Reconstruction Codes for DNA Sequences with Uniform Tandem-Duplication Errors

Yonatan Yehezkeally, Student Member, IEEE, and Moshe Schwartz, Senior Member, IEEE

Abstract—DNA as a data storage medium has several advantages, including far greater data density compared to electronic media. We propose that schemes for data storage in the DNA of living organisms may benefit from studying the reconstruction problem, which is applicable whenever multiple reads of noisy data are available. This strategy is uniquely suited to the medium, which inherently replicates stored data in multiple distinct ways, caused by mutations. We consider noise introduced solely by uniform tandem-duplication, and utilize the relation to constant-weight integer codes in the Manhattan metric. By bounding the intersection of the cross-polytope with hyperplanes, we prove the existence of reconstruction codes with greater rates than known error-correcting codes.

Index Terms—DNA storage, reconstruction, string-duplication systems, tandem-duplication errors

I. INTRODUCTION

DNA is attracting considerable attention in recent years as a medium for data storage, due to its high density and longevity [7]. Data storage in DNA may provide integral memory for synthetic-biology methods, where such is required, and offer a protected medium for long-period data storage [4], [38]. In particular, storage in the DNA of living organisms is now becoming feasible [36]; it has varied usages, including watermarking genetically modified organisms [3], [14], [32] or research material [19], [38], and even affords some concealment to sensitive information [8]. Naturally, therefore, data integrity in such media is of great interest.

Several recent works have studied the inherent constraints of storing and retrieving data from DNA. While desired sequences (over quaternary alphabet) may be synthesized (albeit, while suffering from substitution noise), generally data can only be read by observation of its subsequences, quite possibly an incomplete observation [20]. Moreover, the nature of DNA and current technology results in asymmetric errors which depend upon the dataset [12]. The medium itself also introduces other types of errors which are atypical in electronic storage, such as symbol/block-deletion and adjacent transpositions (possibly complemented) [13]. Finally, the purely combinatorial problem of recovering a sequence from the multiset of all its subsequences (including their numbers of incidence), was also studied, e.g., [1], [37], as well as coding schemes involving only these multisets (or their profile vectors – describing the incidence frequency of each subsequence) [35].

This work was presented in part at ISIT’2018.

The authors are with the Department of Electrical and Computer Engineering, Ben-Gurion University of the Negev, Beer Sheva 8410501, Israel (e-mail: yonatany@post.bgu.ac.il; schwartz@ee.bgu.ac.il).

Other works were concerned with data storage in the DNA of a living organism. While this affords some level of protection to the data, and even propagation (through DNA replication), it is also exposed to specific noise mechanisms due to mutations. Examples of such noise include symbol insertions, deletion, substitutions (point-mutation), and duplication (including tandem- and interspersed-duplication). Therefore, schemes for data storage in live DNA must address data integrity and error-correction.

In an effort to better understand these typical noise mechanisms, their potential to generate the diversity observed in nature was studied. [11] classified the capacity and/or expressiveness of the systems of sequences over a finite alphabet generated by four distinct substring duplication rules: end-duplication, tandem-duplication, palindromic-duplication, and interspersed-duplication. [16] fully characterized the expressiveness of bounded tandem-duplication systems, proved bounds on their capacity (and, in some cases, even exact values). [18] later showed that when point-mutations act together with tandem-duplication as a sequence-generation process, they may actually increase the capacity of the generated system. [2] looked at the typical duplication distance of binary sequences; i.e., the number of tandem-duplications generating a binary sequence from its root. It was proven that for all but an exponentially small number of sequences that number is proportional to the sequence length. Further, when tandem-duplication is combined with point-mutations (here, only within the duplicated string), it was shown that the frequency of substitutions governs whether that distance becomes logarithmic.

The generative properties of interspersed-duplication were also studied from a probabilistic point of view. [10] showed (under assumption of uniformity) that the frequencies of incidence for each subsequence converge to the same limit achieved by an i.i.d. source, thus reinforcing the notion that interspersed-duplication is–on its own–capable of generating diversity. [9] specifically looked at tandem- and end-duplication, and found exact capacities in the case of duplication length 1 by a generalization of the Pólya urn model that applies to strings. It also tightly bounded the capacity of complement tandem-duplication, a process where the duplicated symbol is complemented (using binary alphabet).

