Abstract. In this paper, using the Maclaurin series of the functions \((1 + x)^{1/x}\), some inequalities from papers \([2]\) and \([5]\) are generalized. For arbitrary Maclaurin series some general limits of Keller’s type are defined and applying for generalization of some well known results.

Keyword. Constant \(e\); Carleman’s inequality; Keller’s limit; approximations

1. Introduction

Let us start from the function

\[
\psi(x) = \begin{cases} (1 + x)^{1/x} & : x \geq -1 \wedge x \neq 0, \\ e & : x = 0 \end{cases}
\]

(1)

where \(e\) is the base of the natural logarithm. In view of its importance in study Carleman inequality and Keller’s Limit, many interesting and important results have been obtained for this function and related functions.

In \([3]\), the following result was established:

\[
\psi(x) = \begin{cases} e^x & : x \geq -1 \wedge x \neq 0, \\ e & : x = 0 \end{cases}
\]

(2)

for \(x \in (-1, 1)\) and where sequence \(e_n\) (\(n \in N_0 = N \cup \{0\}\)) is determined by

\[
e_0 = 1, \\
e_n = (-1)^n \sum_{k=0}^{n} \frac{(1)^{n+k} S_1(n + k, k)}{(n + k)!} \sum_{m=0}^{n} \frac{(-1)^m}{(m - k)!} ;
\]

(3)

where \(S_1(p, q)\) is the Stirling’s number of the first kind \((p, q) \in N\). For the Stirling’s numbers of the first kind the following recurrence relation is true

\[
S_1(p + 1, q) = -pS_1(p, q) + S_1(p, q - 1),
\]

for \(p > q\): \(S_1(p, p) = 1\) and \(S_1(p, q) = 0\) for \(p < q\) \((p, q \in N)\); see for example [3], [4]. Let us notice that sign of the Stirling’s number of the first kind \(S_1(p, q)\) is equal to \((-1)^{p-q}\). Initial values of the sequence of fractions

\[
e_0 = 1, \quad e_1 = \frac{1}{2}, \quad e_2 = \frac{11}{24}, \quad e_3 = -\frac{7}{16}, \quad e_4 = \frac{2447}{5760}, \quad e_5 = -\frac{959}{2304}, \quad e_6 = \frac{238043}{580608}, \ldots \tag{5}
\]

are tabulated with the sequences A055505 and A055535 in [5]. Based on the Lemma 2 from [3] (for \(t = 1\)), from the representation [4] we obtain

\[
e_n = e^{-1} \sum_{k=1}^{\infty} \frac{S_1(n + k, k)}{(n + k)!}, \tag{6}
\]

where \(n \in N\).

Let us consider the following sequence of partial sums:

\[
e_n(x) = e \left(1 + \sum_{k=1}^{n} (-1)^k f_k x^k\right), \tag{7}
\]

for

\[
f_k = (-1)^k e_k = (-1)^k e^{-1} \sum_{i=1}^{\infty} \frac{S_1(k + 1, i)}{(k + 1)!}, \tag{8}
\]

where \(x \in (-1, 1)\) and \(n \in N_0\).

The first aim of the present paper is to establish the monotoneity properties for the \(e_n(x)\).

In [5] and [6], the authors proved that for any \(c \in R\) the following Keller’s type limit holds:

\[
\lim_{n \to \infty} \left[(n + 1) \left(1 + \frac{1}{n + c}\right)^{n+c} - n \left(1 + \frac{1}{n + c - 1}\right)^{n+c-1}\right] = e. \tag{9}
\]

The second aim of the present paper is to define some general limits of Keller’s type, related to some limits stated in [5] and [6].

