Asymptotic distribution of independent, not necessarily identically distributed, random vectors given their sum

Dimbihery Rabenoro
Laboratoire de Statistique Théorique et Appliquée, Université Pierre et Marie Curie, France

Abstract
In this paper we present a conditional principle of Gibbs type for independent nonidentically distributed random vectors. We obtain this result by performing Edgeworth expansions for densities of sums of independent random vectors.

Keywords Conditional limit theorem, Exponential change of measure, Edgeworth expansion.

1 Introduction
1.1 Context and scope
Let \((X_j)_{j \geq 1}\) be a sequence of independent, not necessarily identically distributed (i.d.), random vectors (r.v.) valued in \(\mathbb{R}^d\), \(d \geq 1\). Let \((k_n)_{n \geq 1}\) be a sequence of integers with \(1 \leq k_n < n\), for all \(n \geq 1\). We write \(k\) instead of \(k_n\). We assume that the \((X_j)\) have a common support \(S_X\). For \(a \in S_X\) and \(n \geq 1\), let \(Q_{nak}\) be a regular version of the conditional distribution of \(X_1^k := (X_1, ..., X_k)\) given \(\{S_{1,n} = na\}\), where \(S_{1,n} := \sum_{j=1}^{n} X_j\). Such a version exists since \(\mathbb{R}^d\) is a Polish space (see (Stroock, 1994)). In this paper, we study the asymptotic behaviour (as \(n \to \infty\)) of \(Q_{nak}\).

This question is closely related to the well-known Gibbs Conditioning Principle (GCP) (see (Stroock and Zeitouni, 1991)), which states that when the r.v.’s are independent and identically distributed (i.i.d.) and valued in any Polish space, the distribution of \(X_1^k\) given \(\left\{ \frac{1}{n} \sum_{j=1}^{n} f(X_j) = a \right\}\), where \(f\) is a measurable real function, converges weakly to some limit distribution. Let \(P_X\) be the common law of the \((X_j)\). Denote by \(B(\mathbb{R}^d)\) the Borel \(\sigma\)-algebra of \(\mathbb{R}^d\). Then, under suitable conditions, the GCP asserts that for fixed \(k\), we have for any \(B \in (B(\mathbb{R}^d))^k\) and \(a \neq \mathbb{E}_{P_X}[f]\),

\[
\lim_{\delta \to 0} \lim_{n \to \infty} P \left( X_1^k \in B \bigg| A(a, \delta) := \left\{ \frac{1}{n} \sum_{j=1}^{n} f(X_j) \in [a - \delta, a + \delta] \right\} \right) = (\gamma^a)^k(B), \tag{1.1}
\]

where the measure \(\gamma^a\), called a Gibbs measure, minimizes the relative entropy \(H(\cdot|P_X)\) under an energy constraint. Let \(\theta^a \in \mathbb{R}\) be a solution of the equation

\[
\frac{d}{d\theta} \Phi^f(\theta) = a, \quad \text{where} \quad \Phi^f(\theta) := \int_{\mathbb{R}^d} \exp(\theta f(x)) dP_X(x). \tag{1.2}
\]
Then \( \gamma_\alpha \) is absolutely continuous (a.c.) with respect to (w.r.t.) \( P_X \), with
\[
\frac{d\gamma_\alpha}{dP_X}(x) = \frac{\exp(\theta^a f(x))}{\Phi_J(\theta^a)}.
\]
(1.3)
The GCP extends to the case where \( k \to \infty \) as \( n \to \infty \), provided that \( k = o(n) \). (See (Dembo and Zeitouni, 1996)).

It has an interpretation in Statistical Mechanics, since it describes the distribution of a typical small subset in a system composed of a very large number \( n \) of particles, under a constraint of averaged energy. The classical approach to obtain statements of the form (1.1) is to interpret the event \( A(a, \delta) \) in terms of the empirical distribution and to use Sanov’s large deviations theorem (see Section 7.3. in (Dembo and Zeitouni, 1993)). However, this method uses the exchangeability of the \((X_j)\) under the conditioning event, which does not hold anymore when the r.v.’s are not i.d.

In this paper, we consider the conditioning point approach of (Diaconis and Freedman, 1988). Instead of enlarging the conditioning event as in (1.1), this approach uses that, when all the \( X_j \)’s are a.c. w.r.t the Lebesgue measure on \( \mathbb{R}^d \), \( Q_{nak} \) may be defined by a conditional density (see Fact 2 below). We prove that this method can be applied to r.v.’s which are not i.d. More precisely, we generalize Theorem 1.6 in (Diaconis and Freedman, 1988), which holds, when \( k = o(n) \), for a sequence of i.i.d. r.v.’s valued in \( \mathbb{R} \) (\( d = 1 \)). We extend it to a sequence of independent non i.d. r.v.’s. valued in \( \mathbb{R}^d \) with \( d \geq 1 \).

We obtain that \( Q_{nak} \) is asymptotically approximated in total variation distance, by the product of \( k \) probability measures \((\gamma_{j,n}^\alpha)_{1 \leq j \leq k} \) described as follows. For any \( j \geq 1 \), let \( \Phi_j(\cdot) := \int_{\mathbb{R}^d} \exp(\cdot, x) dP_{X_j}(x) \) be the moment generating function (mgf) of \( X_j \). Then, for any \( n \geq 1 \) and \( 1 \leq j \leq k \), \( \gamma_{j,n}^\alpha \) is a.c. w.r.t. \( P_j := P_{X_j} \), with
\[
\frac{d\gamma_{j,n}^\alpha}{dP_j}(x) = \frac{\exp(\theta_n^\alpha, x)}{\Phi_j(\theta_n^\alpha)}, \quad \text{for } x \in \mathbb{R}^d,
\]
(1.4)
where for any \( n \geq 1 \), \( \theta_n^\alpha \in \mathbb{R}^d \) is a solution of the equation
\[
\frac{1}{n} \sum_{j=1}^{n} \nabla \log \Phi_j(\theta) = a.
\]
(1.5)

Although our conditioning event is less general than in the GCP, our result still has a Statistical Mechanics interpretation, as explained in the conclusion of Section 2. After some preliminary results in Section 3, we precise our assumptions in Section 4. Then, we state and prove our main theorem in Section 5, while some technical lemmas are deferred to the Appendix.

### 1.2 Notations and elementary Facts

All the densities considered are w.r.t. the Lebesgue measure on \( \mathbb{R}^d \). For any r.v. \( X \), we denote by \( P_X \) its distribution and by \( p_X \) its density if it exists. When \( X = X_j \), set \( P_j := P_{X_j} \) and \( p_j := p_{X_j} \).

**Definition 1.** Let \( X \) be a r.v. valued in \( \mathbb{R}^d, d \geq 1 \). Denote by \( \Phi_X \) its mgf. Let \( \Theta_X := \{ \theta \in \mathbb{R}^d : \Phi_X(\theta) < \infty \} \).

For any \( \theta \in \Theta_X \), denote by \( \tilde{X}^\theta \) a random vector having the tilted density, defined by
\[
p_{\tilde{X}^\theta}(x) := \frac{\exp(\theta, x) p_X(x)}{\Phi_X(\theta)}.
\]
(1.6)

**Fact 1.** For any \( \theta \in \Theta_X \), the mean of the r.v. \( \tilde{X}^\theta \) is equal to the gradient of \( \kappa \) at \( \theta \). Thus,
\[
\mathbb{E}[\tilde{X}^\theta] = \nabla \kappa(\theta).
\]
(1.7)

The covariance matrix of \( \tilde{X}^\theta \) is equal to the Hessian matrix of \( \kappa \) at \( \theta \). Thus, for any \( 1 \leq i,j \leq d \),
\[
\left[ \text{Cov}(\tilde{X}^\theta) \right]_{i,j} = \left[ \frac{\partial^2 \kappa}{\partial \theta_i \partial \theta_j}(\theta) \right]_{i,j}.
\]
(1.8)
When \( X = X_j \), for \( \theta \in \Theta X \), set \( \tilde{P}_j^\theta := P_{\tilde{X}_j^\theta} \) and \( \tilde{q}_j^\theta := p_{\tilde{X}_j^\theta} \). We will prove in Section 2.1 that, for a suitable choice of \( a \), the equation (1.5) has a unique solution denoted by \( \theta^a_n \). The r.v. having the associated tilted density will be denote simply by \( \tilde{X} \), which means that \( \theta^a_n \) is implicit. We will denote

\[
\tilde{X}_j := \tilde{X}_j^\theta_n; \quad \tilde{P}_j := \tilde{P}_j^\theta_n; \quad \tilde{p}_j := \tilde{p}_j^\theta_n.
\]

Let \( U \) and \( V \) be r.v.'s having respective densities \( p_U \) and \( p_V \) and a joint density denoted by \( p_{(U,V)} \). Then, there exists a conditional density of \( U \) given \( V \), denoted as follows.

\[
p(U = u | V = v) = \frac{p(U,V)(u,v)}{p_V(v)}.
\]

**Fact 2.** Let \((X_j)_{j \geq 1}\) be a sequence of independent r.v.'s valued in \( \mathbb{R}^d \), \( d \geq 1 \). For any \( n \geq 1 \), let \( J_n \) be a subset of \( \{1,\ldots,n\} \) such that \( \alpha_n := |J_n| < n \). Let \( L_n \) be the complement of \( J_n \) in \( \{1,\ldots,n\} \). Set \( S_{L_n} := \sum_{j \in L_n} X_j \). Then, there exists a conditional density of \((X_j)_{j \in J_n}\) given \( S_{1,n} \), defined by

\[
p((X_j)_{j \in J_n} = (x_j) | S_{1,n} = s) = \frac{\prod_{j \in J_n} p_j(x_j)^{p_{S_{L_n}}(s - \sum_{j \in J_n} x_j)}}{p_{S_{1,n}}(s)}, \tag{1.9}
\]

**Proof.** For any measurable function \( \phi : (\mathbb{R}^d)^{\alpha_n} \times \mathbb{R}^d \rightarrow \mathbb{R}^d \), we calculate

\[
\mathbb{E}[\phi((X_j)_{j \in J_n}; S_{1,n})] = \int \phi((x_j); s_{1,n}) \left\{ \prod_{j=1}^n p_j(x_j) \right\} \, dx_1 \ldots dx_n, \quad \text{where} \quad s_{1,n} = \sum_{j=1}^n x_j. \tag{1.10}
\]

Then, we apply the change of variables formula with the diffeomorphism of class \( C^1 \) defined by

\[
(x_1, \ldots, x_{n-1}, x_n) \mapsto (x_1, \ldots, x_{n-1}, s_{1,n}). \tag{1.11}
\]

We obtain thus that the joint density of \((X_j)_{j \in J_n}\) and \( S_{1,n} \) is the numerator of (1.9). \( \square \)

## 2 Statistical Mechanics setting

In this Section, we recall the foundations of Statistical Mechanics as developed in (Khinchin, 1949).

### 2.1 The Phase Space

Let \( G \) be a mechanical system with \( s \) degrees of freedom. The state of \( G \) is described by values of its \( 2s \) dynamical variables denoted by \( q_1, \ldots q_s; p_1, \ldots p_s \). In other words, there is a one-to-one correspondence which associates to each possible state of \( G \), a point of an Euclidian space \( \Gamma \), whose coordinates are the values of \((q_i, p_i)_{1 \leq i \leq s} \). \( \Gamma \) is called the phase space of \( G \). During any interval of time \( \Delta t \), each point \( P \in \Gamma \) describes a curve corresponding to some successive changes of states of \( G \) during \( \Delta t \). Thus, the whole space \( \Gamma \) is transformed into itself during \( \Delta t \). This motion of \( \Gamma \) is called its natural motion. A subset \( M \) of \( \Gamma \) which is stable under the natural motion is called an invariant part of \( \Gamma \). From point of view of physics, the most important function on \( \Gamma \) is the total energy of \( G \), denoted by

\[
E = E(q_i; p_i), \quad 1 \leq i \leq s. \tag{2.1}
\]
Assume that $G$ is an isolated system. Then, by the law of conservation of energy, the function $E$ has a constant value. Consequently, for any constant $a$, the set

$$\Sigma_a := \{ E = a \} \subset \Gamma$$

(2.2)
is an invariant part of $\Gamma$ and is called a surface of constant energy. We can assume that $E$ is positive over $\Gamma$. Set

$$V_x := \{ E < x \} \subset \Gamma \quad \text{and} \quad V(x) := \text{Volume of } V_x.$$

(2.3)
$V(\cdot)$ is a monotone function which increases from 0 to $\infty$ as $x$ varies between the same limits. Then, we have the following lemma.

**Lemma 1.** Let $f(\cdot)$ be a function defined on $\Gamma$, integrable over $V_x$. Then,

$$\frac{d}{dx} \int_{V_x} f(P) dV = \int_{\Sigma_x} f(P) \frac{d\Sigma}{\| \text{Grad}(E) \|}.$$

(2.4)

where $dV$ and $d\Sigma$ are the volume elements of $\Gamma$ and of $\Sigma_x$.

