudes as follows.
• We put $w_3 := 1$. If $3$ is a pointed set with 3 elements, we denote $w_{0,3} := A$, and $w_{1,1} := D$.

• For disconnected objects, we put $w_{(g_i, N_i)} := \bigcup_{i \in I} w_{g_i, N_i}$.

• If $(g, N)$ is a connected object, we define inductively for $2g - 2 + \#N \geq 2$

$$w_{(g, N)} := \sum_{b \in N \setminus \{1\}} \theta_{g, N(b)}(B^b, w_{g, N(b)})$$

$$+ \frac{1}{2} \left( \theta_{g-1, N(\ast)}(C, w_{g-1, N(\ast)}) + \sum_{h + h' = g} \theta_{(h,1) \cup J, (h',1') \cup J'}(C, w_{h,1 \cup J \cup h',1' \cup J'}) \right),$$

where the $'$ in the last sum means we discard terms involving $(0, \{1\})$ or $(0, \{1,2\})$.

Proposition 4.4 The assignment $(g_i, N_i) \mapsto \bigcup_{i \in I} w_{g_i, N_i} \in \prod_{i \in I} e(g_i, N_i)$ is well-defined and functorial. In particular, $w_{g,[1,n]}$ is well-defined and functorial. In particular, $w_{g,[1,n]}$ is well-defined and functorial.

Proof. The proof proceeds by induction and is very easy. Indeed, thanks to the induction hypothesis and the properties required for the glueing morphisms, the automorphism group of $(g, N)$ just permutes the terms in (23).

4.2 Sums over fatgraphs

We resume the discussion of Section 3.6. Recall that any $G \in G_1^{g,n}$ determines an ordered decompositions into pairs of pants $(P_1, \ldots, P_{2g-2+n})$ of $\Sigma(G)$, each of them having ordered boundary components (in particular $\pi_0(\partial P_i)$ is a pointed set), as well as a type map $X : [1, 2g - 2 + n] \to \{A, B', C, D\}$. In a strict target theory $e$ we have a glueing morphism

$$\theta^G : \prod_{i=1}^{3g-3+n} e(0, \pi_0(\partial P_i)) \to e(g, n).$$

Unfolding the recursive definition (23) as we did in Section 3.6 (without the complications due to the consideration of isotopy classes) yields

Proposition 4.5 Let $(A, B, C, D)$ be an admissible initial data for a strict target theory $e$. For any stable $(g, n)$, the strict GR amplitude takes the form

$$w_{g,n} = \sum_{G \in G_1^{g,n}} \theta^G((X_i)_{i=1}^{3g-3+n}).$$

4.3 From GR to strict GR

We can associate to any target theory $E$ a strict target theory $e$. This is done by choosing, for each $(g, N)$, a reference surface $\Sigma_{g,N}$ in $\mathcal{B}$ with $N = \pi_0(\partial \Sigma_{g,N})$ (identifying $1$ with $\partial \Sigma_{g,N}$), and letting for $(g, \#N) = (0,3)$

$$e(g, N) := E(\Sigma_{g,N})^{\Gamma_0}_{\Sigma_{g,N}}.$$

In the special case $\#N = 3$, we specify below $e(0, N)$ to be a certain subspace of $E(\Sigma_{0,N})$. The action of $\Gamma_{\Sigma_{e,N}}$ on $E_{\Sigma_{e,N}}$ factors into an action of $\mathcal{G}_{N,\{1\}}$ on $e(g, N)$. We therefore obtain a functor $e : \mathcal{B} \to \mathcal{E}$.
We induce union morphisms for e from the union maps on E in the obvious way. To define glueing morphisms for e, we assemble the glueing morphisms for E. More precisely, if κ ∈ ℂg,N, let Σκ denote, among the associated reference surface. We let ℙg,N(κ) ∈ ℙΣg,N be the set of homotopy classes [P] such that Σ − P is diffeomorphic to Σκ, in such a way that the pointed set π0(∂Σ − P) is isomorphic to the pointed set π0(∂Σκ). For each [P] ∈ ℙg,N(κ), we pick two isomorphisms φp : P → Σ0,1,2,3 and ψp : Σκ → Σ − P in ℌ1. Any other choice is related to (φp, ψp) by post-composition with pure mapping classes on the connected components of Σ0,1,2,3 ∪ Σκ.

Then we define
\[ \theta_κ := \sum_{[P] ∈ ℙg,N(κ)} Θ_P ∘ (E(φ_P), E(ψ_P)) \]  
(24)

We choose e(0, {1, 2, 3}) to be any subspace of E(Σ0,1,2,3) on which this linear map is well-defined and continuous. We remark that the linear map \( \theta_κ : e(0, \{1, 2, 3\}) × e(κ) \to E(Σ(κ,N)) \) does not depend on the choices of \([P], φ_P, ψ_P\) above. And, since all elements in the sum (24) are related by the action of the pure mapping classes of Σg,N, the morphism \( \theta_κ \) actually takes values in \( e(g, N) = E(Σ(κ,N))^Γ_{Σg,N} \).

Using (24) we deduce the following result.

**Corollary 4.6** Assume E is a target theory, together with admissible initial data \((A, B, C, D)\), and denote Ω the outcome of GR. Construct a (non-canonical) strict target theory e as above and induce an e-valued initial data by specialising \((A, B, C, D)\) to the reference surfaces \(Σ_{0,3}\) and D to the reference \(Σ_{1,1}\). Denote w the corresponding outcome of strict GR. Then for any connected object \((g, N)\), we have \(w_{g,N} = ΩΣ_{g,N}\).

Observe that by the decay axiom and Theorem 3.9, the GR initial data does induces strict GR initial data. We note that the above construction is non-canonical as it involves the choice of reference surfaces \(Σ_{g,N}\). However, if the target theory E is such that \(Γ_{Σ}^0\) acts trivially on \(E(Σ)\), the construction is independent of these choices and therefore canonical. More generally, we have by an argument similar to Proposition 3.10 that

**Proposition 4.7** Let E be a target theory, e a strict target theory, and η : E → e a natural transformation which is compatible with the union and glueing morphisms. If \(J = (A, B, C, D)\) is an E-valued admissible initial data, then \(η(J)\) is a strict initial data, and we have the relation between the corresponding GR and strict GR amplitudes

\[ w_η(J) = η(Ω^J). \]

5 A symmetric version of the geometric recursion

In the recursive definition (8), the single boundary component in ∂.Σ plays a special role, and this propagates at each step of the recursion. This is the reason why we have used the category \(B_1\) instead of \(B\). We now describe a version of GR where all boundary components play the same role. We will propose sufficient conditions on the initial data for this symmetric GR to be well-defined.

**Definition 5.1** Let \(B_s\) be the full subcategory of \(B\) whose objects Σ are such that \(∂.Σ = ∅\).

In this appendix, it is assumed that all surfaces are objects of \(B_s\), unless stated otherwise. If Σ is a connected object in \(B_s\) and \(b_1\) a choice of boundary component, we can form the object \(Σ_{b_1}\) of
\( \mathcal{B}_1 \) by reversing the orientation of \( b_1 \). The sets of homotopy classes of embedded pairs of pants \( \mathcal{P}_{\Sigma_{b_1}} \) and \( \mathcal{P}^{d}_{\Sigma_{b_1}} \) for \( d \in \{ \varnothing \} \cup \pi_0(\partial \Sigma_{b_1}) \) describing in Section 2.3 the type of excisions from the object \( \Sigma_{b_1} \) in \( \mathcal{B}_1 \) are here denoted \( \mathcal{P}_{\Sigma_{b_1}} \) and \( \mathcal{P}^{d}_{\Sigma_{b_1}} \). If \( [P] \in \mathcal{P}_{\Sigma_{b_1}} \), the surface \( \Sigma - P \) is a priori an object in \( \mathcal{B}_1 \). We automatically make it an object of \( \mathcal{B}_b \) by forcing the orientation of each boundary components to agree with the orientation of the surface.

The notion of symmetric target theory \( E : \mathcal{B}_b \to \mathcal{C} \) is defined as in Section 3.1, by replacing \( \mathcal{B}_1 \) with \( \mathcal{B}_b \) and requiring functorial glueing morphisms denoted \( \Theta_P \) and indexed by \( b_1 \in \pi_0(\partial \Sigma) \) and \( [P] \in \mathcal{P}_{\Sigma_{b_1}} \).

### 5.1 Initial data

**Definition 5.2** Initial data for a given symmetric target theory \( E \) are functorial assignments

- of \( A_P \in E(P) \) for any pair of pants \( P \).
- of \( B_P^{b_1,b_2} \in E(P) \) for any pair of pants \( P \) for which an ordered pair \( (b_1,b_2) \) of distinct boundary components has been selected.
- of \( C_P^{b_1} \in E(P) \) for any pair of pants \( P \) for which some \( b_1 \in \pi_0(\partial P) \) has been selected.
- of \( D_T \in E(T) \) for any torus \( T \) with one boundary component.

An initial data is called admissible if it satisfies the decay properties (as in Definition 3.7) and the four symmetry properties stated below.

In the following relations, \( X \) will denote any genus 0 surface with 4 ordered boundary components \( (b_i)_{i=1}^4 \), and \( \text{IO} \) any surface with genus 1 with 2 ordered boundary components \( (b_1,b_2) \). If \( [P] \in \mathcal{P}_{X,b_1} \), we recall that \( \gamma_P \) is the unique boundary component of \( P \) which is interior to \( X \). If \( (\beta, \beta') \) is an ordered pair of boundary components of \( X \) or \( \text{IO} \), we denote by \( \sigma_{\beta,\beta'} \) any mapping class that exchanges \( \beta \) and \( \beta' \).

**BA relation.**

\[
(\sigma_{b_1,b_2} - \text{Id})\left[ \sum_{[P] \in \mathcal{P}_{X,b_1}^{b_1,b_2}} \theta_P(B_P^{b_1,b_2}, A_{X-P}) \right] = 0.
\]  

(25)

**BB-CA relation.**

\[
(\sigma_{b_1,b_2} - \text{Id})\left[ \sum_{[P] \in \mathcal{P}_{X,b_1}^{b_1,b_2}} \theta_P(B_P^{b_1,b_2}, B_P^{\gamma_P,b_1}) + \sum_{[P] \in \mathcal{P}_{X,b_1}^{b_1,b_2}} \theta_P(B_P^{b_1,b_3}, B_P^{b_2,\gamma_P}) + \sum_{[P] \in \mathcal{P}_{X,b_1}^{b_1,b_2}} \theta_P(C_P^{b_1}, A_{X-P}) \right] = 0.
\]  

(26)

**BC relation.**

\[
(\sigma_{b_1,b_2} - \text{Id})\left[ \sum_{[P] \in \mathcal{P}_{X,b_1}^{b_1,b_2}} \theta_P(B_P^{b_1,b_2}, C_P^{\gamma_P,b_1}) + \sum_{[P] \in \mathcal{P}_{X,b_1}^{b_1,b_2}} \theta_P(C_P^{b_1,b_3}, B_P^{b_2,\gamma_P}) + \sum_{[P] \in \mathcal{P}_{X,b_1}^{b_1,b_2}} \theta_P(C_P^{b_1}, A_{X-P}) \right] = 0.
\]  

(27)

**D relation.**

\[
(\sigma_{b_1,b_2} - \text{Id})\left[ \sum_{[P] \in \mathcal{P}_{X,b_1}^{b_1,b_2}} \theta_P(B_P^{b_1,b_2}, D_{\text{IO}-P}) + \frac{1}{2} \sum_{[P] \in \mathcal{P}_{X,b_1}^{b_1,b_2}} \theta_P(C_P^{b_1}, A_{\text{IO}-P}) \right] = 0.
\]  

(28)
We note that, due to the properties of the initial data, the validity of these relations for one choice of braidings $\sigma_{b_1,b_2}, \sigma_{b_2,b_3}$ and $\sigma_{b_3,b_4}$ imply their validities for all choice of braidings.

![Figure 7: The three types of terms in the BB-CA relation. The same three types of terms appear in the BA and BC relations. These relations take an H-I-X form, and provide a geometric incarnation for the (purely algebraic) H-I-X relations found in quantum Airy structures and the topological recursion, see Section 6.2.](image)

5.2 Definition

Let $(A,B,C,D)$ be admissible initial data for a symmetric target theory $E : \mathcal{B}_s \rightarrow \mathcal{C}$.

**Definition 5.3** We define the symmetric GR amplitudes as follows.

- We put $\Omega_{\emptyset} := 1 \in E(\emptyset)$.
- If $P$ is a pair of pants in $\mathcal{B}_s$, we put $\Omega_P = A_P$.
- If $T$ is a torus with one boundary in $\mathcal{B}_s$, we put $\Omega_T = D_T$.
- For disconnected surfaces in $\mathcal{B}_S$, we declare $\Omega_{\Sigma} = \bigsqcup_{a \in \pi_0(\partial \Sigma)} \Omega_{\Sigma(a)}$.
- If $\Sigma$ is a connected surface in $\mathcal{B}_s$ with $\chi_{\Sigma} \leq -2$, let us make a choice of a boundary component $b_1$. We seek to inductively define as in (8)

$$
\Omega_{\Sigma} = \sum_{b \in \pi_0(\partial \Sigma) \setminus \{b_1\}} \sum_{[P] \in \mathcal{P}_{\Sigma,b_1}} \Theta_P(B_{P,b}, \Omega_{\Sigma-P}) + \frac{1}{2} \sum_{[P] \in \mathcal{P}_{\Sigma,b_1}} \Theta_P(C_{P,b_1}, \Omega_{\Sigma-P}) \tag{29}
$$

as an element of $E(\Sigma)$.
We now have to check that, step by step, this assignment does not depend on the choice of \( b_1 \).

**Theorem 5.4** The assignment \( \Sigma \mapsto \Omega_\Sigma \) is well-defined for any surface in \( \mathbb{B}_\alpha \). More precisely, the series (29) converges absolutely for any of the semi-norms \( |\cdot|_{i,\alpha} \) to a unique limit. This limit is an element of \( \mathcal{T} \mathcal{E}(\Sigma) \) which is functorial. In particular \( \Omega_\Sigma \) is invariant under braidings of all boundary components.

**Proof.** As the convergence and functoriality under mapping classes that respect \( b_1 \) can be adressed as in Theorem 3.9, we focus on the justification – at each step of the induction – of the invariance under the braiding of \( b_1 \) with another component. We denote \( \Omega_{\Sigma,b_i} \) the right-hand side of (29), to stress its potential dependence in the choice of the boundary component. As the result for connected surfaces automatically implies the result for all surfaces, we assume in the rest of the proof that \( \Sigma \) is connected. The result obviously holds when \( \chi_\Sigma = -1 \).

**Step 1.** We first study the case of genus 0 with 4 boundaries, that is \( \Sigma = X \). The functoriality of the glueing morphisms imply that \( \sigma_{b_1,b_2} \Omega_{X,b_1} = \Omega_{X,b_2} \). The \( \text{BA} \) relation therefore means that \( \Omega_{X,b_1} = \Omega_{X,b_2} \). So, \( \Omega_X \) is a well-defined, functorial assignment in \( E(X) \).

**Step 2.** We prove the result likewise for a surface \( \Sigma \) with genus 1 with 2 boundary components, which we arbitrarily order \((b_1,b_2)\). Applying (29) with chosen boundary component \( b_1 \) yields

\[
\Omega_{\text{IO},b_1} := \sum_{[P] \in \mathcal{P}_{\Sigma,b_1}} \Theta_P(B_{X,b_2}^1, D_{\text{IO},b_2}) + \frac{1}{2} \sum_{c \in \mathcal{C}_{\Sigma,b_1}} \Theta_P(C_{X,b_2}^b, A_{\text{IO},b_2})
\]

and this is invariant under braidings \( \sigma_{b_1,b_2} \) according to relation D.

**Step 3.** So far we have proved the result up to \( \chi_\Sigma \geq -2 \). Assume it holds for surfaces with Euler characteristic larger than or equal to a \( \chi_0 \leq -2 \), and consider \( \Sigma \) of Euler characteristic \( \chi_0 - 1 \).

If \( \Sigma \) has only 1 boundary component, then \( \Omega_\Sigma \), defined by (29), does not depend on any choice, and functoriality from the induction hypothesis, of the initial data and glueing maps imply that \( \Omega_\Sigma \) is functorial for such surfaces. If \( \Sigma \) has \( n \geq 2 \) boundary components, we order them arbitrarily \((b_1, \ldots , b_n)\) and we shall prove invariance of \( \Omega_{\Sigma,b_1} \) under the braiding \( \sigma_{b_1,b_2} \). Let us compute \( \Omega_{\Sigma,b_1} \) from (29), i.e. excise pair of pants \( P \) in all possible classes \([P] \in \mathcal{P}_{\Sigma,b_1}\). We want to replace the contribution of some of the connected components of \( \Sigma - P \) with the GR formula unambiguously defined from the previous induction steps. We distinguish several cases in doing so.

- When \([P] \in \mathcal{P}_{\Sigma,b_1}, (\gamma_P^1, \gamma_P^2)\) are the connected components of the multicurve \( \gamma_P \) along which we excised – they are ordered by our definition of excision in § 2.3. We denote by \( \mathcal{S}_\Sigma \) the connected component of \( \Sigma - P \), which contains \( b_2 \) and \( \Sigma'_P \) the other connected component of \( \Sigma - P \). If \( \Sigma_P \) is a pair of pants bounded by \( \gamma_P^1 \) for some \( k \in \{ 1, 2 \} \), \( b_2 \) and another \( b_i \) for \( i \geq 3 \) we have that \( \Omega_{\Sigma,P} = A_{\Sigma,P} \), and leave \( \Omega_{\Sigma_P} \) as is. We denote by \( \mathcal{P}_{\Sigma,b_1}^{c_{\Sigma,b_1}} \), the set of \([P]\)s leading to this situation. We observe that the contributions for \( k = 1 \) and 2 from \( \mathcal{P}_{\Sigma,b_1}^{c_{\Sigma,b_1}} \) are equal, since \( C_{P}^{b_{ij}} \) is invariant under braidings of its two last boundaries. The subset \( \mathcal{P}_{\Sigma,b_1}^{c_{\Sigma,b_1}} \subseteq \mathcal{P}_{\Sigma,b_1} \) will consist of those \([P]\)s for which \( \Sigma_P \) is not a pair of pants. For these we have that \( \Omega_{\Sigma,b_1} \) is given by the GR formula (29) with \( b_2 \) the chosen boundary, i.e. excise \( Q \) from \( \Sigma - P \) in all possible ways specified by \([Q] \in \mathcal{P}_{\Sigma - P,b_2}\). If \([Q] \in \mathcal{P}_{\Sigma - P,b_2}^{c_{\Sigma - P,b_2}} \), then it gives the contribution \( C_{P}^{b_{ij}} \) and if \([Q] \in \mathcal{P}_{\Sigma - P,b_2}^{c_{\Sigma - P,b_i}} \), for \( b_j \) a boundary component of \( \Sigma - P \) distinct from \( b_2 \), we get \( B_{Q}^{b_{b_i}} \).

- When \( c \in \mathcal{P}_{\Sigma,b_1}^{c_{\Sigma,b_1}} \), we have that \( \Omega_{\Sigma - P} \) is given by the GR formula (29) with \( \gamma_P \) as the chosen boundary component. We are therefore excising a second time with all possible \([Q] \in \mathcal{P}_{\Sigma - P,\gamma_P}\). If \([Q] \in \mathcal{P}_{\Sigma - P,\gamma_P}^{c_{\Sigma - P,\gamma_P}} \), then we get a \( C_{Q}^{b_{ij}} \), while if \([Q] \in \mathcal{P}_{\Sigma - P,\gamma_P}^{c_{\Sigma - P,\gamma_P}} \) for some \( i \geq 3 \) we get a \( B_{Q}^{b_{b_i}} \).
• When $c \in \mathcal{P}_{\Sigma,b_2}$ for $i \geq 3$, we have that $\Omega_{\Sigma-\gamma'}$ is given by the GR formula (29) with $b_2$ the chosen boundary component, i.e., perform a second excision specified by $[Q] \in \mathcal{P}_{\Sigma-\gamma'}$.

For $[Q] \in \mathcal{P}_{\Sigma-\gamma'}$, we get $B_{\gamma,Q}^{\gamma'}$. In the remaining cases, $[Q] \in \mathcal{P}_{\Sigma-\gamma'}$ for some $j \geq 3$ with $j \neq i$, we get a $B_{\gamma,Q}^{\gamma'}$.

