Abstract

Given a bounded Lipschitz domain $D \subset \mathbb{R}^d$, a Calderón-Zygmund operator $T$ and a growth function $\omega(x)$ of type $n$, we solve the problem when the truncated operator $T_D f = T(f \chi_D) \chi_D$ sends the Zygmund space $\mathcal{C}_\omega(D)$ into itself. The solution is a T(P) theorem on sufficient and necessary condition for the space $\mathcal{P}_n$ of polynomials of degree no more than $n$:

$$T_D \mathcal{P}_n \subset \mathcal{C}_{\tilde{\omega}}(D),$$

where $\tilde{\omega}(x) = \frac{\omega(x)}{1 + \int_x^1 \omega(t)t^{-n-1} dt}$.

Keywords: truncated Calderón-Zygmund operators, Zygmund spaces, T(P) theorem

2008 MSC: 42B20

1. Introduction.

1.1. Truncated Calderón-Zygmund operators.

A $C^k$-smooth homogeneous Calderón-Zygmund operator is a principal value convolution operator

$$Tf(y) = PV \int f(x)K(y - x)dx,$$

where $dx$ denotes Lebesgue measure in $\mathbb{R}^d$ and
\[
K(x) = \frac{\Omega(x)}{|x|^d}, \quad x \neq 0,
\]
$\Omega(x)$ is a homogeneous function of degree 0, $C^k$-differentiable on $\mathbb{R}^d \setminus 0$ and with zero integral on the unit sphere. Given a domain $D \subset \mathbb{R}^d$, we consider a modification of $T$. The operator defined by the formula
\[
T_D f = T(\chi_D f)\chi_D
\]
is called to be a truncated Calderón-Zygmund operator.

1.2. Growth functions and Zygmund spaces.

A continuous increasing function $\omega : [0, \infty) \to [0, \infty)$, $\omega(0) = 0$ is called a growth function \cite{6}, if it satisfies the doubling condition
\[
\sup_{t>0} \frac{\omega(2t)}{\omega(t)} < \infty.
\] (1)

This guarantees polynomial growth of $\omega$. So, define the type (see also \cite{6}) of the growth function as a positive integer $n = n(\omega)$, such that the two following properties are satisfied:

1. For some $0 \leq \varepsilon < 1$ a function $\frac{\omega(t)}{t^{n+\varepsilon}}$ is almost decreasing, that means that there is a constant $C > 0$, such that
\[
\frac{\omega(x)}{x^{n+\varepsilon}} > C\frac{\omega(y)}{y^{n+\varepsilon}}, \quad 0 < x < y < 1.
\] (2)

2. For some $0 < \alpha < 1$ a function $\frac{\omega(t)}{t^{n+\varepsilon}}$ is almost increasing, that means that the diverse inequality to (2) takes place.

The type of a growth function characterizes smoothness of integer order of the Zygmund spaces defined as follows. Let $dx$ denote the Lebesgue measure in $\mathbb{R}^d$. Let $Q$ be a cube in $\mathbb{R}^d$ with edges parallel to coordinate axes, let $|Q|$ denote the volume of $Q$ and let $\ell = \ell(Q)$ be its side length. Let finally $P_n$ be the space of polynomials of degree no more than $n$.

Given a growth function $\omega$ of the type $n$, the homogeneous Zygmund space $C_{\omega}(D)$ in arbitrary domain $D \subset \mathbb{R}^d$ is defined for $f \in L_{loc}^1(D,dx)$ by the Campanato seminorm
∥f∥_{ω,D} = \sup_{Q\subset D} \inf_{P\in P_n} \frac{1}{\omega(\ell)} \|f - P\|_{L^1(Q, dx/|Q|)}.

(3)

In fact, the arguments used in the studies of the classical $BMO(\mathbb{R}^d)$ and Lipschitz spaces $Lip_\alpha(\mathbb{R}^d)$ (see [2, 12] and [10, Section 1.2]) guarantee that, when $\omega$ is of positive type $n$, we may replace the $L^1$-norm in (3) by $L^p$-norm with $1 \leq p \leq \infty$ in an arbitrary domain $D$. The seminorms under consideration are equivalent and define the same space. This equivalence for different $1 \leq p \leq \infty$ is very useful for us in what follows. The proof of equivalence based on the Calderón-Zygmund lemma is given in Proposition 2 in Section 2.

Also, we may replace the growth function $\omega$ by a $C^\infty$-smooth function $\omega_1$ of the same type, so that seminorms $|||_{ω,D}$ and $|||_{ω_1,D}$ are equivalent and define the same space. Hence, in what follows we assume that $\omega$ is extended as $C^\infty$-smooth function on $(0, \infty)$.

Remark 1. We consider only the space $\mathcal{P}_n(D)$ of approximating polynomials with $n$, equaled to the type of modulus $\omega$.

If we replace the degree $n$ of the space of approximating polynomials by arbitrary integer $k$ in (3) and obtain the space $\mathcal{C}_{ω,k}(D)$, then we distinguish several cases.

In fact, if $k > n$ the arguments (see, e.g. [10, 3], where the Marchaud type inequality for local polynomial approximations are adapted), guarantee that, the seminorms define the same space modulo polynomials $\mathcal{P}_k(D)$.

If one can take $\varepsilon = 0$ in (2), then $k = n - 1$ is admitted for order of the space of approximating polynomials $\mathcal{P}_{n-1}(D)$. In this case we obtain the proper Lipschitz space $\mathcal{C}_{ω,n-1}(D)$. This one differs from the Zygmund space $\mathcal{C}_{ω}(D) = \mathcal{C}_{ω,n}(D)$, and is not invariant under convolution Calderón-Zygmund operators, when $D = \mathbb{R}^d$. By this reason we do not consider Lipschitz spaces $\mathcal{C}_{ω,n-1}(D)$ in the paper.

In all other cases, when $k < n$, the space $\mathcal{C}_{ω,k}(D)$ is trivial and coincides with the space of approximating polynomials $\mathcal{P}_k(D)$.

Also, we mention that when exactly $\varepsilon > 0$ in (2) then the Zygmund space $\mathcal{C}_{ω}(D)$ is called the Lipschitz space, and it is also called the Hölder space, if $\omega(t) = t^s$ for real $s > 0$.

Observe, that in the paper we do not consider Campanato spaces defined by the seminorm (3) when the type $n = 0$. 

3
1.3. T(P) theorem

The spaces $C_\omega(\mathbb{R}^d)$ are known to be invariant under certain smooth convolution Calderón-Zygmund operators (See, Peetre [13], Janson [6, 7]). In the setting of function spaces defined on domains $D \subset \mathbb{R}^d$, the following result of Mateu, Orobitg and Verdera (Main Lemma [11]) (see, also Anikonov [1]) is crucial.

**Theorem 1.** Let $D$ be a bounded domain with the $C^{1+\alpha}$-smooth boundary, $0 < \alpha < 1$. Then the smooth homogeneous Calderón-Zygmund operator $T_D$ with an even kernel sends the Lipshitz space $\text{Lip}_\alpha(D)$ into itself.