Let $M$ be a measurable subset of $\Sigma_x$. Then in the natural motion of $\Gamma$, $M$ is transformed into a set $M' \subset \Sigma_x$. However, if we define the measure of $M$ by $\mu(M) := \int_M d\Sigma$, then in general, $\mu(M) \neq \mu(M')$. We are deprived of important mathematical tools without this invariance. Therefore, we consider another measure of any set $M$ contained in $\Sigma_x$ as follows. At each point of $M$, draw the outward normal to $\Sigma_x$ to its intersection with the infinitely near surface $\Sigma_x + dx$. Denote by $D$ the bounded part of $\Gamma$ which is filled by these normal vectors. Then set

$$\mathcal{M}(M) := \int_D dV = \int_{x < E < x + dx} 1_D(P) dV.$$

(2.5)

This volume is clearly invariant with respect to the natural motion. Its ratio to $\Delta x$ and the limit of this ratio as $\Delta x \to 0$ are also invariant. Now, by Lemma 1, this limits is

$$\int_{\Sigma_x} 1_D(P) \frac{d\Sigma}{\| \text{Grad}(E) \|} = \int_M \frac{d\Sigma}{\| \text{Grad}(E) \|}.$$

(2.6)

Therefore, we obtain an invariant measure on subsets of $\Sigma_x$ by considering the measure $\mathcal{M}$ defined by

$$\mathcal{M}(M) = \int_M \frac{d\Sigma}{\| \text{Grad}(E) \|}.$$

(2.7)

**Definition 2.** The measure $\Omega(x)$ of the whole surface $\Sigma_x$ is

$$\Omega(x) = \int_{\Sigma_x} \frac{d\Sigma}{\| \text{Grad}(E) \|} = \mathcal{M}(\Sigma_x).$$

(2.8)

Assume that for all $P$, $f(P) = 1$ in Lemma 1. Then we obtain that

$$\Omega(x) = V'(x).$$

(2.9)

The function $\Omega(\cdot)$ determines the most important features of the mechanical structure of $G$ and is therefore called the structure function of $G$. 

4
Definition 3. We denote by \( x_1, \ldots, x_{2s} \) the dynamical coordinates of a point of \( \Gamma \), where the order of numeration is irrelevant. Assume that the energy \( E = E(x_1, \ldots, x_{2s}) \) can be written as

\[
E(x_1, \ldots, x_{2s}) = E_1(x_1, \ldots, x_r) + E_2(x_{r+1}, \ldots, x_{2s})
\]  
(2.10)

We say that the set \( \{ x_1, \ldots, x_{2s} \} \) is decomposed in two components, that is

\[
\{ x_1, \ldots, x_{2s} \} = \{ x_1, \ldots, x_r \} \bigcup \{ x_{r+1}, \ldots, x_{2s} \},
\]  
(2.11)

which we write

\[
G = G_1 \bigcup G_2.
\]  
(2.12)

A component defined in this sense does not necessarily coincide with a separate physical subsystem of \( G \). The isolated character of such components is of a purely energy nature.

Each component, being a subset of dynamical coordinates, has its own phase space. With obvious notations, if \( G = G_1 \bigcup G_2 \) then

\[
\Gamma = \Gamma_1 \times \Gamma_2 \quad \text{and} \quad dV = dV_1dV_2.
\]  
(2.13)

Let \( \Omega, \Omega_1 \) and \( \Omega_2 \) be the respective structure functions of \( G, G_1 \) and \( G_2 \). Then we prove that

\[
\Omega(x) = \int_0^\infty \Omega_1(y)\Omega_2(x-y)dy.
\]  
(2.14)

We deduce readily that if \( G = G_1 \bigcup G_2 \bigcup \ldots G_n \), then

\[
\Omega(x) = \int \left\{ \prod_{i=1}^{n-1} \Omega_i(u_i)du_i \right\} \Omega_n \left( u - \sum_{i=1}^{n-1} u_i \right).
\]  
(2.15)

In order to be able to split \( G = G_1 \bigcup G_2 \) in two components in this sense, we need to neglect the mixed terms of energy interactions which would involve variables from both \( G_1 \) and \( G_2 \).

2.2 Reduction to Probability Theory

We shall now consider the dynamical variables \( (x_1, \ldots, x_{2s}) \) as a random vector \( X = (X_1, \ldots, X_{2s}) \). We still assume that \( G \) is an isolated system, so that the natural motion of \( \Gamma \) is limited within \( \Sigma_{na} \) and the support of \( X \) is contained in \( \Sigma_{na} \). We assume that the distribution law of \( X \) is given by

\[
P(X \in M) = \frac{M(M)}{M(\Sigma_{na})} \int_M \frac{d\Sigma}{\|\text{Grad}(E)\|}, \quad \text{for any set } M \subset \Sigma_{na}.
\]  
(2.16)

Assume that \( G \) is divided into two components \( G^{(1)} \) and \( G^{(2)} \). Therefore, we can write \( X = (X^{(1)}; X^{(2)}) \) with \( X^{(1)} = (X_1, \ldots, X_r) \) and \( X^{(2)} = (X_{r+1}, \ldots, X_{2s}) \). Then, we can prove that for any subset \( M_1 \) contained in \( \Gamma_1 \),

\[
P(X^{(1)} \in M_1) = \frac{1}{\Omega(na)} \int_{M_1} \Omega^{(2)}(na - E_1)dV_1.
\]  
(2.17)

Consequently, the distribution law of \( X^{(1)} \) is absolutely continuous w.r.t the Lebesgue measure with density given by

\[
p_{X^{(1)}}(x^{(1)}) = \frac{\Omega^{(2)}(na - E_1(x^{1}))}{\Omega(na)}, \quad \text{for any } x^{1} \in \Gamma_1.
\]  
(2.18)
We can then deduce that the random variable $E_1$ is absolutely continuous w.r.t the Lebesgue measure with density given by

$$p_{E_1}(x) = \frac{\Omega^{(1)}(x)\Omega^{(2)}(na-x)}{\Omega(na)}.$$  \hfill (2.19)

Let $\Psi(\cdot)$ be the Laplace transform of the function $\Omega(\cdot)$, called the partition function of $G$. We assume that for any $\alpha > 0$,

$$\Psi(\alpha) := \int \exp(-\alpha x)\Omega(x)dx < \infty$$  \hfill (2.20)

Then, we have the following facts.

**Fact 3.** For any constant $c > 0$, there exist a unique solution $\beta^a_n > 0$ to the equation of unknown $\alpha$

$$-\frac{d}{d\alpha}\log\Psi(\alpha) = c.$$  \hfill (2.21)

**Fact 4.** The partition function of a system $G$ is equal to the product of the partition functions of its components.

We introduce now the family $(U^\alpha)_{\alpha > 0}$ of distribution laws conjugate with the system $G$, defined by

$$U^\alpha(x) = \frac{1}{\Psi(\alpha)} \exp(-\alpha x)\Omega(x) \quad \text{if } x \geq 0,$$  \hfill (2.22)

and

$$U^\alpha(x) = 0 \quad \text{if } x < 0.$$  \hfill (2.23)

For any $\alpha > 0$, $U^\alpha(x)$ is the probability density of a random variable $\tilde{X}^\alpha$, since

$$U^\alpha(x) \geq 0 \quad \text{and} \quad \int U^\alpha(x)dx = 1.$$  \hfill (2.24)

Furthermore, we have the following

**Fact 5.** For any $\alpha > 0$,

$$\mathbb{E}[\tilde{X}^\alpha] = \int xU^\alpha(x)dx = -\frac{d}{d\alpha}\log\Psi(\alpha).$$  \hfill (2.25)

### 2.3 Gibbs Measure

We intend to evaluate the energy $E_1$ of a given component $G^{(1)}$ of $G$. However, we can not approximate directly the structure functions which appear in (2.19). Instead, we will be able to approximate the $U^\alpha$’s, since they are densities. In that purpose, we assume that $G$ is divided into a large number $n$ of components and that $G^{(1)}$ is a collection of some of them, that is

$$G = \bigcup_{j=1}^n g_j = G^{(1)} \bigcup G^{(2)}, \quad \text{where} \quad G^{(1)} = \bigcup_{j=1}^k g_j \quad \text{and} \quad k < n.$$  \hfill (2.26)

We still assume that $G$ is an isolated system, so that its energy has some constant value denoted by $na$, where $a$ is the average energy of $g_1, \ldots, g_n$.

Let $(U_1^\alpha)_{\alpha > 0}$ (resp. $(U_2^\alpha)_{\alpha > 0}$) be the family of distribution laws conjugate with $G^{(1)}$ (resp. $G^{(2)}$). Using that $\Omega(x) = \Psi(\alpha)\exp(\alpha x)U^\alpha(x)$, we readily get that for any $\alpha > 0$,

$$p_{E_1}(x) = U_1^\alpha(x)U_2^\alpha(na-x)\frac{U_2^\alpha(na)}{U^\alpha(na)}.$$  \hfill (2.27)

The objective is now to evaluate $U_2^\alpha(na-x)$ and $U^\alpha(na)$. We can prove the following fact.
Fact 6. Assume that $G = \bigcup_{j=1}^{n} g_j$. Then, for any $\alpha > 0$, 

$$U^\alpha(x) = \int \left\{ \prod_{j=1}^{n-1} u_j^\alpha(y_j) dy_j \right\} u_n^\alpha \left( x - \sum_{j=1}^{n-1} y_j \right),$$

where for all $1 \leq j \leq n$, the $(u_j^\alpha)_{\alpha>0}$ are the distribution laws conjugate with $g_j$.

In other words, for any $\alpha > 0$, one can interpret $U^\alpha(\cdot)$ as the density of a sum of independent random variables $X_j^\alpha$, which are not necessarily identically distributed.

The Theory of Probability provides then an asymptotic approximation of $U^\alpha(\cdot)$. More precisely, we may apply the following Central Limit Theorem.

Theorem 1. Consider a sequence of independent random variables $(X_j)_{j \geq 1}$ with probability densities $(u_j)_{j \geq 1}$ and characteristic functions $(g_j)_{j \geq 1}$, that is $g_j(t) = \int \exp(itx)u_j(x)dx$.

Let $(a_j)_{j \geq 1}$ be the sequence of expectations of the $X_j$'s and for $2 \leq \ell \leq 5$, let $(\alpha^\ell)_{\ell \geq 1}$ be the sequence of their centered absolute moments of order $\ell$. Assume that

1. For any $j \geq 1$, $u_j$ is differentiable and there exists $L > 0$ such that $\sup_{j \geq 1} \int |u_j'(x)|dx < L$.
2. There exist $0 < \alpha < \beta_n^\alpha$ such that $\inf_{j \geq 1} a_j^2 > \alpha$ and $\sup_{j \geq 1} \max_{2 \leq \ell \leq 5} a_j^\ell \leq \beta_n^\alpha$.
3. There exist positive constants $\lambda$ and $\tau$ such that in the region $|t| \leq \tau$, $\sup_{j \geq 1} |g_j(t)| > \lambda$.
4. For any $0 < c_1 < c_2$, there exists $\rho = \rho(c_1, c_2) < 1$ such that for any $t \in (c_1, c_2)$, $\sup_{j \geq 1} |g_j(t)| < \rho$.

Set $A_n = \sum_{j=1}^{n} a_j$ and $B_n = \sum_{j=1}^{n} a_j^2$. Let $U_n(x)$ be the density of $\sum_{j=1}^{n} X_j$. Then,

$$U_n(x) = \frac{1}{(2\pi B_n)^{1/2}} \exp \left[ -\frac{(x - A_n)^2}{2B_n} \right] + v_n,$$

where

$$v_n = o \left( \frac{1 + |x - A_n|}{n^{3/2}} \right) \text{ for } |x - A_n| < 2\log^2 n$$

and

$$v_n = o \left( \frac{1}{n} \right) \text{ for all } x.$$

Recall that $(U^\alpha)_{\alpha>0}$ is the family of distribution laws conjugate with $G$, which is composed of $n$ components. We will write $U^\alpha$, the number $n$ being omitted. We assume that for any $\alpha > 0$, for very large $n$, the densities $(U_i^\alpha)_{1 \leq i \leq n}$ satisfy the assumptions (1), (2), (3), (4). This essentially means that the components $(g_i)$ are of a small number of different kinds, which is a reasonable assumption.