Finally, error-correcting codes for data affected by tandem-duplication have been studied in [17], which presented a construction of optimal-size codes for correcting any number of errors under uniform tandem-duplication (fixed duplication length), computing their (and thus, the optimal-) capacity. It also presented a framework for the construction of optimal
codes for the correction of a fixed number of errors. Next, it studies bounded tandem-duplications, where a characterization of the capacity of error-correcting codes is made for small constants. In general, it characterized the cases where the process of tandem-duplication can be traced back uniquely. More recently, a flurry of activity in the subject includes works such as [24]–[27] which provide some implicit and explicit constructions for uniform tandem-duplication codes, as well as some bounds.

However, classical error-correction coding ignores some properties of the DNA storage channel; namely, stored information is expected to be replicated, even as it is mutated. This lends itself quite naturally to the reconstruction problem [31], which assumes that data is simultaneously transmitted over several noisy channels, and a decoder must therefore estimate that data based on several (distinct) noisy versions of it. Solutions to this problem have been studied in several contexts. It was solved in [31] for sequence reconstruction over finite alphabets, where several error models were considered, such as substitutions, transpositions and deletions. Moreover, a framework was presented for solving the reconstruction problem in general cases of interest in coding theory, utilizing a graph representation of the error model, which was further developed in [29], [30]. The problem was also studied in the context of permutation codes with transposition and reversal errors [21]–[23], and partially solved therein. Later, applications were found in storage technologies [5], [6], [39], [40], since modern application might preclude the retrieval of a single data point, in favor of multiple-point requests. However, the problem hasn’t been addressed yet for data storage in the DNA of living organisms, where it may be most applicable.

In this paper, we study the reconstruction problem over DNA sequences, with uniform tandem-duplication errors. The main contributions of the paper are the following: We show that reconstruction codes in this setting are necessarily error-correcting codes with appropriately chosen minimum distance, based on the uncertainty parameter. We also show that in two asymptotic regimes, we can always obtain higher rate than currently known error-correcting codes. These asymptotic regimes include what we believe is the most interesting one, where the uncertainty is sublinear, and the time (number of mutations) is bounded by a constant.

The paper is organized as follows: In Section II we present notations and definitions. In Section III we demonstrate that reconstruction codes are error-correcting codes and find their requisite minimal-distance, as a function of the reconstruction parameters. In Section IV we then study bounds on the sizes of such codes by an isometric embedding to constant-weight codes in the Manhattan metric. Finally, in Section V we show that by considering reconstruction codes we improve the capacity of known error-correcting codes, and conclude with closing remarks in Section VI.

II. PRELIMINARIES

Throughout this paper, though human DNA is composed of four nucleotide bases, we observe the more general case of sequences over a finite alphabet; since the alphabet elements are immaterial to our discussion, we denote it throughout as \( Z_q \). We observe the set of finite sequences (also: words) over \( Z_q \). For any two words \( u, v \in Z_q \), we denote their concatenation \( uv \). For each word \( x \in Z_q^k \), we denote its length \( |x| = n \). We also take special note of the set of words with length higher than or equal to some \( 0 < k < N \), which we denote \( Z_q^{\geq k} \). For ease of notation, we let \( N \) stand for the set of non-negative integers throughout the paper; when an integer is assumed to be strictly positive, we make special note of that fact.

For \( 0 < k \in N, i \in N \), we define a tandem-duplication of duplication-length \( k \) by the mappings

\[
\mathcal{T}_{k,i}(x) \triangleq \begin{cases} 
   uvw & x = uvw, |u| = i, |v| = k, \\
   x & \text{otherwise}.
\end{cases}
\]

If \( y = \mathcal{T}_{k,i}(x) \) and \( y \neq x \) (which occurs whenever \( |x| \geq i+k \)), we say that \( y \) is a descendant of \( x \), and denote \( x \xrightarrow{k} y \). In what follows, we focus on the uniform tandem-duplication model (i.e., we fix \( k \)) because of its simplicity.

Furthermore, a given sequence \( \{x_j\}_{j=0}^t \subseteq Z_q^k \) such that for all \( 0 \leq j < t, x_j \xrightarrow{k} x_{j+1} \), we say that \( x_0 \) is a t-descendant of \( x_0 \), and denote \( x_0 \xrightarrow{k} x_t \). For completeness, we also denote \( x \xrightarrow{0} x \). Finally, if there exists some \( t \in N \) such that \( x \xrightarrow{k} y \), we also denote \( y \xrightarrow{k} y \).

