In this paper we bridge this gap by proposing a mechanism to generate $\Lambda$ and the quantitative estimates based entirely on known fundamental features of the physics involved. The origin of the cosmological term, we suggest, is to be found in the microscopic structure of spacetime and its interaction with matter. We will work under the hypothesis that discreteness of geometry and Lorentz invariance at low energies are fundamental aspects of quantum gravity. Based on these two fundamental features we propose a phenomenological model for quantum-gravity-induced violations of energy conservation depending only on the fundamental constants $G, c, \hbar$ and a few parameters of the standard model (SM). We show that our simple proposal resolves the two limitations of the previous examples and predicts a contribution to the cosmological constant of the correct order of magnitude.

One of the most important constraints on the form of quantum discreteness at Planck scales comes from the observed validity of Lorentz invariance at QFT scales. As shown in [6, 7] this rules out the simple atomistic view of a spacetime foam selecting a preferred ‘rest-frame’ at the Planck scale. This result, which severely constrains phenomenological ideas, is corroborated by a large collection of empirical evidence [8]. A more subtle theoretical characterization of space-time discreteness at Planck’s scale is necessary.

We think that the key for understanding Planckian discreteness lies in the relational nature of physics partly uncovered by Einstein’s theory of gravity [9]. In general relativity, geometry can only be probed by the matter degrees of freedom. The metric has a clear physical meaning only when rulers and clocks are introduced. More precisely, the construction of observables (diffeomorphism invariant quantities) requires the use of relational notions involving a mixture of geometric and matter degrees of freedom. The difficulty of actually defining such quantities is, in fact, one of the most severe technical problems in formal approaches to quantum gravity. In our view such relational perspective is essential for understanding discreteness at the Planck scale. We are thus rejecting the notion of a spacetime foam acting as an empty...
arena where matter, if there placed, would reveal its pre-existing features. Quantum discreteness should arise primarily via the interactions of gravity with those other degrees of freedom, which by their nature, are able to select a preferential rest-frame where the fundamental scale $\ell_p$ acquires an invariant meaning. In other words, within the relational approach we are advocating, it is clear that, in order to be directly sensitive to the discrete scale $\ell_p$, the probing degrees of freedom must themselves carry their intrinsic scale. Thus massless (scale-invariant) fields are ruled out as leading probes of discreteness simply because they cannot be associated with any local notion of rest frame, and thus, of a fundamental length scale. This argument identifies massive fields as the natural candidates for probes of spacetime discreteness. Such discreteness must be thus thought as becoming relevant, or as ‘awaken’, by the interactions of gravity with such scale-invariance-breaking fields. The immediate possibility arising from such considerations (and framed in a phenomenological perspective) is that low energy quantum field theoretical excitations of massive fields could interact with the underlying quantum gravity microstructure and exchange ‘energy’ with it 1.

In order to study the phenomenological implications of these ideas one needs a ‘mean field’ or macroscopic description of the quantity parametrizing the phenomenon. An obvious choice is the trace of the energy-momentum tensor $\mathbf{T}$ — which for a fluid in thermal equilibrium is simply given by $\mathbf{T} = -\rho + 3P$ — which signals the breaking of conformal invariance, and hence, the presence of massive degrees of freedom. Via Einstein’s equations $\mathbf{T}$ is related to the scalar curvature $\mathbf{R} = -8\pi G \mathbf{T}$. Therefore, the presence of massive fields (suitable probes of discreteness according to our rationale) is geometrically captured by a non trivial $\mathbf{R}$.