Applying Theorem 1, we obtain that for any $\alpha > 0$, (2.29) holds for $U^\alpha$, with $A_n = \mathbb{E}[\widetilde{X}^\alpha]$ and $B_n = \text{Var}(\widetilde{X}^\alpha)$. We get from Fact 5 that $A_n = -\frac{d}{d\alpha} \log \Phi(\alpha)$. Then, (2.21) implies that there exists a unique $\beta^*_n > 0$ such that

$$A_n = \left( -\frac{d}{d\alpha} \log \Psi(\alpha) \right)_{\alpha=\beta^*_n} = na.$$
We deduce that
\[ U_{\beta_n}^a(na - x) = \frac{1}{(2\pi B_n)^{1/2}} + o(n^{-3/2}). \] (2.33)

We assume that the number \( k \) of components of \( G^{(1)} \) satisfies that \( k = o(n) \). Therefore, \( n - k \sim n \) and we may apply Theorem 1 to \( U_{\beta_n}^a \) to obtain that
\[ U_{\beta_n}^a(na - x) = \exp \left[ \frac{-(x-A_{1,k})^2}{2B_{k+1,n}} \right] + o \left( \frac{1}{n} \right), \] (2.34)
where \( A_{1,k} = \sum_{j=1}^{k} \mathbb{E}[\tilde{X}_j^a] \) and \( B_{k+1,n} = \sum_{j=k+1}^{n} \text{Var}(\tilde{X}_j^a) \). The assumptions of Theorem 1 imply that \( B_n \)
and \( B_{k+1,n} \) are respectively of order \( n \) and \( n - k \), and are therefore of the same order since \( k = o(n) \). Consequently, for any \( x > 0 \),
\[ \frac{U_{\beta_n}^a(na - x)}{U_{\beta_n}^a(na)} = \left\{ \exp \left[ \frac{-(x-A_{1,k})^2}{2B_{k+1,n}} \right] \right\} \{1 + o(1)\} \] (2.35)

However, if we only consider those \( x \) such that \( x - A_{1,k} = o(n^{1/2}) \), we obtain that
\[ \exp \left[ \frac{-(x-A_{1,k})^2}{2B_{k+1,n}} \right] = \{1 + o(1)\}. \] (2.36)

Therefore, writing (2.27) for \( \alpha = \beta_n^a \), we get that for \( x \) satisfying \( x - A_{1,k} = o(n^{1/2}) \),
\[ p_{E_1}(x) = U_{\beta_n}^a(x) \{1 + o(1)\}. \] (2.37)

Thus, when \( x \) belongs to an interval of wide radius (equal to \( n^{1/2} \)), the density of \( E_1 \) is approximated by \( U_{\beta_n}^a(x) \), which is the density of a Gibbs measure. One can interpret (2.37) as follows. \( G \) is an isolated system divided in two components: a small one, \( G^{(1)} \), immersed in a large heat bath \( G^{(2)} \). \( G^{(1)} \) and \( G^{(2)} \) interact only by exchanges of energy and their temperatures are equal to the same value \( T \) when thermal equilibrium is reached. Then, the distribution of energy in \( G^{(1)} \) and in any small component of \( G \) is given by (2.37), and the parameter \( \beta_n^a \), usually called an inverse temperature, is equal to \( \frac{1}{k_B T} \), where \( k_B \) is Boltzmann’s constant.

2.4 Conclusion

We have the following analogies between the mathematical point of view and the statistical mechanics one.

\[ S_{1,k} \leftrightarrow \text{Energy of } g_1 \bigcup \ldots \bigcup g_k \]
\[ \text{Density of } S_{1,k} \leftrightarrow \text{Structure function of } g_1 \bigcup \ldots \bigcup g_k \]
\[ \text{Moment generating function of } S_{1,k} \leftrightarrow \text{Partition function of } g_1 \bigcup \ldots \bigcup g_k \]
\[ \theta_n^a \leftrightarrow \beta_n^a \]

Notice that, although the energies \( (e_i) \) of the components \( (g_i) \) are the analogues of the \( (X_i) \), the \( (e_i) \) are not stochastically independent. However, splitting \( G \) in components \( (g_i) \) in this sense, gives raise to some \( (U_i^a) \) such that \( (U^a) \) is the density of a sum of independent random variables \( (\tilde{X}^a_i) \). The assumptions on the \( (\tilde{X}^a_i) \) of Theorem 1 are actually analytical conditions of uniformity on their densities \( (U_i^a) \). They mean that the components \( (g_i) \) have rather similar characteristics, although they are not identical. Now, we have from (2.37) that
\[ p(S_{1,k} = x|S_{1,n} = na) \leftrightarrow \frac{\Omega^{(1)}(x)\Omega^{(2)}(na-x)}{\Omega(na)} = U_1^n(x)U_2^n(na-x) \approx \frac{\Omega^{(1)}(x)\exp(-\beta_n^k x)}{\Phi_{1,k}(\theta^n_k)}. \]

Therefore, we expect that \( p(S_{1,k} = x|S_{1,n} = na) \) should be approximated by \( \frac{p(S_{1,k} = x)\exp(\theta^n_k x)}{\Phi_{1,k}(\theta^n_k)} \), where \( \Phi_{1,k} \) is the mgf of \( S_{1,k} \). This approximation is a consequence of our general result, which is therefore natural.

## 3 Preliminary Results

### 3.1 Existence of the tilted density

We suppose throughout the text that the functions \( (\Phi_j)_{j \geq 1} \) have the same domain of finiteness denoted by \( \Theta \), which is assumed to be of non void interior. We write, for any \( j \geq 1 \),

\[ \Theta := \left\{ \theta \in \mathbb{R}^d : \Phi_j(\theta) < \infty \right\}. \]

For any set \( E \subset \mathbb{R}^d \), we denote respectively by \( \text{int}(E) \), \( \text{cl}(E) \) and \( \text{conv}(E) \) the interior, the closure and the convex hull of \( E \). Let \( S_X \) be the common support of the \( (X_j)_{j \geq 1} \). Set

\[ C_X := \text{cl}(\text{conv}(S_X)). \]

**Definition 4.** Let \( f \) be a convex function on \( \mathbb{R}^d \). Set \( \text{dom}(f) := \{x \in \mathbb{R}^d : f(x) < \infty\} \). Assume that \( \text{int}(\text{dom}(f)) \neq \emptyset \) and \( f \) is differentiable throughout \( \text{int}(\text{dom}(f)) \). Then, for any boundary point \( x \) of \( \text{dom}(f) \), we say that \( f \) is steep at \( x \) if

\[ \|\nabla f(x_i)\| \to \infty \quad (3.1) \]

whenever \((x_i)\) is a sequence of points in \( \text{int}(\text{dom}(f)) \) converging to \( x \). Furthermore, \( f \) is called steep if it is steep at all boundary point of \( \text{dom}(f) \).

We have the following characterization of steepness, which is Theorem 5.27 in *Barndorff-Nielsen Ole, 2014*.

**Theorem 2.** Let \( f \) be a convex function on \( \mathbb{R}^d \). Assume that \( \text{int}(\text{dom}(f)) \neq \emptyset \) and that \( f \) is differentiable throughout \( \text{int}(\text{dom}(f)) \). Then \( f \) is steep if and only if for any \( z \in \text{int}(\text{dom}(f)) \) and any boundary point \( x \in \text{dom}(f) \),

\[ \frac{df}{d\lambda}(x + \lambda(z-x)) \downarrow -\infty, \quad \text{as} \ \lambda \downarrow 0. \quad (3.2) \]

**Fact 7.** Assume that for all \( j \geq 1 \), \( \kappa_j \) is steep. For all \( n \geq 1 \), set

\[ \overline{\kappa}_n := \frac{1}{n} \sum_{j=1}^{n} \kappa_j. \quad (3.3) \]

Then, for all \( n \geq 1 \), \( \overline{\kappa}_n \) is steep.

**Proof.** For all \( n \geq 1 \), \( \overline{\kappa}_n \) clearly satisfies the assumptions of Theorem 2. Now, for all \( j \geq 1 \), \( \kappa_j \) being steep, \( \kappa_j \) satisfies (3.2). We deduce readily that \( \overline{\kappa}_n \) satisfies (3.2), which implies that \( \overline{\kappa}_n \) is steep.

**Definition 5.** Let \( C \) be an open convex subset of \( \mathbb{R}^d \). Let \( f \) be a strictly convex and differentiable function on \( C \). Assume that \( f \) is steep. Then the pair \((C,f)\) is said to be of Legendre type.

**Definition 6.** Let \( f \) be a convex function on \( \mathbb{R}^d \). Its conjugate function is defined on \( \mathbb{R}^d \) by

\[ f^*(a) = \sup_{x \in \mathbb{R}^d} \{ (x,a) - f(x) \} \quad (3.4) \]
We have the following result, which is Theorem 5.33. in (Barndorff-Nielsen Ole, 2014).

**Theorem 3.** Let \( f \) be a convex and lower semi-continuous function. Let \( C = \text{int}(\text{dom}(f)) \) and \( C^* = \text{int}(\text{dom}(f^*)) \). If the pair \((C, f)\) is of Legendre type, then the gradient mapping \( \nabla f \) is a homeomorphism from the open convex set \( C \) onto the open convex set \( C^* \), and \( \nabla(f^*) = (\nabla f)^{-1} \).

Then, we can state and prove the main result of this Section.

**Theorem 4.** Assume that for all \( j \geq 1 \), \( \kappa_j := \log \Phi_j \) is strictly convex and steep. Then, for all \( n \geq 1 \) and any \( a \in \text{int}(C_X) \), there exists a unique \( \theta_a^n \in \text{int}(\Theta) \) such that

\[
\nabla \kappa_n(\theta_a^n) = a. \tag{3.5}
\]

Namely, for any \( n \geq 1 \) and \( a \in \text{int}(C_X) \),

\[
\theta_a^n = \nabla (\kappa_n)(a). \tag{3.6}
\]

**Proof.** For all \( n \geq 1 \), \( \text{dom}(\kappa_n) = \Theta \) is an open convex set and \( \kappa_n \) is strictly convex and differentiable on \( \text{int}(\Theta) \), since by assumption, the \( \kappa_j \)'s are. Now, we get from Fact 7 that \( \kappa_n \) is steep. Therefore, the pair \((\Theta, \kappa_n)\) is of Legendre type. Furthermore, \( \kappa_n \) is lower semi-continuous. Therefore, we obtain from Theorem 3 that the gradient mapping \( \nabla \kappa_n : \Theta \rightarrow \text{int}(\text{dom}(\kappa_n)^*) \) is a homeomorphism. We conclude the proof by Lemma 2 below.

**Lemma 2.** For any \( n \geq 1 \), we have that \( \text{int}(\text{dom}(\kappa_n)^*)) = \text{int}(C_X) \).

**Proof.** The proof is given in Appendix.

### 3.2 Sufficiency Theory

**Definition 7.** Let \((E, A)\) be a measurable space. Let \( \Sigma \) be a sub \( \sigma \)-algebra of \( A \). Let \( P \) and \( Q \) be probability measures on \((E, A)\). We say that \( \Sigma \) is sufficient w.r.t. \( P \) and \( Q \) if for all \( A \in A \),

\[
P(A|\Sigma) = Q(A|\Sigma) \text{ almost everywhere (a.e.) } P \text{ and a.e. } Q. \tag{3.7}
\]

**Lemma 3.** Assume that \( \Sigma \subset A \) is sufficient w.r.t. \( P \) and \( Q \). Then

\[
\|P - Q\|_\Sigma = \|P - Q\|_A. \tag{3.8}
\]

**Proof.** The proof is elementary. See Lemma (2.4) in (Diaconis and Freedman, 1987) for details.

**Lemma 4.** Let \( \mathcal{P} \) be a probability measure on \((\mathbb{R}^d)^k, \mathcal{B}((\mathbb{R}^d)^k)) \) with density \( p \) w.r.t the Lebesgue measure. Let \( T \) be the map defined on \((\mathbb{R}^d)^k\) by \( T(x) = \sum_{i=1}^{k} x_i \), for \( x = (x_i)_{1 \leq i \leq k} \in (\mathbb{R}^d)^k \). Then, the map \( \nu_\mathcal{P} \) defined on \( \mathbb{R}^d \times \mathcal{B}((\mathbb{R}^d)^k) \) by

\[
\nu_\mathcal{P}(t, A) = \frac{\int_{L_t \cap A} p(x) d\sigma^t(x)}{\int_{L_t} p(x) d\sigma^t(x)} \quad \text{if } L_t \cap A \neq \emptyset, \quad \text{and} \quad \nu_\mathcal{P}(t, A) = 0 \quad \text{if } L_t \cap A = \emptyset \tag{3.9}
\]

is a regular conditional \( \mathcal{P} \)-distribution for \( I_d \) given \( T \), where \( I_d \) is the identity map on \((\mathbb{R}^d)^k\).