2. Monotoneity properties of the \(e_n(x)\)

The next statements are true:

**Lemma 2.1.** The sequence \(f_n\) is strictly monotonic decreasing.

**Proof.** Based on the recurrence relation for the Stirling’s numbers of the first kind the following equalities are true

\[
f_{n+1} = (-1)^{n+1} e^{-1} \sum_{i=1}^{\infty} \frac{S_1(n + i + 1, i)}{(n + i + 1)!} = (-1)^{n+1} e^{-1} \sum_{i=1}^{\infty} \frac{-(n+i)S_1(n + i, i) + S_1(n + i - 1, i - 1)}{(n + i + 1)!}
\]

\[
= (-1)^{n+1} e^{-1} \sum_{i=1}^{\infty} \frac{-(n+i+1)S_1(n + i, i) + S_1(n + i - 1, i - 1)}{(n + i + 1)!}
\]

\[
= (-1)^{n+1} e^{-1} \sum_{i=1}^{\infty} \frac{S_1(n + i, i) + (-1)^{n+1} e^{-1} \sum_{i=1}^{\infty} S_1(n + i - 1, i - 1)}{(n + i + 1)!}. \tag{10}
\]

Therefore, based on sign of Stirling’s numbers of the first kind, we have the conclusion that

\[
f_n - f_{n+1} = (-1)^n e^{-1} \sum_{i=1}^{\infty} \frac{S_1(n + i, i) + S_1(n + i - 1, i - 1)}{(n + i + 1)!} > 0. \tag{11}
\]

**Corollary 2.2.** The sequence \(f_n\) is convergent.
Theorem 2.3. Let us form the sequence
\[ e_n(x) = e \left( 1 + \sum_{k=1}^{n} (-1)^k f_k x^k \right), \] for \( x \in (-1, 1) \) \((n \in \mathbb{N})\). For \( x \neq 0 \) is true:
(i) if \( x \in (0, 1) \) then
\[ e_1(x) < e_2(x) < \ldots < e_{2k-1}(x) < \ldots < e(x) < \ldots < e_{2k}(x) < \ldots < e_2(x) < e_0(x); \]
(ii) if \( x \in (-1, 0) \) then
\[ e_0(x) < e_1(x) < e_2(x) < \ldots < e_{2k+1}(x) < \ldots < e(x). \]
For \( x = 0 \) is true that \( e_n(0) = e(0) = e \ (n \in \mathbb{N}). \)

**Proof.** Theorem obviously follows from the fact that for fixed \( x \in (0, 1) \) the following \( f_k x^k \) are true \( (f_k > 0, f_{k+1} x^{k+1} < f_k x^k) \) and \( \lim_{k \to \infty} (f_k x^k) = \lim_{k \to \infty} f_k \cdot \lim_{x \to 0} x^k = 0 \). \( \square \)

**Corollary 2.4.** Based on the previous Theorem we obtain proofs of Lemma 2.1 from \[ 2 \] and Theorem 1 from \[ 2 \] over \( (0, 1) \).