The effect on the propagation of massive fields must be realized in a deviation from the geodesic motion of free particles due to a ‘friction-like’ force encoding the noisy interaction with the underlying spacetime granularity. As argued in the previous paragraphs, the force should depend on the mass $m$, the 4-velocity $u^\mu$, the spin $s^\mu$ of the classical particle (the only spacetime related intrinsic features defining a particle), and a time-like unit vector $\xi^\mu$ specifying the local frame defined by the matter that curves spacetime. For instance, in cosmology $\xi = \partial_t$ is naturally associated with the time-arrow of the co-moving cosmic fluid. In addition, and according to our preceding arguments, the force should be proportional to the particle’s mass, endowing it with a characteristic length scale: the Compton wave-length. Dimensional analysis gives an essentially unique expression which is compatible with the above requirements 2,

$$u^\mu \nabla_\mu u^\nu = \alpha \frac{m}{m_p^2} \text{sign}(s \cdot \xi)\mathbf{R} s^\nu,$$  \hspace{1cm} (1)

where $\alpha > 0$ is a dimensionless coupling 3.

The factor $\text{sign}(s \cdot \xi)$ makes the force genuinely friction-like. This is apparent when one considers the change of the mechanical energy of the particle $E \equiv -m u^\mu \xi_\nu$ (defined in the frame defined by $\xi^\mu$) along the particles world-line, namely

$$\dot{E} \equiv -m u^\mu \nabla_\mu (u^\nu \xi_\nu) = -\alpha \frac{m^2}{m_p^2} (s \cdot \xi)\mathbf{R} - m u^\mu u^\nu \nabla_\nu (\xi_\mu).$$  \hspace{1cm} (2)

The last term in (2) encodes the standard change of $E$ associated to the non-Killing character of $\xi^\mu$. The first term on the right encodes the friction that damps out any motion with respect to $\xi^\mu$. Energy is lost into the fundamental granularity until $u^\mu = \xi^\mu$ and the particle is at rest with the cosmological fluid, and thus $\dot{E} = 0$.

The simplest dynamics for the spin that is consistent with (1), the conservation of $s \cdot s$, and $s \cdot p = 0$ is

$$u^\mu \nabla_\mu s^\nu = \alpha \frac{m}{m_p^2} \text{sign}(s \cdot \xi)\mathbf{R} (s \cdot s) u^\nu.$$  \hspace{1cm} (3)

This is only a minimalistic solution, other terms can be added. We will investigate these aspects elsewhere as they might be important for phenomenology; however, they do not affect the main point in this letter.

In this respect, it is also important to point out that the violations of the equivalence principle and Lorentz invariance implied by (1) and (3) can be readily checked not to be in conflict with well known observational bounds by many orders of magnitude [20] for $\alpha \sim O(1)$. A simple

2 Higher curvature corrections could be added, but these are highly suppressed by the Planck scale and are thus negligible for the central point of this letter. A term proportional to $\epsilon_{\mu\nu\rho\sigma} \xi^\mu s^\nu u^\rho u^\sigma$ is also allowed but does not affect the results.

3 There is a remarkable formal similarity of equation (1) with others arising in well understood situations. We have the Mathisson-Papapetrou-Dixon equations [18] describing the dynamics of idealized extended objects in GR,

$$u^\mu \nabla_\mu p_\rho = -\frac{1}{2} R_{\mu\nu\rho\sigma} u^\nu S^{\sigma\rho},$$

where $u^\mu$ represents the 4-velocity of the object, $P^\mu$ its 4-momentum, $S^{\mu\rho}$ its spin and $R_{\mu\nu\rho\sigma}$ is the Riemann tensor. Moreover, we note that the characterization of WKB-trajectories of the Dirac theory on a pseudo-Riemannian geometry [19], to lowest order in $h$, is given by

$$u^\nu \nabla_\nu (m u_\mu) = -\frac{1}{2} \mathbf{R} u^\nu (S^{\sigma\rho}) + O(h^2).$$

The previous is equivalent to (1) if one considers an effective $R_{\mu\nu\rho\sigma} \propto m^2 / L_p^4 \text{sign}(s \cdot \xi) R_{(\mu\rho \nu \sigma)}$ taken to encode a pure torsion-related structure as $\dot{R}_{(\mu\rho \nu \sigma)} = 0$ (from the first Bianchi identities).