Keeping in mind the constraint $\chi_{\Sigma} < -2$, this list exhausts all possible situations, in particular this process will not pull out contributions of a $D$. We also stress that $\Sigma'$ may be empty in some situations, in which case we use $\Omega_{\emptyset} = 1 \in \text{K}$ and the union axiom of § 3.1 for the emptyset. The result is

\[
\Omega_{\Sigma,b_1} = \sum_{i=3}^{n} \sum_{c \in \mathcal{P}_{\Sigma,b_1}} \Theta_{P}(C^{b_1}_{P}, A_{S_P}, \Omega_{S_P}) + \sum_{[P] \in \mathcal{P}_{\Sigma,b_2}} \sum_{[Q] \in \mathcal{P}_{\Sigma-\gamma'}} \frac{1}{2} \Theta_{P}(C^{b_1}_{P}, \Theta_{Q}(C^{b_2}_{Q}, \Omega_{\Sigma-\gamma'}-Q)) + \sum_{i=3}^{n} \sum_{[P] \in \mathcal{P}_{\Sigma,b_2}} \sum_{[Q] \in \mathcal{P}_{\Sigma-\gamma'}} \frac{1}{2} \Theta_{P}(C^{b_1}_{P}, \Theta_{Q}(B^{b_2}_{Q}, \Omega_{\Sigma-\gamma'}-Q))
\]

\[
+ \sum_{[P] \in \mathcal{P}_{\Sigma,b_2}} \sum_{[Q] \in \mathcal{P}_{\Sigma-\gamma'}} \frac{1}{2} \Theta_{P}(B^{b_1}_{P}, \Theta_{Q}(C^{b_1}_{Q}, \Omega_{\Sigma-\gamma'}-Q)) + \sum_{i=3}^{n} \sum_{[Q] \in \mathcal{P}_{\Sigma-\gamma'}} \Theta_{P}(B^{b_1}_{P}, \Theta_{Q}(B^{b_2}_{Q}, \Omega_{\Sigma-\gamma'}-Q))
\]

\[
+ \sum_{i=3}^{n} \sum_{[P] \in \mathcal{P}_{\Sigma,b_1}} \sum_{[Q] \in \mathcal{P}_{\Sigma-\gamma'}} \frac{1}{2} \Theta_{P}(B^{b_1}_{P}, \Theta_{Q}(C^{b_2}_{Q}, \Omega_{\Sigma-\gamma'}-Q)) + \sum_{i=3}^{n} \sum_{[Q] \in \mathcal{P}_{\Sigma-\gamma'}} \Theta_{P}(B^{b_1}_{P}, \Theta_{Q}(B^{b_2}_{Q}, \Omega_{\Sigma-\gamma'}-Q))
\]

\[
+ \sum_{j \geq 3} \sum_{i \neq 1} \Theta_{P}(B^{b_1}_{P}, \Theta_{Q}(B^{b_2}_{Q}, \Omega_{\Sigma-\gamma'}-Q)).
\]

We have ten multisums on the right, which we will denote $(\mathcal{S})_{i=1}^{10}$ respecting their order of appearance.

First we observe that $\mathcal{S}_2$ is a sum over the set of $([\gamma_P], [Q]) \in \mathcal{P}_{\Sigma,b_1} \times \mathcal{P}_{\Sigma,b_2}$, such that there exist non-intersecting representatives $\gamma_P$ and $\gamma_Q$ associated to $P$ and $Q$ respectively and cutting along $\gamma_P \cup \gamma_Q$ will not produce a component which is a pair of pants containing as boundaries $b_2$ and some other $b_i$ for some $i \geq 3$. This sum is manifestly invariant under $\sigma_{b_1,b_2}$. The same kind of argument also applies to $\mathcal{S}_{10}$.

Inspection of $\mathcal{S}_3 + \mathcal{S}_8$ reveals that the sum of these two terms must be invariant under $\sigma_{b_1,b_2}$, since we can use composition of gluings on one multicurve at a time.
Figure 9: Geometric origin of the ten terms (respecting their order) in (30).

We now consider $\mathcal{S}_9 + \mathcal{S}_7 + \mathcal{S}_1$. First we invoke composition of gluing for the summands in $\mathcal{S}_9$ and $\mathcal{S}_7$, so as to reduce each summand to one gluing along one multicurve. If we now compare the summands of $\mathcal{S}_9$, $\mathcal{S}_7$ and $\mathcal{S}_1$ with the three terms in the BB-CA relation, we find they match. We now reorganise the three multisums of $\mathcal{S}_9$, $\mathcal{S}_7$ and $\mathcal{S}_1$, into a sum over all possible isotopy classes of embeddings of a surface $X$ of genus 0 and 4 boundary components, where three of its boundary components go to $b_1, b_2$ and $b_i$, for some fixed $i \geq 3$, followed by a sum as in the BB-CA relation locally in each of these embedded surfaces $X$. For each embedding of $X$ we can now invoke the BB-CA relation to conclude that all together $\mathcal{S}_9 + \mathcal{S}_7 + \mathcal{S}_1$ is invariant under $\sigma_{b_1, b_2}$.

Finally, we consider $\mathcal{S}_4 + \mathcal{S}_5 + \mathcal{S}_6$. We reorganise these three sums to first be a sum over all isotopy classes of embeddings of a surface $X$ of genus zero and four boundary components, where two of its
boundary components goes to $b_1, b_2$ and the other two are mapped to the interior of $\Sigma$, followed by a sum as in the BC relation in each of these embedded surfaces $X$. Examining the summands of $S_4, S_5$ and $S_6$ and using associativity of gluings, we observe that for each embedding of $X$, we can now invoke the BC relation to conclude all together that $S_4 + S_5 + S_6$ is invariant under $\sigma_{b_1, b_2}$. □

**Remark 5.5** It is easy to see that this proof is still valid if the BB-CA relation is replaced by the relation

$$\left(\sigma_{b_1, b_2} - \text{Id}\right) \left(\sum_{[P] \in P_{b_2, \Sigma, b_1}} \Theta_P(B_{1, b_2}^{b_1}, B_{\Sigma, -P}^{b_3, \gamma_P}) + \sum_{[P] \in P_{b_2, \Sigma, b_1}} \Theta_P(B_{1, b_2}^{b_1}, B_{\Sigma, -P}^{b_3, \gamma_P}) + \sum_{[P] \in P_{b_2, \Sigma, b_1}} \Theta_P(C_{b_1}^{b_1} A_{\Sigma, -P})\right) = 0$$

(31)

obtained by replacing $B_{\Sigma, -P}^{b_2, \gamma_P}$ by $B_{\Sigma, -P}^{b_3, \gamma_P}$ in the BB-CA relation. This correspond to choosing $b_3$ instead of $\gamma_P$ as the reference boundary in the step 3 of the proof when $[P] \in P_{b_2, \Sigma, b_1}$. By the induction hypothesis, this choice does not affect the result.

### 5.3 Main properties

There is a forgetful functor $\mathcal{B}_1 \to \mathcal{B}_s$ which reverses the orientation of the boundary component and is compatible with union and glueing morphisms. If $E_s : \mathcal{B}_s \to \mathcal{C}$ is a symmetric target theory, the composition of this forgetful functor with $E_s$ gives a target theory $E$. If $(A, B, C, D)$ is an $E_s$-valued admissible initial data and $\Omega_\Sigma$ the outcome of symmetric GR, then $(A, B, C, D)$ can be considered as an $E$-valued convergent initial data in the obvious way. And, for this convergent initial data, GR generates $\Omega_\Sigma = \Omega_{\Sigma}$, as the defining formula (8) is identical to (29). This little argument shows that symmetric GR is a particular case of GR where the initial data satisfies extra relations. Therefore, all the properties listed in § 3.5-3.6 also hold for symmetric GR.

### 5.4 Strict symmetric GR

One can also formulate a symmetric version of the strict GR. The category $\mathcal{B}_s$ is constructed in the same way as $\mathcal{B}_1$, except that we replace pointed sets by sets. Strict symmetric target theories in this context are functors $e : \mathcal{B}_s \to \mathcal{C}$ satisfying axioms parallel to § 4.1.

**Definition 5.6** Initial data for strict symmetric GR is a quadruple $(A, B, C, D)$ where

$$A \in e(0, \{1, 2, 3\})^{\mathcal{B}_3}, \quad B \in e(0, \{1, 2, 3\}), \quad C \in e(0, \{1, 2, 3\})^{\mathcal{B}_{(2,3)}}, \quad D \in e(1, \{1\}).$$

We also require that the initial data satisfies the four relations below. The first three ones involve glueing maps in $(0, \{1, 2, 3, 4\})$, the last one glueing maps in $(2, \{1\})$, and $\sigma_{i,j}$ stands for the transposition of $i$ and $j$. In these formulas, $*$ stands for a distinguished element, $a$ and $b$ for extra elements, all outside of the original set $(1, 2, 3, 4)$.

**BA relation.**

$$\left(\sigma_{1,2} - \text{Id}\right) \left(\theta_{(0, \{ *, 3,4\})}(B, A) + \theta_{(0, \{ *, 2,4\})}(B, A) + \theta_{(0, \{ *, 2,3\})}(B, A)\right) = 0.$$

**BB-AC relation.**

$$\left(\sigma_{1,2} - \text{Id}\right) \left(\theta_{(0, \{ *, 3,4\})}(B, B) + \theta_{(0, \{ *, 2,4\})}(B, B) + \theta_{(0, \{ *, 2,3\})}(C, A)\right) = 0.$$
BC relation.

\[
(\sigma_{1,2} - \text{Id})(\theta_{(0,\{3,4\})}(B,C) + \theta_{(0,\{2,4\})}(C,B) + \theta_{(0,\{2,3\})}(C,B)) = 0.
\]

D relation.

\[
(\sigma_{1,2} - \text{Id})(\theta_{(1,\{1\})}(B,D) + \frac{1}{2}\theta_{(0,\{1,a,b\})}(C,A)) = 0.
\]

Given a strict symmetric target theory and initial data, we define \( w_s \in e(s) \) for any object \( s \) in \( \overline{B}_s \) by the same formulas as in Definition 4.3.

**Proposition 5.7** For any stable \((g,n)\), \( w_{g,n} \) is a well-defined element of \( e(g,n)^{\otimes n} \). In other words, \((g,n) \mapsto w_{g,n} \) is a functorial assignment from \( B_s \).

**Proof.** The proof uses the same recollection of terms as done in the proof of functoriality of the symmetric GR in Theorem 5.4, with only (heavily simplifying) difference that the sums over homotopy class is replaced by one of our \((0,3)\)-glueing maps, as is already apparent in comparing the 4 relations here to the 4 relations in § 5.1.

As explained for GR/symmetric GR in § 5.3, strict symmetric GR inherits in the obvious way the properties of strict GR described in Section 4.3, upon replacing everywhere pointed sets with sets.

### 6 Relation to topological recursion

This section gives examples of strict symmetric GR coming from the topological recursion (TR) and its many variants. There is nothing really new here, but we include these examples for pedagogical reasons. The most obvious class of example comes from two-dimensional topological quantum field theories (TQFTs). We then include in this formalism the Kontsevich-Soibelman approach to topological recursion (KS-TR) [19, 5] based on algebraic structures called “quantum Airy structures”, and review its relation with Eynard–Orantin topological recursion of [13] based on the geometry of spectral curves.

The strict GR can be described in some sense as a (possibly non-symmetric) generalisation of the TR of [13, 19], in which the complexity of the spaces \( e(g,\{1,\ldots,n\}) \) increases when \( 2g-2+n \) increases. This should be compared with Section 6.1-6.2, where these spaces do not depend on \( g \). Adopting this perspective, we may say in light of Corollary 4.6 that a natural transformation from a target theory to a strict target theory maps GR to TR. The richer structure which appears in the construction of GR due to infinite sums over homotopy class and mapping class group considerations is not seen at the level of the corresponding TR, as everything has been incorporated into finitely many glueing maps and the action of mapping class groups has been reduced to the action of permutation groups.

We nevertheless stress that target theories are allowed to contain much more information than their strict counterpart. Indeed, they are functors from the category \( B_1 \) which reflects \((2+1)\)-dimensional topology (surfaces and their mapping classes) while \( \overline{B}_1 \) only reflects the classification of 2-dimensional compact orientable manifolds and therefore has a simple combinatorial structure. One can find many examples of \( E(\Sigma) \) having a geometric meaning and carrying naturally non-trivial mapping class group actions. The gain between GR and strict GR will become clear in Section 8 and onwards, where we construct and use the first non-trivial examples of target theories based on Teichmüller spaces, and provide examples of natural transformations from GR to strict GR (in application of Proposition 4.7) by integration over moduli spaces.

34
6.1 Example from 2d TQFTs

We consider 2d TQFTs in the category Vect of finite-dimensional complex vector spaces to illustrate the idea – which is standard and elementary – but one may try to adapt a similar construction for more fancy, higher-categorical notions of TQFTs.

A 2d TQFT is equivalent to the data of a unital Frobenius algebra $A$, i.e. an object in Vect equipped with a pairing and a commutative associative product which is invariant for the pairing – see e.g. [7, 1]. Using the pairing, we have canonical identifications between $A$ and $A^*$, and therefore distinguished elements $b^i \in \text{Hom}(\text{Sym}^2(A^*), \mathbb{C})$, $\mu \in \text{Sym}^3(A^*)$, representing the pairing and the product. The TQFT amplitudes are the element

$$F_{g,n} \in \text{Hom}(A^\otimes n, \mathbb{C})$$

defined for any $(g,n)$ as follows. Take a pair of pants decomposition $(P_1, \ldots, P_{2g-2+n})$ of a connected surface of genus $g$ with $n$ boundaries, and form the tensor product

$$\left( \bigotimes_{i=1}^{2g-2+n} \mu \right) \in (A^*)^{6g-6+3n}.$$

Then, each time $P_i$ has a common boundary component with $P_j$, we use the pairing to contract a copy of $A$ in the $i$-th factor together with a copy of $A$ in the $j$-th factor. This makes a total of $3g-3+n$ pairings, so we are left with an element of $(A^*)^\otimes n = \text{Hom}(A^\otimes n, \mathbb{C})$ which is by definition $F_{g,n}$. The axioms of a Frobenius algebra implies that the result is independent of the choice of a pair of pants decomposition, and thus only depends on $g$ and $n$, and is symmetric under permutation of the $n$ remaining factors of $A$.

**Strict symmetric target theory.** Vect is a rather simple full subcategory of our category $\mathcal{C}$. For each stable $(g,n)$, we choose $e(g,n) = \text{Hom}(A^\otimes n, \mathbb{C})$. The union map comes from the tensor product (in this case the functor $e$ is monoidal) and the morphisms are composition of tensors – using as many times as necessary the canonical identification $A \simeq A^*$.

**Initial data.** We take $A = B = C = \mu$ representing the product. We also take $D = \langle H, \cdot \rangle$ where $H = \sum_i c_i^2$ in terms of an orthogonal basis $(e_i)_i$. The four relations characterising symmetric initial data are satisfied because, in each of them, each of the three terms in the left-hand side are separately symmetric under the permutation $\sigma_{1,2}$ due to the properties of the product.

**The amplitudes.** With this initial data, it is easy to see that $w_{1,1} = F_{1,1} = D$, and to prove recursively that, if one writes the $w_{g,n}$ as sum over the set $G_{g,n}$ of fatgraphs described in Section 3.6, each term uniquely defines a topological class of a pair of pants decomposition, and the value assigned to each fatgraph is by construction the TQFT amplitude $F_{g,n}$. So, for any $2g-2+n > 0$, the strict GR amplitudes are

$$w_{g,n} = \# G_{1}^{g,n} \cdot F_{g,n}.$$ 

6.2 Example from quantum Airy structures

A larger class of examples of strict symmetric GR is provided by the approach of Kontsevich-Soibelman approach to topological recursion [19, 5].

We first outline this theory. Let $V$ be a vector space over $\mathbb{C}$, which we here assume to be finite-dimensional for simplicity. One can easily handle infinite-dimensionality if equipped with an increasing
filtration by finite-dimensional subspaces. Let $\mathcal{W}_V^h$ be the Weyl algebra of $V$, i.e. the unital algebra generated over $\mathbb{C}[[\hbar]]$ by $T^*V = V \oplus V^*$ with relations

$$\forall (v, \lambda) \in V \times V^*, \quad [v, \lambda] = \hbar \lambda(v) \in \mathbb{C}[[\hbar]].$$

**Definition 6.1** A quantum Airy structure is the data of a linear map $L : V \to \mathcal{W}_V^h$ such that there exists a basis $(x_i)_{i \in I}$ of linear coordinates on $V$ in which $L$ takes the form

$$L_i = \hbar \partial x_i - \sum_{a,b \in I} \left( \frac{1}{2} A_{a,b}^i x_a x_b - \hbar B_{a,b}^i x_a \partial x_b - \frac{\hbar^2}{2} C_{a,b}^i \partial x_a \partial x_b \right) - \hbar D^i,$$

and satisfies the Lie algebra relations

$$\forall (i,j) \in I^2, \quad [L_i, L_j] = \sum_{a \in I} h f_{i,j}^a L_a$$

for some scalars $A_{j,k}^i = A_{k,j}^i$, $B_{j,k}^i$, $C_{j,k}^i = C_{k,j}^i$, $D^i$ and $f_{i,j}^k = -f_{j,i}^k$.

This notion is closely related to the quantization of Lagrangians in $T^*V$ which are tangent to the zero section at $0$ and defined by quadratic equations. The constraints (32) impose relations on the coefficients of $L$.

**Lemma 6.2** [5] Equation (32) is equivalent to the system of equations indexed by $i,j,k,\ell \in I$

1. $A_{j,k}^i = A_{k,j}^i$.
2. $f_{i,j}^k = B_{j,k}^i - B_{i,k}^i$.
3. $\sum_{a \in I} B_{j,a}^i A_{k,a}^j + B_{k,a}^i A_{\ell,a}^j + B_{\ell,a}^i A_{a,k}^j = (i \leftrightarrow j)$.
4. $\sum_{a \in I} B_{j,a}^i B_{k,a}^j + B_{k,a}^i B_{\ell,a}^j + C_{\ell,a}^j A_{a,k}^j = (i \leftrightarrow j)$.
5. $\sum_{a \in I} B_{j,a}^i C_{k,a}^j + C_{k,a}^i B_{\ell,a}^j + C_{\ell,a}^j B_{a,k}^j = (i \leftrightarrow j)$.
6. $\sum_{a \in I} B_{j,a}^i D^a + \frac{1}{2} \sum_{a,b \in I} C_{a,b}^i A_{a,b}^j = (i \leftrightarrow j)$.

The third, fourth and fifth relation have the same index structure, and take the form of H-I-X relations. This was explained from a Lie algebraic perspective in [5]. The structure of the axioms for the initial data of the (strict) symmetric GR in Section 5 is modelled on these relations. In the non strict case, it gives them geometric content as coming from different (homotopy class of) pair of pants decompositions of a sphere with four boundaries.

We can also assemble the coefficients of a quantum Airy structure into tensors

$$A \in \text{Hom}(V \otimes^3 \mathbb{C}), \quad B \in \text{Hom}(V \otimes V, V), \quad C \in \text{Hom}(V, V \otimes V), \quad D \in \text{Hom}(V, \mathbb{C}),$$

and the relations in Lemma 6.2 are then tensorial relations, where the sum over intermediate indices are replaced by composition of linear maps.

To any quantum Airy structure, one may associates amplitudes $F_{g,n} \in \text{Hom}(V^\otimes n, \mathbb{C})$ in the following way.
Theorem 6.3 \cite{19, 5} Let $L$ be a quantum Airy structure. There exists a unique $F \in \mathcal{h}^{-1}(\text{Sym} V^*)[[\mathcal{h}]]$ without constant term, which we can decompose into

$$F = \sum_{g \geq 0} \frac{\mathcal{h}^{g-1}}{n!} F_{g,n}, \quad F_{g,n} \in \text{Sym}^n V^*,$$

and such that $F_{0,1} = 0$, $F_{0,2} = 0$ and

$$\forall i \in I, \quad L_i \cdot \exp(F) = 0.$$

In fact, $F_{g,n}$ is uniquely determined by the initial data $F_{0,3} = A$ and $F_{1,1} = D$, and a recursion on $2g-2+n > 0$. If we denote $(e_i)_{i \in I}$ the basis of $V$ mentioned in Definition 6.1, and

$$F_{g,n}[i_1, \ldots, i_n] := F_{g,n}(e_{i_1} \otimes \cdots \otimes e_{i_n}),$$

this recursion takes the form

$$F_{g,n}[i_1, \ldots, i_n] = \sum_{m=2}^{n} \sum_{a \in I} B^i_{i_m,a} F_{g,n-1}[a, i[2,n] \setminus \{m\}] + \sum_{a, b \in I} \frac{1}{2} C^i_{a,b} \left( F_{g-1,n+1}[a, b, i[2,n]] + \sum_{h+h'=g} F_{g,1+\#J}[a, J] F_{g',1+\#J'}[b, J'] \right).$$

(33)

Here $\exp(F)$ is sometimes called the partition function or wave function, and this theorem characterises it as the solution of differential constraints forming a Lie algebra. The only point which may not be obvious is the existence of $F$ – which amounts to prove symmetry of the $F_{g,n}$ obtained by the recursion (33). This theorem is proved by a general argument in \cite{19}, and by direct computation from Lemma 6.2 in \cite{5}.