We have already extended this theorem on the range of spaces of weak smoothness between $\text{Lip}_\alpha(D)$ and $BMO(D)$ in [17]. Our main purpose is to extend Theorem 1 on the Zygmund spaces with higher orders of smoothness. The proof of Theorem 1 uses a certain T1 theorem, while in our case we need in another kind of propositions, when we check boundedness not only of the characteristic function, but of a finite collection of polynomials restricted to the domain. This argument was proved originally by Tolsa and Pratz [14] for Sobolev spaces on domains and was called a T(P) theorem.

**Theorem 2.** Let $D$ be a Lipschitz domain, $T$ a $C^n$—smooth convolution Calderón-Zygmund operator, $n \in \mathbb{N}$ and $p > d$. Then the operator $T$ is bounded in Sobolev space $W^{n,p}(D)$ if and only if $TP|_D \in W^{n,p}(D)$ for any polynomial restricted to the domain $P \in \mathcal{P}_{n-1}(D)$.

We also prove a T(P) theorem for the Zygmund spaces. Before formulating the main result, define the growth function associated with $\omega$ of type $n = n(\omega)$ by formula

$$
\tilde{\omega}(x) = \frac{\omega(x)}{1 + \int_x^\infty \omega(t)t^{-n-1}dt}.
$$

(4)

If $\omega(x)$ is a growth function of type $n$, then $\tilde{\omega}(x)$ is of type $n$, too. Further, if $\omega$ of type $n$ is a Dini regular growth function, that is, the integral

$$
\int_0^\infty \frac{\omega(t)}{t^{n+1}}dt
$$

converges, then $\tilde{\omega}(x)$ is equivalent to $\omega(x)$ and $C_\omega(D) = C_{\tilde{\omega}}(D)$.

Our main result is a following non symmetric T(P) theorem:
**Theorem 3.** Let $\omega$ be a growth function of type $n$ and let $D \subset \mathbb{R}^d$ be a Lipshitz domain. Let $T$ be a $C^{n+1}$-smooth homogeneous Calderón-Zygmund operator. Then the following statements are equivalent:

- a) The truncated operator $T_D$ is bounded on the Zygmund space $C_\omega(D)$,
- b) For any polynomial, restricted to the domain $P \in \mathcal{P}_n(D)$,

$$T_DP \in C_{\tilde{\omega}}(D).$$

**Remark 2.** We assume that the underlying domain is Lipschitz and do not consider more general domains (e.g., uniform domains).

Further, in applications, we assume that $D$ is even more smooth. It turns out that the smoothness of the boundary of a domain $D$ is by one point smoother than the smoothness of the space $C^\omega_{\text{int}}(D)$ (see Theorem 1 and Theorem 4). Therefore, we restrict our attention on the Lipschitz domains (as Prats and Tolsa did in [14]).

In fact, all that we need is to extend functions from the Zygmund spaces defined on domains to ambient space $\mathbb{R}^d$. This reminds us the Stein book [16] about extension of the functions from Lipschitz spaces on arbitrary sets. In this paper we apply the approach to extension in BMO (Jones [8]) and Besov spaces (DeVore, Sharpley [3]) on domains.

To do this job, we define a variant of Zygmund space $C^\omega_{\text{int}}(D)$ distinct from the initial one. We take the supremum in the seminorm below with respect to all cubes $Q \subset D$ separated from the boundary $\partial D$ for $f \in L^1_{\text{loc}}(D)$:

$$\|f\|_{\omega,D}^\text{int} = \sup_{Q:2Q \subset D} \inf_{P \in \mathcal{P}_n} \frac{1}{\omega(\ell)} \|f - P_Q\|_{L^1(Q, dx/|Q|)}.$$  \hfill (5)

In fact, we will show that for a Lipshitz domain $D$, the seminorms (3) and (5) are equivalent and define the same space $C^\omega_{\text{int}}(D) = C_\omega(D)$. Moreover, in this case the functions from the space $C^\omega_{\text{int}}(D)$ are extended to the ambient space $\mathbb{R}^d$. The precise statement is formulated as Proposition 1 in Section 2.

**1.4. Applications of $T(P)$ theorem.**

In the sequel of the present paper we give applications of the $T(P)$ theorem, where we restrict our attention to operators with an even kernel, that is, $K(-x) = K(x)$. Also, we assume that the boundary of an underlying domain satisfies a certain Lyapunov type condition of smoothness.
Checking the condition b) of Theorem 3 we establish a relationship between smoothness properties of the boundary of a domain and boundedness of the truncated Calderón-Zygmund operator in the Zygmund spaces.

**Theorem 4.** Let $\omega(t)$ be a growth function of type $n$, $D \subset \mathbb{R}^d$ be a bounded Lipschitz domain, such that the outward unit normal $N$ to $\partial D$ is defined locally as $C^\omega$-smooth vector function. Let $T$ be an even $C^{n+1}$-smooth homogeneous Calderón-Zygmund operator, then $T_D$ is bounded on the Zygmund space $C^\omega(D)$.

Here we say that $f$ is $C^\omega$-smooth in $x_0$, if $f$ is $n$-times differentiating and for a Taylor polynomial $P_{x_0}$ of order $n$ around $x_0$ one has

$$|f(x) - P_{x_0}(x)| \lesssim \omega(|x - x_0|)$$

with a constant independent of $x_0$.

1.5. Organization and notation

In Section 2 we introduce basic notation and set up some necessary preliminaries, we prove equivalence of seminorms for different $p'$-s and extend functions from $C^\omega_{int}(D)$ to ambient space $\mathbb{R}^d$. Theorem is obtained in Section 3.

As usual, the letter $C$ will denote a constant, which may be different at each occurrence and which is independent of the relevant variables under consideration. Notation $A \lesssim B$ means that there is a fixed positive constant $C$ such that $A < CB$. If $A \lesssim B \lesssim A$, then we write $A \approx B$. We write $A \lesssim_{a,b} B$, if a corresponding constant depends on $a,b$.

2. Auxiliary results.

2.1. Approximating polynomials.

Recall $Q$ be a cube in $\mathbb{R}^d$ with edges parallel to coordinate axes, let $|Q|$ denote the volume of $Q$ and let $\ell = \ell(Q)$ be its side length, and let $x_0$ be a centre of $Q$. The following Lemma is easy corollary (see, [10, 3]) from equivalence of norms in finite dimensional spaces of polynomials.
Lemma 1. Let $P = \sum_{|\mu| \leq n} a_\mu (x - x_0)^\mu$ be a polynomial in $\mathbb{R}^d$ of degree no more than $n$, and $\mu = (\mu_1, ..., \mu_d)$ - multiindex with $\mu_k$, $k = 1, ..., d$, nonnegative integers, $|\mu| = |\mu_1| + ... |\mu_d|$. Then

$$\sup_{x \in Q} |P(x)| \leq \sum_{|\mu| = 0}^n |a_\mu| |\mu| \lesssim_{n,d} n \int_Q |P(x)| dx.$$

Lemma 2. Let $Q_1 \subset Q_2$ be two cubes in $\mathbb{R}^d$, then for any polynomial $P \in \mathcal{P}_n$

$$\|P\|_{L^1(Q_2; dx/|Q_2|)} \lesssim_{n,d} \left( \frac{\ell_2}{\ell_1} \right)^n \|P\|_{L^1(Q_1; dx/|Q_1|)}$$

with a constant from the right inequality of Lemma 1.