1 Some ideas with similar conceptual underpinning have been explored in the context of laboratory searches for quantum gravity phenomenology [13–15]. For a discussion of the implications for the information problem in black hole evaporation see [16, 17].
indication comes from comparison of the value of $R$ at the electro weak (EW) transition in cosmology (a regime where our effects will be important) to that associated with, say, the gravitational effect of a piece of lead: this gives $R_{\text{ew}}/R_{\text{lead}} \sim 10^{-24}$.

Coming back to the main argument, the diffusion of energy for a single particle, induced by (1), implies the lack of energy-momentum conservation for a fluid constituted by an ensemble of such particles (we will compute this below). However, violations of energy-momentum conservation are incompatible with general covariance and hence with the standard general relativity description of gravity. Fortunately, there is a simple relaxation of general covariance (originally studied by Einstein) from full coordinate invariance down to spacetime volume preserving coordinate transformations. Such modification—which we only take as an effective low energy description of a (in a suitable sense) general covariant fundamental physics— is called unimodular gravity (UG), and its field equations are just the trace-free part of the standard Einstein’s equations

$$R_{\mu \nu} - \frac{1}{4} R g_{\mu \nu} = 8 \pi G \left( T_{\mu \nu} - \frac{1}{4} T g_{\mu \nu} \right).$$

(4)

Defining $J_\mu \equiv (8 \pi G) \nabla^\nu T_{\nu \mu}$, assuming UG integrability $dJ = 0$ , and using Bianchi identities, one obtains [5]

$$R_{\mu \nu} - \frac{1}{2} R g_{\mu \nu} + \left\{ \Lambda_0 + \int \frac{J}{A} \right\} g_{\mu \nu} = 8 \pi G T_{\mu \nu},$$

(5)

where $\Lambda_0$ is a constant of integration, and $\tau$ is a one-dimensional path from some reference event. Thus, the energy-violation current $J$ is the source of a term in Einstein’s equations satisfying the dark energy equation of state. An additional, often alluded feature of UG is that it is generally covariant (originally studied by Einstein) from full coordinate invariance down to spacetime volume preserving coordinate transformations. Such modification—which we only take as an effective low energy description of a (in a suitable sense) general covariant fundamental physics—is called unimodular gravity (UG), and its field equations are just the trace-free part of the standard Einstein’s equations

$$R_{\mu \nu} - \frac{1}{4} R g_{\mu \nu} = 8 \pi G \left( T_{\mu \nu} - \frac{1}{4} T g_{\mu \nu} \right).$$

(4)

Defining $J_\mu \equiv (8 \pi G) \nabla^\nu T_{\nu \mu}$, assuming UG integrability $dJ = 0$ , and using Bianchi identities, one obtains [5]

$$R_{\mu \nu} - \frac{1}{2} R g_{\mu \nu} + \left\{ \Lambda_0 + \int \frac{J}{A} \right\} g_{\mu \nu} = 8 \pi G T_{\mu \nu},$$

(5)

where $\Lambda_0$ is a constant of integration, and $\ell$ is a one-dimensional path from some reference event. Thus, the energy-violation current $J$ is the source of a term in Einstein’s equations satisfying the dark energy equation of state. An additional, often alluded feature of UG is that the vacuum energy does not gravitate [3, 21, 22].

Now we compute $J_\nu \equiv 8 \pi G \nabla^\nu T_{\mu \nu}$ as implied by (1). For a particle species $i$ (the interactions between different species are neglected here as their effect lead only to very small corrections) one has $T_{\mu \nu}^{(i)}$ 4

$$T_{\mu \nu}^{(i)}(x) \equiv \int p_\mu p_\nu f^i(x, p, s_r) Dp Ds_r,$$

(6)

where $f^i(x, p, s_r)$ encodes the particle distribution in phase space with $s_r$ denoting the value of the spin of the particle in its rest frame, $Dp = \delta(p^2 + m^2)^2 dp$, and $Ds_r$ is the standard measure on the sphere of the spin directions. Simple kinetic theory allows to express $\nabla^\nu T_{\mu \nu}$ as (see equation 2.113 in [23])

$$\nabla^\nu T_{\mu \nu}^{(i)} \equiv - \frac{\int m_i F_\mu f^i(x, p, s_r) Dp Ds_r}{m_i^2 \int f^i(x, p, s_r) Dp Ds_r},$$