**Proof.** The proof is given in Appendix.
Lemma 5. Let $T$ be the map defined on $(\mathbb{R}^d)^k$ by $T(x) = \sum_{i=1}^k x_i$, for $x = (x_i)_{1 \leq i \leq k} \in (\mathbb{R}^d)^k$. Let $\Sigma$ the sub $\sigma$-algebra of $\mathcal{B}((\mathbb{R}^d)^k)$ generated by $T$. Then, for any $\theta \in \Theta$,

$$\|Q_{nak} - \tilde{P}_{1,k}^\theta\|_\Sigma = \|Q_{nak} - \tilde{P}_{1,k}^\theta\|_A,$$

where $\tilde{P}_{1,k}^\theta := \prod_{j=1}^k \tilde{P}_j^\theta$. (3.10)

Proof. Let $\theta \in \Theta$. Recall that $Q_{nak}$ and $\tilde{P}_{1,k}^\theta$ are a.c. w.r.t. the Lebesgue measure with respective densities $q_{nak}$ and $\tilde{P}_1^\theta$, given by

$$q_{nak}(x_1^k) = \frac{p_1^k(x_1^k)ps_{k+1,n}(na - T(x_1^k))}{ps_{1,n}(na)}, \text{ where } p_1^k(x_1^k) := \prod_{j=1}^k p_j(x_j),$$

and

$$\tilde{P}_1^\theta(x_1^k) = \frac{p_1^k(x_1^k) \exp(\theta, T(x_1^k))}{\Phi^k_1(\theta)}, \text{ where } \Phi^k_1 := \prod_{j=1}^k \Phi_j.$$

(3.11)

(3.12)

Since on $L_t$, we have that $T(x_1^k) = t$, we deduce readily that for any $t \in \mathbb{R}^d$ and $A \in \mathcal{B}((\mathbb{R}^d)^k)$,

$$\nu_{Q_{nak}}(t, A) = \nu_{\tilde{P}_{1,k}^\theta}(t, A) = \frac{\int_{L_t \cap A} p_1^k(x_1^k) d\sigma^t(x)}{\int_{L_t} p_1^k(x_1^k) d\sigma^t(x)} \quad \text{if } L_t \cap A \neq \emptyset,$$

and

$$\nu_{Q_{nak}}(t, A) = \nu_{\tilde{P}_{1,k}^\theta}(t, A) = 0 \quad \text{if } L_t \cap A = \emptyset.$$  

(3.13)

(3.14)

Consequently, $\Sigma$ is sufficient w.r.t $Q_{nak}$ and $\tilde{P}_{1,k}^\theta$, which concludes the proof. \hfill \Box

3.3 Edgeworth expansion

We obtain from the following theorem (theorem 19.3 in (Bhattacharya and Rao, 1976)) an Edgeworth expansion for a sequence of independent random vectors.

Theorem 5. Let $\{X_n : n \geq 1\}$ be a sequence of independent random vectors with values in $\mathbb{R}^d$, having zero means and average positive-definite covariance matrices $V_n$ for any $n$ large enough. Set

$$B_n := (V_n)^{-1/2}, \quad \text{where } V_n := \frac{1}{n} \sum_{j=1}^n \text{Cov}(X_j).$$

(3.15)

Assume that

$$\lim_{n \to \infty} \frac{1}{n} \sum_{j=1}^n \mathbb{E} \left[ \|B_n X_j\|^4 \right] < \infty.$$  

(3.16)

Assume also the existence of an integer $p > 0$ such that for $n \geq p + 1$ and $0 \leq m \leq n - p$, the functions

$$g_{m,n}(t) := \prod_{j=m+1}^{j=m+p} \mathbb{E} \left[ \exp \left\{ i \langle t, B_n X_j \rangle \right\} \right]$$

(3.17)
satisfy
\[ \gamma := \sup_{n \geq p+1} \sup_{0 \leq m \leq n-p} \int g_{m,n}(t) dt < \infty \] (3.18)
and, for all \( b > 0 \),
\[ \delta(b) := \sup_{n \geq p+1} \sup_{0 \leq m \leq n-p} g_{m,n}(t) < 1. \] (3.19)
Then the distribution \( Q_n \) of \( n^{-1/2} B_n S_n \) has a density \( q_n \) for all \( n \) large enough, and
\[ \sup_{x \in \mathbb{R}^d} (1 + \|x\|^4) \left| q_n(x) - \left[ \phi(x) + n^{-1/2} P_1(-\phi : \{X_{\nu,n}\})(x) \right] \right| = O\left( \frac{1}{n} \right), \] (3.20)
where \( P_1(-\phi : \{X_{\nu,n}\})(x) = \phi(x) P_1^#(x) \) and
\[ P_1^#(x) = \sum_{|\nu| = 3} X_{\nu,n} H_3^{(\nu)}(x), \] (3.21)
where \( H_3^{(\nu)} \) is a polynomial function of degree 3 which vanish at 0 and \( X_{\nu,n} \) is the average of the \( \nu \)th cumulants of \( B_n X_j \) with \( 1 \leq j \leq n \), for \( |\nu| = 3 \). See (7.20) in (Bhattacharya and Rao, 1976) for the precise expressions.

**Proof.** We write hereafter a sketch of the proof. For a given nonnegative integral vector \( \alpha \) with \( |\alpha| \leq 4 \), set
\[ h_n(x) = x^\alpha \left( q_n(x) - \left[ \phi(x) + n^{-1/2} P_1(-\phi : \{X_{\nu,n}\})(x) \right] \right) \] (3.22)
Let \( \hat{h}_n \) be the Fourier transform of \( h_n \). Then, the Fourier inversion theorem implies that
\[ \sup_{x \in \mathbb{R}^d} |h_n(x)| \leq (2\pi)^{-d} \int |\hat{h}_n(t)| dt \] (3.23)
The aim is then to bound \( \int |\hat{h}_n(t)| dt \), by splitting it into a sum of three integrals which are bounded by some \( O\left( \frac{1}{n} \right) \). The key point is that these controls are made at fixed \( n \). \( \square \)

We recall that all the notations \( \tilde{\cdot} \) considered in the sequel pertain to \( \theta = \theta_n^\alpha \).

**Corollary 1.** For \( n \geq 1 \), let \( J_n \) be a subset of \( \{1, \ldots, n\} \) and \( L_n \) be its complement in \( \{1, \ldots, n\} \). Set \( \alpha_n := |J_n| \) and assume that
\[ \lim_{n \to \infty} |L_n| = \lim_{n \to \infty} n - \alpha_n = \infty. \] (3.24)
Set
\[ \tilde{V}_{L_n} := \frac{1}{n - \alpha_n} \sum_{j \in L_n} \text{Cov}(X_j). \] (3.25)
Assume that
\[ \lim_{n \to \infty} \lambda_{\min}(\tilde{V}_{L_n}) > 0, \] (3.26)
which implies in particular that for all \( n \) large enough, \( \tilde{V}_{L_n} \) is positive-definite, so that we may set
\[ \tilde{B}_{L_n} := \left( \tilde{V}_{L_n} \right)^{-1/2}. \] (3.27)
Suppose that

\[
\lim_{n \to \infty} \frac{1}{n - \alpha_n} \sum_{j \in L_n} \mathbb{E} \left[ \left\| \widetilde{B}_{L_n} \left( \widetilde{X}_j - m_j(\theta_n^a) \right) \right\|^4 \right] < \infty.
\] (3.28)

Suppose also that there exists an integer \( p > 0 \) such that for all \( n \) larger than some \( N_p \), to insure that \( \alpha_n \geq p + 1 \), the functions

\[
\tilde{g}_{m,n}(t) := \prod_{j=m+1}^{m+p} \mathbb{E} \left[ \exp \left\{ i \langle t, \tilde{B}_{L_n} \tilde{X}_{j} \rangle \right\} \right] \quad (0 \leq m \leq \alpha_n - p)
\] (3.29)
satisfy

\[
\bar{\gamma} := \sup_{n \geq N_p} \sup_{0 \leq m \leq \alpha_n - p} \int \tilde{g}_{m,n}(t) \, dt < \infty,
\] (3.30)

and, for all \( b > 0 \),

\[
\bar{\delta}(b) := \sup_{n \geq N_p} \sup_{0 \leq m \leq \alpha_n - p} \sup_{\|t\| > b} \tilde{g}_{m,n}(t) < 1.
\] (3.31)

Then the density \( \overline{q}_{L_n} \) of \( S_{L_n} = \alpha_n^{-1/2} \widetilde{B}_{L_n} \left( \widetilde{S}_{L_n} - \sum_{j \in L_n} m_j(\theta_n^a) \right) \) satisfies

\[
\sup_{x \in \mathbb{R}^d} (1 + \|x\|^4) \left| \overline{q}_{L_n}(x) - \left[ \phi(x) + \alpha_n^{-1/2} \tilde{P}_1 \left( -\phi : \{ \overline{\chi}_{\nu,L_n} \} \right) (x) \right] \right| = O \left( \frac{1}{\alpha_n} \right),
\] (3.32)

where \( \overline{\chi}_{\nu,L_n} \) is the average of the \( \nu \)th cumulants of \( \tilde{B}_{L_n} \left( \widetilde{X}_j - m_j(\theta_n^a) \right) \) with \( j \in L_n \), for \( |\nu| = 3 \).

Proof. We need to perform an Edgeworth expansion when, instead of a sequence \( \{ X_n : n \geq 1 \} \) of independent random vectors, we consider a triangular array whose row of index \( n \) is composed of the \( \alpha_n \) independent random vectors

\[
(\widetilde{X}_j - m_j(\theta_n^a))^\theta_n^a, \quad \text{where we recall that } \mathbb{E} \left[ \widetilde{X}_j^\theta_n^a \right] = m_j(\theta_n^a).
\] (3.33)

Therefore, in the framework of triangular arrays, we can write analogously these controls, for a fixed row of the array. So, we consider the row of index \( n \) of the triangular array defined by (3.33). A careful study of the preceding proof implies that (3.32) holds if the assumptions of this corollary hold. \( \square \)

4 Assumptions and Examples

4.1 Assumptions

The following assumptions are essentially those of our main Theorem, since they imply those of the Preliminary Results.

(\(\text{Supp}\)) : The \( (X_j), j \geq 1 \) have a common support \( S_X \), and they have positive densities \( p_j \).

(\(\text{Mgf}\)) : The mgf’s \( (\Phi_j)_{j \geq 1} \) have the same domain of finiteness \( \Theta \), and \( \text{int}(\Theta) \neq \emptyset \).

(\(\text{Sdp}\)) : For all \( j \geq 1 \), \( \kappa_j := \log \Phi_j \) is a strictly convex and steep function.

(\(\text{Bd}\)) : For any \( a \in \text{int}(C_X) \), the sequence \( (\theta_n^a)_{n \geq 1} \) is bounded.
Remark 1. The convexity of $\Theta$ implies that $\text{cl}(\text{int}(\Theta)) = \text{cl}(\Theta)$.

Remark 2. (Bd$\theta$) is reasonable, since $\nabla \pi_n$ is a mean of functions. We will see that, when $d = 1$, it can be replaced by a natural uniformity assumption, denoted by (Uf). It implies that, for any $a \in \text{int}(C_X)$, there exists a compact subset $K_a$ of $\mathbb{R}^d$ such that

$$\left(\theta_n^a\right)_{n \geq 1} \subset K_a \subset \text{cl}(\Theta).$$

We keep this notation throughout the text.

Denote by [Ad] the set of assumptions (Bd$\theta$), (Cv), (AM4) and (Cf1), (Cf2), (Cf3).

Remark 3. [Ad] is natural since it concerns each individual r.v. $X_j$, $j \geq 1$. Thereby, the order of the r.v.’s is irrelevant (as in Statistical Mechanics), which makes sense since we intend to study the distribution of any small subset of r.v.’s among those defining the global constraint $\{ S_{1,n} = na \}$.

Remark 4. Most of the assumptions in [Ad] are of the form $\sup_{j \geq 1} \sup_{\theta \in K} F_j(\theta)$, where for any $j \geq 1$, $F_j$ is a continuous function. Therefore, for fixed $j \geq 1$, $\sup_{\theta \in K} F_j(\theta) < \infty$, since $K$ is compact. So [Ad] is a convenient to check set of uniformity assumptions.