We denote the set of t-descendants of \( x \in Z_q^k \) as

\[
D_t^k(x) \triangleq \bigcup_{y \in Z_q^k} \{ x \xrightarrow{k} y \},
\]

for some \( t \in N \). We also denote the descendant cone of \( x \) by

\[
D_t(x) \triangleq \bigcup_{y \in Z_q^k} D_t^k(y).
\]

We say that \( x \in Z_q^k \) is irreducible if \( x \in D_t^k(y) \) implies \( y = x \). We exclude from the definition shorter words, for which the condition vacuously holds. We denote by \( \text{Irr}_k \) the set of all irreducible words, and \( \text{Irr}_k(n) \triangleq \text{Irr}_k \cap Z_q^n \).

It was shown in [18], [28] that for each word \( x \in Z_q^k \), a unique irreducible word exists for which \( x \) is a descendant. We call it the root of \( x \), and denote it by \( R_k(x) \). This induces an equivalence relation by \( x \sim_k y \) if \( R_k(x) = R_k(y) \).

We also follow [18] in defining, for \( x \in Z_q^k \), \( \text{Pref}_k(x) \) as the length-k prefix of \( x \), and \( \text{Suff}_k(x) \) as its suffix; i.e., if \( x = uu'v = v'u \) where \( |u| = |v| = k \), then \( \text{Pref}_k(x) = u \) and \( \text{Suff}_k(x) = v \). Using this notation, we define an embedding \( \phi_k : Z_q^k \rightarrow Z_q^k \times Z_q^k \)

\[
\phi_k(x) \triangleq (\text{Pref}_k(x), \text{Suff}_{|x|-k}(x) - \text{Pref}_{|x|-k}(x)).
\]

It is seen in [18] that this mapping is indeed injective. Further, it was shown that, defining \( \zeta_{k,i} : Z_q^k \rightarrow Z_q^k \times Z_q^k \) by

\[
\zeta_{k,i}(a, b) \triangleq \begin{cases} 
   (a, b_1 0^k b_2) & b = b_1 b_2, |b_1| = i, \\
   (a, b) & \text{otherwise},
\end{cases}
\]

where \( 0 < k \in N, i \in N \), we have \( \phi_k(\mathcal{T}_{k,i}(x)) = \zeta_{k,i}(\phi_k(x)) \).

The simplicity of \( \zeta_{k,i} \) in comparison to \( \mathcal{T}_{k,i} \) motivates the analysis of tandem-duplications using the \( \phi_k \) images of sequences.
If \( b \in \mathbb{Z}_q^k \) is composed of the subsequences
\[
b = 0^{s_1}w_10^{s_2} \cdots w_m0^{s_{m+1}}; \quad w_1, \ldots, w_m \in \mathbb{Z}_q \setminus \{0\}
\]
we define
\[
\mu(b) \triangleq 0^{s_1 \mod k}w_10^{s_2 \mod k} \cdots w_m0^{s_{m+1} \mod k},
\]
\[
\sigma(b) \triangleq \left( \frac{s_1}{k}, \ldots, \frac{s_{m+1}}{k} \right).
\]

We may note that \( \text{wt}_H(b) = \text{wt}_H(\mu(b)) = m \), where \( \text{wt}_H \) is the Hamming weight, and \( \sigma(b) \in \mathbb{N}^{\text{wt}_H(b) + 1} = \mathbb{N}^{\text{wt}_H(\mu(b)) + 1} \).

We also observe that \( b \) is recoverable from \( \sigma(b), \mu(b) \). It was proven in [18, Cor. 10] that if \( \phi_k(x) = (a, b) \) then
\[
\phi_k(R_k(x)) = (a, \mu(b)).
\]
Thus, if \( x, y \in \mathbb{Z}_q^{\geq k}, \phi_k(x) = (a_1, b_1) \) and \( \phi_k(y) = (a_2, b_2) \), then \( x \sim_k y \) if and only if \( a_1 = a_2 \) and \( \mu(b_1) = \mu(b_2) \).

Moreover, \( x \in \text{Irr}_k \) if and only if \( \sigma(b_1) = (0, 0, \ldots, 0) \). Note that, equivalently, we may say that \( b \) contains no zero-runs of length \( k \); such sequences are called \((0, k - 1)_q\)-Run-Length-Limited, or \((0, k - 1)_q\)-RLL.

For \( x \in \text{Irr}_k \), \( \phi_k(x) = (a, b) \), we denote \( m(x) \triangleq \text{wt}_H(b) \) and define \( \psi_x : D_k^1(x) \to \mathbb{N}^{m(x) + 1} \) by \( \psi_x(y) \triangleq \sigma(b) \), where \( \phi_k(y) = (a, b') \).