(7)

where 0-components refer to the time direction $\xi^\mu$. Assuming thermal equilibrium at temperature $T$, and ignoring the negligible additional effects of the force on the distribution, we have $f^i(x, p, s_r) = f^i_T(p)$ where the later is the standard Boltzmann distribution.

Isotropy of the equilibrium configuration implies that only the 0-component of (7) is non trivial. Then the result follows first from the fact that

$$\int |s_0| Ds_r = \frac{2 \pi p |s|}{m} \int |\cos(\theta)| \sin(\theta) d\theta = \frac{2 \pi p |s|}{m},$$

$$\int \left[ \frac{2 \pi p |s|}{m} \right] f_T(p) Dp = 4 \pi |s| T \left[ 1 + \mathcal{O} \left( \log \left( \frac{m}{T} \right) \right) \frac{m^2}{T^2} \right].$$

Therefore, in the relativistic regime $T \gg m$ one has

$$J_\nu \equiv (8 \pi G) \nabla^\nu T_{\mu \nu} = 4 \pi \alpha \frac{T}{m_p^2} R \left[ 8 \pi G \sum_i |s_i| T^4 \right] \xi^\nu,$$

(8)

where in the last line we write an approximation valid for the case where a single $|s| = h/2$ fermion species dominates. This approximation will be useful in the application of the formula to cosmology.

We now focus on the effects of (8) in the dynamics of the early universe when its macroscopic geometry is well approximated by the flat FLRW metric

$$ds^2 = -dt^2 + a(t)^2 d\tilde{x}^2,$$

(9)

and where the local frame $\xi = \partial_t$ is identified with comoving observers. As only massive particles with spin are subjected to the frictional force (1), the diffusion mechanism in cosmology starts when such particles first appeared. According to the standard model—whose validity is assumed from the end of inflation—this corresponds to the electro-weak (EW) transition time. We further assume that a protective symmetry enforces $\Lambda_0 = 0$ (see for instance [24, 25]).

We are now ready to estimate the effective cosmological constant predicted by our model. Using (5), and (8)
one gets

\[ \Lambda = \frac{2\pi \alpha \hbar}{m_p^3} \int_{t_0}^{t_w} \left[ 8\pi G (\rho - 3P) \right]^2 T \, dt, \quad (10) \]

with \( t_0 \) the present time. It is convenient to change the integration variable in (10) from co-moving time \( t \) to temperature \( T \) given the essentially direct relation between the two quantities. During the relevant period, of radiation domination, the matter fields are assumed to be in thermal equilibrium. The density of the universe is then given by, \( \rho = \pi^2 g_* T^4 / (30h^3) \) where \( g_* \approx 100 \) is the effective degeneracy factor for the temperatures of interest \([26]\). Taking into account that temperature scales like \( a^{-1} \), using Friedman equation, and \( H(a) = \dot{a}/a \), one gets,

\[ \frac{dT}{T} = -\frac{da}{a} = -\frac{8\pi G}{3} \frac{\pi^2 g_* T^4}{h^3} \frac{\dot{a}}{H(a)} dt. \quad (11) \]