3. General limits of Keller's type

Let us consider an arbitrary Maclaurin series
\[ g(x) = \sum_{k=0}^{\infty} a_k x^k, \] for \( x \in (-\varrho, \varrho) \) and some \( \varrho \in (0, \infty) \), wherein \( a_k \) \((k \in \mathbb{N})\) is some real sequence. Therefore exist a convergent asymptotic expansion
\[ G(y) = g \left( \frac{1}{y} \right) = \sum_{k=0}^{\infty} a_k y^k, \]
for \( y \in \mathbb{R} \setminus \{0\} \) and \( \left| \frac{1}{y} \right| < \min \{1, \varrho\} \). Then, the first general limit of Keller's type of the function \( g \) we define by
\[ L_1 = \lim_{y \to \infty} \left( (y+1)G(y) - yG(y-1) \right). \]
We consider the function \( (y+1)G(y) - yG(y-1) \) for values \( y > 1 + \max \left\{ \frac{1}{\varrho}, \frac{1}{\varrho} \right\} \). Using the binomial expansion
\[ \frac{1}{(y-1)^k} = \frac{1}{y^k} \left( 1 - \frac{1}{y} \right)^k = \sum_{i=0}^{k} \frac{k^i (k-i)^{k-i-1}}{i!} \frac{1}{y^i}, \] for \( \frac{1}{y} < 1 \) and \( k \in \mathbb{N} \), we obtained, for \( y > 1 + \max \left\{ \frac{1}{\varrho}, \frac{1}{\varrho} \right\} \), the following convergent asymptotic expansion
\[ (y+1)G(y) - yG(y-1) = (y+1) \left( a_0 + \sum_{k=1}^{\infty} \frac{a_k}{y^k} \right) - y \left( a_0 + \sum_{k=1}^{\infty} \frac{a_k}{y^{k-1}} \right) = a_0 + \sum_{k=1}^{\infty} \frac{(y+1)a_k}{y^k} - \sum_{k=1}^{\infty} \frac{a_k}{y^{k-1}}. \]
For \( y > 1 + \max \left\{ \frac{1}{\varrho}, \frac{1}{\varrho} \right\} \) let us determine the representation
\[ (y+1)G(y) - yG(y-1) = a_0 + a_1 \frac{y}{y^2} + a_2 \frac{a_2 + a_3}{y^3} + a_3 + a_4 \frac{y^4}{y^4} + \ldots - \left( \begin{array}{ccc} (0)^2 a_1 & (1)^2 a_2 & (2)^2 a_3 & (3)^2 a_4 & \cdots \end{array} \right) \]
\[ + \left( \begin{array}{ccc} (1)^1 a_2 & (2)^1 a_3 & (3)^1 a_4 & \cdots \end{array} \right) \]
\[ + \left( \begin{array}{ccc} (2)^0 a_3 & (3)^0 a_4 & \cdots \end{array} \right) \]
\[ + \left( \begin{array}{ccc} (3)^0 a_4 & \cdots \end{array} \right) \]
\[ + \cdots \]
\[ (y+1)G(y) - yG(y-1) = a_0 - \frac{a_1 + a_2}{y^2} - \frac{a_1 + 3a_2 + 2a_3}{y^3} - \frac{a_1 + 4a_2 + 6a_3 + 3a_4}{y^4} - \frac{a_1 + 5a_2 + 10a_3 + 10a_4 + 4a_5}{y^5} - \frac{a_1 + 6a_2 + 15a_3 + 20a_4 + 15a_5 + 5a_6}{y^6} \] (20)

Finally, for \( y > 1 + \max\{1, \frac{1}{y}\} \), we obtained the following convergent asymptotic expansion

\[ (y+1)G(y) - yG(y-1) = a_0 - \sum_{k=2}^{\infty} \sum_{i=1}^{k-1} \binom{k}{i-1} a_i + \binom{k}{k-1} - 1 \frac{a_k}{y^k}. \] (21)

Let us remark that coefficients \( \binom{k}{0}, \binom{k}{1}, \binom{k}{2}, \ldots, \binom{k}{k-1}, \binom{k}{k-1} - 1 \) respectively to \( a_1, a_2, a_3, \ldots \), \( a_{k-1}, a_k \) are tabulated as the sequence A193815 in [7]. The above expansion (21) is sufficient to conclude that

\[ L_1 = \lim_{y \to \infty} \left( (y+1)G(y) - yG(y-1) \right) = a_0. \] (22)

Specially, if \( g(x) = e(x) \), i.e. \( G(y) = g \left( \frac{1}{y} \right) = \left( 1 + \frac{1}{y} \right)^y \), then

\[ L_1 = \lim_{y \to \infty} \left( \frac{(y+1)^{y+1}}{y^y} - \frac{y^y}{(y-1)^{y-1}} \right) = e. \] (23)

Next we use some expansion of type (21) for generalization of some results for limits of Keller’s type from the paper [5]. The second general limit of Keller’s type of the function \( g \) we define by

\[ L_2 = \lim_{y \to \infty} \left( (y+1)G(y+c) - yG(y+c-1) \right), \] (24)

for arbitrary \( c \in \mathbb{R} \). Similar to the above discussion, we can obtain

\[ (y+1)G(y+c) - yG(y+c-1) = a_0 + \sum_{k=2}^{\infty} \sum_{i=1}^{k-1} \binom{k-1}{i-1} a_i - \left( \sum_{i=1}^{k-1} \binom{k-1}{i-1} \right) a_i + \binom{k}{k-1} - 1 \frac{a_k}{(y+c)^k}. \] (25)

From (25), we can get immediately the limit (9).

4. Conclusions

In this paper, the monotoneity properties of the functions \( e_n(x) \) were established and some general limits of Keller’s type are defined. We believe that the results will lead to a significant contribution toward the study of Carleman inequality and Keller’s limit.