Definition 1. Given a function $f \in C_\omega(D)$, a cube $Q \subset D$ we say that $P_Q$ is a polynomial of near best approximation for $f$ in $Q$ if

$$\|f - P_Q\|_{L^1(Q; dx/|Q|)} \lesssim \omega(\ell) \|f\|_{s,D},$$

with a constant not depending on $f$, $Q$.

We can choose this polynomial in some "unified" manner without changing the space [10, Ch.1]. Put $Q_0 = [-1/2, 1/2]^n$, and let $\mathbb{P}$ be an arbitrary projection from $L^1(Q_0; dx)$ onto the subspace $\mathcal{P}_n$. Since $\mathcal{P}_n$ is finite dimensional, clearly, $\mathbb{P}$ is bounded on $L^p(Q_0; dx)$, $1 \leq p \leq \infty$. We transplant $\mathbb{P}$ to an arbitrary cube $Q$ by using a shift and a dilation. Then the norm on $L^p(Q; dx/|Q|)$ of the resulting projection $\mathbb{P}_Q$ does not depend on $Q$. This implies, particularly that

$$\|\mathbb{P}_Q(f)\|_{L^\infty(Q)} \lesssim \frac{1}{|Q|} \int |f|$$

with a constant independent of $Q$ and $f$. Moreover, if $u$ is an arbitrary polynomial in $\mathcal{P}_n$, then $\mathbb{P}_Q(f - u) = \mathbb{P}_Q(f) - u$, hence we see that

$$\|\mathbb{P}_Q(f) - u\|_{L^\infty(Q)} \lesssim \|f - u\|_{L^1(Q; dx/|Q|)}.$$

So, in what follows, we assume that $P_Q = \mathbb{P}_Q(f)$ is a polynomial of near best approximation in $Q$ in any $L^p(Q)$-metric, $1 \leq p \leq \infty$.

The triangle inequality easily implies
Lemma 3. Let $Q_1 \subset Q_2$ be two cubes in $D$, let $P_{Q_1}, P_{Q_2} \in P_n$ be two polynomials of near best approximation for the function $f \in C_\omega(D)$ in $Q_1$ and $Q_2$, then

$$\|P_{Q_1} - P_{Q_2}\|_{L^1(Q_2, dx/|Q_2|)} \lesssim_{n,d} \left( \frac{\ell_2}{\ell_1} \right)^n \omega(\ell_1) \|f\|_{\omega,D}$$

with a constant depending on ones from Lemma 7.

Definition 2. A bounded domain $D \subset \mathbb{R}^d$ is called a $(\delta, R)$–Lipschitz domain if, for each $a \in \partial D$, there exists a function $A : \mathbb{R}^{d-1} \to \mathbb{R}$ with $\|\nabla A\|_\infty \leq \delta$ and a cube $Q$ with side length $R$ and centre $a$ such that, after a suitable shift and rotation,

$$D \cap Q = \{(x, y) \in (\mathbb{R}^{d-1}, \mathbb{R}) \cap Q : y > A(x)\}.$$

The cube $Q$ is called an $R$-window of domain.

Without risk of confusion, we will omit parameters $\delta$ and $R$, and consider Lipschitz domains in general.

The following argument concerning the space $C^{\text{int}}_\omega(D)$ is essentially used in [8, Lemma 2.2] in related estimates.

Lemma 4. If $f \in C^{\text{int}}_\omega(D)$, and $Q_1$ and $Q_2$ are neighbor Whitney cubes, $\ell_1 \leq \ell_2$. Let $P_{Q_1}, P_{Q_2} \in P_n$ be two polynomials of near best approximation of $f$, then

$$|P_{Q_1} - P_{Q_2}| \lesssim \omega(\ell_2) \|f\|^{\text{int}}_{\omega,D}$$

Proof. If $Q_1$ and $Q_2$ are neighbor Whitney cubes, then $\ell_2 \leq 4\ell_1$ and, so, $\ell_2 \approx \ell_1$. Find dyadic cubes $Q'_2 \subset Q_2$, $Q'_1 \subset Q_1$, such that $\ell(Q'_2) = \ell(Q'_1) = \ell_1/2$, and $Q'_2$ and $Q'_1$ are touching. Let $Q_3$ be a dyadic cube with $\ell(Q_3) = 2\ell(Q'_1)$, such that contains $Q'_1$ and $Q'_2$. It is obvious, that $2Q_3 \subset D$, hence by (6)

$$|P_{Q_3} - P_{Q'_2}|, |P_{Q_3} - P_{Q'_1}| \lesssim \omega(\ell_1) \|f\|^{\text{int}}_{\omega,D}$$

Hence,

$$|P_{Q_2} - P_{Q_1}| \leq |P_{Q_2} - P_{Q'_2}| + |P_{Q'_2} - P_{Q_3}| + |P_{Q'_1} - P_{Q_3}| + |P_{Q_1} - P_{Q'_1}| \lesssim \omega(\ell_1) \|f\|^{\text{int}}_{\omega,D},$$

that is claimed. □
2.2. Whitney covering.

Consider a given dyadic grid of semi-open cubes in $\mathbb{R}^d$. Given a cube $Q$, let $sQ$ denote the cube with the same centre as $Q$ and with side length $s\ell(Q)$.

**Definition 3.** We say that a collection of cubes $W$ is a Whitney covering of a Lipschitz domain $D$ if

1. The cubes in $W$ are dyadic.
2. The cubes have pairwise disjoint interiors.
3. The union of the cubes in $W$ is $D$.
4. There is an estimate
   
   $$diam(Q) \leq dist(Q, \partial D) \leq 4diam(Q).$$

5. Two neighbor cubes $Q$ and $R$ (i.e. $\bar{Q} \cup \bar{R} \neq \emptyset$) satisfy $\ell(Q) \leq 4\ell(R)$
6. The family of $\{6/5Q\}_{Q \in W}$ has finite superposition, that is,

   $$\sup_D \sum_{Q \in W} \chi_{6/5Q} < \infty$$

We do not prove here the existence because such coverings are well known and widely used in the literature (see Stein [16, Ch.6]).

Recall that we consider a $R$-window $Q$ to be a cube centered at $x \in \partial D$, with side-length $\ell(Q) = R$ inducing a Lipschitz parametrization of the boundary. The following property is taken from [14]. Each $Q$ induces a vertical direction, given by the eventually rotated $x_d$ axis. The following is an easy consequence of the previous statements and the fact that the domain is Lipschitz:

7. The number of Whitney cubes in a window with the same side-length intersecting a given vertical line is uniformly bounded. Here the vertical direction is the one induced by the window.

This is the last property of the Whitney cubes we need to point out. In fact, we consider a Whitney covering $W$ of a Lipschitz domain $D$, as well as a Whitney covering $W'$ of a complement $D' = \mathbb{R}^d \setminus \text{clos}(D)$.

2.3. Imbedding of the Zygmund space in $L^1$.

In fact, we may strengthen condition $f \in L_{loc}^1(D)$ by a result:

**Proposition 1.** Given a growth function $\omega(t)$ of type $n$ and a bounded Lipschitz domain $D \subset \mathbb{R}^d$, then $C^\text{int}_\omega(D) \subset L^1(D)$. 