We prove hereunder that [Ad] implies the assumptions of Corollary 1. We also prove that (Bd$\theta$) and (Cf2) imply (Cf1).
4.1.1 Covariance

**Fact 8.** Assume that \((Bd\theta)\) holds and that for any compact \(K \subset \text{cl}(\Theta),\)

\[
\lambda^K_{\text{min}} := \inf_{j \geq 1} \inf_{\theta \in K} \lambda_{\text{min}}(C^\theta_j) > 0. \tag{4.7}
\]

Then,

\[
\lim_{n \to \infty} \lambda_{\text{min}}(\bar{V}_{L_n}) > 0. \tag{4.8}
\]

**Proof.** Recall from the Courant-Fischer min-max theorem that for any Hermitian matrix \(M,\)

\[
\lambda_{\text{min}}(M) = \inf_{\{x \in \mathbb{R}^d : x \neq 0\}} \frac{x^t M x}{x^t x}. \tag{4.9}
\]

Let \(K_a\) be a compact subset of \(\text{int}(\Theta)\) such that \((\theta_a^n)_{n \geq 1} \subset K_a.\) Then, for any \(\theta \in K_a,\) any \(x \in \mathbb{R}^d (x \neq 0),\) and any \(j \in L_n,\)

\[
\frac{x^t C^\theta_j x}{x^t x} \geq \lambda_{\text{min}}(C^\theta_j) \geq \lambda^K_{\text{min}}. \tag{4.10}
\]

Therefore, for all \(n \geq 1,\)

\[
\inf_{\theta \in K_a} \lambda_{\text{min}}(\bar{V}_{L_n}) = \inf_{\theta \in K_a} \inf_{\{x \in \mathbb{R}^d : x \neq 0\}} \frac{x^t \bar{V}_{L_n} x}{x^t x} \geq \lambda^K_{\text{min}} > 0. \tag{4.11}
\]

\[\square\]

4.1.2 Absolute Moments of order 4

**Fact 9.** \((AM4), (Bd\theta)\) and \((Cv)\) imply that \((3.28)\) holds.

**Proof.** For any \(j \in L_n,\)

\[
\mathbb{E} \left[ \left\| \bar{B}_{L_n} \left( \bar{X}_j - m_j(\theta_a^n) \right) \right\|^4 \right] \leq \lambda_{\text{min}} \left( \bar{V}_{L_n} \right)^{-2} \mathbb{E} \left[ \left\| \bar{X}_j - m_j(\theta_a^n) \right\|^4 \right]. \tag{4.12}
\]

Therefore, \((3.28)\) holds if \(\lim_{n \to \infty} \lambda_{\text{min}} \left( \bar{V}_{L_n} \right) > 0\) and \((Bd\theta)\) together with \((AM4)\) hold. \[\square\]

4.1.3 Characteristic function

**Lemma 6.** Assume that \((Bd\theta)\) and \((Cf1)\) hold. Then, \((3.30)\) holds for any \(p > \frac{1}{\delta_{K_A}}.\)

**Proof.** The proof is given in Appendix. \[\square\]

**Corollary 2.** Assume that \((Bd\theta)\) and \((Cf2)\) hold. Then, \((Cf1)\) holds for all \(t \in \mathbb{R}^d, t \neq 0,\) with \(\delta_K = 1.\)

**Proof.** The proof is given in Appendix. \[\square\]

**Lemma 7.** Assume that \((Bd\theta)\) and \((Cf3)\) hold. Then, \((3.31)\) holds for any \(p > 0.\)

**Proof.** Let \(p > 0, n \geq N_p\) and \(0 \leq m \leq \alpha_n - p.\) For any \(b > 0\) and \(t \in \mathbb{R}^d\) such that \(\|t\| > b,\) we have that

\[
\bar{g}_{m,n}(t) := \prod_{j=m+1}^{m+p} \left| \tilde{\zeta}_j \left( \bar{B}_{L_n} t \right) \right| \leq (\epsilon_{K_A, \lambda_{\text{min}} b})^p < 1. \tag{4.13}
\]

\[\square\]
4.2 The one-dimensional case

Assume here that \( d = 1 \). For any r.v. \( X \) or for a sequence \((X_j)_{j \geq 1}\) of i.i.d. r.v.’s, set

\[
\kappa := \log(\Phi_X) ; \quad m := \frac{d\kappa}{d\theta} \quad \text{and} \quad s^2 := \frac{d^2\kappa}{d\theta^2}.
\]

When \( X = X_j \), we write \( \kappa_j, m_j \) and \( s_j^2 \).

**Fact 10.** For any \( \theta \in \Theta_X \),

\[
\mathbb{E}[\bar{X}^\theta] = m(\theta) \quad \text{and} \quad \text{Var}(\bar{X}^\theta) = s^2(\theta). \tag{4.14}
\]

In the sequel, \( \Theta \) and \( \mathcal{S}_X \) pertain to r.v.’s \( X_j; \ j \geq 1 \), with common support and common domain of finitness of their mgf’s. Since \( \Theta \) and \( \text{conv}(\mathcal{S}_X) \) are convex, \( \text{int}(\Theta) \) and \( \text{int}(C_X) \) are open convex subsets of \( \mathbb{R} \), which are open intervals. Therefore, we can write \( \text{int}(\Theta) = (\alpha, \beta) \) and \( \text{int}(C_X) = (A, B) \), where \( \alpha, \beta, A, B \) may be finite or not.

**Definition 8.** Let \( f : (\alpha, \beta) \rightarrow (A, B) \) be a differentiable function. Consider the following property.

\( \mathcal{H} \)

For all \( \theta \in \text{int}(\Theta) \), \( \frac{df}{d\theta}(\theta) > 0 \) and \( \lim_{\theta \to \alpha} f(\theta) = A \); \( \lim_{\theta \to \beta} f(\theta) = B \).

**Fact 11.** If \( f \) satisfies \( \mathcal{H} \), then \( f \) is a homeomorphism from \( \text{int}(\Theta) = (\alpha, \beta) \) to \( \text{int}(C_X) = (A, B) \).

If \( d > 1 \), then Theorem 3 requires that \( \pi_n \) is steep, in the sense of Definition 4, while when \( d = 1 \), this notion of steepness is not necessary to get the conclusion of Theorem 3. Indeed, for all \( n \geq 1 \), \( \frac{d\pi_n}{d\theta} \) is a homeomorphism from \( \text{int}(\Theta) \) to \( \text{int}(C_X) \), provided that \( \frac{d\pi_n}{d\theta} \) satisfies \( \mathcal{H} \). Consider the following assumptions.

\( \mathcal{H}_\kappa \)

For all \( j \geq 1 \), \( m_j := \frac{d\pi_n}{d\theta} \) satisfies \( \mathcal{H} \).

\( \mathcal{U}f \)

There exist functions \( f_+ \) and \( f_- \) which satisfy \( \mathcal{H} \) and such that

\[
\forall j \geq 1, \ \forall \theta \in \Theta, \quad f_-(\theta) \leq m_j(\theta) \leq f_+(\theta). \tag{4.15}
\]

**Fact 12.** \( \mathcal{H}_\kappa \) implies that \( \frac{d\pi_n}{d\theta} \) is a homeomorphism from \( \text{int}(\Theta) \) to \( \text{int}(C_X) \) and in particular that for any \( a \in \text{int}(C_X) \), for any \( n \geq 1 \), there exists a unique \( \theta_n(a) \) such that

\[
\frac{d\pi_n}{d\theta}(\theta_n(a)) = \frac{1}{n} \sum_{j=1}^{n} m_j(\theta_n(a)) = a. \tag{4.16}
\]

**Fact 13.** The uniformity assumption \( \mathcal{U}f \) implies that \( \mathcal{B}d\theta \) holds.

**Proof.** For any \( j \geq 1 \) and \( n \geq 1 \), we have that

\[
f_-(\theta_n(a)) \leq m_j(\theta_n(a)) \leq f_+(\theta_n(a)). \tag{4.17}
\]

Therefore, for all \( n \geq 1 \),

\[
f_-(\theta_n(a)) \leq \pi_n(\theta_n(a)) = a \leq f_+(\theta_n(a)), \tag{4.18}
\]

which implies that

\[
(f_+)^{-1}(a) \leq \theta_n(a) \leq (f_-)^{-1}(a). \tag{4.19}
\]

We deduce from these considerations that, when \( d = 1 \), we can replace \( \mathcal{S}tp \) and \( \mathcal{B}d\theta \) by respectively \( \mathcal{H}_\kappa \) and \( \mathcal{U}f \).
4.3 Examples

4.3.1 Normal distribution

For any \( j \geq 1 \), \( X_j \) is a r.v. with normal distribution. Set \( \mu_j := \mathbb{E}[X_j] \) and \( \Gamma_j := \text{Cov}(X_j) \). Assume that

\[
\sup_{j \geq 1} \| \mu_j \| < \infty \quad \text{and} \quad 0 < \inf \lambda_{\min}(\Gamma_j) \leq \sup \lambda_{\max}(\Gamma_j) < \infty. \tag{4.20}
\]

We recall that, for any \( j \geq 1 \), for all \( \theta \in \Theta = \mathbb{R}^d \),

\[
\kappa_j(\theta) = \mu_j^T \theta + \frac{1}{2} \theta^T \Gamma_j \theta \quad \text{and} \quad \nabla \kappa_j(\theta) = \left( (\mu_j)_\ell + \sum_{\ell' = 1}^d (\theta_{\ell'}) (\Gamma_j)_{\ell' \ell} \right)_{1 \leq \ell \leq d}. \tag{4.21}
\]

So, for all \( \theta \in \mathbb{R}^d \), the Hessian matrix of \( \kappa_j \) at \( \theta \) is equal to \( \Gamma_j \). Since for all \( \theta \in \mathbb{R}^d \), this matrix is equal to \( C^\theta_j \), we get that \((Cv)\) holds. Since for any \( j \geq 1 \), \( \Gamma_j \) is positive definite, we deduce also that \( \kappa_j \) is strictly convex. Clearly, \( \nabla \kappa_j \) satisfies \((3.1)\), so that \( \kappa_j \) is steep and \((Stp)\) holds.

Set \( \bar{\mu}_n := \frac{1}{n} \sum_{j=1}^n \mu_j \) and \( \bar{\Gamma}_n := \frac{1}{n} \sum_{j=1}^n \Gamma_j \). We get after some elementary calculations that for any \( a \in \text{int}(C_X) \) and \( n \geq 1 \), the equation \( \nabla \kappa_n(\theta) = a \) is equivalent to

\[
(\bar{\Gamma}_n) \theta = a - \bar{\mu}_n. \tag{4.22}
\]

Then, \((4.20)\) implies readily that \((4.22)\) defines a unique \( \theta^a_n \) and that the sequence \( (\theta^a_n)_{n \geq 1} \) is bounded, so that \((Bd\theta)\) holds. Finally, it is straightforward to get from the expression of \( p_j \) and the boundedness conditions, that \((AM4)\) and \((Cf2)\) hold.

4.3.2 Gamma distribution

Fix \( t > 0 \). For any \( j \geq 1 \), \( X_j \) is a random variable \((d = 1)\) with distribution \( \Gamma(k_j, t) \), such that

\[
2 < k_- := \inf_{j \geq 1} k_j \leq k_+ := \sup_{j \geq 1} k_j < \infty. \tag{4.23}
\]

For any \( j \geq 1 \) and \( x \geq 0 \),

\[
p_j(x) = \frac{x^{k_j-1} \exp(-\frac{x}{t})}{\Gamma(k_j)t^{k_j}} \tag{4.24}
\]

Recall that for any \( j \geq 1 \),

\[
S_X = C_X = (0; \infty) \quad ; \quad \Phi_j(\theta) = (1 - t\theta)^{-k_j} \quad ; \quad \Theta = (-\infty, \frac{1}{t}). \tag{4.25}
\]

We check readily that \((Mgf)\), \((Stp)\) and \((Cv)\) hold, since, for any \( j \geq 1 \) and \( \theta \in \Theta \),

\[
\kappa_j(\theta) = -k_j \log(1 - \theta t) \quad ; \quad m_j(\theta) = k_j t(1 - \theta t)^{-1} \quad ; \quad s_j^2(\theta) = k_j(1 - \theta t)^{-1} \left[ 1 + \theta t(1 - \theta t)^{-1} \right]. \tag{4.26}
\]

Furthermore, \((Uf)\) holds, since for any \( j \geq 1 \) and \( \theta \in \Theta \),

\[
f_-(\theta) := \frac{(k_-)t}{1 - \theta t} \leq m_j(\theta) \leq f_+(\theta) := \frac{(k_+)t}{1 - \theta t}. \tag{4.27}
\]

Now, we have that, for any \( j \geq 1 \) and \( \theta \in \Theta \),

\[
\bar{p}_j^\theta(x) = \frac{x^{k_j-1} \exp \left[ x (\theta - \frac{1}{t}) \right]}{\Phi_j(\theta) \Gamma(k_j)t^{k_j}}. \tag{4.28}
\]

For \( \theta \in \Theta \), we have that \( \theta - \frac{1}{t} < 0 \). Thereby, we deduce readily that \((AM4)\) holds. We also get \((Cf2)\), since \( \frac{d \bar{p}_j^\theta}{dx}(x) \) is of the form \( P(x) \exp \left[ x (\theta - \frac{1}{t}) \right] \), where \( P \) is a polynomial function.
5 Main Result

In the sequel, for any probability measures \( P \) and \( Q \) on \( \mathbb{R}^k \), we denote the total variation distance between \( P \) and \( Q \) by

\[
\|P - Q\|_{TV} := \sup_{B \in \mathcal{B}(\mathbb{R}^k)} |P(B) - Q(B)|.
\]

5.1 Theorem of Diaconis and Freedman

**Theorem 6.** Let \( (X_j)_{j \geq 1} \) be a sequence of i.i.d. random variables \((d = 1)\). Assume that \( \Theta = (\alpha, \beta) \) and \( S_X = (A, B) \), where \( \alpha, \beta, A, B \) may be finite or not. This implies that \( \text{int}(\Theta) = (\alpha, \beta) \) and \( \text{int}(C_X) = (A, B) \). Assume that the function

\[
m := \frac{d}{d\theta} \left( \log(\Phi_X) \right)
\]

satisfies \((\mathcal{H})\)

and that for any \( \theta \in \Theta \),

\[
\mathbb{E} \left[ \left( \frac{\bar{X}^\theta - m(\theta)}{s(\theta)} \right)^4 \right] < \infty. \tag{5.1}
\]

Suppose that there exists \( \nu \geq 1 \) such that for any \( \theta \in \Theta \),

\[
\int |\mathbb{E} \left[ \exp \left( i \frac{\bar{X}^\theta}{s(\theta)} \right) \right]|^\nu dt < \infty, \tag{5.2}
\]

and that for any \( \theta \in \Theta \), for all \( b > 0 \),

\[
\sup_{|t| > b} \left| \mathbb{E} \left[ \exp \left( i \frac{\bar{X}^\theta}{s(\theta)} \right) \right] \right| < 1. \tag{5.3}
\]

Assume that \( \frac{k}{n} \to 0 \) and \( k \to \infty \), as \( n \to \infty \). Set \( \gamma := \frac{1}{2} \mathbb{E} \left[ |1 - Z^2| \right] \), where \( Z \) is of standard normal distribution. Then, for any \( a \in S_X \),

\[
\left\| Q_{nak} - \bar{P}_1^k \right\|_{TV} = \frac{k}{n} \gamma + o \left( \frac{k}{n} \right), \tag{5.4}
\]

where \( \bar{P}_1^k \) is the joint distribution of independent r.v.’s \((\bar{X}_j)_{1 \leq j \leq k} \), having the tilted density defined by \( \theta^a \) such that \( m(\theta^a) = a \).