**Strict symmetric target theory.** For any stable $(g,n)$, we put $e(g,n) = \text{Hom}(V^{\otimes n}, \mathbb{C})$. The union map is provided by the tensor product, and the gluing map by the composition of linear maps.

**The amplitudes.** The constraints on the tensors $(A, B, C, D)$ described in Lemma 6.2 are exactly the ones characterising symmetric initial data. This is in fact the reason why we have postulated these relations in Definition 5.6, as well as their non-strict counterpart in Definition 5.2. The proof of Theorem 5.4 (of which Proposition 5.7 was a direct consequence) follows the same scheme as the proof of symmetry of $F_{g,n}$ in \cite{5}, except that it incorporates homotopy class considerations (which are absent in the strict version). Comparison of (33) with Definition 4.3 shows directly that $F_{g,n} = w_{g,n}$.

**Remark 6.4** The third constraint in Lemma 6.2 motivates the adoption of the BB-CA relation instead of the relation (31) in the definition of symmetric initial data for GR. Indeed, only the BB-CA relation implies this third constraint when we apply a natural transformation to a strict target theory.

### 6.3 Relation to Eynard–Orantin formalism

The original topological recursion of Eynard–Orantin \cite{15} and all its variants formulated in terms of spectral curves determine quantum Airy structures \cite{19, 5} and therefore provide examples of strict symmetric GR. For later use in Section 10.3, we briefly describe this relation. Spectral curves $(S, x, y, \omega_{0,2})$
with simple ramification points provide examples of Airy structures on the vector space $V = \mathcal{A}[[\zeta^2]]$, where $\mathcal{A} = \oplus_{r \in \mathbb{C}} c_r$ and $r \subset S$ is the set of ramification points of $x$. We define a basis of $V$

$$\xi_{r,d}^*(\zeta) = \frac{\zeta^{2d+1}}{(2d+1)!} e_r, \quad (d, r) \in \mathbb{N} \times \tau$$

We have $T^* V = \mathcal{A}[[\zeta^{-2}, \zeta^2]]d\zeta$ and we make it a symplectic vector space with the skew-symmetric 2-form

$$\langle f_1, f_2 \rangle = \text{Res}_{\zeta = 0} \left( f_1 \left| \int \frac{f_2}{\zeta} \right. \right)_{\mathcal{A}}$$

where $(\cdot, \cdot)_{\mathcal{A}}$ is the symmetric pairing making $(e_r)_{r \in \tau}$ orthonormal. We already have an isotropic subspace $dV \subset T^* V$, and the data of $\omega_{0,2}$ specifies another isotropic subspace $V'$ such that $dV \oplus V' = T^* V$, as follows. We first define the basis of 1-forms on $S$ indexed by $d \geq 0$ and $r \in \tau$

$$d\xi_{r,d}(z_0) = \text{Res}_{z = r} \left( \frac{(2d+1)!}{\zeta^{2d+2}} \int_{r}^{z} \omega_{0,2}(\cdot, z_0) \right)$$

where we use the local coordinate $\zeta(z) = \sqrt{2(x(z) - x(r))}$ when $z$ is in the neighborhood of $r$. The Laurent expansion of $d\xi_{r,d}$ near $z \to r'$ defines an element $\xi_{r,d}^{(r')} \in \mathbb{C}[\zeta^{-1}, \zeta^1]d\zeta$. We then set

$$\xi_{r,d}(\zeta) = \sum_{r \in \tau} \xi_{r,d}^{(r')}(\zeta) - \xi_{r,d}^{(r')}(-\zeta)$$

which indeed gives an isotropic subspace supplement to $dV \subset T^* V$. The amplitudes $F_{g,n} \in \mathcal{A}^n$ of Theorem 6.3 give the decomposition of the Eynard–Orantin multidifferentials $\omega_{g,n} \in H^0(S^n, K_S(*t)^{\otimes n})_{\mathbb{R}}^*$ on the basis (34), that is for $2g - 2 + n > 0$

$$\omega_{g,n}(z_1, \ldots, z_n) = \sum_{d_1, \ldots, d_n \geq 0} F_{g,n}(\xi_{r_1,d_1} \otimes \cdots \otimes \xi_{r_n,d_n}) \otimes_{i=1}^{n} \xi_{r_i,d_i}(z_i)$$

and the sum truncates to $d_1 + \cdots + d_n \leq 2g - 2 + n$.

7 Teichmüller theory background

7.1 Teichmüller spaces

Let $\Sigma$ be a stable bordered surface. If we consider the space of smooth metrics modulo conformal equivalence on $\Sigma$, we obtain a space of conformal classes of metrics on $\Sigma$, which is a $\text{Diff}_0(\Sigma, \partial \Sigma)$ fiber bundle over Teichmüller space. Here $\text{Diff}_0(\Sigma, \partial \Sigma)$ is the group of diffeomorphisms of $\Sigma$, which are isotopic to the identity relatively to the boundary (see e.g. [11]).

Then, $T_{\Sigma}$ is in bijection with the set of hyperbolic metrics on $\Sigma$, for which the boundaries are geodesic, modulo diffeomorphisms which are isotopic to the identity relatively to the boundary. We further recall that when $\Sigma$ has type $(g, n)$, $T_{\Sigma}$ is a smooth manifold of dimension $6g - 6 + 3n$.

We denote $T_{\partial \Sigma} = \mathbb{R}^+_{\text{pos}}(\partial \Sigma)$ and $p_{\partial} : T_{\Sigma} \to T_{\partial \Sigma}$ the perimeter map. We stress that $\mathbb{R}^+_{\text{pos}}$ is the real positive axis, excluding $0$. If $L$ is an assignment of positive real numbers to the boundary components of $\Sigma$, we denote $T_{\Sigma}(L) = p_{\partial}^{-1}(L)$.

We can of course also describe the Teichmüller space in terms of complex structures on $\Sigma$, e.g. $T_{\Sigma}$ is also the set of equivalence classes of diffeomorphisms $\mu$ from $\Sigma$ to a bordered Riemann surface $S$. If $\mu_i : \Sigma \to S_i$ with $i = 1, 2$ are two diffeomorphisms as above, we declare them equivalent if there exists a biholomorphic map $\Phi : S_1 \to S_2$, such that $\mu_2^{-1} \circ \Phi \circ \mu_1$ is isotopic to the identity on $\Sigma$ among such
diffeomorphisms. When $\Sigma$ is stable, the pure mapping class group $\Gamma^0_{\Sigma}$ acts on the Teichmüller spaces $\mathcal{T}_\Sigma$ and $\mathcal{T}_\Sigma(L)$ properly discontinuously, possibly with finite stabilizers: the quotients are the moduli spaces $\mathcal{M}_\Sigma$ and $\mathcal{M}_\Sigma(L)$.

7.2 Bounds on the number of multicurves

If $\sigma$ is a hyperbolic metric on $\Sigma$ and $\gamma$ is a simple closed curve, there is a unique shortest geodesic in the homotopy class of $\gamma$, and we denote $\ell_\sigma(\gamma)$ its length. The length of a multicurve is by definition the sum of lengths of its components.

The length spectrum is the sequence $(l_{\sigma,i})_{i \geq 1}$ of lengths of isotopy classes of simple closed curves (which are not isotopic to the boundary) in $\Sigma^0$, in weakly increasing order. The systole $\text{sys}_\sigma = l_{\sigma,1}$ is the shortest of these lengths. We will exploit the following result.

**Lemma 7.1** Let $\varepsilon \in (0,1)$. Let $\sigma$ be a hyperbolic metric on a connected bordered surface $\Sigma$ with non-zero boundary lengths. For any $t \in [0, \ell_\sigma(\partial \Sigma))$ there exists another hyperbolic metric $\tilde{\sigma}$ on $\Sigma$ such that

- $t = \ell_{\tilde{\sigma}}(\partial \Sigma) < \ell_\sigma(\partial \Sigma)$.
- $l_{\tilde{\sigma},i} \leq \ell_{\sigma,i}$ for any $i \geq 1$.
- if $l_{\sigma,i} < \varepsilon$, then $l_{\tilde{\sigma},i} = l_{\sigma,i}$.
- if $l_{\sigma,i} \geq \varepsilon$, then $l_{\tilde{\sigma},i} \geq \varepsilon$.

**Proof.** We use a slight modification of the proof of [24, Theorem 3.3], which Hugo Parlier communicated to us. By the collar lemma, two simple closed geodesics of length $\varepsilon \leq 1 \leq 2 \ln(1 + \sqrt{2})$ cannot intersect. Let $\sigma(0)$ be a hyperbolic metric on $\Sigma$. We introduce the set $S_0$ of $\gamma \in \mathcal{S}_1^0(\Sigma)$ such that $\ell_{\sigma(0)}(\gamma) \leq \varepsilon$, and denote $\Sigma_0 := \Sigma$. We denote $\Sigma_0'$ the surface obtained by cutting $\Sigma_0$ along each of the curves which belong to $S_0$. We are going to construct for each $t \in [0, \ell_\sigma(\partial \Sigma))$ a finite set of simple closed curves $S_t$ and hyperbolic metric $\sigma(t)$ on $\Sigma$ such that

$$\ell_{\sigma(t)}(\partial \Sigma) = \ell_\sigma(\partial \Sigma) - t, \quad \forall i \geq 1, \quad l_{\sigma(t),i} \leq l_{\sigma(0),i}. \tag{36}$$

In this process we will always denote $\Sigma'_t$ the surface $\Sigma_t$ cut along the geodesics that represent the elements of $S_t$. We start to decrease the length as in [24, Theorem 3.3.1] on each boundary component of the connected components of $\Sigma'_0$ which do not belong to $S_0$, so that the length spectrum of $\Sigma_0$ decreases continuously. This defines a new hyperbolic metric $\sigma(t)$ satisfying (36) for $t \geq 0$ small enough and we keep $S_t := S_0$. If for $t \in [0, \ell_\sigma(\partial \Sigma))$ all simple closed geodesics which are not in $S_t$ have $\sigma(t)$-length $> \varepsilon$, the algorithm terminates. Otherwise, there exists a minimal $t^* \in (0, \ell_{\sigma(0)}(\partial \Sigma))$ such that some simple closed geodesic in $\Sigma$ has $\sigma(t^*)$-length $\varepsilon$. We add all of those curves to $S_t$ ($= S_0$ if $t < t^*$) to form an updated set $S_{t^*}$. We then continue to decrease the length of the boundary components of $\Sigma'_t$ which are not elements of $S_t$, continuously decreasing the $\sigma(t)$-length spectrum, and repeat our update each time we meet simple closed geodesics of $\sigma(t)$-length exactly $\varepsilon$. For any $t$, the curves collected in $S_t$ cannot intersect due to the previous observation, and there are at most $3g-3+n$ non-intersecting simple closed geodesics in the interior of a surface of genus $g$ with $n$ boundary components. Therefore, $\# S_t \leq 3g-3+n$ for any $t$, and $S$ can only be updated finitely many times. The construction makes sure that for all $t$, the two last requirements hold, while (36) meets the two first requirements. \qed
We will need a well-known estimate on the number of multicurves of bounded length, which we can make uniform in the boundary length using the previous lemma. We also state a similar estimate for multicurves not intersecting a given one, which will be used in Section 8.2.

**Theorem 7.2** Let $\Sigma$ be a surface of type $(g,n)$ and $\mu$ a fixed primitive multicurve in $\Sigma$ with $k$ components. For any $\varepsilon \in (0,1)$, there exists $N_\varepsilon > 0$ depending only on $(g,n,\varepsilon)$ such that, for any $\sigma \in \mathcal{I}_\Sigma$ and $L > 0$

\[
\#\{ c \in M_\Sigma \mid \ell_\sigma(c) \leq L \text{ and } c \cap \mu = \emptyset \} \leq N_\varepsilon L^{6g - 6 + 2(n - k)} \prod_{\gamma \in S_\Sigma} \frac{1}{L_\sigma(\gamma)}
\]

In particular, if $\mu = \emptyset$ and $\text{sys}_\sigma \geq \varepsilon$, the right-hand side is equal to $N_\varepsilon L^{6g - 6 + 2n}$.

**Proof.** We first assume $\mu = \emptyset$. We start from the result of Mirzakhani [22, Proposition 3.6] stating that, if $(\Sigma, \tilde{\sigma})$ only has punctures (i.e., boundaries of length 0), for any $\varepsilon \in (0,1)$, there exists a constant $N'_\varepsilon > 0$ depending only on $(\varepsilon, g, n)$ such that

\[
\#\{ c \in M_\Sigma \mid \ell_\tilde{\sigma}(c) \leq L \} \leq N'_\varepsilon L^{6g - 6 + 2n} \prod_{\gamma \in S_\Sigma} \frac{1}{L_\tilde{\sigma}(\gamma)}
\]  

(37)

If $\sigma$ is a hyperbolic metric on $\Sigma$ with non-zero boundary lengths, Theorem 7.1 provides us with $\tilde{\sigma}$ having punctures, such that $l_{i,\tilde{\sigma}} \leq l_{i,\sigma}$ for any $i \geq 1$, and

\[
\prod_{\gamma \in S_\Sigma} \frac{1}{L_\tilde{\sigma}(\gamma)} \geq e^{3g - 3 + n} \prod_{\gamma \in S_\Sigma} L_\sigma(\gamma)
\]

The prefactor of $\varepsilon$ represent the short curves with respect to $\tilde{\sigma}$ which were not short for $\sigma$: by design they cannot have length shorter than $\varepsilon$ and there cannot be more than $3g - 3 + n$ of them. Therefore

\[
\#\{ c \in M_\Sigma \mid \ell_\sigma(c) \leq L \} \leq N_\varepsilon L^{6g - 6 + 2n} \prod_{\gamma \in S_\Sigma} \frac{1}{L_\sigma(\gamma)}
\]

for another constant $N_\varepsilon$ depending only on $(\varepsilon, g, n)$. When $\mu \neq \emptyset$, we apply this result for $\Sigma^\mu$ to conclude. $\square$

### 7.3 Bounds on the number of small pairs of pants

**Definition 7.3** Given a connected $\Sigma$ in $\mathcal{B}_1$, we say that $[P] \in \mathcal{P}_\Sigma$ is (the homotopy class of) a $\sigma$-small pair of pants if

\[
\ell_\sigma(\partial P \cap \Sigma^0) \leq \ell_\sigma(\partial P \cap \partial \Sigma)
\]

In other words, if $[P] \in \mathcal{P}_\Sigma^0$, for some $b \in \pi_0(\partial, \Sigma)$, this means $\ell_\sigma(\gamma_P) \leq \ell_\sigma(b_1) + \ell_\sigma(b)$, while if $[P] \in \mathcal{P}_\Sigma^0$, this means $\ell_\sigma(\gamma_P^0) + \ell_\sigma(\gamma_P^0) \leq \ell_\sigma(b_1)$.

In this paragraph we prove a finiteness result for small pairs of pants.

**Proposition 7.4** For any $\varepsilon \in (0,1)$ and $\sigma \in \mathcal{I}_\Sigma$ such that $\text{sys}_\sigma \geq \varepsilon$, the number of $\sigma$-small pairs of pants in a surface $\Sigma$ of type $(g,n)$ with respect to $\sigma$ is upper bounded by a constant $Q_{g,n,\varepsilon} > 0$.

The proof, to which Parlier contributed, relies on the following lemma which provides a uniform estimate on the number of closed curves, and is a variant of [10, Lemma 6.6.4] proved in [25, Lemma 2.4].
Lemma 7.5 Let $(\Sigma, \sigma)$ be a hyperbolic surface of genus $g \geq 2$ without boundaries. The number of primitive closed geodesics of length smaller than $L > 0$ is bounded by $(g - 1)e^{L/2}$. ■

Proof of Proposition 7.4. Let us fix $\sigma \in \mathcal{T}_\Sigma$. For each $[P] \in \mathcal{P}_\Sigma$, there is a unique representative of $[P]$ embedded with geodesic boundaries in $\Sigma$ of respective lengths $L_1, L_2, L_3$. This hyperbolic pair of pants can be obtained by gluing two hyperbolic right-angled hexagons, whose boundary arcs have successive lengths $(L_1/2, d_{1,2}, L_2/2, d_{2,3}, L_3/2, d_{1,3})$, with separate identification of the second, fourth and sixth boundary arcs – which are called “seams”. Then $d_{i,j}$ is the distance between the $i$-th and $j$-th boundaries in $P$.

Fix $b \in \pi_0(\partial_i \Sigma)$. For $[P] \in \mathcal{P}_b^\partial$, the ordering of boundary components of $P$ is such that $L_1 = \ell_\sigma(b_1)$, $L_2 = \ell_\sigma(b)$ and $L_3 = \ell_\sigma(\gamma_P)$. We recall from Section 2.3 that $[P]$ is uniquely determined by the free homotopy class (in $\Sigma$) of the seam $c_P$ between $b_1$ and $b$ (that is, between the first and the second boundary of $P$), which has length $d_{1,2}$. Hyperbolic trigonometry (see e.g. [10]) gives

$$\cosh(d_{1,2}) = \frac{\cosh(L_3/2) + \cosh(L_1/2)\cosh(L_2/2)}{\sinh(L_1/2)\sinh(L_2/2)} \tag{38}$$

Let us fix $\varepsilon < 1$ and assume $L_1, L_2 \geq \varepsilon$. Using the elementary bounds

$$\frac{1}{2}e^x \leq \cosh(x) \leq e^x \quad x \geq 0$$
$$\sinh(x/2) \geq \frac{1}{2}e^{x/2} \quad x \geq \varepsilon$$
$$\cotanh(x) \leq \frac{2}{x} \quad x \geq \varepsilon$$

we deduce that

$$\frac{e^{d_{1,2}}}{2} \leq \frac{1 + e^{(L_3 - L_2 - L_1)/2}}{(\varepsilon/2)^2}$$

For $\sigma$-small pairs of pants, we have $L_3 \leq L_2 + L_1$ hence

$$d_{1,2} \leq 2\ln(4/\varepsilon).$$

By considering the image of $c_P$ in the double of $\Sigma$, which is a closed surface of genus $g^d = 2g + n - 1$, the subset of $\sigma$-small pairs of pants in $\mathcal{P}_\Sigma^\partial$ injects into the set of primitive closed geodesics of length bounded by $4\ln(4/\varepsilon)$. Therefore, there are less than $(2g - 2 + n)e^6(4/\varepsilon)^4 \sigma$-small pairs of pants of this type. This is a fortiori true assuming $\text{sys}_\sigma \geq \varepsilon$.

For $[P] \in \mathcal{P}_\Sigma^\partial$, the ordering of the boundary is such that $L_1 = \ell_\sigma(b_1)$, $L_2 = \ell_\sigma(\gamma_{b_1}^1)$ and $L_3 = \ell_\sigma(\gamma_{b_1}^2)$. Likewise, $[P]$ is uniquely determined by the free homotopy class (in $\Sigma$) of the curve $c_P$ that starts from $b_1$, travel in the first hexagon to reach the seam in between $\gamma_{b_1}^1$ and $\gamma_{b_1}^2$ (the second and third boundaries in $P$) and comes back to $b_1$ through the second hexagon. By hyperbolic trigonometry in one of the pentagon cut out by $c_P$ in the first hexagon, we have

$$\cosh(\ell_\sigma(c_P)/2) = \frac{\sinh(d_{1,2})\sinh(L_2/2)}{\sqrt{\sinh^2(L_1/2) + \cosh^2(L_3/2) + \cosh^2(L_2/2) + 2\cosh(L_1/2)\cosh(L_2/2)\cosh(L_3/2)}}$$

With elementary bounds we get under the assumption $L_1 \geq \varepsilon$

$$\frac{e^{\ell_\sigma(c_P)}}{4} \leq \frac{1 + e^{L_3 - L_1} + e^{L_2 - L_1} + 2e^{(L_3 - L_2 - L_1)/2}}{(\varepsilon/2)^2}$$

For $\sigma$-small pairs of pants, we have $L_2 + L_3 \leq L_1$ and a fortiori $L_3 \leq L_1$ and $L_2 \leq L_1$. Since $1 < 4/\varepsilon$, we obtain

$$\ell_\sigma(c_P) \leq \ln(128/\varepsilon^2).$$

Repeating the previous argument we deduce that there are less than $(2g - 2 + n)e^6(128/\varepsilon^2)^2 \sigma$-small pairs of pants in $\mathcal{P}_\Sigma^\partial$ whenever $\ell_\sigma(b_1) \geq \varepsilon$, and a fortiori when $\text{sys}_\sigma \geq \varepsilon$. □

41
7.4 Comparing different hyperbolic metrics

If $\Sigma$ does not have boundaries, the Teichmüller distance $d_T$ makes $\mathcal{T}_\Sigma$ a complete metric space. We can use $d_T$ to compare lengths of curves with respect to different metrics on $\Sigma$, due to the following result of Wolpert.