We will now focus just on the leading contributions. In the ultra-relativistic regime standard thermodynamics leads to the expression

\[ \rho - 3P \approx m_t^2 T^2 / 2h^3, \quad (12) \]

where \( m_t \) is the top mass. Replacing the leading term in (12) and (11) into (10) one gets

\[ \Lambda \approx 16\alpha \sqrt{\frac{5\pi^3}{g_*}} \frac{m_t^4 T_{ew}^3}{m_p^2 h^2} \, \epsilon(T_{ew}), \quad (13) \]

where

\[ \epsilon(T_{ew}) = -\frac{3}{T_{ew}^2} \int_{T_{ew}}^{T_{end}} \left( 1 - \frac{T^2}{T_{ew}^2} \right)^2 T^2 dT \quad (14) \]

is a dimensionless correction factor that takes into account the temperature dependence of the quark mass during the EW-transition, namely \( m_t^2(T) = m_t^2(1 - T^2/T_{ew}^2) \). The end temperature \( T_{end} \) is the one satisfying \( 2 m_t(T_{end}) = T_{end} \) when the top quark’s abundance decreases dramatically. The contribution of other fields in the standard model, as well as those tied to simple dark matter models such as WIMPS will not affect the order of magnitude of the estimate \([5]\). We note that aside from the correction factor, \( \epsilon(T) \approx 10^{-3} - 10^{-4} \) in the range of interest, equation (13) could have been guessed from dimensional analysis. After substitution of the different quantities involved and taking for example \( T_{ew} \approx 100 \text{ GeV} \) \([27, 28]\), and adding the gauge boson contributions (not included in (13)) we find

\[ \Lambda \approx 4\alpha \Lambda_{obs} \quad (15) \]

where \( \Lambda_{obs} \) is the observed value of the cosmological constant. For other values of \( T_{ew} \) see Figure 1 where we plot the value of the dimensionless coupling \( \alpha \) needed to fit the observed values as a function of \( T_{ew} \). These results are an order of magnitude estimate; a refined calculation would require detailed considerations of the dynamics of the electro-weak transition. However, such details are not expected to modify our result in essential ways.

![Figure 1: The value of the phenomenological parameter \( \alpha \), see eq. (1), that fits the observed value of \( \Lambda_{obs} \) as a function of the EW transition scale \( T_{ew} \) in GeV. The contributions from the massive gauge bosons of the standard model have been included.](image-url)

We believe that our proposal has important implications of various types. At the theoretical level it provides a novel view that could reconcile Planckian discreteness and Lorentz invariance and gives possibly valuable insights guiding the search for a theory of quantum gravity. At the empirical level our analysis opens a new path for searches of new physical manifestations of the gravity/quantum interface.

Concerning the later, we note that one might use (8) to estimate the amount of energy loss in local experiments. Presently (neglecting the cosmic expansion), we find \( \rho \approx -\alpha (\rho/\rho_{\text{water}})^{10^{-70}} \text{g/(cm}^3\text{s)} \) where \( \rho_{\text{water}} \) is the density of sea water. The amount of energy produced is maximal at the EW transition when the density of the universe \( \rho(T_{ew}) \approx 10^{25} \text{g/cm}^3 \), and corresponds to a relative change of energy density in a Hubble time of \( \Delta \rho/\rho \approx 10^{-51} \). Such a minuscule level of energy loss cannot have significant effects on the matter dynamics, and thus would be very hard, but not impossible to detect. Nevertheless, we have seen that such small energy losses can explain the observed late time acceleration of the expansion rate of our universe.

\(^{5}\) Massive gauge bosons do not change the order of magnitude estimate, as \( m_Z^2/n_t = 1/2 \) and \( g_{2\gamma\gamma} = 3/2 \). In (13) this leads to a factor \((3/4)^2(1/2)^4 \approx 3/4 \) times 2 as the spin of the bosons is twice that of the fermions, i.e. their contributions is about 7% of that coming from top-quark. From (8) one can work out the precise corrections which are included in Figure 1.
Finally, as the model links $\rho$ and its evolution with the present value of the cosmological constant, and $\rho$ directly enters in the computation of the structure formation leading to galaxies, stars and eventually humans, this framework opens, in principle, a path that might help in addressing the longly debated ‘coincidence problem’ [26].