5.2 Main Theorem and Proof

**Theorem 7.** When \( d > 1 \), assume that \((Mgf), (Stp), (Bd\theta), (Cv), (AM4), (Cf2), (Cf3)\) hold. (See Section 4 for weaker assumptions). When \( d = 1 \), we can replace \((Stp)\) and \((Bd\theta)\) by respectively \((Hk)\) and \((Uf)\). If \( k = o(n) \), then for any \( a \in \text{int}(C_X) \),

\[
\left\| Q_{nak} - \bar{P}_1^k \right\|_{TV} = O \left( \frac{k}{n} \right), \tag{5.5}
\]

where \( \bar{P}_1^k \) is the joint distribution of independent r.v.’s \((\bar{X}_j)_{1 \leq j \leq k} \).
Proof. Let \( n \geq 1 \). Let \( R_{nak} \) be the distribution of \( S_{1,k} := \sum_{j=1}^{k} X_j \) given \( S_{1,n} = na \). Let \( \widetilde{R}_{1,k} \) be the distribution of \( \widetilde{S}_{1,k} := \sum_{j=1}^{k} \widetilde{X}_j \). Then, we obtain from Sufficiency Theory (Section 3.2) that

\[
\left\| Q_{nak} - \widetilde{P}_{1,k} \right\|_{TV} = \left\| R_{nak} - \widetilde{R}_{1,k} \right\|_{TV}.
\] (5.6)

Now, by Scheffe’s theorem, we deduce that

\[
\left\| Q_{nak} - \widetilde{P}_{1,k} \right\|_{TV} = \int \left[ p(S_{1,k} = t \mid S_{1,n} = na) - p_{\widetilde{S}_{1,k}}(t) \right] dt.
\] (5.7)

Then, we can check readily the following invariance of the conditional density: for any \( t \in \mathbb{R}^d \),

\[
p(S_{1,k} = t \mid S_{1,n} = na) = p(\widetilde{S}_{1,k} = t \mid \widetilde{S}_{1,n} = na) = p_{\widetilde{S}_{1,k}}(t) \left( \frac{p_{\widetilde{S}_{k+1,n}}(na - t)}{p_{\widetilde{S}_{1,n}}(na)} \right).
\] (5.8)

For any integers \( \ell, m \) with \( 1 \leq \ell \leq m \), we denote by \( f_{\ell,m} \) the density of \( \widetilde{S}_{\ell,m} := \sum_{j=\ell}^{m} \widetilde{X}_j \). Therefore, we deduce readily from (5.6), (5.7) and (5.8) that

\[
\left\| Q_{nak} - \widetilde{P}_{1,k} \right\|_{TV} = \int \left| \frac{f_{k+1,n}(na - t)}{f_{1,n}(na)} - 1 \right| f_{1,k}(t) dt.
\] (5.9)

First, we need to normalize in order to perform Edgeworth expansions. Recall that if \( X \) is a random vector with density \( p_X \), then the normalized random vector \( \underline{X} \) has a density given by

\[
p_X(x) = \det \left[ \text{Cov}(X)^{-1/2} \right] p_X \left( \text{Cov}(X)^{-1/2}(x - E[X]) \right).
\] (5.10)

Set

\[
\bar{t} := \text{Cov}(\widetilde{S}_{1,k})^{-1/2}(t - E[\widetilde{S}_{1,k}]) = k^{-1/2} \bar{B}_{1,k} \left[ t - \sum_{j=1}^{k} m_j(\theta_n^a) \right]
\] (5.11)

and

\[
t^# := \text{Cov}(\widetilde{S}_{k+1,n})^{-1/2}(na - t - E[\widetilde{S}_{k+1,n}]) = (n-k)^{-1/2} \bar{B}_{k+1,n} \left[ \sum_{j=1}^{k} m_j(\theta_n^a) - t \right]
\] (5.12)

Therefore, \( \bar{t} \) and \( t^# \) are linked by

\[
t^# = - \left[ \frac{k}{n-k} \right]^{1/2} \bar{B}_{k+1,n}(\bar{B}_{1,k})^{-1} \bar{t}.
\] (5.13)

Lemma 8. Let \( 0 < \theta_1 < 1 \). Then,

\[
\frac{f_{k+1,n}(na - t)}{f_{1,n}(na)} = \left[ 1 + \mathcal{O} \left( \frac{k}{n} \right) \right] \exp \left( -\frac{\| t^# \|^2}{2} \right) + \mathcal{O} \left( \frac{\sqrt{k}}{n} \right) \| \bar{t} \| + \mathcal{O} \left( \frac{1}{n} \right).
\] (5.14)

(5.14) holds uniformly in \( n, k, a, t \) with \( k < \theta_1 n \).
Proof. For any integers \( \ell, m \) with \( 1 \leq \ell \leq m \), we denote by \( g_{\ell,m} \) the density of the normalized r.v. associated to \( S_{\ell,m} \). So, we have that

\[
\frac{f_{k+1,n}(na-t)}{f_{1,n}(na)} = \frac{\det (\text{Cov}(\tilde{S}_{k+1,n}))^{1/2}}{\det (\text{Cov}(\tilde{S}_{1,n}))^{1/2}} \frac{g_{k+1,n}(t^\#)}{g_{1,n}(0)} \tag{5.15}
\]

The assumptions allow us to perform Edgeworth expansions to obtain that

\[
g_{1,n}(0) = \phi(0) + O\left(\frac{1}{n}\right), \quad \text{since } \tilde{P}_1(0) = 0. \tag{5.16}
\]

and

\[
g_{k+1,n}(t^\#) = \phi(t^\#) + \frac{1}{(n-k)^{1/2}} \tilde{P}_1 (-\phi : \{\chi_{\nu,L_n}\}) (t^\#) + O\left(\frac{1}{n-k}\right) \tag{5.17}
\]

where \( L_n = \{k+1, \ldots, n\} \) and \( \tilde{P}_1 (-\phi : \{\chi_{\nu,L_n}\}) (t^\#) = \phi(t^\#) \tilde{P}_1^\# (t^\#) \), with

\[
\tilde{P}_1^\# (t^\#) = \sum_{|\nu|=3} \chi_{\nu,L_n} H_{3}^{(\nu)}(t^\#). \tag{5.18}
\]

Now, for \( |\nu| = 3 \), the \( \nu \)-cumulant of a centered random vector is equal to its \( \nu \)-moment. See (6.21) in (Bhattacharya and Rao, 1976) for details. Furthermore, the cumulants are invariant by any translation. Therefore,

\[
\chi_{\nu,L_n} = \frac{1}{n-k} \sum_{k+1 \leq j \leq n} E[(\tilde{B}_{L_n} \tilde{X}_j)^{|\nu|}]. \tag{5.19}
\]

Then, we have that

\[
|\chi_{\nu,L_n}| \leq \frac{1}{n-k} \sum_{k+1 \leq j \leq n} E \left[ |(\tilde{B}_{L_n} \tilde{X}_j)^{|\nu|}| \right] \leq \frac{1}{n-k} \sum_{k+1 \leq j \leq n} E \left[ \|\tilde{B}_{L_n} \tilde{X}_j\|_{\infty}^{|\nu|} \right]. \tag{5.20}
\]

Now, we have that

\[
\|\tilde{B}_{L_n} \tilde{X}_j\|_{\infty}^{3} = \|\tilde{B}_{L_n} \tilde{X}_j\|_{3}^{3} \leq A \|\tilde{B}_{L_n}\|_{3} \|\tilde{X}_j\|_{3}^{3}, \tag{5.21}
\]

where \( A \) is an absolute constant which appears by equivalence of the norms. Now, the assumptions on the covariance matrices and on the absolute moments of order 4 imply that \( E \left[ \|\tilde{B}_{L_n} \tilde{X}_j\|_{\infty}^{|\nu|} \right] = O(1) \), so that \( \chi_{\nu,L_n} = O(1) \) and

\[
g_{k+1,n}(t^\#) = \phi(t^\#) \left[ 1 + O\left(\frac{1}{(n-k)^{1/2}}\right) \sum_{|\nu|=3} H_{3}^{(\nu)}(t^\#) \right] + O\left(\frac{1}{n-k}\right) \tag{5.22}
\]

Now, since \( H_{3}^{(\nu)}(0) = 0 \), we can factorize by \( t^\# \) in \( \sum_{|\nu|=3} H_{3}^{(\nu)}(t^\#) \) and get that

\[
\phi(t^\#) O\left(\frac{1}{(n-k)^{1/2}}\right) \left| \sum_{|\nu|=3} H_{3}^{(\nu)}(t^\#) \right| = O\left(\frac{1}{(n-k)^{1/2}}\right) O\left(\|t^\#\|\right) = O\left(\frac{\sqrt{k}}{n-k}\right) \|\tilde{t}\| \tag{5.23}
\]
We deduce readily, after some elementary calculations, that

\[ \frac{g_{k+1,n}(t^\#)}{g_{1,n}(0)} = \exp \left( -\frac{\|t\|^2}{2} \right) + O \left( \frac{\sqrt{k}}{n} \right) \|\tilde{t}\| + O \left( \frac{1}{n} \right) \]  \hfill (5.24)

Now,

\[ \frac{\det \left( \text{Cov}(\tilde{S}_{k+1,n}) \right)}{\det \left( \text{Cov}(\tilde{S}_{k+1,n}) \right)} = \det \left[ I_d + \left( \text{Cov}(\tilde{S}_{k+1,n}) \right)^{-1} \text{Cov}(\tilde{S}_{1,k}) \right] \]  \hfill (5.25)

Furthermore, we have that

\[ \left| \left( \text{Cov}(\tilde{S}_{k+1,n}) \right)^{-1} \right| \leq \frac{1}{n-k} \left\| \left( \tilde{B}_{k+1,n} \right) \right\|^2 \leq \frac{1}{(n-k)\left( \lambda_{\min}^{K_a} \right)^2} \text{ and } \left\| \text{Cov}(\tilde{S}_{1,k}) \right\| \leq k \left( \lambda_{\max}^{K_a} \right)^2 \]  \hfill (5.26)

Therefore,

\[ \left| \left( \text{Cov}(\tilde{S}_{k+1,n}) \right)^{-1} \text{Cov}(\tilde{S}_{1,k}) \right| = O \left( \frac{k}{n-k} \right). \]  \hfill (5.27)

Consequently, performing a Taylor expansion of \( \det \) at \( I_d \), we obtain that

\[ \det \left[ I_d + \left( \text{Cov}(\tilde{S}_{k+1,n}) \right)^{-1} \text{Cov}(\tilde{S}_{1,k}) \right] = 1 + \text{Tr} \left[ \left( \text{Cov}(\tilde{S}_{k+1,n}) \right)^{-1} \text{Cov}(\tilde{S}_{1,k}) \right] + o \left( \frac{k}{n-k} \right). \]  \hfill (5.28)

Now, we have that \( \text{Tr} \left[ \left( \text{Cov}(\tilde{S}_{k+1,n}) \right)^{-1} \text{Cov}(\tilde{S}_{1,k}) \right] = O \left( \frac{k}{n-k} \right) \), since \( \text{Tr}(\cdot) = \text{Trace}(\cdot) \) is a linear and continuous mapping. Therefore,

\[ \frac{\det \left( \text{Cov}(\tilde{S}_{1,n}) \right)^{1/2}}{\det \left( \text{Cov}(\tilde{S}_{k+1,n}) \right)^{1/2}} = \left[ 1 + O \left( \frac{k}{n-k} \right) \right]^{1/2} = 1 + O \left( \frac{k}{n} \right) \]  \hfill (5.29)