**Theorem 7.6** [28, Lemma 3.1]. Let $\Sigma$ be a surface without boundaries, and $\gamma$ a non-null homotopic simple closed curve. Then for any two hyperbolic metrics $\sigma, \sigma'$ on $\Sigma$

$$e^{-2d_T(\sigma, \sigma')} \leq \frac{\ell_{\sigma'}(\gamma)}{\ell_{\sigma}(\gamma)} \leq e^{2d_T(\sigma, \sigma')}$$

The result is also true if $\Sigma$ has boundaries, provided we use the Teichmüller distance on $\mathcal{T}_{\Sigma^d}$, where recall that $\Sigma^d$ is the surface without boundary obtained by doubling $\Sigma$ along $\partial \Sigma$.

**Remark 7.7** If $\phi : \Sigma \to \Sigma'$ is a morphism between surfaces in $\mathcal{B}$, then $\phi$ induces a continuous map $\mathcal{T}_\Sigma \to \mathcal{T}_{\Sigma'}$ which is an isometry for the respective Teichmüller distances.

8 Functions on Teichmüller space

The first non-trivial example of target theories comes from spaces of functions on Teichmüller spaces. If $X$ is a topological space, $\mathcal{F}(X)$ denotes either the space $\mathbb{R}^X$ of all functions, or the space $\mathcal{M}(X)$ of all measurable functions, or the space $\mathcal{C}^0(X)$ of all continuous functions.

8.1 Target theory and geometric recursion

If $\varepsilon > 0$, we denote $\mathcal{T}_\Sigma^\varepsilon = \{ \sigma \in \mathcal{T}_\Sigma \mid \forall \gamma \in S_\Sigma \quad \ell_{\sigma}(\gamma) \geq \varepsilon \}$

the $\varepsilon$-thick part of the Teichmüller space. In other words, $\sigma$ belongs to the $\varepsilon$-thick part if the systole and the length of each boundary component are bounded below by $\varepsilon$.

**VECTOR SPACES AND TOPOLOGY** – We take $\mathcal{F}_\Sigma = (0, 1)$ and for any $\varepsilon \in (0, 1)$, we let $E^\varepsilon(\Sigma) = \mathcal{F}(\mathcal{T}_\Sigma^\varepsilon)$.

If $\sigma \in \mathcal{T}_\Sigma^\varepsilon$, we set

$$F_{\varepsilon, \sigma} = \left\{ \sigma' \in \mathcal{T}_\Sigma^\varepsilon : \sup_{\gamma \in S_\Sigma} \left| \ln \frac{\ell_{\sigma'}(\gamma)}{\ell_{\sigma}(\gamma)} \right| \leq 2 \right\}$$

By Theorem 7.6, $F_{\varepsilon, \sigma}$ contains the ball of radius 1 centered at $\sigma$ for the Teichmüller distance. We equip $E^\varepsilon(\Sigma)$ with the semi-norms indexed by $\mathcal{F}_\Sigma^\varepsilon = \mathcal{F}(\mathcal{T}_\Sigma^\varepsilon)$

$$|f|_{\varepsilon, \sigma} = \sup_{\sigma' \in F_{\varepsilon, \sigma}} |f(\sigma')|$$

This makes $E^\varepsilon(\Sigma)$ a locally convex, complete Hausdorff topological vector space which is functorial in $\Sigma$. The projective limit of these spaces is $E(\Sigma) = \mathcal{F}(\mathcal{T}_\Sigma)$. Since any compact can be covered by finitely many balls of radius 1 for the Teichmüller distance, the topology on $E(\Sigma)$ is the topology of convergence on any compact, and the map $\varrho_\varepsilon : E(\Sigma) \to E^\varepsilon(\Sigma)$ consists in restricting the domain of a function on Teichmüller space to the $\varepsilon$-thick part.

**UNION MORPHISMS** – Using the canonical homeomorphism $\mathcal{T}_{\Sigma_1 \cup \Sigma_2} \cong \mathcal{T}_{\Sigma_1} \times \mathcal{T}_{\Sigma_2}$, we define the union morphism for $f_1 \in E(\Sigma_i)$ and $(\sigma_1, \sigma_2) \in \mathcal{T}_{\Sigma_1 \cup \Sigma_2}$ by

$$(f_1 \cup f_2)(\sigma_1, \sigma_2) = f_1(\sigma_1)f_2(\sigma_2)$$
Gluing morphisms – If \([P] \in \mathcal{P}_\Sigma\) and \(\sigma \in \mathcal{T}_\Sigma\), there is a unique representative \(f : P \to \Sigma\) of \([P]\) such that \(f(P)\) has geodesic boundaries with respect to \(\sigma\). We denote \(\sigma_P\) and \(\sigma_{\Sigma - P}\) the restriction of the hyperbolic metric \(\sigma\) to \(f(P)\) and \(\Sigma \setminus f(P)\), which are indeed hyperbolic metrics for which the boundary components of the two subsurfaces are geodesic. We take as the glueing of \(f_1 \in E(\Sigma)\) and \(f_2 \in E(\Sigma - P)\) evaluated at \(\sigma \in \mathcal{T}_\Sigma\)

\[ \Theta_P(f_1, f_2)(\sigma) = f_1(\sigma_P)f_2(\sigma_{\Sigma - P}) \]

Lemma 8.1 \(\bigcirc\) and \(\Theta_P\) are bilinear morphisms in the category \(\text{Pro-}\mathcal{V}\).

Proof. As the case of \(\bigcirc\) follows similar steps but is simpler, we only discuss the glueing morphism. Due to the inclusion \(S_P \cup S_{\Sigma - P} \subseteq S_\Sigma\), we know that if \(\varepsilon \in (0,1)\) and \(\sigma\) is in the \(\varepsilon\)-thick part of \(\mathcal{T}_\Sigma\), the restrictions \(\sigma_P\) and \(\sigma_{\Sigma - P}\) are also in the \(\varepsilon\)-thick part of their respective Teichmüller spaces. We can therefore take \(h_\varepsilon = (\varepsilon, \varepsilon)\) in the definition 3.3 of bilinear morphisms and it suffices to check the continuity of the map

\[ \Theta_P^{\varepsilon,\varepsilon} : E_\varepsilon(P) \times E_\varepsilon(\Sigma - P) \to E_\varepsilon(\Sigma). \]

If \(\sigma \in \mathcal{A}_\Sigma^\varepsilon\), we note that that the image of \(F_{\varepsilon,\sigma}\) via the restriction maps \(q_P : \mathcal{T}_\Sigma \to \mathcal{T}_P\) and \(q_{\Sigma - P} : \mathcal{T}_\Sigma \to \mathcal{T}_{\Sigma - P}\) are respectively included in \(F_{\varepsilon,\sigma_P}\) and \(F_{\varepsilon,\sigma_{\Sigma - P}}\). Therefore

\[ |\Theta_P^{\varepsilon,\varepsilon}(f_1, f_2)|_{\varepsilon,\sigma} \leq |f_1|_{\varepsilon,\sigma_P} |f_2|_{\varepsilon,\sigma_{\Sigma - P}} \]

which ensures continuity. \(\square\)

So far, we have obtained a pre-target theory. We use the hyperbolic length to induce length functions turning it into a target theory.

Length functions – For any \(\varepsilon \in (0,1)\) and \(\sigma \in \mathcal{A}_\Sigma^\varepsilon\), we let

\[ l_{\varepsilon,\sigma}(\gamma) = \ell_{\sigma}(\gamma) \]  

(41)

As a direct consequence of Theorem 7.2 and Proposition 7.4, we have

Lemma 8.2 The length functions satisfy the polynomial growth, the small pair of pants and the restriction axioms of Section 3.2, and turn \(E(\Sigma) = \mathcal{F}(\mathcal{T}_\Sigma)\) into a target theory. \(\blacksquare\)

Initial data and admissibility – An initial data for this target theory amounts to a quadruple \((A, B, C, D)\) where \(A, B, C \in \mathcal{F}(\mathcal{T}_P) \cong \mathcal{F}({\mathbb{R}}_+^3)\) such that

\[ X(L_1, L_2, L_3) = X(L_1, L_3, L_2), \quad X \in \{A, C\} \]

and \(D_T \in \mathcal{F}(\mathcal{T}_T)\) is a functorial assignment for tori \(T\) with one boundary component. By construction of our seminorms (39)-(40), the condition of admissibility amounts to requiring, for any \(\varepsilon > 0\), the existence of \(t \geq 0\) such that for all \(s \geq 0\), there exists \(M_{\varepsilon,s} > 0\) for which, for any \(L_1, L_2, L_3, \ell, \ell' \geq \varepsilon\) and \(\sigma \in \mathcal{T}_T^\varepsilon\)

\[ |A(L_1, L_2, L_3)| \leq M_{\varepsilon,0} (1 + L_1)^t (1 + L_2)^t (1 + L_3)^t \]

\[ |B(L_1, L_2, \ell)| \leq M_{\varepsilon,s} \left( \frac{(1 + L_1)^t (1 + L_2)^t}{1 + [L_1 + L_2 - \ell]_+} \right)^s \]

\[ |C(L_1, \ell, \ell')| \leq M_{\varepsilon,s} \left( \frac{(1 + L_1)^t}{1 + [L_1 - \ell - \ell']_+} \right)^s \]

\[ |D_T(\sigma)| \leq M_{\varepsilon,0} \left( 1 + \ell_{\sigma}(\partial T) \right)^t \]
Geometric recursion – Let us specialize our main result in this context. We seek to define a functorial assignment \( \Sigma \mapsto \Omega_\Sigma \in \mathcal{F}(\mathcal{T}_\Sigma) \) for any object \( \Sigma \) in \( \mathcal{B}_1 \). For pairs of pants \( P \) and tori with one boundary component \( T \)

\[
\Omega_P(\sigma) = A(\bar{\ell}_\sigma(\partial P)), \quad \Omega_T = D_T
\]

where \( \bar{\ell}_\sigma(\partial P) \) is the triple of boundary lengths of \( P \) in which \( \partial P \) appears first. For disconnected surfaces

\[
\Omega_{\Sigma_1\cup\cdots\cup\Sigma_k}(\sigma_1, \ldots, \sigma_k) = \prod_{i=1}^k \Omega_{\Sigma_i}(\sigma_i)
\]

For connected surfaces \( \Sigma \) with \( \chi_\Sigma \leq -2 \)

\[
\Omega_\Sigma(\sigma) = \sum_{b \in \pi_0(\partial, \Sigma)} \sum_{[P] \in \mathcal{P}_\Sigma^b} B(\bar{\ell}_\sigma(\partial P)) \Omega_{\Sigma-P}(\sigma_{\Sigma-P}) + \frac{1}{2} \sum_{[P] \in \mathcal{P}_\Sigma^b} C(\bar{\ell}_\sigma(\partial P)) \Omega_{\Sigma-P}(\sigma_{\Sigma-P}) \tag{43}
\]

where \( \bar{\ell}_\sigma(\partial P) \) is the ordered triple of boundary lengths of \( P \). Theorem 3.9 specializes to

**Corollary 8.3** If \((A, B, C, D)\) is an admissible initial data in the above sense, \( \Sigma \mapsto \Omega_\Sigma \) is a well-defined functorial assignment. More precisely, the series (43) converge absolutely and uniformly on any compact of \( \mathcal{T}_\Sigma \), and there exists \( u \geq 0 \) depending only on the topological type of \( \Sigma \), such that for any \( \varepsilon > 0 \), we have a constant \( K_\varepsilon > 0 \) depending only on \( \varepsilon \) and the topological type of \( \Sigma \) such that

\[
\forall \sigma \in \mathcal{T}_\Sigma \quad |\Omega_\Sigma(\sigma)| \leq K_\varepsilon \prod_{b \in \pi_0(\partial \Sigma)} (1 + \ell_\sigma(b))^u \tag{44}
\]

This result can be proved in a slightly simpler way than the general Theorem 3.9. As the strategy to prove it in fact inspired the general scheme of target theories and Theorem 3.9, it is worth recalling the main steps. The idea is to first prove absolute convergence of the series pointwise in Teichmüller space. First, we split off the sum (43) the contribution of the small pairs of pants over small pairs of pants, which are finitely many due to Proposition 7.4. For the remaining sum we know by Theorem 7.2 there exists \( O(\lambda^d) \) terms for which the hyperbolic lengths of curves along which we cut is \( \leq \lambda \), for some \( d > 0 \). Since \( B \) and \( C \) decay faster than any power law with respect to the lengths of curves along which we cut, we have a uniform control for \( \Omega_{\Sigma-P} \) by induction hypothesis, we obtain absolute convergence of the series. As the estimate is uniform for \( \sigma \) in any given compact (to see this we use Theorem 7.6), we deduce uniform convergence of the GR series on any compact. One can bound the absolute value of the series by a constant depending only on the systole (due to Theorem 7.2) and the boundary lengths, and it is important in the proof to make sure that the bound (44) is stable by induction.

### 8.2 Strong admissibility and behavior at the boundary

We analyse the behaviour of GR amplitudes \( \Omega_\Sigma(\sigma) \) when \( \sigma \) approaches the boundary of \( \mathcal{T}_\Sigma \), i.e. when some curves are pinched. For this we need to assume some uniform control of the initial data over \( \mathcal{T}_\Sigma \).

We first show it results in a uniform control of the GR amplitudes over \( \mathcal{T}_\Sigma \). If \( \varepsilon \in (0, 1) \), we denote

\[
S^{\varepsilon}_{\Sigma, \sigma} := \{ \gamma \in S^\sigma_{\Sigma} \mid \ell_\sigma(\gamma) \leq \varepsilon \}
\]

Notice that the curves in this set cannot intersect, in particular this set is finite.
Definition 8.4 We say that initial data $(A, B, C, D)$ are strongly admissible if there exists $t \geq 0$, $\eta \in [0, 2)$ and for any $s \geq 0$, there exists $M_s > 0$ for which for any $L_1, L_2, L_3, \ell, \ell' > 0$, we have

\[
|A(L_1, L_2, L_3)| \leq M_0 (1 + L_1)^t (1 + L_2)^t (1 + L_3)^t \\
|B(L_1, L_2, \ell)| \leq M_s \frac{(1 + L_1)^t (1 + L_2)^t}{\ell^\eta (1 + \ell - L_1 - L_2)} \\
|C(L_1, \ell, \ell')| \leq M_s \frac{(1 + L_1)^t}{(\ell')^{\eta} (1 + [\ell + \ell' - L_1])} \\
\]

and there exists $u_{1,1} \geq 0$, $\eta' \in [0, 2)$ such that for any $\varepsilon \in (0, 1)$, there exists $K_{1,1, \varepsilon} > 0$ for which for any $L_1 > 0$, we have

\[
|D_T(\sigma)| \leq K_{1,1, \varepsilon} \left(1 + \ell_s(\partial T)\right)^{u_{1,1}} \frac{1}{\prod_{\gamma \in S_{T,\varepsilon}^0} (\ell_s(\gamma))^{\eta'}}
\]

We notice that either $S_{T,\varepsilon}^0$ is empty or contains a single curve.

Under certain conditions, we can specify $D$ from the data of $C$.

Lemma 8.5 If $C$ satisfies the relevant condition in (45) with $\eta = 0$, then setting

\[
D_T(\sigma) := \sum_{\gamma \in S_T^0} C(\ell_s(\partial T), \ell_s(\gamma), \ell_s(\gamma))
\]

yields a well-defined $\Gamma_T$-invariant function on $\mathcal{T}_T$ which satisfies (46) with $\eta' = 1$.

Proof. Let $L_1 = \ell_s(\partial T)$. We write for any $s > 0$

\[
|D_T(\sigma)| \leq M_0 (1 + L_1)^t \cdot \#\{\gamma \in S_T^0 \mid \ell_s(\gamma) \leq 2L_1\} \\
+ M_s \sum_{L \geq L_1, 2L \leq 2N/2} \frac{(1 + L_1)^t \cdot \#\{\gamma \in S_T^0 \mid L \leq \ell_s(\gamma) < L + 1/2\}}{(1 + 2L - L_1)^s}
\]

With Theorem 7.2 for $\mu = \emptyset$, we deduce

\[
|D_T(\sigma)| \leq \frac{N_s (1 + L_1)^t}{\prod_{\gamma \in S_{T,\varepsilon}^0} \ell_s(\gamma)} \left\{ M_0 (1 + L_1)^t (2L_1)^2 + \sum_{L > 2} M_s (L_1 + L)^2 \right\}
\]

Choosing $s = 4$ makes the right-hand side of (49) convergent and we deduce the claimed bound. In particular, the series (47) is absolutely convergent on any compact of $\mathcal{T}_T$. \hfill \Box

Later, when we will say that $(A, B, C)$ is a strongly admissible initial data, it will be implicit that we choose $D$ equal to (47). Lemma 8.5 shows that this choice indeed makes $(A, B, C, D)$ a strongly admissible initial data in the sense of Definition 8.4.

Lemma 8.6 Let $(A, B, C, D)$ be a strongly admissible initial data with $\eta = 0$ and $\eta' = 1$. Then, for any $\Sigma$ in $\mathcal{B}_1$ and $\varepsilon \in (0, 1)$, there exists $u \geq 0$ depending only on the topological type of $\Sigma$ and $K_{\varepsilon} > 0$ depending only on $\varepsilon$ and the topological type of $\Sigma$, such that for any $\sigma \in \mathcal{T}_\Sigma$

\[
|\Omega_{\Sigma}(\sigma)| \leq K_{\varepsilon} \frac{\prod_{\beta \in \Sigma} (1 + \ell_s(\beta))^n}{\prod_{\gamma \in S_{T,\varepsilon}^0 \ell_s(\gamma)}^n}
\]

Proof. It is enough to prove the result for connected $\Sigma$. The case of pairs of pants and tori with one boundary component is clear from the $A$ and $D$ bounds. In general, consider $\Sigma$ an object of $\mathcal{B}_1$.
of type \((g, n)\) with \(2g - 2 + n \geq 2\), and assume the result holds for all surfaces of Euler characteristic \(2 - 2g - n\). By the GR formula \((43)\), we have for \(\sigma \in \mathcal{T}_\Sigma\)

\[
|\Omega_\Sigma(\sigma)| \leq \sum_{[P] \in \mathcal{P}_\Sigma} |X_P(\ell_\sigma(\partial P))| |\Omega_{\Sigma-P}(\sigma|_{\Sigma-P})|
\]

for \(X_P\) which is equal to \(B\) or \(C\) depending on the type of \([P]\). We will analyse separately various contributions to this sum.

We first remark for any \([P] \in \mathcal{P}_\Sigma\), we can write

\[
|\Omega_{\Sigma-P}(\sigma|_{\Sigma-P})| \leq K'_\varepsilon \prod_{\beta \in \pi_0(\partial(\Sigma-P))} (1 + \ell_\sigma(\beta))^{u'} \prod_{\gamma \in S^0_\varepsilon,\sigma|_{\Sigma-P}} \ell_\sigma(\gamma)
\]

where we can choose constants \(u' \geq 0\) depending only on the topological type of \(\Sigma\), and \(K'_\varepsilon\) depending only on \(\varepsilon \in (0, 1)\) and the topological type of \(\Sigma\).

\[
S^0_{\Sigma-P,\sigma|_{\Sigma-P}} \subseteq S^0_{\Sigma,\sigma}
\]

If \(\mu\) is a subset of \(S^0_{\Sigma,\sigma}\) and \(8 \subseteq S^0_{\Sigma,\sigma}\), we denote \(S[\mu]\) the set of \(\gamma \in S\) that do not intersect \(\mu\). Since simple curves of length \(\leq \varepsilon \leq 1\) cannot intersect, we have a disjoint union

\[
S^0_{\Sigma,\sigma} = \mu \cup S^0_{\Sigma,\sigma}[\mu]\quad (51)
\]

Likewise, if \(\Omega \subseteq \mathcal{P}_\Sigma\), we denote \(\Omega[\mu]\) the set of \([P] \in \Omega\) such that \(\mu \in (\Sigma-P)\). Since

\[
\mathcal{P}_\Sigma = \bigcup_{\mu \subseteq S^0_{\Sigma,\sigma}} \mathcal{P}_\Sigma[\mu]
\]

where the union may not be disjoint, and \(\#S^0_{\Sigma,\sigma} \leq 3g - 3 + n\), it is enough to control the sums over \([P] \in \mathcal{P}_\Sigma[\mu]\). The map \([P] \mapsto \partial P \cap \Sigma^\circ\) sends \(\mathcal{P}_\Sigma[\mu]\) to the set of multicurves that do not intersect \(\mu\) and has fibers of cardinality at most 2. We can then use Theorem 7.2 to estimate the number of such multicurves with bounded length. This will be used several times in the following inequalities, together with the induction hypothesis \((50)\) and the assumptions on \(B\) and \(C\).