9
Proof. It is sufficient to prove that \( f \chi_Q \in L^1(D) \) for every \( R \)-window \( Q \). Indeed, since \( f \in L^1_{\text{loc}}(D) \) and the boundary \( \partial D \) of the domain may be covered by a finite number of \( R \)-windows, we clearly obtain that \( f \in L^1(D) \). Let us choose a finite covering \( \{ Q_j \}_j \) of \( \partial D \) by \( R \)-windows and a constant \( \| f \|_{L^1_{\text{loc}}(D)} = \int_{D \cup |Q_j|} |f| \), corresponding to \( \{ Q_j \}_j \) and \( f \). Fix an \( R \)-window \( Q \) and decompose as follows:

\[
\int_Q |f| = \sum_{S \in \mathcal{W} : S \cap Q \neq \emptyset} \int_S |f|.
\]

(7)

We estimate the number \( \#_k \) of Whitney cubes \( S \) of the size \( \ell(S) = 2^{-k} \) in sum (7). Using property 7 of Definition 3 we obtain

\[
\#_k \lesssim \left( \frac{\ell(Q)}{\ell(S)} \right)^{d-1} \lesssim \left( \frac{R}{2^{-k}} \right)^{d-1}.
\]

(8)

Also consider a chain of touching Whitney cubes, lying "above" the cube \( S \). Let us enumerate these cubes as \( \{ S_j \}_{j=0,...,b} \), where \( S = S_0 \) and \( S_b \) is the first Whitney cube lying in \( D \setminus Q \). With a convenient choice of \( R \)-windows \( \{ Q_j \} \) we may assume that \( \ell(S_b) \geq r_1 > 0 \), where \( r_1 \) depends on \( \delta, R \) from Definition 2 and does not depend on \( S \). Again, using property 7 of Definition 3 we estimate the number of cubes in the chain \( \{ S_j \}_{j=0,...,b} \) as follows:

\[
b \lesssim \log \frac{\ell(Q)}{\ell(S)} + 1 \approx \log \frac{R}{2^{-k}} + 1.
\]

Take polynomials \( P_{S_j} \) of near best approximation in \( S_j \). By the telescopic summation with respect to the chain \( \{ S_j \}_{j=0,...,b} \) and by Lemma 4 we have

\[
\int_S |f| = \int_{S_0} |f - P_{S_0}| + \sum_{j=1}^b \int_{S_0} |P_{S_j} - P_{S_{j-1}}| + \int_{S_0} |P_{S_b}|
\]

\[\lesssim 2^{-kd} \left( \sum_{j=0}^b \omega(2^{-j}) \| f \|_{\text{int}}^{\omega,D} + \frac{1}{|S_j|} \int_{S_j} |f| \right)\]

\[\lesssim 2^{-kd} \left( \sum_{j=0}^k \omega(2^{-j}) \| f \|_{\text{int}}^{\omega,D} + \| f \|_{L^1_{\text{loc}}(D)} \right).
\]
Combining the above estimate with (8), we obtain

\[
\int_Q |f| \lesssim \sum_{k=0}^\infty 2^{-kd} \left( \sum_{j=0}^k \omega(2^{-j}) \|f\|_{\omega,D}^{\text{int}} + \|f\|_{L^1_{\text{loc}}(D)} \right)
\]

\[
\lesssim \sum_{k=0}^\infty 2^{-k} \left( \sum_{j=0}^k \omega(2^{-j}) \|f\|_{\omega,D}^{\text{int}} + \|f\|_{L^1_{\text{loc}}(D)} \right)
\]

\[
\lesssim \sum_{k=0}^\infty 2^{-k} \sum_{j=0}^k \omega(2^{-j}) \|f\|_{\omega,D}^{\text{int}} + \|f\|_{L^1_{\text{loc}}(D)} \sum_{k=0}^\infty 2^{-k} = I + II.
\]

The second summand is bounded by \(C(\delta, R)\|f\|_{L^1_{\text{loc}}(D)}\). It remains to estimate the first summand, where we change order of summing and obtain

\[
I = \sum_{j=0}^\infty \omega(2^{-j}) \sum_{k=j}^\infty 2^{-k} \|f\|_{\omega,D}^{\text{int}}
\]

\[
\lesssim \sum_{j=0}^\infty \omega(2^{-j}) 2^{-j} \|f\|_{\omega,D}^{\text{int}}
\]

\[
\lesssim \int_0^1 \omega(t) dt \|f\|_{\omega,D}^{\text{int}}
\]

\[
\lesssim \|f\|_{\omega,D}^{\text{int}}
\]

with constants depending on \(\delta, R\). Therefore, we have

\[
\|f\|_{L^1(D)} \lesssim_{\delta, R} \|f\|_{\omega,D}^{\text{int}} + \|f\|_{L^1_{\text{loc}}(D)}
\]

and, so, we proved Proposition 1. \(\square\)

2.4. Equivalence of seminorms for different \(p\)'s in Zygmund spaces.

**Proposition 2.** Given a growth function \(\omega\) and a bounded domain \(D \subset \mathbb{R}^d\), the seminorms

\[
\|f\|_{\omega,D,p} = \sup_{Q \subset D} \inf_{b_Q \in C} \frac{1}{\omega(t)} \|f - b_Q\|_{L^p(Q,dx/|Q|)}
\]

are equivalent and define the same space \(C_\omega(D)\), provided \(1 \leq p \leq \infty\).
Proof. It is sufficient to obtain an estimate
\[ \sup_Q |f - P_Q| \lesssim \omega(\ell) \|f\|_{\omega,D} \tag{9} \]
with constant independent of \(Q\), and where \(P_Q = P_{Q}(f)\) is a polynomial of near best approximation.

The proof based on the Calderón-Zygmund lemma [10, Ch.1]:

Lemma 5. Given a cube \(Q\), a function \(f \in L^1(Q)\) and a number \(A > 1/|Q|\int_Q |f|\), there exists at most countable family \(\{Q_i\}\) of cubes with mutually disjoint interiors and such that

1. \(|f| \leq A\) a.e. on \(Q \cup Q_i\);
2. \(A \leq |f|_{Q_i} \leq 2^d A\);

We apply Lemma 5 to the function \(|f - P_Q(f)|\) such that \(\|f\|_{\omega,D,1} = 1\), \(A = 2\omega(\ell)\), where \(Q \subset D\) is a cube and \(\ell = \ell(Q)\), and \(\{P_Q\}\) is an unified family of projections. On the first step we obtain a family \(Q'_i\) of subcubes of \(Q\) with the following properties:

1. \(|f - P_{Q'}(f)| \leq 2\omega(\ell')\) a.e. on \(Q' \cup Q'_i\);
2. \(|P_{Q'}(f) - P_{Q'}(f)| = |P_{Q'}(f - P_{Q'}(f))| \lesssim 1/|Q'_{i}| \int_{Q'_i} |f - P_{Q'}(f)| \lesssim 2^{d+1}\omega(\ell);\)

3. \(\sum |Q'_i| < 1/2\omega(\ell) \int_Q |f - P_Q(f)| \leq |Q|/2.\)