**Lemma 9.** If \( k = o(n) \), and \( \|t^\#\| < \theta_2 < \infty \), then uniformly in \( a \) and \( t \), we have that

\[ \frac{f_{k+1,n}(na-t)}{f_{1,n}(na)} = 1 + O \left( \frac{k}{n} \right) + O \left( \frac{k}{n} \right) \|\tilde{t}\|^2 + O \left( \frac{\sqrt{k}}{n} \right) \|\tilde{t}\| + O \left( \frac{k^2}{n^2} \right) \|\tilde{t}\|^4 + O \left( \frac{1}{n} \right) \]  \hfill (5.30)

**Proof.** Since \( \|t^\#\| \) is bounded, we get from the Taylor-Lagrange inequality that

\[ \exp \left( -\frac{\|t^\#\|^2}{2} \right) = 1 - \frac{\|t^\#\|^2}{2} + O \left( \|t^\#\|^4 \right) = 1 + O \left( \frac{k}{n-k} \right) \|\tilde{t}\|^2 + O \left( \frac{k^2}{(n-k)^2} \right) \|\tilde{t}\|^4 \]  \hfill (5.31)

Therefore,

\[ 1 + O \left( \frac{k}{n} \right) \exp \left( -\frac{\|t^\#\|^2}{2} \right) = 1 + O \left( \frac{k}{n} \right) + O \left( \frac{k}{n} \right) \|\tilde{t}\|^2 + O \left( \frac{k^2}{n^2} \right) \|\tilde{t}\|^4 \]  \hfill (5.32)

\[ \square \]
Lemma 10. For $\nu = 1, 2, 3, 4$ we have that

$$
\int \left\| \tilde{\eta} \right\|^{\nu} f_k(t) dt = \mathcal{O}(1) \quad (5.33)
$$

Proof. We only need to prove the case $\nu = 4$. Setting $I_4 := \int \left\| \tilde{\eta} \right\|^{4} f_k(t) dt$, we readily obtain that

$$
I_4 = \int \left\| k^{-1/2} B_{1,k} \left( \sum_{j=1}^{k} \tilde{X}_j - m_j(\theta_n^a) \right) \right\|^{4} dP \leq k^{-2} \left\| B_{1,k} \right\|^{4} \int \left( \sum_{j=1}^{k} \left\| \tilde{X}_j - m_j(\theta_n^a) \right\| \right)^{4} dP. \quad (5.34)
$$

Since the $\left( \tilde{X}_j - m_j(\theta_n^a) \right)$ are centered and mutually independent, we obtain that

$$
I_4 \leq k^{-2} \left\| B_{1,k} \right\|^{4} \left[ \sum_{j=1}^{k} \int \left\| \tilde{X}_j - m_j(\theta_n^a) \right\|^{4} dP + \sum_{j_1 \neq j_2} \int \left\| \tilde{X}_{j_1} - m_{j_1}(\theta_n^a) \right\|^2 \left\| \tilde{X}_{j_2} - m_{j_2}(\theta_n^a) \right\|^2 dP \right]. \quad (5.35)
$$

The assumption on the absolute moments of order 4 and the inequality of Cauchy-Schwartz imply that

$$
\sum_{j=1}^{k} \int \left\| \tilde{X}_j - m_j(\theta_n^a) \right\|^{4} dP = \mathcal{O}(k) \quad \text{and} \quad \sum_{j_1 \neq j_2} \int \left\| \tilde{X}_{j_1} - m_{j_1}(\theta_n^a) \right\|^2 \left\| \tilde{X}_{j_2} - m_{j_2}(\theta_n^a) \right\|^2 dP = \mathcal{O}(k^2). \quad \text{Then,}
$$

since $\left\| B_{1,k} \right\|^{4} = \mathcal{O}(1)$, we conclude from (5.35) that $I_4 = \mathcal{O}(1)$. 

We are now able to prove (5.5). Setting $\kappa(t) := \left| f_{k+1,a}(na-t) - f_{1,k}(t) \right|$, we have that

$$
\left\| Q_{nak} - \tilde{P}_{1,k} \right\|_{TV} = \int_{\| t^\# \| \leq \theta_2} \kappa(t) dt + \int_{\| t^\# \| > \theta_2} \kappa(t) dt. \quad (5.36)
$$

Now, Lemma 9 and Lemma 10 imply that

$$
\int_{\| t^\# \| \leq \theta_2} \kappa(t) dt = \mathcal{O} \left( \frac{k}{n} \right) \quad (5.37)
$$

On the other hand, we get from Lemma 8 and Lemma 10 that

$$
\int_{\| t^\# \| > \theta_2} \kappa(t) dt = \int_{\| t^\# \| > \theta_2} \left[ 1 + \mathcal{O} \left( \frac{k}{n} \right) \right] \exp \left( -\frac{\| t^\# \|^2}{2} \right) - 1 \left| f_k(t) dt + \mathcal{O} \left( \frac{k}{n} \right) \right) \quad (5.38)
$$

Recall that $\| t^\# \| = \mathcal{O} \left( \sqrt{\frac{k}{n}} \right) \| \tilde{\eta} \|$. Therefore, $\| t^\# \| > \theta_2$ implies that there exists an absolute constant $A$, with $0 < A < \infty$, such that $A \sqrt{\frac{k}{n}} \| \tilde{\eta} \| > \theta_2$. This is equivalent to $\| \tilde{\eta} \|^4 > A^{-4} \theta_2^4 \left( \frac{k}{n} \right)^2$. Then, since

$$
\left[ 1 + \mathcal{O} \left( \frac{k}{n} \right) \right] \exp \left( -\frac{\| t^\# \|^2}{2} \right) - 1 \quad \text{is uniformly bounded, we get from Markov's inequality and Lemma 10 that}
$$

$$
\int_{\| t^\# \| > \theta_2} \left[ 1 + \mathcal{O} \left( \frac{k}{n} \right) \right] \exp \left( -\frac{\| t^\# \|^2}{2} \right) - 1 \left| f_k(t) dt = \mathcal{O} \left( \frac{k^2}{n^2} \right) \right. \quad (5.39)
$$

\[\square\]
6 Appendix

6.1 Proof of Lemma 2

Proof. We adapt the proof of Theorem 9.1. (ii) in (Barndorff-Nielsen Ole, 2014). So, it is enough to prove that

\[ \text{int}(C_X) \subset \text{dom}((\mathcal{F}_n)^*) \subset C_X. \]  \hfill (6.1)

Let \( t \notin C_X \). Let \( H \) be a hyperplane separating \( C_X \) and \( t \) strongly, and let \( e \) be the unit vector in \( \mathbb{R}^d \) which is normal to \( H \) and such that \( C_X \) lies in the negative halfspace determined by \( H \) and \( e \). For any \( r > 0 \), we have that

\[ \ell_n(re; t) := \langle re, t \rangle - \mathcal{F}_n(re) = \frac{1}{n} \left[ \sum_{j=1}^{n} (rd - \kappa_j(re)) \right], \quad \text{where } d := (e, t). \]  \hfill (6.2)

Since \( t \notin C_X \), we obtain from (5) of Section 7.1 in (Barndorff-Nielsen Ole, 2014) that for all \( 1 \leq j \leq n \), \( rd - \kappa_j(re) \longrightarrow \infty \) as \( r \longrightarrow \infty \). Therefore, \( \ell_n(re; t) \longrightarrow \infty \) as \( r \longrightarrow \infty \). So \( (\mathcal{F}_n)^*(t) = \sup_{\theta \in \Theta} \{ \langle \theta, t \rangle - \mathcal{F}_n(\theta) \} = \infty \), which means that \( t \notin \text{dom}((\mathcal{F}_n)^*) \). Consequently, \( \text{dom}((\mathcal{F}_n)^*) \subset C_X \).

Conversely, let \( t \in \text{int}(C_X) \). Applying Jensen’s inequality, we have that for any \( \theta \in \mathbb{R}^d \),

\[ \mathcal{F}_n(\theta) \geq \log E[\exp(\langle \theta, S_{1,n}/n \rangle)]. \]  \hfill (6.3)

Now, we apply Lemma 9.1. in (Barndorff-Nielsen Ole, 2014) (which follows readily from Markov’s inequality) to the random vector \( S_{1,n}/n \) to get that for any \( \theta, \tau \in \mathbb{R}^d \),

\[ \langle \theta, \tau \rangle - \log E[\exp(\langle \theta, S_{1,n}/n \rangle)] \leq -\log \rho_n(\tau) \]  \hfill (6.4)

where

\[ \rho_n(\tau) = \inf_{e} P(\langle e, S_{1,n}/n \rangle \geq \langle e, \tau \rangle), \]  \hfill (6.5)

the infimum being taken over all unit vectors in \( \mathbb{R}^d \). Then, Lemma 9.2. in (Barndorff-Nielsen Ole, 2014) implies that, since \( t \in \text{int}(C_X) \), we have that \( \rho_n(t) > 0 \). Consequently, we have that \( t \in \text{dom}((\mathcal{F}_n)^*) \), since for any \( \theta \in \mathbb{R}^d \),

\[ \langle \theta, t \rangle - \mathcal{F}_n(\theta) \leq \langle \theta, t \rangle - \log E[\exp(\langle \theta, S_{1,n}/n \rangle)] \leq -\log \rho_n(t) < \infty, \]  \hfill (6.6)

and \( \rho_n(t) \) is independent of \( \theta \). \( \square \)

6.2 Proof of Lemma 4

6.2.1 A Preliminary result

Let \( \Omega \) be an open subset of \( \mathbb{R}^{m+q} = \mathbb{R}^m \times \mathbb{R}^q \). Let \( T \) be a function of class \( C^1 \) from \( \Omega \) to \( \mathbb{R}^q \) such that for any \( a \in \Omega \), the differential at \( a \) of \( T \) in the second direction (of \( \mathbb{R}^q \)) is invertible. Define the map \( h : \mathbb{R}^{m+q} \longrightarrow \mathbb{R}^{m+q} \) by

\[ h : (x_1, \ldots, x_m; x_{m+1}, \ldots, x_{m+q}) \mapsto (x_1, \ldots, x_m; T(x_1, \ldots, x_{m+q})) \]  \hfill (6.7)

The local inversion theorem implies that for any \( a \in \Omega \), there exist an open neighborhood \( \omega_a \) of \( a \) and open sets \( U_a \subset \mathbb{R}^m \) and \( T_a \subset \mathbb{R}^q \) such that \( h \) induces a diffeomorphism of class \( C^1 \) from \( \omega_a \) to \( U_a \times T_a \). Denote by \( \xi_a \) the inverse of the restriction of \( h \) to \( \omega_a \).
Lemma 11. Assume that for any \( a \in \Omega \), and any \((u, t) \in U_a \times T_a\),
\[
|J_{\xi_a}(u, t)| = 1,
\]
where \( J_{\xi_a}(u, t) \) is the determinant of the Jacobian matrix of \( \xi_a \) at \((u, t)\). For any fixed \( t \in T_a \), let \( \xi_a^t \) be the map from \( U_a \) to \( \omega_a \) defined by \( \xi_a^t(u) = \xi_a(u, t) \). Then, \( \xi_a^t \) is a diffeomorphism of class \( C^1 \) and clearly, we have that
\[
\xi_a^t(U_a) = \{ T = t \} \cap \omega_a.
\]
For any \( u \in U_a \), let \( g_{\xi_a}(u) \) be the Gram determinant of the partial derivatives of \( \xi_a^t \) at \( u \). Assume that \( g_{\xi_a}(u) \) is independent of \( u, t \) and \( a \), that is
\[
g_{\xi_a}(u) = g,
\]
for some constant \( g > 0 \). For any \( t \in \mathbb{R}^q \), set \( L_t := \{ T = t \} \). Then, for any measurable non-negative function \( f \) on \( \Omega \), we have that
\[
\int_{\Omega} f(x)dx = \frac{1}{\sqrt{g}} \int_{\{t:L_t \cap \Omega \neq \emptyset\}} \left( \int_{L_t \cap \Omega} f(x) d\sigma^t(x) \right) dt,
\]
where \( \sigma^t \) is the natural measure on the submanifold \( L_t \cap \Omega \).

Proof. We recall that \( \sigma^t \) is a Borel measure on \( L_t \), defined as follows for any submanifold \( V \) of dimension \( p \). Let \( \omega \) be a neighborhood of a point of \( V \) such that there exists a local parametrization \((U, \xi)\) of \( V \), where \( U \) is an open subset of \( \mathbb{R}^p \) with \( \xi(U) = V \cap \omega \). Then, we define a measure \( \sigma_\omega \) on \( V \cap \omega \) by
\[
\sigma_\omega = \xi(\sqrt{g} \lambda_U),
\]
where \( \lambda_U \) is the Lebesgue measure on \( U \) and \( g_\xi \) is the Gram determinant of the partial derivatives of \( \xi \). Then, \( \sigma \) is a Borel measure on \( V \), satisfying that for any such \( \omega \), the restriction of \( \sigma \) to \( V \cap \omega \) is \( \sigma_\omega \).