If \(b \in \pi_0(\partial(S),\Sigma)\), decomposing the sum over \([P] \in \mathcal{P}^0_{\Sigma}[\mu]\) into small or non-small pairs of pants, we obtain for any \(s > 0\)

\[
\sum_{[P] \in \mathcal{P}^0_{\Sigma}[\mu]} |B(\ell_\sigma(b_1), \ell_\sigma(b), \ell_\sigma(\gamma_P))| |\Omega_{\Sigma-P}(\sigma|_{\Sigma-P})| \\
\leq 2K'_\varepsilon \prod_{\beta \in \pi_0(\partial(\Sigma))} (1 + \ell_\sigma(\beta))^{u'} \prod_{\gamma \in S^0_{\mu,\Sigma}} \ell_\sigma(\gamma) \\
\cdot \left\{ \ell_\sigma(b_1) + \ell_\sigma(b) \right\}^{6g-n+2n} \left(1 + \ell_\sigma(b_1) + \ell_\sigma(b)\right)^{u'} \\
\sum_{\ell \in \ell_\sigma(b_1) + \ell_\sigma(b) + 2n} \frac{(L + 1)^{6g-6+2n} (L + 2)^{u'}}{
\left(1 + \left[L - \ell_\sigma(b_1) - \ell_\sigma(b)\right]\right)^{u'}}
\}
\]

(52)

By \((51)\), we recognize the inverse product of \(\ell_\sigma(\gamma)\) over all \(\gamma \in S^0_{\Sigma,\sigma}\). Choosing a value \(s > (6g - 6 + 2n + u') + 1\) makes the sum over \(L\) convergent and the right-hand side of \((52)\) is bounded by

\[
K''_\varepsilon \prod_{\beta \in \pi_0(\partial(\Sigma))} (1 + \ell_\sigma(\beta))^{u} \\
\prod_{\gamma \in S^0_{\varepsilon,\sigma}} \ell_\sigma(\gamma)
\]

(53)

for \(u = u' + t + (6g - 6 + 2n)\) and some \(K''_\varepsilon > 0\) which only depends on \((g, n, \varepsilon)\). A similar argument leads to bound the sum over \([P] \in \mathcal{P}^0_{\Sigma}[\mu]\) by \((53)\) for a perhaps larger constant \(K_\varepsilon\). Then, summing
over all subsets $\mu \subseteq S_{\Sigma, \sigma}^{\circ}$ we get that $|\Omega_{\Sigma}(\sigma)|$ is bounded by (53) for a perhaps larger constant $K_\varepsilon$. This completes the proof by induction.

We would like to isolate the dominant contribution of the GR sums when some curves are pinched. As we mainly want to illustrate the mechanism, we will impose stronger assumptions on the initial data that facilitate the analysis. First, we will consider that $D$ comes from a $C$ as in (47). If it was not the case, we could easily extend our analysis by adopting a suitable assumption for $D$. Let us introduce a notation for the set of ordered pairs of pants decomposition that appear by unfolding the GR sum. More precisely, we introduce the functorial assignment $\Sigma \mapsto \Omega_{\Sigma}$ from $B_1$ to the category of countable sets that is uniquely defined by the following properties

- $\Omega_p = \{P\}$ and $\Omega_T$ is the set of oriented simple closed curves in $T^\circ$.

- disjoint unions of surfaces are sent to cartesian products of sets.

- if $\Sigma$ is connected with Euler characteristic $\le -2$, we have

$$\Omega_{\Sigma} = \bigsqcup_{[P]\in \rho_{\Sigma}} \Omega_{\Sigma, P}.$$ 

Any element $Q \in \Omega_{\Sigma}$ determines

- a decomposition $(Q_1, \ldots, Q_{3g-3+n})$ of $\Sigma$ into pairs of pants with ordered boundary components.

- a primitive multicurve $c_Q$ with ordered components, consisting of the boundary components of the $Q_i$'s that are not boundary components of $\Sigma$, with their order prescribed by their apparition in the recursive construction of $Q$.

- a type map $X: \{1, \ldots, 3g - 3 + n\} \to \{A, B, t, \frac{1}{2}C\}$.

and the GR formula can be rewritten

$$\Omega_{\Sigma}(\sigma) = \sum_{Q \in \Omega_{\Sigma}} \prod_{i=1}^{3g-3+n} X_i(\sigma|_{Q_i}).$$ (54)

If $\mu \in M_{\Sigma}'$ we denote $\Omega_{\Sigma}[\mu]$ the set of $Q \in \Omega_{\Sigma}$ such that $\mu$ does not intersect $c_Q$, which is tantamount to saying that $\mu \subseteq c_Q$.

**Proposition 8.7** Let $(A, B, C, D)$ be initial data and $\tau: \mathbb{R}_{\ge 0} \to \mathbb{R}_+$ be a decreasing function such that

$$\tau(x + y) \le \tau(x) \tau(y), \quad \tau(1) < 1.$$ (55)

We assume there exists $t, M \ge 0$ such that, for any $L_1, L_2, L_3, \ell, \ell' > 0$

$$|A(L_1, L_2, L_3)| \le M (1 + L_1)^t(1 + L_2)^t(1 + L_3)^t,$$

$$|B(L_1, L_2, \ell)| \le M (1 + L_1)^t(1 + L_2)^t \tau(\ell),$$

$$|C(L_1, \ell, \ell')| \le M (1 + L_1)^t \tau(\ell) \tau(\ell'),$$ (56)

and that $D$ is specified by (47). Let $\Sigma$ be an object of type $(g, n)$ in $B_1$, $\mu$ be a primitive multicurve in $\Sigma$ and introduce

$$\Omega_{\Sigma}^{[\mu]}(\sigma) = \sum_{Q \in \Omega_{\Sigma}[\mu]} \prod_{i=1}^{3g-3+n} X_i(\sigma|_{Q_i}).$$
Let $\varepsilon \in (0, 1)$. There exists $u \geq 0$ depending only on $(g, n)$ and $K_{\varepsilon} > 0$ depending only on $(\varepsilon, g, n)$ such that, for any $\sigma \in \Omega_\Sigma$ such that all simple simple closed curves in $\Sigma^n$ with length $\leq \varepsilon$ must be components of $\mu$, we have

$$|\Omega_\Sigma^{[\mu]}(\sigma)| \leq K_{\varepsilon} \prod_{b \in \pi_0(\partial \Sigma)} (1 + \ell_\sigma(b))^u,$$

and

$$|\Omega_\Sigma^{[\mu]}(\sigma) - \Omega_\Sigma^{[\mu]}(\sigma)| \leq K_{\varepsilon} \prod_{b \in \pi_0(\Sigma)} (1 + \ell_\sigma(b))^u \sum_{\nu < \mu} \prod_{m \in \pi_0(\mu \setminus \nu)} \frac{\tau^4\left(\ln(1/\ell_\sigma(m))\right)}{\ell_\sigma(m)} \left(1 + 4\ln(1/\ell_\sigma(m))\right)^{6g - 6 + 2n}.$$

Equation (55) in particular implies that $\tau(l)$ is bounded for $l \geq 0$, and if $\tau < e^{-1/4}$, then

$$\forall s \geq 0 \lim_{l \to 0} \frac{\tau^4\left(\ln(4/\ln(l))\right)}{l} \ln^s(1/l) = 0,$$

so the error bound in (58) tends to 0 when $\ell_\sigma(\mu) \to 0$.

When $\mu$ has $3g - 3 + n$ components, it determines a pair of pants decomposition and $\Omega_\Sigma^{[\mu]}$ contains only finitely many terms of (54), which can only differ by the ordering of the pairs of pants in this decomposition and the ordering of their boundary components – these orderings are determining the type $(A, B, C)$ of each factor. In the situation of Proposition 8.7, one can therefore consider that GR designs a mapping class group invariant function globally defined on $\Omega_\Sigma$ and with prescribed asymptotic behavior specified by the functions $(A, B, C)$ when a maximal number of curves are pinched.

**Proof of Proposition 8.7.** For each $Q \in \Omega_\Sigma$, the corresponding term in (54) is a function of the lengths of the boundary components of $Q_1, \ldots, Q_{3g - 3 + n}$, which is bounded by the product of polynomials factors and $\tau$ factors. We observe that each component $\delta$ of $c_Q$ bounds at most two pairs of pants $Q_i$ and $Q_j$ for some $i, j \in \{1, \ldots, 3g - 3 + n\}$. If $i = j$, then the length of $\delta$ only appears in a factor $C(\ell_\sigma(\delta'), \ell_\sigma(\delta), \ell_\sigma(\delta))$ for some other $\delta'$, and its absolute value is bounded by

$$M \left(1 + \ell_\sigma(\delta')\right)^4 \tau(\ell_\sigma(\delta)) \leq M \tau(0) \left(1 + \ell_\sigma(\delta')\right)^4 \tau(\ell_\sigma(\delta)).$$

If $i \neq j$, we can always assume $i < j$, and $\ell_\sigma(\delta)$ appears only as a variable of $X_i$ resulting into a factor of $\tau(\ell_\sigma(\delta))$ in the upper bound, and as a variable of $X_j$ resulting into a factor $(1 + \ell_\sigma(\delta))^4$ in the upper bound. As a result, we have

$$\left|\prod_{i=1}^{3g-3+n} X_i(\sigma|Q_i)\right| \leq M' \prod_{b \in \pi_0(\partial \Sigma)} (1 + \ell_\sigma(b))^t \prod_{\delta \in \pi_0(c_Q)} (1 + \ell_\sigma(\delta))^4 \tau(\ell_\sigma(\delta))$$

for some constant $M' > 0$ depending only on $g$ and $n$.

Let $\nu \subset \mu$. If $Q \in \Omega_\Sigma^{[\nu]}$, we consider the multicurve $c_Q^{[\nu]} = \sum_{\delta \in \pi_0(c_Q^{[\nu]})} \delta$. It must intersect each component of $\mu \setminus \nu$ at least twice. More precisely, if $\delta \in \pi_0(c_Q^{[\nu]})$ and $m \in \pi_0(\mu \setminus \nu)$ we denote $I_{\delta, m}$ the number of intersections of $\delta$ and $m$, and the aforementioned constraint means that

$$\sum_{\delta \in \pi_0(c_Q^{[\nu]}) I_{\delta, m} \geq 2. \quad (60)$$

By the collar lemma we must have for any $\delta \in \pi_0(c_Q^{[\nu]})$ the upper bound

$$\ell_\sigma(\delta) \geq \sum_{m \in \pi_0(\mu \setminus \nu)} I_{\delta, m} w(\ell_\sigma(m)), \quad w(l) = 2 \text{arcsinh}\left(\frac{1}{\sinh(l/2)}\right).$$
We have \( w(l) \geq 2 \ln(4/l) \) for all \( l > 0 \). In particular

\[
\ell_\sigma(\delta) \geq \Lambda_{\sigma, \delta} := \sum_{m \in \pi_0(\mu \setminus \nu)} 2 I_{\delta, m} \ln(4/\ell_\sigma(m)),
\]

and

\[
\ell_\sigma(c_Q[\nu]) \geq \Lambda_{\sigma} [\nu] := \sum_{m \in \pi_0(\mu \setminus \nu)} 4 \ln(4/\ell_\sigma(m)).
\]

Let \( k = \# \pi_0(\nu) \) and \( d' = 3g - 3 + n - k \). We have

\[
\left| \sum_{Q \in \Omega_{\nu}[\nu]} \prod_{i=1}^{3g-3+n} X_i(\sigma|Q_i) \right| \leq M' 2^{k t} \prod_{b \in \pi_0(\partial \Sigma)} (1 + \ell_\sigma(b))^t \prod_{0 < \delta_1, ..., \delta_{d'} \leq \nu} \sum_{\delta_1, ..., \delta_{d'} \leq \nu} (2 + \Lambda_{\sigma, \delta_i} + L_i)^t \gamma \left( \Lambda_{\sigma, \delta_1} + L_i, \ldots, \Lambda_{\sigma, \delta_k} + L_k \right),
\]

where we sum over multicurves \( \delta \) with ordered boundary components \( \delta_1, \ldots, \delta_k \) which do not intersect \( \nu \). The prefactor \( 2^{k t} \) comes from the polynomial factor in (59) and the fact that components of \( \nu \in \mu \) have length \( \leq \varepsilon \leq 1 \). We then use the sub-exponentiality of \( \gamma \) and (60), and Theorem 7.2 to estimate the number of multicurves of length \( \leq \sum_{i=1}^{d'} (1 + L_i + \Lambda_{\sigma}[\nu]) \), noticing that the ordering of the multicurve only contribute to an extra factor that depends only on \( (g, n) \). The result is an upper bound of the form

\[
\left| \sum_{Q \in \Omega_{\nu}[\nu]} \prod_{i=1}^{3g-3+n} X_i(\sigma|Q_i) \right| \leq M'' N \epsilon \prod_{b \in \pi_0(\partial \Sigma)} (1 + \ell_\sigma(b))^t \prod_{m \in \pi_0(\mu \setminus \nu)} \frac{\tau \left( \ln(4/\ell_\sigma(m)) \right)}{\ell_\sigma(m)}
\]

\[
\cdot \left\{ \sum_{L_1, \ldots, L_{d'} \geq 0} \prod_{i=1}^{d'} \gamma(L_i) \left( 2 + L_i + \Lambda_{\sigma}[\nu] \right)^t \left( \sum_{i=1}^{d'} \left( \Lambda_{\sigma}[\nu] + 1 + L_i \right) \right)^{6g-6+2n} \right\}
\]

for some constant \( M'' \) depending only on \( (g, n) \). We observe that, since the sub-exponentiality and the condition \( \tau(1) < 1 \) implies that for any \( s \geq 0 \)

\[
\sum_{L>0} \gamma(L) L^s \leq \sum_{L>0} \gamma(1)^L L^s < +\infty.
\]

Hence, using that \( \tau \) is decreasing to replace \( 4/\ell_\sigma(m) \) by \( 1/\ell_\sigma(m) \),

\[
\left| \sum_{Q \in \Omega_{\nu}[\nu]} \prod_{i=1}^{3g-3+n} X_i(\sigma|Q_i) \right| \leq K \epsilon \left( 1 + \Lambda_{\sigma}[\nu] \right)^{6g-6+2n} \prod_{b \in \pi_0(\partial \Sigma)} (1 + \ell_\sigma(b))^t \prod_{m \in \pi_0(\mu \setminus \nu)} \frac{\tau \left( \ln(1/\ell_\sigma(m)) \right)}{\ell_\sigma(m)}
\]

for some constant \( K \epsilon \) depending only on \( (g, n, \varepsilon) \). In particular, if \( \nu = \mu \), since \( \Lambda_{\sigma}[\mu] = 0 \) we get the desired bound (57), and summing over the strict subsets \( \nu \subset \mu \) gives the desired error bound (58) after we use the crude upper bound

\[
\left( 1 + \sum_{m \in \pi_0(\mu \setminus \nu)} 4 \ln(4/\ell_\sigma(m)) \right)^{6g-6+2n} \leq (1 + 4d' \ln 4)^{6g-6+2n} \prod_{m \in \pi_0(\mu \setminus \nu)} (1 + \ln(1/\ell_\sigma(m)))^{6g-6+2n}.
\]

\[\square\]

8.3 Integration and topological recursion

In this paragraph, we study the integration of GR amplitudes valued in \( E(\Sigma) = \text{Mes}(\Sigma) \) over the moduli space of bordered Riemann surfaces with fixed boundary lengths, with respect to the Weil–Petersson measure \( \mu_{WP} \). This is the volume form associated with Weil–Petersson symplectic form \( \omega_{WP} \). Our normalization convention is

\[
\omega_{WP} = \sum_{j} \omega_{\Sigma} \wedge d\tau_j
\]

49
in Fenchel–Nielsen coordinates [30]. For convenience of notations, if $\Sigma \to \Omega_\Sigma$ is a functorial assignment, we will write $\Omega_{g,n}$ for the (uniquely defined) function on $\mathcal{M}_{g,n} \neq \mathcal{M}_{g,n}$ that is induced by $\Omega_{g,n}$, where $\Sigma_{g,n}$ is a bordered surface of genus $g$ with $n$ boundary components labeled $(\partial_1 \Sigma)_{i=1}^n$, which is an object of $\mathcal{B}_1$ for the choice $\partial_1 \Sigma = \partial_2 \Sigma$.

**Theorem 8.8** Let $(A,B,C,D)$ be measurable, strongly admissible initial data, and consider the corresponding GR amplitudes $\Omega_{\Sigma}$. For any $g \geq 0$ and $n \geq 1$ such that $2g - 2 + n > 0$ and $L \in \mathbb{R}^n_+$, the function $\Omega_{g,n}$ is integrable on $\mathcal{M}_{g,n}(L)$, and the integrals denoted

$$V \Omega_{g,n}(L) = \int_{\mathcal{M}_{g,n}(L)} \Omega_{g,n} \, d\mu_{WP}.$$ 

satisfy the topological recursion

$$V \Omega_{g,n}(L_1, \ldots, L_n) = \sum_{m=2}^n \left[ \frac{d}{d\ell} B(L_1, L_m, \ell) V \Omega_{g,n-1}(\ell, L_2, \ldots, L_m, \ldots, L_n) \right] + \frac{1}{2} \int_{\mathbb{R}^n_+} d\ell d\ell' \ell' C(L_1, \ell, \ell') \left( V \Omega_{g-1,n+1}(\ell, \ell', L_2, \ldots, L_n) + \sum_{h,h'=g} V \Omega_{h',1+\# J}(\ell, J) V \Omega_{h',1+\# J'}(\ell', J') \right)$$

with initial data

$$V \Omega_{0,3}(L_1, L_2, L_3) = A(L_1, L_2, L_3), \quad V \Omega_{1,1} = V D(L) := \int_{\mathcal{M}_{1,1}(L)} D \, d\mu_{WP}.$$ 

This result and its proof has a natural reformulation in light of Section 4. Noting that $e(\Sigma) = \text{Mes}(\mathbb{R}^n_+(\Omega_{\Sigma}))$ is strict target theory in a natural way, Theorem 8.8 can be interpreted by saying that the integration with respect the Weil–Petersson measure is a (partially defined) natural transformation between $e$ and the $E(\Sigma) = \text{Mes}(\gamma_{\Sigma})$. The fact that the geometric recursion implies the topological recursion after integration expresses the compatibility with natural transformations stated in Proposition 4.7.

**Proof of Theorem 8.8.** The integrability for $\eta = 0$ and $\eta' = 1$ follows from the uniform bound of Lemma 8.6 and the argument of Mirzakhani’s [22, p111–112]. We now sketch the proof for the stronger result, which is based on similar ideas and a generalization of the integration lemma in [20]. We first remark that, if we replace $(A,B,C,D)$ with their absolute value, it is easy to prove by induction on $2g - 2 + n > 0$ that, under our assumptions, the formulas (61) produce well-defined, finite functions that are uniformly bounded by a polynomial in $L_1, \ldots, L_n$. This comes from the fact that the measure of integration is $\ell \, d\ell$, making a function bounded by $\ell^{-\eta}$ integrable near 0 provided $\eta < 2$. Near $\ell \to \infty$ the integrability comes from the decay faster than any power $\ell^{s}$ for fixed $L_i$’s. By Tonelli’s theorem, in order to prove the Theorem in general, it is sufficient to justify that the integrals of the GR amplitudes for the initial data $(|A|, |B|, |C|, |D|)$ satisfy this recursion – without caring in the intermediate computations whether the integrals are finite or equal to $+\infty$.