Now, we apply the above construction to the function \(|f - P_{Q'}(f)|\) for every cube \(Q'\) from the family \(Q'_i\) and \(A = 2\omega(\ell')\). On the second step we obtain a family \(Q''_i\) of subcubes of \(Q'\) with the following properties:

1. \(|f - P_{Q''}(f)| \leq 2\omega(\ell'')\) a.e. on \(Q' \cup Q''_{i}\);
2. \(|P_{Q''}(f) - P_{Q''}(f)| = |P_{Q''}(f - P_{Q''}(f))| \lesssim 1/|Q''_{i}| \int_{Q''_i} |f - P_{Q''}(f)| \lesssim 2^{d+1}\omega(\ell');\)

3. \(\sum |Q''_i| < 1/2\omega(\ell'') \int_{Q'} |f - P_{Q'}(f)| \leq |Q'|/2.\)
Summing in item 3 with respect to all cubes of the family $Q_i'$, we obtain
\[ \sum |Q''| \leq \sum |Q'|/2 \leq |Q|/4. \]
Also, we have
\[ |f - P_Q(f)| \leq |f - P_{Q'}(f)| + |P_{Q''}(f) - P_{Q'}(f)| \leq 2\omega(\ell') + 2^{d+1}\omega(\ell) \leq 2^{d+1}(\omega(\ell') + \omega(\ell)) \text{ a.e. on } \cup Q' \setminus \cup Q'' . \]
Iterating, we obtain families of imbedded cubes \( \{Q^k_j\}, \ k = 0,..n, \) such that every cube $Q^k_j$ is imbedded in an appropriate cube $Q^k_{i_k-1}$ and
\[ \sum_i |Q^k_i| < \frac{|Q|}{2^k}. \] (10)
Also, we have
\[ |f - P_Q(f)| \leq 2^d \sum_{k=1}^{n-1} \omega(\ell(Q^k_j)) \text{ a.e. on } \cup Q^{n-1} \setminus \cup Q^n \] (11)
for a sequence of imbedded cubes $Q \supset Q'_j \supset \ldots \supset Q^{n-1}_{i_{n-1}}$.
Let $n$ tend to $\infty$ in the sum in (11), then by (10) we have
\[ \sum_{k=1}^{\infty} \omega(\ell(Q^k_j))) \lesssim \sum_{k=1}^{\infty} \omega \left( \frac{\ell}{2^{k/d}} \right) \]
\[ \approx \int_{\ell}^\infty \omega \left( \frac{\ell}{u^{1/d}} \right) \frac{du}{u} \]
\[ \approx \int_0^{\ell} \omega(t) \frac{du}{u} \]
\[ \lesssim \omega(\ell) \]
since \( \frac{\omega(t)}{t^{1-\alpha}} \) is almost increasing.
Thus, $\sup_Q |f - P_Q(f)| \lesssim \omega(\ell)$ a.e. on $Q$ with constant independent of $Q$ and the proof is finished. $\Box$
2.5. Extension lemma

To construct an extension, we first define a $C^\infty$-smooth partition of unity $\{\psi_Q\}_{Q \in W'}$ associated with the Whitney covering $W'$ of $D'$. This means that each bump function satisfies the following conditions: $\psi_Q$ is $C^\infty$-smooth, $\chi_{4/5Q} \leq \psi_Q \leq \chi_{5/4Q}$, $Q \in W'$ and $\sum_{Q \in W'} \psi_Q = \chi_{D'}$.

Given a Whitney cube $Q \in W'$, define a Whitney cube $\tilde{Q} \in W$, called reflective to $Q$, if it is a maximal cube such that $\text{dist}(Q, \tilde{Q}) \leq 2\text{dist}(Q, \partial D)$. Let $P_Q$ be a polynomial of near best approximation of $f$ in $\tilde{Q}$.

Define an extension of $f$ by

$$\tilde{f} = f \chi_D + \sum_{Q \in W', \ell(Q) \leq R} \psi_Q P_Q. \tag{12}$$

We are ready to formulate an Extension lemma.

**Proposition 3.** Given $f \in C^\text{int}_\omega(D)$, then the function $\tilde{f}$, defined by (12), satisfies the following properties:

1. $\tilde{f}$ has a compact support;
2. $\tilde{f}$ is $C^\infty$-smooth in $D' = \mathbb{R}^d \setminus \text{clos}(D)$;
3. $\tilde{f} \in L^\infty(\mathbb{R}^d, dx) \cap C_\omega(\mathbb{R}^d)$ and
   $$\|\tilde{f}\|_{\omega, \mathbb{R}^d} \lesssim \|f\|_{\omega, D}^{\text{int}} + \|f\|_{L^\infty(D, dx)}.$$

**Proof.** The properties 1) and 2) are obvious. To prove 3), we have to estimate supremum in (13) with $D = \mathbb{R}^d$.

First, we consider only small cubes $Q$ in $\mathbb{R}^d$ such that $2Q \cap \partial D \neq \emptyset$. To define exactly the value of smallness, we need in a result, which is essentially [3, Lemma 5.2], and which is proved for a wider class of domains.

**Lemma 6.** Let $D$ be a Lipschitz domain and $f \in L^1(D, dx)$. There exist three positive constants $C$, $c$, $r_0$, depending only on the Lipschitz constants of $D$, such that if $Q$ is a cube in $\mathbb{R}^d$ with $\ell(Q) < r_0$ and such that $2Q \cap \partial D \neq \emptyset$, then

$$\int_Q |\tilde{f} - \tilde{P}_Q| dx \leq C \sum_{S \subset Q, S \in W'} \int_{S'} |f - f_{S'}| dx,$$

where $\tilde{P}_Q$ is a appropriate polynomial in $\mathcal{P}_n$ and $S' = 9/8S$ for each cube $S$. 

14
We choose a parameter $r_0 < R$ such that the cube $cQ$ lies in a certain $R$-window and conditions of lemma above and Definition 2 hold.

For any Whitney cube $S \in W$, we have that $2S' \subset D$; hence,

$$I = \int_Q |\tilde{f} - \tilde{P}_Q| dx \leq C\|f\|_{\omega,D}^{\text{int}} \sum_{S \subset cQ, S \in W} \omega(\ell(S))\ell(S)^d.$$ 

Now, we estimate the number of cubes of the same size in the sum. Property 7 from Definition 3 guarantees that, for any Whitney cube $S \subset cQ$, there exists a vertical line (defined by axis $x_d$) intersected with finitely many of Whitney cubes of the size $\ell(S)$. This number is estimated from above by a constant $C$ depending on the Lipschitz constant of the Lipschitz domain $D$. Thus, we may estimate the number $\sharp(S)$ of all cubes of the size $\ell(S)$ intersected with $cQ$ by

$$\sharp(S) \lesssim \left(\frac{\ell(cQ)}{\ell(S)}\right)^{d-1}.$$ 

Let $s$ be an integer such that $2^s = \ell(S)$ and let $n$ be an integer such that $2^n \leq \ell(cQ) < 2^{n+1}$. Then

$$\sharp(S) \lesssim \left(\frac{2^n}{2^s}\right)^{d-1}$$

with a constant independent of $Q$. So, we have

$$I \lesssim \sum_{s=\infty}^{n} \left(\frac{2^n}{2^s}\right)^{d-1} \omega(2^s)(2^s)^d\|f\|_{\omega,D}^{\text{int}}$$

$$= (2^n)^{d-1} \sum_{s=\infty}^{n} 2^s\omega(2^s)\|f\|_{\omega,D}^{\text{int}} \lesssim$$

$$\lesssim (2^n)^d\omega(2^n)\|f\|_{\omega,D}^{\text{int}}$$

$$\approx \|Q\|\omega(\ell(Q))\|f\|_{\omega,D}^{\text{int}},$$

and we are done for small cubes near the boundary.