Now, we have \( \Omega = \bigcup_{a \in \Omega} \omega_a \), from which we can extract a countable subcover, that is \( \Omega = \bigcup_{n \geq 1} \omega_{a_n} \).

Without loss of generality, we can assume that the \( \omega_{a_n} \) are non-overlapping and that
\[
\Omega = \left( \bigcup_{n \geq 1} \omega_{a_n} \right) \cup \mathcal{N},
\]
for some negligible set \( \mathcal{N} \). Therefore, \( f = \sum_{n \geq 1} f 1_{\omega_{a_n}} \) a.e., so
\[
\int_{\{t:L_t \cap \Omega \neq \emptyset\}} \left( \int_{L_t \cap \Omega} f(x) d\sigma^t(x) \right) dt = \sum_{n \geq 1} \int_{\{t:L_t \cap \omega_{a_n} \neq \emptyset\}} \left( \int_{L_t \cap \omega_{a_n}} f(x) d\sigma_{a_n}^t(x) \right) dt,
\]
where \( \sigma_{a_n}^t \) is the natural measure on the submanifold \( L_t \cap \omega_{a_n} \). Now, (6.9) implies that the couple \( (U_{a_n}, \xi_{a_n}^t) \) is a local parametrization of the submanifold \( L_t \). Furthermore, we clearly have that \( \{ t : L_t \cap \omega_{a_n} \neq \emptyset \} = T_{a_n} \). Therefore,
\[
\int_{\{t:L_t \cap \Omega \neq \emptyset\}} \left( \int_{L_t \cap \Omega} f(x) d\sigma^t(x) \right) dt = \sum_{n \geq 1} \int_{T_{a_n}} \left( \int_{U_{a_n}} f(\xi_{a_n}^t(u)) \sqrt{g_{\xi_{a_n}^t}(u)} du \right) dt.
\]
Now, we obtain from (6.10) and the definition of $\xi_{an}$ that
\[
\int_{\{t : L_t \cap \Omega \neq \emptyset\}} \left( \int_{L_t \cap \Omega} f(x) d\sigma^t(x) \right) dt = \sqrt{g} \sum_{n \geq 1} \int_{i_{an}} \left( \int_{U_{i_{an}}} f(\xi_{an}(u,t)) du \right) dt. \tag{6.15}
\]
We deduce from Fubini’s theorem and the change of variables formula that, under (6.8),
\[
\int_{\{t : L_t \cap \Omega \neq \emptyset\}} \left( \int_{L_t \cap \Omega} f(x) d\sigma^t(x) \right) dt = \sqrt{g} \sum_{n \geq 1} \int_{\Omega} f(x) dx = \sqrt{g} \int_{\Omega} f(x) dx. \tag{6.16}
\]

6.2.2 Proof of Lemma 4
Proof. For any open set $A \subset (\mathbb{R}^d)^k$ and any measurable set $B \subset \mathbb{R}^d$,
\[
\mathcal{P}(A \cap \{T \in B\}) = \int_A 1_B(T(x)) p(x) dx. \tag{6.17}
\]
The map $h : (\mathbb{R}^d)^k \rightarrow (\mathbb{R}^d)^k$ is defined by
\[
h : x = (x_1, ..., x_{k-1}; x_k) \mapsto (x_1, ..., x_{k-1}; T(x)) \tag{6.18}
\]
We readily get from the local inversion theorem that $h$ is a local diffeomorphism of class $\mathcal{C}^1$. Furthermore, for any $a \in (\mathbb{R}^d)^k$, the maps $\xi_a$ and $\xi_{at}$ are defined by
\[
\xi_a : (u, t) = (u_1, ..., u_{k-1}; t) \mapsto (u_1, ..., u_{k-1}; t - s_{1,k-1}), \tag{6.19}
\]
where $s_{1,k-1} = \sum_{i=1}^{k-1} u_i$, and
\[
\xi_{at} : u \mapsto (u; t - s_{1,k-1}) \tag{6.20}
\]
We readily check that (6.8) and (6.10) hold here. Therefore, we get from the preceding Lemma that
\[
\mathcal{P}(A \cap \{T \in B\}) = \frac{1}{\sqrt{g}} \int_{\{t : L_t \cap A \neq \emptyset\}} 1_B(t) \left( \int_{L_t \cap A} p(x) d\sigma^t(x) \right) dt. \tag{6.21}
\]
In particular, applying (6.21) with $A = (\mathbb{R}^d)^k$, we get that for any $B \in \mathcal{B}(\mathbb{R}^d)$,
\[
(\mathcal{P}T^{-1})(B) = \frac{1}{\sqrt{g}} \int_{\mathbb{R}^d} 1_B(t) \left( \int_{L_t} p(x) d\sigma^t(x) \right) dt. \tag{6.22}
\]
Therefore, the probability measure $\mathcal{P}T^{-1}$ is a.c. w.r.t. the Lebesgue measure, with
\[
\frac{d(\mathcal{P}T^{-1})}{dx} = \frac{1}{\sqrt{g}} \int_{L_t} p(x) d\sigma^t(x). \tag{6.23}
\]
So, we deduce from (6.21) that for any open set $A$,
\[
\mathcal{P}(A \cap \{T \in B\}) = \int_B \nu_p(t, A)(\mathcal{P}T^{-1})(dt) \tag{6.24}
\]
First, we clearly have that for any fixed \( t \in \mathbb{R}^d \), the map \( A \mapsto \nu_p(t, A) \) is a probability measure. We deduce from this fact and the monotone class theorem that (6.24) holds for any Borel set \( A \).

Finally, we need to prove that for any fixed Borel set \( A \), the map \( t \mapsto \nu_p(t, A) \) is measurable. Notice that \( L_t \cap A = \emptyset \) if and only if \( t \in T(A) \). Therefore, it is enough to prove that \( T(A) \) is a Borel set and that the map \( t \mapsto \int_{L_t \cap A} p(x)d\sigma^t(x) \) is measurable.

For the first point, write \( A = F \cup (A \cap F^c) \), for some \( F \in \mathcal{F}_\sigma \) included in \( A \) (which means that \( F \) is a countable union of closed sets). The key point is then that \( A \cap F^c \) is negligible w.r.t. the Lebesgue measure, and so is \( T(A \cap F^c) \), which is obtained using that \( T \) is Lipschitz. We conclude by the completeness of the Lebesgue measure.

For the second point, it is enough to prove it when \( A = \omega_a \), for some \( a \in A \). Then, we have that

\[
\int_{L_t \cap \omega_a} p(x)d\sigma^t(x) = \sqrt{g} \int_{U_a} p(u; t - s_{1,k-1})du,
\]

which is clearly measurable w.r.t \( t \).

### 6.3 Proof of Lemma 6

Proof. Let \( a \in \text{int}(C_X) \). Consequently, we may apply (4.3) to \( K_a \). We set \( \delta := \delta_{K_a}, C := C_{K_a} \) and \( R := R_{K_a} \). Now, for any \( p > 0 \), any \( n \) large enough to insures that \( \alpha_n \geq p + 1 \), and any \( 0 \leq m \leq \alpha_n - p \),

\[
\int \tilde{g}_{m,n}(t)dt = \int_{\{t: \lVert \tilde{B}_{L_n}t \rVert \geq R\}} \tilde{g}_{m,n}(t)dt + \int_{\{t: \lVert \tilde{B}_{L_n}t \rVert < R\}} \tilde{g}_{m,n}(t)dt.
\]

Then, for \( \lVert \tilde{B}_{L_n}t \rVert \geq R \), we get from (4.3) that

\[
|\tilde{\xi}_j(\tilde{B}_{L_n}t)| \leq \frac{C}{\lVert \tilde{B}_{L_n}t \rVert^\delta}.
\]

Furthermore, setting \( \lambda_{\text{min}} := \lambda_{\text{min}}^{K_a} \), we have that \( \lVert \tilde{B}_{L_n}t \rVert \geq \lambda_{\text{min}} \lVert t \rVert \). Therefore,

\[
\int_{\lVert \tilde{B}_{L_n}t \rVert \geq R} \tilde{g}_{m,n}(t)dt = \int_{\lVert \tilde{B}_{L_n}t \rVert \geq R} \prod_{j=m+1}^{m+p} |\tilde{\xi}_j(\tilde{B}_{L_n}t)|dt \leq C^p \int_{\lVert \tilde{B}_{L_n}t \rVert \geq R} \frac{1}{(\lambda_{\text{min}} \lVert t \rVert)^\delta} dt.
\]

So, if \( p > \frac{1}{\delta} \), then \( \int_{\lVert \tilde{B}_{L_n}t \rVert \geq R} \tilde{g}_{m,n}(t)dt \leq D_{K_a} < \infty \), for some constant \( D_{K_a} \) depending only on \( a \).

Notice that, without loss of generality, we can assume that \( R > 2C^{\frac{1}{\delta}} \). Therefore, (4.3) implies that for all \( t \) satisfying \( \lVert \tilde{B}_{L_n}t \rVert \geq R \), for all \( j \geq 1 \),

\[
|\tilde{\xi}_j(\tilde{B}_{L_n}t)| \leq \frac{C}{R^\delta} < 1.
\]

Therefore, we obtain from Theorem 1, Chapter 1 in (Petrov, 1975) that for all \( t \) satisfying \( \lVert \tilde{B}_{L_n}t \rVert < R \), for all \( j \geq 1 \),

\[
|\tilde{\xi}_j(\tilde{B}_{L_n}t)| \leq 1 - \frac{1 - (\frac{C}{R^{1/\delta}})^2}{2R^2} \lVert \tilde{B}_{L_n}t \rVert^2.
\]
Setting $\Gamma := \frac{1-(C_R\delta)^2}{8R^2}$, we deduce that for all $t$ satisfying $\|\tilde{B}_n t\| < R$, for all $j \geq 1$,

$$
\xi_j(\tilde{B}_n t) \leq \exp \left( -\Gamma \|\tilde{B}_n t\|^2 \right) \leq \exp \left( -\Gamma \lambda_{\min}^2 \|t\|^2 \right)
$$

(6.31)

Consequently,

$$
\int_{\|\tilde{B}_n t\| < R} \tilde{g}_{m,n}(t) dt \leq \int_{\|\tilde{B}_n t\| \geq R} \exp \left( -p\Gamma \lambda_{\min}^2 \|t\|^2 \right) dt.
$$

(6.32)

Therefore,

$$
\int_{\|\tilde{B}_n t\| < R} \tilde{g}_{m,n}(t) dt \leq E_K a < \infty,
$$

(6.33)

for some constant $E_K a$ depending only on $a$. So, we obtain that

$$
\sup_{n \geq N_p} \sup_{0 \leq m \leq \alpha_n - p} \int \tilde{g}_{m,n}(t) dt \leq D_K a + E_K a < \infty
$$

(6.34)

**Lemma 12.** Let $p \in L^1(\mathbb{R}^d)$, $d \geq 1$. Let $\hat{p}$ be the characteristic function of $p$, defined for all $t \in \mathbb{R}^d$ by $\hat{p}(t) := \int \exp(it, x)p(x)dx$. Assume that $p \in C^1(\mathbb{R}^d)$ and that for all $\ell \in \{1, \ldots, d\}$, $\frac{\partial p}{\partial x_\ell} \in L^1(\mathbb{R}^d)$. Then, there exists an absolute constant $C$ such that for all $t \in \mathbb{R}^d$,

$$
|\hat{p}(t)| \leq \frac{C}{\|t\|}
$$

(6.35)

**Proof.** Let $t = (t_\ell)_{1 \leq \ell \leq d} \in \mathbb{R}^d$. For any $\ell \in \{1, \ldots, d\}$, we have that

$$
t_\ell \hat{p}(t) = i \left( \frac{\partial p}{\partial x_\ell} \right)
$$

(6.36)

The preceding equality is obtained by applying a multidimensional version of integration by parts, which holds when one of the involved functions has compact support. Then, notice that $p$ can be approximated in $L^1$-norm by a sequence of functions of compact support. We deduce that

$$
\|t_\ell \hat{p}(t)\|_\infty = \left\| \frac{\partial p}{\partial x_\ell} \right\|_\infty \leq \left\| \frac{\partial p}{\partial x_\ell} \right\|_{L^1} < \infty.
$$

(6.37)

Setting $C := \max_{1 \leq \ell \leq d} \left\| \frac{\partial p}{\partial x_\ell} \right\|_{L^1}$, we deduce that for all $t \in \mathbb{R}^d$,

$$
|\hat{p}(t)| \leq \frac{C}{\|t\|}
$$