Consider $\Sigma$ of type $(g,n)$ with $2g - 2 + n \geq 2$, $L \in \mathbb{R}^n_+$ and let $\gamma$ be a multicurve in with ordered components $\gamma_1, \ldots, \gamma_k$ in $\Sigma$. We consider the orbifold

$$\mathcal{M}_{\Sigma}^n(L) = \mathcal{F}_{\Sigma}(L) \bigg/ \bigcap_{i=1}^k \text{Stab}(\gamma_i),$$

50
where \( \text{Stab}(\gamma_i) \) is the stabiliser of \( \gamma_i \) in \( \Gamma_0^2 \). It is equipped with the Weil–Petersson symplectic structure, and with an \( \prod_{i=1}^{k}(\mathbb{R}/2^{−i}\mathbb{Z}) \) action induced by the moment map \( L^+(\sigma) = (\ell^+_{x}(\gamma_i)/2)_{i=1}^{k} \), where
\[
t_i = \begin{cases} 
1 & \text{if } \gamma_i \text{ separates off a torus with one boundary component} \\
0 & \text{otherwise}
\end{cases}
\]
The presence of \( 2^{−i} \) comes from the fact that the half-Dehn twist belongs to \( \text{Stab}(\gamma_i) \) when \( \gamma_i \) separates off a torus with one boundary component.

If we include \( \gamma \) into a pair of pants decomposition and consider the associated Fenchel–Nielsen coordinates \((l_j, \tau_j)\), the Weil–Petersson symplectic form on \( \mathcal{T}_\Sigma \) takes the form
\[
\omega_{WP} = \sum_j dl_j \wedge d\tau_j.
\]

With this description, one can check that for each \( \ell \in \mathbb{R}_+^k \), the symplectic quotient \( (L^+)^{-1}(\ell)/U(1)^k \) is a symplectic orbifold which is symplectomorphic to a moduli space \( \mathcal{M}_{\Sigma^*}(L, \ell, \ell) \), which is the cartesian product of moduli spaces of bordered Riemann surfaces associated with each connected component of \( \Sigma^* \), where boundary components that were originally in \( \Sigma \) have fixed length \( L \), boundary components that come from a \( \gamma_i \) have length \( \ell_i \), and each factor associated with a component of \( \Sigma^* \) which is a torus with one boundary component \( \gamma_i \) should be the double cover \( M_{1,1}(\ell_i) \) instead of the usual moduli space \( M_{1,1}(\ell_i) = \mathcal{M}_{1,1}(\ell_i)/(\text{elliptic involution}) \).

We deduce that if \( f \) is a nonnegative measurable function on \( \mathcal{M}_{\Sigma^*}^2 \) which is invariant under the torus action, it induces a measurable function \( \tilde{f} \) on \( \mathcal{M}_{\Sigma^*}^2 \) for each \( \ell \in \mathbb{R}_+^k \) and we have for any \( \ell \in \mathbb{R}_+^k \)
\[
\int_{\mathcal{M}_{\Sigma^*}^2} f \, d\mu_{WP} = \int_{\mathbb{R}_+^k} \prod_{i=1}^{k} dl_i \int_{\mathcal{M}_{\Sigma^*}(L, \ell, \ell)} \tilde{f} \, d\mu_{WP}
\]

We use that the fibers of the moment map have volume \( \prod_{i=1}^{k} 2^{−i} \ell_i \) but the factors of 2 disappear after we replaced the symplectic quotient spaces \( \mathcal{M}_{\Sigma^*}(L, \ell, \ell) \) with the usual moduli space of bordered Riemann surfaces \( \mathcal{M}_{\Sigma^*}(L, \ell, \ell) \).

We apply this discussion to the GR amplitudes associated with \( (|A|, |B|, |C|, |D|) \), denoted again \( \Omega_\Sigma \) for convenience of the proof. In each \( \Gamma_0^2 \)-orbit \( \mathcal{O} \in \mathcal{P}_\Sigma \), let us choose arbitrarily a representative \( [P_\mathcal{O}] \) and denote \( \gamma_\mathcal{O} \) the multicurve with ordered components \( \partial P_\mathcal{O} \cap \Sigma^0 \). We have
\[
\int_{\mathcal{M}_{\Sigma}(L)} \left( \sum_{[P] \in \mathcal{O}} X_\mathcal{O}(\tilde{\ell}_{\sigma}(\partial P)) \Omega_{\Sigma^*}(\sigma|_{\Sigma^*}) \right) d\mu_{WP}(\sigma)
\]
\[
= \int_{\mathcal{M}_{\Sigma}(L)} \left( \sum_{[P] \in \mathcal{O}} X_\mathcal{O}(\tilde{\ell}_{\sigma}(\partial P)) \Omega_{\Sigma^*}(\sigma|_{\Sigma^*}) \right) d\mu_{WP}(\sigma)
\]
where \( X_\mathcal{O} \) is the function \( B \) or \( C \) depending on the type of \( \mathcal{O} \). The integral of the GR amplitude is obtained by summing the result of integration over all \( \Gamma_0^2 \)-orbits \( \mathcal{O} \in \mathcal{P}_\Sigma \). Since the function in the right-hand side of (63) does not depend on the twist along the components of \( \gamma_\mathcal{O} \), we can apply (62).

For the orbit \( \mathcal{O} = \gamma_b \) with \( b \in \pi_0(\partial, \Sigma) = \{2, \ldots, n\} \), we have \( X_\mathcal{O} = B \) and \( \Sigma - P_\mathcal{O} \) has type \( (g, n - 1) \), hence
\[
\int_{\mathcal{M}_{\Sigma}(L)} \left( \sum_{[P] \in \mathcal{O}} X_\mathcal{O}(\tilde{\ell}_{\sigma}(\partial P)) \Omega_{\Sigma^*}(\sigma|_{\Sigma^*}) \right) d\mu_{WP}(\sigma)
\]
\[
= \int_{\mathbb{R}_+^k} dl \partial B(L_1, L_b, \ell) \int_{\mathcal{M}_{g, n - 1}(L_1, L_2, \ldots, L_{n})} \Omega_{g, n - 1} d\mu_{WP}
\]
If $\mathcal{O} \subseteq \mathcal{P}^0$, $\gamma_\mathcal{O}$ has two components, $X_\mathcal{O} = \frac{1}{2} C$ and we rather obtain
\[
\int_{\mathcal{M}_\Sigma(L)} \left( \sum_{[P] \in \mathcal{O}} X_\mathcal{O}(\ell_\sigma(\partial P)) \Omega_{\Sigma-P}(\sigma|_{\Sigma-P}) \right) d\mu_{WP}(\sigma)
= \frac{1}{2} \int_{\mathbb{R}^2} d\ell d\ell' C(L_1, \ell, \ell') \left( \int_{\mathcal{M}_{\Sigma-P}([P]\ell, [P]\ell', \ell_2, \ldots, \ell_n)} \Omega_{\Sigma-P}(\sigma) \right)
\]
with the appropriate labelling of boundary components of $\Sigma - P_\mathcal{O}$. Summing over $\mathcal{O}$ reconstructs all the terms in (61) and justifies the claim. \hfill \Box

8.4 (Lack of) symmetry

If $\Omega_\Sigma$ is obtained by symmetric GR, then it is invariant under braidings of all boundary components of $\Sigma$ and the corresponding functions $V \Omega_{g,n}(L_1, \ldots, L_n)$ are symmetric in their $n$ variables. Otherwise, the GR amplitudes $\Omega_\Sigma$ are not a priori invariant under braidings of $\partial \Sigma$ with other boundary components and $V \Omega_{g,n}(L_1, \ldots, L_n)$ are only invariant under permutation of $L_2, \ldots, L_n$. Sufficient conditions to ensure that $V \Omega_{g,n}$ is symmetric in all variables already appear in a slightly different setting, in Section 5.4. Here they amount to requiring that $A$ is symmetric in its three variables, and the following four conditions to hold for any $L_1, L_2, L_3, L_4 > 0$
\[
\int_{\mathbb{R}^3} d\ell d\ell' B(L_1, L_2, \ell) A(\ell, L_3, L_4) + B(L_1, L_3, \ell) A(L_2, L_4, \ell) = (L_1 \leftrightarrow L_2),
\int_{\mathbb{R}^3} d\ell d\ell' B(L_1, L_2, \ell) B(\ell, L_3, L_4) + B(L_1, L_3, \ell) B(L_2, L_4, \ell) = (L_1 \leftrightarrow L_2),
\int_{\mathbb{R}^3} d\ell d\ell' B(L_1, L_2, \ell) C(\ell, L_3, L_4) + C(L_1, L_3, \ell) B(L_2, \ell, L_4) = (L_1 \leftrightarrow L_2),
\int_{\mathbb{R}^3} d\ell d\ell' B(L_1, L_2, \ell) \cdot VD(\ell) + \frac{1}{2} \int_{\mathbb{R}^2} d\ell d\ell' C(L_1, \ell, \ell') A(L_2, \ell, \ell') = (L_1 \leftrightarrow L_2).
\]

It is possible – see [4] – to have geometrically meaningful GR amplitudes $\Omega_\Sigma$ which are not invariant under all braidings, but for which the integrals $V \Omega_{g,n}$ are symmetric functions of all the length variables.

8.5 Coupling to 2d TQFTs

Let $(A, \cdot, \cdot)$ be a Frobenius algebra, together with an (arbitrary) choice of hermitian norm $|\cdot|_A$. The previous construction can be adapted to
\[
E(\Sigma) = \mathcal{F}(\mathcal{F}_\Sigma, A^{\otimes n}(\partial \Sigma))
\]
where the glueing morphisms now incorporate the pairing in $A$, and the seminorms of these spaces are provided by the supremum of $|\cdot|_A$. The integration of GR amplitudes $\Omega_\Sigma$ then produce functions $V \Omega_{g,n}$ from $\mathbb{R}^n$ to $A^{\otimes n}$.

Another way to describe (65) is to make the tensor product of the strict target theory based on the 2d TQFT of $A$, with the aforementioned target theories of functions over Teichmüller spaces. This tensor product is well-defined because $A$ is a finite-dimensional vector space. When $A$ is semi-simple, the choice of a canonical basis on $A$ gives a natural choice of hermitian norm on $A$. This is a basic example of the fibering procedure described later in Section 9.3.
9 Revisiting Mirzakhani-McShane identities

This section is a review of well-known results, put in the new perspective of the geometric recursion. We also draw easy but noteworthy consequences. Here we work with the target theory $E(\Sigma) = \varnothing(\mathcal{T}_\Sigma)$.

9.1 Mirzakhani identities

Let us consider the following initial data

$$A^M(L_1, L_2, L_3) = 1$$

$$B^M(L_1, L_2, \ell) = 1 - \frac{1}{L_1} \ln \left( \frac{\cosh \left( \frac{L_1}{2} \right) + \cosh \left( \frac{L_1 + \ell}{2} \right)}{\cosh \left( \frac{L_1}{2} \right) + \cosh \left( \frac{L_1 - \ell}{2} \right)} \right)$$

$$C^M(L_1, \ell, \ell') = \frac{2}{L_1} \ln \left( \frac{\exp \left( \frac{L_1}{2} \right) + \exp \left( \frac{L_1 \ell'}{2} \right)}{\exp \left( \frac{L_1}{2} \right) + \exp \left( \frac{L_1 \ell}{2} \right)} \right)$$

$$D^M_T(\sigma) = \sum_{\gamma \in \mathcal{N}_g} C^M(\ell_\sigma(\partial T), \ell_\sigma(\gamma), \ell_\sigma(\gamma))$$

(66)

The functions $B^M$ and $C^M$ can equivalently be expressed in terms of $F(x) = 2\ln(1 + e^{x/2})$ as

$$B^M(L_1, L_2, \ell) = \frac{1}{2L_1} \left( F(L_1 - L_2 - \ell) + F(L_1 + L_2 - \ell) - F(-L_1 + L_2 - \ell) - F(-L_1 - L_2 - \ell) \right)$$

$$C^M(L_1, \ell, \ell') = \frac{1}{L_1} \left( F(L_1 - \ell - \ell') - F(-L_1 - \ell - \ell') \right)$$

(67)

These formulae make clear that $(A, B, C, D)$ is strongly admissible. Mirzakhani’s identities can be reformulated as

**Theorem 9.1** [20] *For any object $\Sigma$ in $\mathcal{B}_1$, $\Omega^M$ is the constant function 1 on $\mathcal{T}_\Sigma$.*

GR does not bring anything new here, except that it stresses that Mirzakhani’s identities should be seen as a recursion producing the constant function 1 on the Teichmüller space. The way Theorem 9.1 is proved in [20] does not require showing a priori the convergence of the series (43) defining $\Omega^M$. Nevertheless, if one takes for granted Theorem 9.1 for the case of the torus with one boundary i.e. $D^M_T(\sigma) = 1$, Theorem 3.9 justifies the absolute convergence of these series uniformly on any compact.

In [20], Mirzakhani used her identities to obtain a recursive formula for the Weil–Petersson volumes of the moduli space of bordered surfaces

$$V\Omega^M_{g,n}(L) = \int_{\mathcal{M}_{g,n}(L)} 1 \cdot d\mu_{WP}$$

and this is a special case of our Theorem 8.8. The initial data for this recursion is

$$V\Omega^M_{0,3}(L_1, L_2, L_3) = 1, \quad VD^M(L_1) = \frac{\pi^2}{12} + \frac{L_1^2}{48}.$$ 

**Theorem 9.2** [14] *This recursion for the Weil–Petersson volumes $V\Omega^M_{g,n}$ is equivalent to the statement that

$$\omega^M_{g,n}(z_1, \ldots, z_n) = \left( \int_{\mathbb{R}_+^n} \prod_{i=1}^n dL_i e^{-z_i L_i} V\Omega^M_{g,n}(L_1, \ldots, L_n) \right) dz_1 \otimes \cdots \otimes dz_n$$

is computed by Eynard–Orantin’s topological recursion for the initial data

$$x(z) = z^2/2, \quad y(z) = -\frac{\sin(2\pi z)}{2\pi}, \quad \omega_{0,2}(z_1, z_2) = \frac{dz_1 \otimes dz_2}{(z_1 - z_2)^2}. \quad (68)$$

53
Remark 9.3 It is an interesting problem to find a mechanism which would explain a priori – without relying on Mirzakhani’s identity/Theorem 9.1 – that $\Omega^M_{\Sigma}$ defined by the inductive formula (43) is invariant under braiding of all boundary components of $\Sigma$. We do not know if Mirzakhani initial data satisfy the four symmetry constraints of Definition 5.2 – if they hold true, it would give such an explanation via our Theorem 5.4. On the other hand, one can check – see e.g. [5, 9] – that Mirzakhani’s initial data (66) satisfy the “averaged” constraints (64), and therefore that the topological recursion for $\Omega^M_{g,n}(L_1, \ldots, L_n)$ does produce a priori symmetric functions of its $n$ length variables.

Let us review the relation between the Weil–Petersson volumes $V\Omega^M_{g,n}(L)$ and intersection theory on Deligne–Mumford compactification of the moduli space $\overline{M}_{g,n}$ of genus $g$ Riemann surfaces $S$ with $n$ labeled punctures $p_1, \ldots, p_n \in S$. We recall that $\overline{M}_{g,n}$ is a complex orbifold for which Poincaré duality holds. Let us denote $\psi$ the first Chern class of the cotangent line bundle $T_{p_i}^*S$ at the $i$-th puncture. We also denote $\kappa_d$ the class of degree $2d$ obtained by pushforward of $\psi^{d+1}_{n+1}$ via the morphism $\overline{M}_{g,n+1} \rightarrow \overline{M}_{g,n}$ forgetting the last puncture. It is well-known that the cohomology class of the Weil–Petersson symplectic form on $\overline{M}_{g,n}$ is $2\pi^2\kappa_1$ [29]. By examination of the symplectic reduction on the space $\overline{M}_{g,n}$ with the moment map $(L_1^2/2)_{n+1}$, Mirzakhani proved

Theorem 9.4 [21] For $2g-2+n > 0$, we have

$$V\Omega^M_{g,n}(L_1, \ldots, L_n) = \int_{\overline{M}_{g,n}} \exp \left( 2\pi^2 \kappa_1 + \sum_{i=1}^n \frac{L_i^2}{2} \psi_i \right),$$

where the exponential is understood by expanding in Taylor series, and keeping only the terms of cohomology degree $2d_{g,n} = 6g - 6 + 2n$.

9.2 Interpolation to Kontsevich’s amplitudes

Let us consider a deformation of Mirzakhani initial data, which consists in rescaling all length variables by a factor $\beta > 0$, namely

$$X^\beta(L_1, L_2, L_3) = X^M(\beta L_1, \beta L_2, \beta L_3), \quad X \in \{A, B, C\}$$

(69)

One easily checks that the initial data $(A^\beta, B^\beta, C^\beta)$ is strongly admissible with constants that can be chosen independently of $\beta \geq 1$. We induce $D^\beta$ from $C^\beta$, that is

$$D^\beta_\gamma(\sigma) = \sum_{\gamma \in \mathcal{S}_T} C^\beta(\beta \ell_\gamma(\partial T), \beta \ell_\gamma(\gamma), \beta \ell_\gamma(\gamma)).$$

This deformation of the Mirzakhani initial data is not induced by a flow on the Teichmüller spaces: except for $\Sigma = \mathcal{P}$, there is no flow on $\mathcal{T}_\Sigma$ which has for effect to rescale the length of all curves by $\beta$. So, $D^\beta$ is a priori not equal to the constant function 1 on $\mathcal{T}_T$ as soon as $\beta \neq 1$. We denote $\Omega^\beta_{\Sigma}$ the corresponding GR amplitudes.

Notice that $\lim_{\beta \rightarrow -\infty} \beta^{-1}F(\beta x) = [x]_+$, and the convergence is uniform for $x \in \mathbb{R}$. Therefore, $(A_\beta, B_\beta, C_\beta)$ converges uniformly on $[\varepsilon, +\infty)^3$ for each $\varepsilon > 0$, to a strongly admissible initial data which we denote $(A^K, B^K, C^K)$. Explicitly

$$A^K(L_1, L_2, L_3) = 1$$
$$B^K(L_1, L_2, \ell) = \frac{1}{2L_1} \left( [L_1 - L_2 - \ell]_+ - [-L_1 + L_2 - \ell]_+ + [L_1 + L_2 - \ell]_+ \right)$$
$$C^K(L_1, \ell, \ell') = \frac{1}{L_1} [L_1 - \ell - \ell']_+$$

(70)

We call it the Kontsevich initial data and we denote $\Omega^K_{\Sigma}$ the corresponding GR amplitudes.
Lemma 9.5 For any object $\Sigma$ in $\mathcal{B}_1$, we have

$$\forall \sigma \in \mathcal{T}_\Sigma, \quad \lim_{\beta \to \infty} \Omega_\Sigma^\beta(\sigma) = \Omega_\Sigma^K(\sigma).$$

and the convergence is uniform for $\sigma$ in any compact of $\mathcal{T}_\Sigma$. Besides, we have for $2g - 2 + n > 0$

$$V\Omega_\Sigma^\beta(L_1, \ldots, L_n) = \beta^{-6g-6+2n} V\Omega_\Sigma^K(\beta L_1, \ldots, \beta L_n)$$

and

$$\lim_{\beta \to \infty} V\Omega_\Sigma^\beta(L_1, \ldots, L_n) = V\Omega_\Sigma^K(L_1, \ldots, L_n) = \int_{\mathcal{H}_{g,n}} \exp\left(\frac{n}{2} L^2 \psi_i\right).$$

In particular $VD^K(L_1) = \frac{L^2}{16\pi}$.

Proof. Since the constants appearing in the admissibility bounds (42) for $(A^\beta, B^\beta, C^\beta)$ can be chosen independently of $\beta \in [1, +\infty)$, the proof of Theorem 3.9 actually shows that the GR series defining $\Omega^\beta$ are uniformly convergent for $\sigma$ in any compact of $\mathcal{T}_\Sigma$ and $\beta \in [1, +\infty)$. Therefore, we can take the limit $\beta \to \infty$ term by term in the series, which yields (71). Likewise, since the constants appearing in the strong admissibility bounds (45) can be chosen independently of $\beta \in [1, +\infty)$, the proof of Theorem 8.8 shows that we can take the term by term $\beta \to \infty$ limit in the topological recursion (61), which yields

$$\lim_{\beta \to \infty} V\Omega_\Sigma^\beta(L_1, \ldots, L_n) = V\Omega_\Sigma^K(L_1, \ldots, L_n).$$

We prove the equality (72) by induction. The case of $(g, n) = (0, 3)$ is clear since $A^\beta = A^K = 1$. For $(g, n) = (1, 1)$, we compute for $L_1 > 0$

$$VD^\beta(L_1) = \int_{M_r(L_1)} \left(\sum_{\gamma \in \mathcal{S}_\gamma} C^M(\beta L_1, \beta \ell, \sigma(\gamma))\right) d\mu_{WP} = \frac{1}{2} \int_{\mathbb{R}_+} d\ell \left(\int_{\mathbb{R}_+} d\tilde{\ell} C^M(\beta L_1, \beta \tilde{\ell})\right) \frac{V D^M(L_1)}{\beta^2}$$

where to get the second line we used the same tricks as in the proof of Theorem 8.8, and the $1/2$ takes into account the fact that $\Gamma^\beta_T$ contains the half-Dehn twist along $\gamma \in S^g_\gamma$. Assume the claim holds for $(g', n')$ such that $2g' - 2 + n' < 2g - 2 + n$. We examine the terms in the topological recursion formula (61) for $V\Omega_\Sigma^\beta$. It contains for instance the terms

$$\sum_{m=2}^n \int_{\mathbb{R}_+} d\ell d\tilde{\ell} B(\beta L_1, \beta L_m, \beta \ell) V\Omega_{\gamma,n-1}^\beta(\ell, L_2, \ldots, \tilde{L}_m, \ldots, L_n)$$

which is $\beta^{-(6g-6+2n-1)}$ times the corresponding terms in the recursion for $V\Omega^M(\beta L_1, \ldots, \beta L_n)$. The $C$-terms are handled in the same way, and this completes the proof of (72).