To deal with large cubes $Q$, $\ell(Q) > r_0$, we will prove that $\tilde{f} \in L^1(\mathbb{R}^d, dx)$. This gives us the required estimate for the large cubes:

$$I = \frac{1}{|Q|} \int_Q |\tilde{f}| dx \leq \frac{1}{r_0^d} \|\tilde{f}\|_{L^1(\mathbb{R}^d, dx)} \lesssim \omega(\ell(Q)).$$
To prove that \( \tilde{f} \in L^1(\mathbb{R}^d, dx) \), we first choose a finite family \( E = \{Q_k\}_{k=1}^{N_0} \) of cubes \( Q_k \) with \( \ell(Q_k) \approx r_0 \) such that \( \partial D \subset \bigcup_{k=1}^{N_0} Q_k \).

Proposition 3 implies that \( \tilde{f} \in L^1(E \cup D, dx) \).

Further, the function \( \tilde{f} \) is \( C^\infty \)-smooth in \( D' \), and the set \( \text{supp} \tilde{f}(D \cup E) \) is compact. Therefore, we have \( \tilde{f} \in L^1(\mathbb{R}^d, dx) \), that is claimed for large cubes.

On the other hand, \( C^\infty \)-smoothness in \( D' \) implies the required estimate (3) for small cubes in \( D' \) which are far from the boundary. Extension lemma is proved. \( \square \)

3. Proof of T(P) theorem

3.1. Sufficiency condition.

Recall that \( D \subset \mathbb{R}^d \) is a Lipschitz domain and let \( \chi_D \) be the characteristic function of \( D \). Let \( T_D \) be a truncated Calderón-Zygmund operator. Fix \( f \in C_\omega(D) \). Let us check that \( T_D f \in C_\omega(D) \). Given a cube \( Q \) with size length \( \ell \), we claim that

\[
I = \frac{1}{|Q|} \int_Q |Tf - S_Q| dx \lesssim \omega(\ell) \|f\| \tag{13}
\]

with an appropriate polynomial \( S_Q \) and \( \|f\| = \|f\|_{L^1} + \|f\|_{L^\infty(D)} \). By Proposition 3, we may consider only cubes \( Q \) such that \( 2Q \subset D \). We start with a modification of a construction from the proof of in [4, Theorem 1.5] (see also [9]). Let \( Q \) be a cube such that \( Q \cap D \neq \emptyset \). Taking into account a polynomial \( P_Q \) of near best approximation for the function \( f \) in a cube \( Q \), we put

\[
f_1 = P_Q \chi_D,
\]

\[
f_2 = (f - P_Q)\chi_{2Q},
\]

\[
f_3 = (f - P_Q)\chi_{D \backslash 2Q}.
\]

Observe that \( f = f_1 + f_2 + f_3 \).

Lemma 7. There exists a constant \( C > 0 \) depending on \( f \) such that, for the functions \( f_k \) with \( k = 2, 3 \), one has

\[
\frac{1}{|Q|} \int_Q |Tf_k - P_{k,Q}| dx \leq C \omega(\ell) \|f\|,
\]

with appropriate polynomials \( P_{k,Q} \).
For \( k = 2 \), we choose \( P_{2,Q} = 0 \). By Hölder inequality we have

\[
I_2 = \frac{1}{|Q|} \int_Q |T_D f_2| dx < \left( \frac{1}{|Q|} \int_Q |T_D f_2|^2 dx \right)^{1/2}.
\]

Then by boundedness of a smooth convolution Calderón-Zygmund operator in \( L^2 \) we obtain

\[
I_2 \lesssim \left( \frac{1}{|Q|} \int_{2Q} |f_2|^2 dx \right)^{1/2} = \left( \frac{1}{|Q|} \int_{2Q} |f - P_Q|^2 dx \right)^{1/2} \lesssim \left( \frac{1}{|Q|} \int_{2Q} |f - P_Q|^2 dx \right)^{1/2} + \left( \frac{1}{|Q|} \int_{2Q} |P_Q - P_{2Q}|^2 dx \right)^{1/2}.
\]

It remains to see that by Proposition 2 (inverse Hölder inequality) the first summand is estimated as \( \lesssim \omega(\ell) \), while the second one is estimated by Lemma 3. So, we are done for \( k = 2 \).

Taking care of third term is not so easy. To estimate oscillation

\[
I_3 = \frac{1}{|Q|} \int_Q |T_D f_3 - P_{3,Q}| dx,
\]

we choose an appropriate polynomial \( P_{3,Q} \). To define \( P_{3,Q} \) let us take an image of the \( f_3 \) under action of a special integral operator with a polynomial kernel. For this consider the \( n \)-Taylor polynomial of the kernel \( K(x) = \frac{Q(x)}{|x|^d} \) of the operator \( T \) around a point \( x_0 \neq 0 \), which is a center of \( Q \)

\[
T K(x_0, x - x_0) = K(x_0) + \langle \nabla K(x_0), x - x_0 \rangle + \ldots + \langle \nabla^n K(x_0), x - x_0 \rangle.
\]

We denote by \( \langle \nabla^j K(x_0), x - x_0 \rangle \) the \( j \)-differential form of \( K \) in \( x_0 \). The polynomial \( P_{3,Q} \) equals to the convolution with the function \( T K(x_0, x - x_0) \) in first variable:

\[
P_{3,Q}(x) = \int T K(u - x_0, x - x_0) f(u) du.
\]

A smooth (of class \( C^{n+1} \)) kernel \( K \) satisfies an estimate

\[
|\nabla^j K(x_0)| \lesssim \frac{1}{|x_0|^{d+j}}, \quad j = 0, ..., n+1, \quad x_0 \neq 0.
\]
For the remainder in the Taylor formula when $u \in \mathbb{R}^d \setminus 2Q$ and $x, x_0 \in Q$ one has

$$|K(u - x_0) - TK(u - x_0, x - x_0)| \lesssim \sup_{|t - x_0| < |x - x_0|} |\nabla^{n+1} K(u - t)||x - x_0|^{n+1} \lesssim \frac{|x - x_0|^{n+1}}{|u - t|^{n+1+d}},$$

with the constants not depending on $u, x, x_0, Q$. Substituting this to estimate $I_3$ we have

$$I_3 \lesssim \frac{C}{|Q|} \int_Q dx \int_{D \setminus 2Q} \frac{|x - x_0|^{n+1}}{|u - t|^{n+1+d}} |f - P_Q|(u) du$$

$$\lesssim \ell^{n+1} \int_{D \setminus 2Q} \frac{|f - P_Q|(u)}{|u - t|^{n+1+d}} du.$$