Finally, the equality

$$\lim_{\beta \to \infty} \beta^{-(6g-6+2n)} V\Omega_{\gamma,n}^M(\beta L_1, \ldots, \beta L_n) = \int_{\mathcal{H}_{g,n}} \exp\left(\frac{n}{2} L^2 \psi_i\right)$$

is immediate once we observe in Theorem 9.4 that $V\Omega_{\gamma,n}^M(\beta L_1, \ldots, \beta L_n)$ is a polynomial of degree $6g - 6 + 2n$ in $\beta$: taking the limit $\beta \to \infty$ extracts the top degree coefficient and yields the right-hand side. \qed
The Laplace transform of the topological recursion (61) for the Kontsevich initial data (70) was first computed in [8] and shows that Eynard–Orantin’s topological recursion for the spectral curve

\[ x(z) = z^2/2, \quad y(z) = -z, \quad \omega_{0,2}(z_1, z_2) = \frac{dz_1 dz_2}{(z_1 - z_2)^2}, \]

is computing

\[
\omega^K_{g,n}(z_1, \ldots, z_n) = \left( \int_{\mathbb{R}_+^n} \prod_{i=1}^n dL_i L_i e^{-z_i (L_i)_{g,n}}(L_1, \ldots, L_n) \right) dz_1 \otimes \cdots \otimes dz_n
\]

\[
= \sum_{m_1 + \cdots + m_n \geq 0} \left( \int_{\mathbb{R}_+^n} \prod_{i=1}^n \psi_i^{m_i} \right) \otimes \frac{(2m_i + 1)!d z_i}{z_i^{2m_i + 2}} \tag{75}
\]

This is one of the many ways to prove the last equality: this statement is equivalent to the Virasoro constraints conjectured by Witten in [27] and proved by Kontsevich in [18] and it has a long history into which we do not enter here.

### 9.3 Fibering over Teichmüller space

Imagine that \( \tilde{E} \) is a pre-target theory, i.e. a target theory without the data of length functions. The typical case we have in mind are functors coming from topological field theories or conformal field theories. We can still construct a target theory by considering functions from Teichmüller space with values in \( \tilde{E} \),

\[ E(\Sigma) = \mathcal{F}(\mathcal{T}_\Sigma, \tilde{E}(\Sigma)) \]

We define the union and glueing morphisms for \( E \) by combining those of \( \tilde{E} \) and those of Sections 8.1. We equip \( E(\Sigma) \) with the seminorms indexed by \( i \in \mathcal{F}_\Sigma \), \( \alpha \in \mathcal{X}_\Sigma^{(i)} \), \( \varepsilon \in (0,1) \) and \( \sigma \in \mathcal{T}_\Sigma^i \) defined by

\[ |f|_{i,\varepsilon,\alpha} = \sup_{\sigma \in \mathcal{F}_{i,\varepsilon}} |f(\sigma')|_{i,\alpha}. \]

We equip \( E \) with the collection of length functions induced by hyperbolic lengths as in (41)

\[ \ell_{(i,\varepsilon,\alpha)}(\gamma) = \ell_\sigma(\gamma), \]

which in fact does not depend on \( i, \varepsilon, \alpha \).

If \((\tilde{A}, \tilde{B}, \tilde{C}, \tilde{D})\) are initial data for \( \tilde{E} \), we can turn it canonically to admissible initial data \((A, B, C, D)\) for \( E \) with the formulae

\[
\begin{align*}
A_P(L_1, L_2, L_3) &= \tilde{A}_P \\
B_P^b(L_1, L_b, \ell) &= B^M(L_1, L_2, \ell) \tilde{B}_P \\
C_P(L_1, \ell, \ell') &= C^M(L_1, \ell, \ell') \tilde{C}_P \\
D_T(\sigma) &= \tilde{D}_T
\end{align*}
\tag{76}
\]

If the mapping class groups act trivially on \( \tilde{E} \), using the Mirzakhani-McShane identity, we deduce that the GR amplitudes for \( E \) attached to (76) will be constant functions on Teichmüller space. This constant value in \( \tilde{E}(\Sigma) \) can be considered as a definition of the GR amplitude for \( \tilde{E} \) with initial data \((\tilde{A}, \tilde{B}, \tilde{C}, \tilde{D})\). An example will appear in Section 10.4.

This trick circumvents the potential absence of length functions in pre-target theories. If the mapping class group act non-trivially on \( \tilde{E}(\Sigma) \), this argument does not apply and the GR amplitudes attached to (76) could \textit{a priori} be interesting functions on the Teichmüller space.

56
10  Statistics of lengths of multicurves

10.1  Generalization of Mirzakhani–McShane identities

Theorem 10.1  Let \((A, B, C, D)\) be an admissible initial data and assume that the corresponding GR amplitude \(\Omega_\Sigma\) is invariant under braiding of all boundary components of \(\Sigma\). Let \(f \in \mathcal{F}(\mathbb{R}_+)\) such that for any \(\varepsilon > 0\) and \(s \geq 0\) there exists \(F_{s, \varepsilon} > 0\) such that

\[
\sup_{\ell \leq \varepsilon} |f(\ell)| \varepsilon^s \leq F_{s, \varepsilon} \tag{77}
\]

Then, for any object \(\Sigma\) in \(\mathcal{B}_1\), the series

\[
\Omega_\Sigma[f](\sigma) := \sum_{c \in M^\prime_\Sigma} \Omega_{\Sigma^c}(\sigma|_{\Sigma^c}) \prod_{\gamma \in \pi_0(c)} f(\ell(\gamma)) \tag{78}
\]

converges absolutely and uniformly for \(\sigma\) in any compact of \(\mathcal{T}_\Sigma\), and it coincides with the GR amplitude associated with the twisted initial data

\[
A[f](L_1, L_2, L_3) = A(L_1, L_2, L_3) \\
B[f](L_1, L_2, \ell) = B(L_1, L_2, \ell) + A(L_1, L_2, \ell) f(\ell) \\
C[f](L_1, \ell, \ell') = C(L_1, \ell, \ell') + B(L_1, \ell, \ell') f(\ell) + B(L_1, \ell, \ell') f(\ell') + A(L_1, \ell, \ell') f(\ell) f(\ell') \\
D_T[f](\sigma) = D_T(\sigma) + \sum_{\gamma \in S_\Psi^\Sigma} A(L_1, \ell(\gamma), \ell(\gamma)) f(\ell(\gamma)) \tag{79}
\]

For a surface of type \((g, n)\), primitive multicurves have at most \(3g - 3 + n\) components, so \(\Omega_\Sigma[f]\) depends polynomially on \(f\). The term of degree 0 in \(f\) corresponds to the empty multicurve belongs to \(M^\prime_\Sigma\) and is equal to \(\Omega_\Sigma\). We recall that \(\Sigma^c\) is the surface \(\Sigma\) cut along \(c\). Although it is not an object in \(\mathcal{B}_1\), choosing arbitrarily a distinguished boundary component in each component of \(\Sigma\) turn it into an object of \(\mathcal{B}_1\) so that \(\Omega_\Sigma\) makes sense independently on the choice made by the assumption of invariance under braiding of all boundary components. As a consequence, \(\Omega_\Sigma[f]\) is also invariant under braiding of all boundary components. We call \((A[f], B[f], C[f], D[f])\) the twisting of \((A, B, C, D)\) by \(f\). For instance, the twisting of Mirzakhani initial data (66) gives access to statistics of the length of multicurves

\[
\Omega^M[f](\sigma) = \sum_{c \in M^\prime_\Sigma} \prod_{\gamma \in \pi_0(c)} f(\ell(\gamma))
\]

The specialization of the proof below to this case amounts to utilizing Mirzakhani–McShane identities as a partition of unity deduce the recursion for \(\Omega^M\). We can also see Theorem 10.1 as a generalization of Mirzakhani–McShane identities, in the sense that the result of GR is identified with an independently defined function on \(\mathcal{T}_\Sigma\).

Proof.  One easily checks that the admissibility of \((A, B, C, D)\) implies the admissibility of \((A[f], B[f], C[f], D[f])\) given the assumption (77). It is enough to prove the result for connected surfaces, and it holds for pairs of pants and tori with one boundary component, since by definition \(\Omega_T[f]\) is given by \(A = A[f]\) and we defined \(D_T[f]\) to be equal to \(\Omega_T[f]\). We now assume that \(\Sigma\) has Euler characteristic \(\leq -2\) and fix \(\sigma \in \mathcal{T}_\Sigma\). Since all sums we consider are absolutely convergent, we can apply Fubini’s theorem to cluster or exchange summations.

If \(c \in M^\prime_\Sigma\), we have by multiplicativity

\[
\Omega_{\Sigma^c}(\sigma) = \prod_{S \in \pi_0(\Sigma^c)} \Omega_S(\sigma|_S), \tag{80}
\]
We denote $\Sigma_{c}^{\gamma}$ the boundary component of $\Sigma^{\gamma}$ containing $\partial_{c} \Sigma$, and recall that (80) is valid for any choice of distinguished boundary components on each $S \neq \Sigma_{c}$. Since $\chi_{\Sigma} \leq -2$, $\Sigma_{c}$ cannot be a torus with one boundary component. The contribution to (78) of primitive multicurves $c$ such that $\Sigma_{c}$ is a pair of pants is equal to

$$
\sum_{b \in \pi_{0}(\partial_{c} \Sigma)} \sum_{[P] \in \mathcal{P}_{\Sigma}^{b}_{c}} A(l_{P}^{1}, l_{P}^{2}, l_{P}^{3}) \Omega_{\Sigma_{c}^{\gamma}, P}[f](\sigma_{\Sigma_{c}^{\gamma}}) + \frac{1}{2} \sum_{[P] \in \mathcal{P}_{\Sigma}^{b}_{c}} A(l_{P}^{1}, l_{P}^{2}, l_{P}^{3}) f(l_{P}^{1}) f(l_{P}^{2}) f(l_{P}^{3}) \Omega_{\Sigma_{c}^{\gamma}, P}[f](\sigma_{\Sigma_{c}^{\gamma}}).
$$

To make the formula shorter we denoted $l_{P}^{b} = \ell_{c}(\partial_{b} P)$. Recall that $\partial_{1} P = \partial_{2} \Sigma$ in any case and $\partial_{2} P = b$ when $[P] \in \mathcal{P}_{\Sigma}^{b}$ (see Section 2.3) so that we can also denote $l_{b}^{b} = l_{P}^{b}$. The 1/2 in the last sum takes into account the fact that boundary components of $[P] \in \mathcal{P}_{\Sigma}^{b}$ are ordered while components of $c$ are not.

For each $c \in M_{\Sigma}^{c}$ such that $\Sigma_{c}$ is not a pair of pants, we insert the GR formula

$$
\Omega_{\Sigma_{c}}(\sigma) = \sum_{[P] \in \mathcal{P}_{\Sigma_{c}}^{b}} X_{P}(\ell_{c}(\partial P)) A_{\Sigma_{c}^{\gamma}} \Omega_{\Sigma_{c}^{\gamma}, P}(\sigma_{\Sigma_{c}^{\gamma}}),
$$

where $X_{P}$ is equal to $B$ or $C$ depending on the type of $[P]$, inside (80) and then (78). We exchange the order of the resulting summations over $c$ and $[P]$, and examine for each $[P] \in \mathcal{P}_{\Sigma_{c}}^{b}$ which $c$ can contribute. For a given $[P] \in \mathcal{P}_{\Sigma_{c}}^{b}$, for some $b \in \pi_{0}(\partial_{c} \Sigma)$, we only receive the contributions of $c \in M_{\Sigma_{c}^{\gamma}}^{b}$ and thus a total contribution

$$
\sum_{b \in \pi_{0}(\partial_{c} \Sigma)} \sum_{[P] \in \mathcal{P}_{\Sigma}^{b}_{c}} B(\ell_{c}(\partial P)) \Omega_{\Sigma_{c}^{\gamma}, P}[f](\sigma_{\Sigma_{c}^{\gamma}}).
$$

For a given $[P] \in \mathcal{P}_{\Sigma}^{b}$, there are three types of $c$ contributing in (78). When $\partial_{2} P$ is component $\gamma_{0}$ of $c$ but not $\partial_{1} P$, we get a total contribution

$$
\frac{1}{2} \sum_{[P] \in \mathcal{P}_{\Sigma}^{b}} B(\ell_{c}(l_{P}^{1}, l_{P}^{2}, l_{P}^{3}) f(l_{P}^{1}) f(l_{P}^{2}) f(l_{P}^{3}) \Omega_{\Sigma_{c}^{\gamma}, P}[f](\sigma_{\Sigma_{c}^{\gamma}}).
$$

Figure 10: The terms in the twisted initial data correspond to either to $\Sigma = P$ (first picture) or to the possible configurations of $[P] \in \mathcal{P}_{\Sigma}$ (in orange) with respect to the multicurve $c$. We have indicated $\gamma_{0} = \partial P \cap c$ in green.

For each $c \in M_{\Sigma}^{c}$, such that $\Sigma_{c}$ is not a pair of pants, we insert the GR formula

$$
\Omega_{\Sigma_{c}}(\sigma) = \sum_{[P] \in \mathcal{P}_{\Sigma_{c}}^{b}} X_{P}(\ell_{c}(\partial P)) A_{\Sigma_{c}^{\gamma}} \Omega_{\Sigma_{c}^{\gamma}, P}(\sigma_{\Sigma_{c}^{\gamma}}),
$$

where $X_{P}$ is equal to $B$ or $C$ depending on the type of $[P]$, inside (80) and then (78). We exchange the order of the resulting summations over $c$ and $[P]$, and examine for each $[P] \in \mathcal{P}_{\Sigma_{c}}^{b}$ which $c$ can contribute. For a given $[P] \in \mathcal{P}_{\Sigma}^{b}$, for some $b \in \pi_{0}(\partial_{c} \Sigma)$, we only receive the contributions of $c \in M_{\Sigma_{c}^{\gamma}}^{b}$ and thus a total contribution

$$
\sum_{b \in \pi_{0}(\partial_{c} \Sigma)} \sum_{[P] \in \mathcal{P}_{\Sigma}^{b}_{c}} B(\ell_{c}(\partial P)) \Omega_{\Sigma_{c}^{\gamma}, P}[f](\sigma_{\Sigma_{c}^{\gamma}}).
$$

For a given $[P] \in \mathcal{P}_{\Sigma}^{b}$, there are three types of $c$ contributing in (78). When $\partial_{2} P$ is component $\gamma_{0}$ of $c$ but not $\partial_{1} P$, we get a total contribution

$$
\frac{1}{2} \sum_{[P] \in \mathcal{P}_{\Sigma}^{b}} B(\ell_{c}(l_{P}^{1}, l_{P}^{2}, l_{P}^{3}) f(l_{P}^{1}) f(l_{P}^{2}) f(l_{P}^{3}) \Omega_{\Sigma_{c}^{\gamma}, P}[f](\sigma_{\Sigma_{c}^{\gamma}}).
$$

58
by summing over the multicurve $c \setminus \gamma_0 \in M_{\Sigma_-}^\ell$. From the situations where $\partial_3 P$ is a component of $c$ but not $\partial_2 P$, we get likewise a total contribution

$$\frac{1}{2} \sum_{[P] \in P_{\Sigma}} B(l^1_P, l^2_P, l^3_P) f(l^1_P) \Omega_{\Sigma_-} [f](\sigma_{\Sigma_-} P)$$

(84)

From the situations where $\partial_2 P$ and $\partial_3 P$ are not components of $c$, we get a total contribution

$$\frac{1}{2} \sum_{[P] \in P_{\Sigma}} C(l^1_P, l^2_P, l^3_P) \Omega_{\Sigma_-} [f](\sigma_{\Sigma_-} P).$$

(85)

by summing over $c \in M_{\Sigma_-}^\ell$. Adding up (81) and (82)–(85), we recognize the definition of the GR amplitudes for the twisted initial data. \hfill \Box

### 10.2 Integration over the moduli space

We keep the notations of Section 8.3 and Theorem 10.1.

**Corollary 10.2** Let $(A, B, C, D)$ be measurable, strongly admissible initial data and $f: \mathbb{R}_+ \rightarrow \mathbb{R}$ be a measurable function for which there exists $\eta \in [0, 2)$ and for any $s \geq 0$ there exists $M_s > 0$ such that for any $\ell > 0$

$$|f(\ell)| \leq \frac{M_s}{\ell^n (1 + \ell)^s}$$

(86)

Then, the twisted initial data (79) is strongly admissible, and the twisted GR amplitudes induce for any $g \geq 0$ and $n \geq 1$ such that $2g - 2 + n > 0$ and any $L \in \mathbb{R}_+^n$ functions $\Omega_{g,n} [f]$ on $M_{g,n} (L)$ which are integrable with respect to $\mu_{WP}$. The integrals

$$V \Omega_{g,n} [f] (L) = \int_{M_{g,n} (L)} \Omega_{g,n} [f] d \mu_{WP}$$

satisfy the topological recursion (61) for twisted initial data, with base cases

$$V \Omega_{0,3} [f] (L_1, L_2, L_3) = A(L_1, L_2, L_3)$$

$$V \Omega_{1,1} [f] (L_1) = V D[f](L_1) = V D(L_1) + \frac{1}{2} \int_{\mathbb{R}_+} d \ell \ell A(L_1, \ell, \ell) f(\ell)$$

**Proof.** We apply Theorem 8.8 and there are only two things left to check. The first one is the strong admissibility of the twisted initial data, which is clear using the assumption (86). The second one is the value of the integral $V \Omega_{1,1} [f] (L_1)$, for which we use the technique explained in the proof of Theorem 8.8 to handle cutting of tori with one boundary components. \hfill \Box

It is also possible to compute $V \Omega_{g,n} [f]$ by direct integration. For this purpose, we need to introduce the set $\mathcal{S}_{g,n}$ of stable graphs of type $(g, n)$.

**Definition 10.3** A stable graph $G$ of type $(g, n)$ consists of the data of

$$(V_G, H_G, \Lambda_G, h, v, i)$$

with the following properties.

- $V_G$ is the set of vertices, equipped with a map $h: V_G \rightarrow \mathbb{N}$.
- $H_G$ is the set of half-edges, $v: H_G \rightarrow V_G$ is a map associating to each half-edge the vertex it is incident to, and $i: H_G \rightarrow H_G$ is an involution.
• $E_G$ is the set of edges, consisting of the 2-cycles of $i$ in $H_G$ (loops at vertices are allowed).

• $\Lambda_G$ is the set of leaves, consisting of the fixed points of $i$, and is equipped with a bijection to \(\{1, \ldots, n\}\).

• \((V_G, E_G)\) defines a connected graph, and we have the genus condition $g = \sum_{v \in V_G} h(v) + b_1(G)$, where $b_1(G)$ is the first Betti number of the graph.

• If $v$ is a vertex, $E(v)$ (resp. $\Lambda(v)$) is the set of edges (resp. leaves) incident to $v$. Denoting $k(v) = |E(v) \cup \Lambda(v)|$ the valency of $v$, we have the stability condition $2h(v) - 2 + k(v) > 0$.

An automorphism of $G$ are permutations in $V_G$ and $H_G$ which respect $h, v$ and $i$. We denote $\text{Aut}(G)$ the group of automorphisms of $G$.

We have a natural bijection $\mathcal{S}_{g,n} \cong M_\Sigma^g/\Gamma_\Sigma^g$: for a primitive multicurve $c$, the edges of the corresponding stable graphs are the components of $c$, the vertices are the connected components of the cut surface $\Sigma^c$ and the map $h$ encodes their genera.