Now, replace $f$ by its extension $\tilde{f}$ according to Lemma 5 and note that $P_Q = \mathbb{P}_Q \tilde{f}$ for $Q \subset D$. We conclude that

$$I_3 \lesssim \ell^{n+1} \int_{\mathbb{R}^d \setminus 2Q} \frac{|\tilde{f} - P_Q|(u)}{|u - t|^{n+1+d}} du.$$

Put $Q_k = (2^k Q \setminus 2^{k-1} Q)$ and split the above integral

$$I_3 \lesssim \ell^{n+1} \sum_{k=1}^{\infty} \frac{1}{(\ell 2^k)^{n+1+d}} \int_{Q_k} |\tilde{f} - P_Q|(u) du.$$

Applying the telescopic summation method, we have

$$I_3 \lesssim \ell \sum_{k=1}^{\infty} \frac{1}{(\ell 2^k)^{d+1}} \left( \int_{Q_k} |\tilde{f} - P_{2^s Q}|(u) du + \sum_{s=0}^{k-1} \int_{Q_k} |P_{2^s Q} - P_{2^{s+1} Q}| \right),$$

where we denoted $P_Q = \mathbb{P}_Q \tilde{f}$ in each inner sum. Applying (6), we have

$$I_3 \lesssim \sum_{k=1}^{\infty} \frac{1}{(2^k)^{n+1}} \sum_{s=0}^{k} (2^{k-s})^n \omega(2^s \ell) \|f\|_\omega$$

18
\[
\sum_{k=1}^{\infty} \frac{1}{2^k} \sum_{s=0}^{k} \frac{1}{2^{sn}} \omega(2^s \ell) \|f\|_\omega.
\]

Changing the order of summing continue
\[
I_3 \lesssim \sum_{s=1}^{\infty} \frac{1}{2^{s(n+1)}} \omega(2^s \ell) \|f\|_\omega
\]
\[
\lesssim \int_1^{\infty} \frac{\omega(t \ell)}{t^{n+2}} dt \|f\|_\omega.
\]

Put a change of variable, take into account that the function \( \frac{\omega(t)}{t^{n+\varepsilon}} \) is almost decreasing for some \( \varepsilon > 0 \) we have
\[
I_3 \lesssim \omega(\ell) \|f\|_\omega,
\]
and we are done.

In fact, we have proved that (13) is equivalent to inequality
\[
\frac{1}{|Q|} \int_Q |TDf_1 - P_{1,Q}|dx = \frac{1}{|Q|} \int_Q |TDf_1|dx \lesssim \|f\|_\omega(\ell)
\]
with an appropriate polynomials \( P_{1,Q} \) and with a constant independent of \( Q \).

Define a function
\[
\xi(r) = 1 + \int_r^1 \frac{\omega(t)dt}{t^{n+1}},
\]
where \( n \) is a type of \( \omega \).

**Lemma 8.** Given \( f \in C_\omega(D) \) and a polynomial \( P_Q \) of near best approximation of the extension \( \tilde{f} \) in a cube \( Q \subset \mathbb{R}^d \), \( \ell < 1 \), then
\[
\|P_Q\|_{L^\infty(D)} \lesssim \|f\|_\omega(\ell)
\]
with a constant independent of \( Q \).

**Proof.** Proof is based on the following simple assertion:

**Lemma 9.** Under hypothesis of Lemma 8 let \( P_Q \) and \( P_{2Q} \) be the polynomials of near best approximation of the extension \( \tilde{f} \) in cubes \( Q \) and \( 2Q \). Let
\[
P_Q(t) = \sum_{k=0}^{[s]} A_{k,Q}(t - t_0)^k
\]

19
and

\[ P_{2Q}(t) = \sum_{k=0}^{[s]} A_{k,2Q}(t - t_0)^k, \]

be the Taylor expansions around \( t_0 \in Q \), and where \( k = (k_1,..k_d) \) is multiindex of non negative integers, \( |k| = k_1 + ..k_d \). Then one has

\[ |A_{k,2Q} - A_{k,Q}| \lesssim \| f \| |\omega(\ell)\ell^{-|k|}, |k| = 0,..,n \quad (16) \]

**Proof.** By definition of the Zygmund space we have

\[ \|P_Q - P_{2Q}\|_{L^\infty(Q)} \lesssim \omega(\ell)\| f \|, \]

then by the Baernstein inequality for any derivative of order \( |k| \leq n \)

\[ \|\partial^k P_Q - \partial^k P_{2Q}\|_{L^\infty(Q)} \lesssim \omega(\ell)\ell^{-|k|}\| f \|, \]

and therefore,

\[ |A_{k,2Q} - A_{k,Q}| \lesssim \omega(\ell)\ell^{-|k|}\| f \|, \]

that is claimed. \( \square \)

Proceed the proof of Lemma 8 by telescopic summation using (16). We have

\[ |A_{k,Q}| \leq \sum_{|i|=0}^{N-1} |A_{k,2^iQ} - A_{k,2^{i+1}Q}| + |A_{k,2^NQ}|, \]

where \( N \) is a minimal positive integer such that \( 2^NQ \supset D \). Since \( N \approx \frac{1}{\ell} \), calculations show that

\[ |A_{k,Q}| \leq \left( 1 + \sum_{|i|=0}^{N-1} \omega(2^i\ell)(2^i\ell)^{-|k|} \right) \| f \| \]

\[ \lesssim \left( 1 + \int_{\ell}^1 \frac{\omega(t)dt}{t^{|k|+1}} \right) \| f \|. \]

Since \( \frac{\omega(t)}{t^n} \) is almost decreasing, then

\[ |A_{k,Q}| \lesssim \left( 1 + \int_{\ell}^1 \frac{\omega(t)dt}{t^{|k|+1}} \right) \| f \| \lesssim \| f \| \]

20
when $|k| < n$. Otherwise, when $|k| = n$ then

$$|A_{k,Q}| \lesssim \left( 1 + \int_{\ell}^{1} \frac{\omega(t)dt}{tn+1} \right) \|f\| \approx \xi(\ell)\|f\|$$

and the last inequality easily implies (15). The proof of Lemma 8 is finished.

We are ready to obtain the sufficiency condition of the $T(P)$ theorem. Indeed, since point (b) of Theorem 3 is fulfilled, then for every cubes $Q, Q' \subset D$ we have inequality

$$\frac{1}{|Q'|} \int_{Q'} |T_{D}f_{1} - S_{Q'}|dx = \frac{1}{|Q'|} \int_{Q'} |T_{D}P_{Q} - S_{Q'}|dx \lesssim \|P_{Q}\|_{\omega(\ell')}^{\frac{\omega(\ell')}{\xi(\ell')}}$$

with an appropriate polynomials $S_{Q'}$ and with a constant independent of $Q'$ and $Q$. Taking into account that $\|P_{Q}\| \lesssim \|P_{Q}\|_{L^{\infty}(D)}$ with a constant independent of $Q$, we easily obtain from Lemma 8 that (17) implies (14), and we are done.

3.2. Necessity condition.

Since $P_{n}(D) \subset C_{\omega}(D)$, then we obtained necessity provided $\varepsilon > 0$ in condition (1) of almost decreasing $\frac{\omega(t)}{t^{n+1}}$. In this case $\xi(\ell)$ is bounded and we proved a standard symmetric $T(P)$ theorem.