**Lemma 10.4** Under the assumptions of Theorem 10.2, we have for $2g - 2 + n > 0$

$$V\Omega_{g,n}[f](L_1, \ldots, L_n) = \sum_{G \in \mathcal{S}_{g,n}} \frac{1}{\#\text{Aut}(G)} \int_{\#\text{Aut}(G)} \prod_{v \in E_G} d\ell_v f(\ell_v) \prod_{v \in V_G} V\Omega_{h(v), k(v)}((\ell_v)_{v \in \text{E}(v)})(L_\lambda)_{\lambda \in \Lambda(v)}$$

**Proof.** Let $\Sigma$ be a bordered surface of type $(g, n)$ with boundary components labeled from $1$ to $n$. We will silently use Fubini’s theorem to rearrange series and integrals, since the series we consider are absolutely convergent and integrable. Let $M_\Sigma^g$ be the set of primitive multicurves with ordered components, and if $c \in M_\Sigma^g$ we denote $G(c)$ the corresponding stable graph. The fiber of the forgetful map $M_\Sigma^g \to M_\Sigma^g$ above $c \in M_\Sigma^g$ has cardinality $\#\text{Aut}(G(c))$. From the definition (78), we obtain

$$V\Omega_{g,n}[f](L) = \int_{M_{g,n}(L)} \left( \sum_{c \in M_\Sigma^g} \Omega_{\Sigma^c}(\sigma|_{\Sigma^c}) \prod_{\gamma \in \pi_0(c)} f(\ell_\gamma(\gamma)) \right) d\mu_{\text{WP}}(\sigma)$$

$$= \int_{M_{g,n}(L)} \left( \sum_{c \in M_\Sigma^g} \frac{1}{\#\text{Aut}(G(c))} \Omega_{\Sigma^c}(\sigma|_{\Sigma^c}) \prod_{\gamma \in \pi_0(c)} f(\ell_\gamma(\gamma)) \right) d\mu_{\text{WP}}(\sigma)$$

For each $G \in \mathcal{S}_{g,n}$, we choose arbitrarily a primitive multicurve with ordered components $c(G)$ that represents $G$, and denote $\gamma_G^c$ its component corresponding to $c \in E_G$. Then,

$$V\Omega_{g,n}[f](L) = \sum_{G \in \mathcal{S}_{g,n}} \frac{1}{\#\text{Aut}(G)} \int_{M_{g,n}(L)} \left( \sum_{c \in M_{g,n}(c(G))} \Omega_{\Sigma^c}(\sigma|_{\Sigma^c}) \prod_{\gamma \in \pi_0(c)} f(\ell_\gamma(\beta)) \right) d\mu_{\text{WP}}(\sigma)$$

$$= \sum_{G \in \mathcal{S}_{g,n}} \frac{1}{\#\text{Aut}(G)} \int_{M_{\Sigma}^{G}(L)} \Omega_{\Sigma^c}(\sigma|_{\Sigma^c}) \prod_{c \in E_G} f(\ell_c(\gamma_G^c)) d\mu_{\text{WP}}(\sigma)$$

The proof is then completed by applying the techniques explained in the proof of Theorem 8.8. \(\square\)

The results of this Section generalize straightforwardly to the target theory $E(\Sigma) = \mathcal{F}(\mathcal{T}_\Sigma, \mathcal{A} \otimes \mathcal{A}^{\pi_0(\partial, \Sigma)})$ where $\mathcal{A}$ is a Frobenius algebra. In such cases, we can choose $f$ to be a function from $\mathbb{R}_+$ to $\text{Sym}^2(\mathcal{A})$, and in (78) the factor $f(\ell_\gamma(\gamma)) \in \text{Sym}^2(\mathcal{A})$ for each $\gamma \in \pi_0(c)$ is paired with the corresponding bivector coming from the two boundary components corresponding to $\gamma$ in $\Sigma^c$, using the pairing $\mathcal{A} \otimes \mathcal{A} \to \mathbb{C}$ and the corresponding isomorphism $\mathcal{A} \cong \mathcal{A}^*$. 

60
10.3 Various ways to compute with Corollary 10.2

As it is the most useful for applications, let us comment further the case of Corollary 10.2 when \( A \in \mathbb{R}[L_1^2, L_2^2, L_3^2], \ VD \in \mathbb{R}[L_1^2] \) and the operators

\[
\begin{align*}
\hat{B}[\varphi_1](L_1, L_2) &= \int_{\mathbb{R}_+} B(L_1, L_2, \ell) \varphi_1(\ell) \ell \, d\ell \\
\hat{C}[\varphi_2](L_1) &= \int_{\mathbb{R}_+^2} C(L_1, \ell, \ell') \varphi_2(\ell, \ell') \ell \, d\ell \, d\ell'
\end{align*}
\]

send even polynomials to even polynomials (from one variable to two variables for \( \hat{B} \), and from two variables to one variable variable for \( \hat{C} \)). We then say the initial data is of polynomial type. This occurs for instance for Mirzakhani initial data (66) – see [21, Section 5] or [9] – and for the Kontsevich initial data (70). Being of polynomial type is preserved by the twisting operation (79). The nature of this operation becomes more transparent if we decompose the initial data on a basis of even polynomials. Namely, if we introduce the scalars \( A_{j,k}^i, B_{j,k}^i, C_{j,k}^i, D^i \) by the formulas

\[
\begin{align*}
A(L_1, L_2, L_3) &= \sum_{i,j,k \geq 0} A_{j,k}^i L_1^2 L_2^2 L_3^2 \ell^{2k} \\
\hat{B}[\ell^{2k}] &= \sum_{i,j,k \geq 0} B_{j,k}^i L_1^{2i} L_2^{2j} \ell^{2k} \\
\hat{C}[\ell^{2j}(\ell')^{2k}] &= \sum_{i \geq 0} C_{j,k}^i L_1^{2i} \\
VD(L_1) &= \sum_{i \geq 0} D^i L_1^{2i}
\end{align*}
\]

we then have a similar decomposition

\[
\begin{align*}
A[f] &= A_{j,k}^i \\
B[f] &= B_{j,k}^i + \sum_{a \geq 0} A_{j,a}^i u_{a,k} \\
C[f] &= C_{j,k}^i + \sum_{a \geq 0} B_{j,a}^i u_{a,k} + \sum_{a,b \geq 0} A_{j,a}^i u_{j,b} u_{a,b} \\
D[f] &= D^i + \frac{1}{2} \sum_{a,b \geq 0} A_{a,b}^i u_{a,b}
\end{align*}
\]

where \( u \) is computed in terms of the odd moments of \( f \)

\[
u_{i,j} = m_{2(i+j)+1}[f], \quad m_k[f] = \int_{\mathbb{R}_+} d\ell \ell^k f(\ell)
\]

Relation to Quantum Airy Structures – Recall the terminology and notations of Section 6.2.

Let us assume that the coefficients \( (A, B, C, D) \) coming from some GR initial data of polynomial type in the target theory \( \text{Mes}(\mathcal{F}_\Sigma, A^{\otimes \pi_0(\mathcal{O})}) \), describe the quantum Airy structure coming from a spectral curve \( (S, x, y, \omega_{0,2}) \) with Jacobi ring \( A \). Since we have

\[
\frac{(2d+1)!}{\zeta^{2d+2}} = \int_{\mathbb{R}_+} d\ell \ell^{2d} e^{-\zeta \ell},
\]

applying the Laplace transform to (35) gives the following relation between Eynard–Orantin multidifferentials and the TR amplitudes \( V\Omega_{g,n} \)

\[
\begin{align*}
\omega_{g,n}(z_1, \ldots, z_n) &= \sum_{r_1, \ldots, r_n} \text{Res} \ldots \text{Res} \left[ \prod_{i=1}^n \left( d\zeta(z'_i) \int_{z'_i}^{z_i} \omega_{0,2}(: z_i) \right) \int_{\mathbb{R}_+} \prod_{i=1}^n dL_i e^{-L_i \zeta(z'_i)} \left( V\Omega_{g,n}(L) \mid e_{r_1} \otimes \cdots \otimes e_{r_n} \right)_A \right]
\end{align*}
\]

(89)
where we used the pairing in $A$ for each of the $n$ tensor factors.

We recognize by comparing (10.3) to [5, Section 4.1] or [9, Section 1.5] that the twisting by $f$ corresponds to a certain change of polarization, therefore to a shift of $\omega_{0,2}$; from the precise relation between the $u$s and the choice of $\omega_{0,2}$ in [5, Section 9], we find from (87) that the twisting amounts to adding to $\omega_{0,2}$ the symmetric holomorphic bidifferential

$$d\zeta_1 d\zeta_2 \in \text{Sym}^2(A[[\zeta]])$$

defined locally near $r^2 \in S^2$.

**Relation with Givental Group Action** – The operation of twisting is in fact known in another context. Sums over stable graphs describe the action of the $R$ element of the symplectic loop group on correlation functions of cohomological field theories introduced by Givental [16, 17]. There, one considers a Frobenius algebra $A$ and a formal series $R \in \text{End}(A)([[t]])$ such that $R(t) = \text{id}_A + O(t)$ and $R(t) R^T(-t) = \text{Id}$, and defines$^4$ $u_{a,b} \in \text{Sym}^2(A)$ by

$$\left(\frac{1\text{d} - R(t_1) \otimes R(t_2)}{t_1 + t_2}\right)[\eta] = \sum_{d_1,d_2 \geq 0} (2d_1 + 1)!!(2d_2 + 1)!! u_{d_1,d_2} t_1^{d_1} t_2^{d_2},$$

(90)

where $\eta \in A^{\otimes 2}$ describes the pairing in $A$. The $u$s coming from an $R$ matrix are not always of the form (87). However, if we only consider $A = \mathbb{C}$, we can make the following observation.

**Lemma 10.5** Assume there exists a measurable test function $f : \mathbb{R}_+ \to \mathbb{C}$ and $R \in \mathbb{C}([[t]])$ such that $u_{d_1,d_2}$ satisfy both (90) and (87) and is not identically 0. Then, there exists a unique $H \in \mathbb{R}_+$ such that, up to adding to $f$ a test function whose odd moments vanish, we have

$$f(t) = -\eta \Theta(H^{1/2} - t), \quad R(t) = e^{Ht/2},$$

**Proof.** We compute from (87)

$$\sum_{d_1,d_2 \geq 0} (2d_1 + 1)!!(2d_2 + 1)!! u_{d_1,d_2} t_1^{d_1} t_2^{d_2} = \int_{\mathbb{R}_+} f(t) e^{(t+t_2)/2} t \text{d}t.$$  

In particular, this generating series depends only on $t_1 + t_2$. Taking into account $R(0) = 1$, this is only possible when $R(t_1) R(t_2) = R(t_1 + t_2)$, that is $R(t) = e^{Ht/2}$ for some $H \in \mathbb{C}$. When this is the case, we compute with (90)

$$(2d_1 + 1)!!(2d_2 + 1)!! u_{d_1,d_2} = -\eta \frac{H^{d_1+d_2+1}}{2^{d_1+d_2+1}(d_1 + d_2 + 1)} \frac{1}{d_1!d_2!}.$$  

Thus

$$u_{d_1,d_2} = -\eta \frac{H^{d_1+d_2+1}}{2(d_1 + d_2 + 1)} \frac{1}{(2d_1 + 1)!(2d_2 + 1)!},$$

(91)

This is satisfied if we choose $H \geq 0$ and $f(t) = -\eta \Theta(H^{1/2} - t)$ and the case $H = 0$ gives vanishing $u$. If $\tilde{f}$ is another test function that yields (91), then

$$\forall k \geq 0, \quad \int_{\mathbb{R}_+} (f(t) - \tilde{f}(t)) t^{2k+1} \text{d}t = 0.$$  

$^4$The Givental group action is usually formulated in the basis such that the index $d$ is directly coupled to the insertion of $\psi^d$ without prefactor. As one can check by comparing with Theorem 9.4, this basis is $\frac{\text{Id}}{\zeta^{2d}}$ in the $\zeta$-variable, hence after Laplace transform $\frac{(2d+1)!!\zeta^{2d}}{\zeta^{2d+1}}$ in the $\zeta$-variable. This explains the $(2d+1)!!$ factors appearing in (90).
10.4 Chern character of the bundle of conformal blocks and length statistics

Let \( Z \) be a modular functor. We denote \( \Lambda \) its associated label set, \( \dagger \) the involution on \( \Lambda \), \( A \) its associated Frobenius algebra with its natural basis \((e_\lambda)_{\lambda \in \Lambda} \) and product \( \mu \) encoding the Verlinde rules. Using the pairing to identify \( A \cong A^* \), we shall consider \( \mu \) as an element of \( A^{\otimes 3} \).

For any \( g, n \geq 0 \) such that \( 2g - 2 + n > 0 \) and \( \lambda \in \Lambda^n \), we have constructed in [6] a bundle \( Z_{g,n}(\lambda) \to \mathcal{M}_{g,n} \) and shows that its Chern character defines a semi-simple cohomological field theory \( w_{g,n} : A^{\otimes n} \to H^*(\mathcal{M}_{g,n}) \) via the formula
\[
w(c_{\lambda_1} \otimes \ldots \otimes c_{\lambda_n}) = \text{Ch}(Z_{g,n}(\lambda)).
\]

Furthermore, this cohomological theory is identified as the result of the Givental group action for the \( R \)-operator\(^5\)
\[
R(t) = e^{t(c/24-\lambda_0)},
\]
where \( \lambda_0 \in \text{End}(A) \) is the operator whose eigenvectors are \( e_{\lambda} \) with eigenvalue given by the conformal dimensions \( r_\lambda \), and \( c \) is the central charge. We refer to [6] for details.

Here we find a rather surprising interpretation of the intersection indices of this cohomological field theories with \( \psi \)-classes in terms of integrals (with respect to the Weil–Petersson measure) of statistics of hyperbolic lengths of multicurves by comparing with Corollary 10.2.

**Proposition 10.6** Assume that for any \( \lambda \in \Lambda \) we have \( c/24 - r_\lambda > 0 \). Consider the following initial data for the target theory \( E(\Sigma) = \text{Mes}(\mathcal{T}_\Sigma, A^{\otimes n}(\Sigma)) \)
\[
A^Z(L_1, L_2, L_3) = \mu
\]
\[
B^Z(L_1, L_2, \ell) = \left( \frac{2\pi}{\sqrt{c/12}} \right)^2 B^M(L_1, L_2, \ell) \mu
\]
\[
C^Z(L_1, \ell, \ell') = \left( \frac{2\pi}{\sqrt{c/12}} \right)^4 C^M(L_1, \ell, \ell') \mu
\]
\[
D^Z(\sigma) = \left( \frac{2\pi}{\sqrt{c/12}} \right)^2 \sum_{\lambda \in \Lambda} \text{rk}(Z_{1,1}(\lambda)) e_\lambda
\]
and set
\[
f(\ell) := - \sum_{\lambda \in \Lambda} \Theta(H_\lambda - \ell) e_\lambda \otimes e_{\lambda^\dagger}, \quad \text{where } H_\lambda := \sqrt{2(c/24 - r_\lambda)}
\]
We denote \( \Omega^Z[f] \) the GR amplitude for the initial data (94) twisted by \( f \). We have for \( 2g - 2 + n > 0 \) and \( \lambda \in \Lambda^n \)
\[
(-1)^n \int_{\mathcal{M}_{g,n}} \text{Ch}[Z_{g,n}(\lambda)] \exp \left( \sum_{i=1}^n \frac{L_i^2}{2} \psi_i \right) \left( V\Omega^Z_{g,n}[f](\frac{\sqrt{c/12}}{2\pi} L) \right)_{\lambda} \equiv \nonumber \]
where in the left-hand side, it is understood that the polynomial function \( V\Omega^Z[f](L) \) is specialized to \( L' = \frac{\sqrt{c/12}}{2\pi} L \in \mathbb{C}^n \).

When the positivity conditions are not satisfied, we can still conclude that the right-hand side of (96) is the analytic continuation of a function \( V\Omega^Z_{g,n}[f] \) in the variables \((H_\lambda)_{\lambda \in \Lambda} \), which coincide in the region \( H_\lambda > 0 \) with the integral of statistics of hyperbolic lengths. Notice in any case that (96)
\(^5\)This formula differs by a sign of \( r_\lambda \) compared to [6]. The reason is that in [6] the contribution of \( \tilde{\psi}_p \) to the Chern character was mistaken for \( \psi_p \) instead of \(-\psi_p \), which should be corrected with this sign.
involves the specialization of Weil–Petersson volumes to purely imaginary lengths. This is sometimes related to surfaces with conic singularities instead of boundaries, see e.g. [23]. Besides, the operator $L_0 - \frac{c}{24}$ gives the hamiltonian in conformal field theory, while $\sqrt{L_0 - \frac{c-1}{24}}$ – which would appear in (95) if one had tensored $Z_{g,n}(\lambda)$ with a squareroot of the Hodge bundle – is the momentum. It is therefore tempting to ask for a physical explanation of Proposition 10.6 in the conformal field theory corresponding to $\mathcal{Z}$ on surfaces of genus $g$ with $n$ conic singularities.

**Proof of Proposition 10.6.** As reviewed in [6], the Frobenius algebra $\mathcal{A}$ of a modular functor admits a basis $(\xi_\lambda)_{\lambda \in \Lambda}$ which is orthogonal for the pairing and such that $\xi_\lambda \times \xi_\mu = \delta_{\lambda,\mu}$ for the product. The $S$-matrix of $\mathcal{Z}$ gives the change of basis

$$\xi_\lambda = \sum_{\mu \in \Lambda} S_{\lambda,\mu} \xi_\mu$$

and the Verlinde formula holds

$$\text{rk}[Z_{g,n}(\lambda)] = \sum_{\mu \in \Lambda} \frac{\prod_{i=1}^n S_{\lambda_1,\mu}}{(S_{1,\mu})^{2g-2+n}}$$

(97)

We consider the Eynard–Orantin multidifferentials $\omega_{g,n}^0$ for the local spectral curve $S = \mathbb{C}$ with

$$x(\zeta) = \zeta^2/2, \quad y(\zeta) = \sum_{\lambda \in \Lambda} S_{1,\lambda} - \frac{\sinh(\sqrt{c/12})}{\sqrt{c/12}} \omega_{0,2}(\zeta_1, \zeta_2) = \sum_{\lambda \in \Lambda} \frac{d\xi_1 \otimes d\xi_2}{(\zeta_1 - \zeta_2)^2} S_{\lambda} \otimes \xi_\lambda$$

(98)

By comparison with Theorem 9.2, we find

$$\frac{\omega_{g,n}^0(\zeta_1, \ldots, \zeta_n)}{d\xi_1 \otimes \cdots \otimes d\xi_n} = \sum_{\lambda \in \Lambda} \left( \frac{(2\pi)^3}{(c/12)^{3/2}} S_{1,\lambda} \right)^{2g-2+n} \int_{\mathbb{R}^n} \prod_{i=1}^n dL_i \ L_i e^{-\zeta_i L_i} V \Omega^M_{g,n} \left( \frac{\sqrt{c/12}}{2\pi} L \right) \xi^n$$

Hence, taking scalar products and using (97), we find

$$\left( \frac{\omega_{g,n}^0(\zeta_1, \ldots, \zeta_n)}{d\xi_1 \otimes \cdots \otimes d\xi_n} \right)_{\mathcal{A}} = (-1)^n \left( \frac{2\pi}{\sqrt{c/12}} \right)^{6g-6+2n} \text{rk}[Z_{g,n}(\lambda)] \int_{\mathbb{R}^n} \prod_{i=1}^n dL_i \ L_i e^{-\zeta_i L_i} V \Omega^M_{g,n} \left( \frac{\sqrt{c/12}}{2\pi} L \right)$$

(99)

Using Mirzakhani–McShane identities (Theorem 9.1), Verlinde formula and tracking the powers of $\frac{2\pi}{\sqrt{c/12}}$ we also find that the integral of the GR amplitudes for the initial data (94) are given by

$$\left( \Omega^\Sigma_{g,n}(\sigma) | e_{\lambda_1} \otimes \cdots \otimes e_{\lambda_n} \right)_{\mathcal{A}} = \left( \frac{2\pi}{\sqrt{c/12}} \right)^{6g-6+2n} \text{rk}[Z_{g,n}(\lambda)] \Omega^\Sigma_{\Sigma}(\sigma)$$

and therefore reproduce up to prefactors the right-hand side of (99) after integration on $\mathcal{M}_{g,n}(L')$ and specialization of the result (which is a polynomial in $L'$) to the values $L' = \sqrt{c/12} L$.

The $R$-operator (93) is the form considered in Lemma 10.5, so it realizes simultaneously (90) and (87) for $f$ given by (95). Theorem [6, Theorem 4.5] identifies the Laplace transform of the right-hand side of (96) with the Eynard–Orantin multidifferentials for the spectral curve obtained from (98) by twisting via this $R$-operator. We then use the correspondence (89) and the fact that the Laplace transform (88) between odd polynomials in $\zeta^{-1}$ and even polynomials in $L$ is an isomorphism to conclude. □