In order to prove necessity when one can take exactly $\varepsilon = 0$, we will find a function $\varphi(x)$ and a polynomial $P_{Q}$ with extremal properties. Take $x = (x_{1}, ..., x_{d}) = (x_{1}, x') \in \mathbb{R}^{d}$ and non negative multiindex $k = (k_{1}, ..., k_{d}) = (k_{1}, k') \in \mathbb{Z}^{d}$. We suppose that $|k| = k_{1} + .. + k_{d} = k_{1} + |k'| = n$, also we may assume that $k_{1} \neq 0$. We put

$$\varphi(x) = \varphi_{k}(x) = x^{k_{1}}\xi(|x_{1}|),$$

in the unit cube $Q_{0}$ centred at 0 and extended as $C^{\infty}$-smooth with compact support in $\mathbb{R}^{d} \setminus 0$.

**Lemma 10.** Let $\varphi(x)$ is given above, then

1. $\varphi(x) \in C_{\omega}(\mathbb{R}^{d})$,

2. For polynomial $P_{Q}$ of near best approximation of $\varphi(x)$ in $Q$, $\ell < 1$ with a centre in 0, there is an estimate $\|P_{Q}\|_{L^{\infty}(Q_{0})} \gtrsim \xi(\ell)$ with constant independent of $Q$. 

21
Proof. First, we prove that $\varphi \in C^\omega(\mathbb{R}^d)$. Observe that the function $\varphi(x)$ is $C^\infty$-smooth when $x \neq 0$. We take a polynomial $p_Q = x^k \xi(\ell)$ and will estimate $S = \frac{1}{|Q|} \int_Q |\varphi - p_Q| dx$ for $Q$ centred in 0. We may assume that $x_1 > 0$, otherwise if $x_1 < 0$ then we change a variable $t = -x_1$ with the same proof. Let us denote $Q = (-\ell, \ell) \times Q'$, where a cube $Q' \subset \mathbb{R}^{d-1}$.

$$S = \frac{1}{|Q|} \int_Q |x^k|(\xi(x_1) - \xi(\ell))dx$$

$$= 2 \frac{1}{|Q|} \int_{Q'} |(x')^k| dx' \int_{0 < x_1 < \ell} x_1^k (\xi(x_1) - \xi(\ell))dx_1$$

$$= C_k \ell^{n-k_1-1} \int_{0 < x_1 < \ell} x_1^k dx_1 \left( \int_{x_1}^1 \frac{\omega(u)}{u^{n+1}} du - \int_{\ell}^1 \frac{\omega(u)}{u^{n+1}} du \right)$$

$$= C_k' \ell^{n-k_1-1} \int_{0 < x_1 < \ell} x_1^k dx_1 \int_{x_1}^\ell \frac{\omega(u)}{u^{n+1}} du$$

(by changing the order of integration)

$$= C_k' \ell^{n-k_1-1} \int_{0 < u < \ell} \frac{\omega(u)}{u^{n+1}} du \int_{0}^{u} x_1^k dx_1$$

$$= C_k \ell^{n-k_1-1} \int_{0 < u < \ell} \frac{\omega(u)}{u^{n-k_1}} du$$

$$\lesssim \ell^{n-k_1-1} \frac{\omega(\ell)}{\ell^{n-k_1}} \approx \omega(\ell),$$

since $\frac{\omega(u)}{u^{n-k_1}}$ is almost increasing when $k_1 > 0$. So, we proved item 1.

In order to prove item 2, note that the polynomial $p_Q$ satisfies an inequality $\|p_Q\|_{L^\infty(Q_0)} \gtrsim \xi(\ell)$. Also, if $P_Q$ is a polynomial of near best approximation of $\varphi(x)$ in $Q$, then by triangle inequality $\sup_{Q_0} |P_Q - p_Q| \lesssim \omega(\ell)$. Consider a positive integer $N$ such that $2^N Q \supset Q_0$. By Lemma 3 we have

$$\sup_{Q_0} |P_Q - p_Q| \lesssim \frac{\omega(\ell)}{\ell^N}.$$ 

Since $\frac{\omega(t)}{t^N}$ is almost decreasing ($\varepsilon = 0$), we have

$$\int_{\ell}^{1} \frac{\omega(t)dt}{t^{n+1}} \gtrsim \frac{\omega(\ell)}{\ell^n} \int_{\ell}^{1} \frac{dt}{t}$$

22
This means that \( \frac{\omega(\ell)}{\ell^n} = o(\xi(\ell)) \), hence the polynomial \( P_Q \) of near best approximation satisfies the same estimate \( \|P_Q\|_{L^\infty(Q_0)} \gtrsim \xi(\ell) \), and we are done. \( \square \)

Now, we are ready to finish the proof of necessity. Define the family of functions \( \{\varphi_\tau(t) = \varphi(t - \tau), \ \tau \in D\} \). In a Lipschitz domain \( D \) all the functions \( \varphi_\tau \chi_D \) has the properties similar to \( \varphi \). That is to say, \( \varphi_\tau \chi_D \in \mathcal{C}_\omega(D) \), and norms in \( \mathcal{C}_\omega(D) \) are uniformly bounded in \( \tau \in D \) by a constant depending only on the Lipschitz constant of the boundary of \( D \). We can choose the polynomials of near best approximation in the form \( P_{\tau,Q}(x) = (x - \tau)^k \xi(\ell) \), so that

\[
\|P_{\tau,Q}\|_{L^\infty(D)} \gtrsim \xi(\ell)
\]

for small cubes \( Q \) centred at \( \tau \), with \( \ell < \text{dist}(\tau, \partial D) \) and with constant independent of \( Q \) and \( \tau \).

We substitute \( f = \varphi_\tau \) in (14), which implies that there exists a polynomial \( S_{\tau,Q} \in \mathcal{P}_n \) such that

\[
\frac{1}{|Q|} \int_Q |TP_{\tau,Q}\chi_D - S_{\tau,Q}|dx \lesssim \omega(\ell)\|\varphi_\tau\|.
\]

Reducing, we obtain

\[
\xi(\ell)\frac{1}{|Q|} \int_Q |T(x - \tau)^k \chi_D - R_{k,\tau,Q}|dx \lesssim \omega(\ell)\|\varphi_\tau\|
\]

for every \( \tau \in D \), \(|k| = n\) and a certain polynomial \( R_{k,\tau,Q} = S_{k,\tau,Q}/\xi(\ell) \).

Rewrite the last inequality in the following form

\[
\frac{1}{|Q|} \int_Q |T(x - \tau)^k \chi_D - R_{k,\tau,Q}|dx \lesssim \frac{\omega(\ell)}{\xi(\ell)} \approx \hat{\omega}(\ell).
\]

For the finite dimensional space \( \mathcal{P}_n(D) \) of polynomials we can find a finite basis consisting of polynomials of type \( (x - \tau)^k \). Therefore, it easily implies that \( T_D \) is a bounded operator from \( \mathcal{P}_n(D) \) into the space \( \mathcal{C}_\hat{\omega}(D) \). The proof of Theorem 3 is finished.
References