Finally, for \( n \geq k \) and \( x, y \in \mathbb{Z}_q^n \) we define
\[
d_k(x, y) \triangleq \min \{ t \in \mathbb{N} \mid D_k^t(x) \cap D_k^t(Y) \neq \emptyset \},
\]
or \( d_k(x, y) = \infty \) if \( \{ t \in \mathbb{N} \mid D_k^t(x) \cap D_k^t(y) \neq \emptyset \} = \emptyset \). It was shown in [18, Lem. 14] that \( d_k(x, y) = \infty \) if and only if \( x \not\sim_k y \), hence \( d_k(\cdot, \cdot) \) is finite on \( D_k(x) \), for any particular \( x \in \mathbb{Z}_q^{\geq k} \). Furthermore, [18, Lem. 19] shows that for any \( x \sim_k y \) with \( |x| = |y| \) it holds that
\[
d_k(x, y) = \frac{1}{2} \| \sigma(b_1) - \sigma(b_2) \|_1,
\]
thus \( d_k(\cdot, \cdot) \) defines a metric on each equivalence class of \( \sim_k \).

### III. RECONSTRUCTION CODES

The reconstruction problem in the context of uniform tandem-duplication errors can be stated as follows: suppose data is encoded in \( C \subseteq \mathbb{Z}_q^n \), and suppose we later are able to read distinct \( x_0, x_1, \ldots, x_N \in D_k^t(c) \) for some specific \( c \in C \) and \( t \in \mathbb{N} \); can we uniquely identify \( c \)?

It is apparent (see [31]) that to allow successful reconstruction we require codes to satisfy the following.

### Definition 1
Take \( N, t, n > 0 \). We say that \( C \subseteq \mathbb{Z}_q^n \) is a \emph{uniform tandem-duplication reconstruction code}, which we abbreviate as \( (N, t, k)_q \)-UTR code, if
\[
\max \{ |D_k^t(c) \cap D_k^t(c')| \mid c, c' \in C, \ c \neq c' \} \leq N.
\]

The purpose of this section is to characterize reconstruction codes. By an evaluation of the size of intersection of descendant cones, we determine the achievable size of \( (N, t, k)_q \)-UTR codes. We shall state the solution to this problem in terms of error-correcting codes for the Manhattan metric, and devote the next section to an observation of such codes.

### A. Structure of descendant cones

Throughout this section we fix some \( x \in \text{Irr}_k \), and denote \( \phi_k(x) = (a, b) \).

As noted above, for all \( y \in D_k^1(x) \), we have \( \phi_k(y) = (a, b') \), with \( \mu(b') = b \) (hence, in particular, \( \text{wt}_H(b') = \text{wt}_H(b) \)). We therefore denote \( m = m(x) = \text{wt}_H(b) \) and make the following definition:

### Definition 2
We let \( \psi_x : D_k^1(x) \to \mathbb{N}^{m+1} \) be defined by \( \psi_x(y) = \sigma(b') \), where \( \phi_k(y) = (a, b') \).

It was noted in the previous section that \( \psi_x \) is then an isometry from \( (D_k^1(x), d_k) \) to \( (\mathbb{N}^{m+1}, \| \cdot \|_1) \).

### Definition 3
We define on \( \mathbb{N}^{m+1} \) the partial order \( b' \preceq b'' \) if for every coordinate \( i = 1, \ldots, m + 1 \) it holds that \( b'_i \leq b''_i \) (\( \preceq \) is the well-known product order).

### Lemma 4
For all \( y, z \in D_k^1(x) \) it holds that \( y \Longrightarrow_k z \) if and only if \( \psi_x(z) = \psi_x(y) + e_j \), for some unit vector \( e_j \in \mathbb{N}^{m+1} \).

**Proof:** Let us denote
\[
\phi_k(y) = (a, 0^{s_1}w_10^{s_2} \cdots w_m0^{s_{m+1}}).
\]

Now note that \( y \Longrightarrow_k z \) if and only if there exists \( i \in \mathbb{N} \) such that \( \phi_k(z) = (c_i, k \phi_k(y)) \) and \( \phi_k(z) \neq \phi_k(y) \), which occurs if and only if there exists \( 1 \leq j \leq m + 1 \) such that
\[
\phi_k(z) = (a, 0^{s_1}w_10^{s_2} \cdots w_{j-1}0^{s_j+k} \cdots w_m0^{s_{m+1}}).
\]

This, in turn, can equivalently be stated as \( \psi_x(z) = \psi_x(y) + e_j \) where \( e_j \) is a unit vector.

### Corollary 5
For all \( y, z \in D_k^1(x) \) it holds that \( y \Longrightarrow_k z \) if and only if \( \psi_x(y) \preceq \psi_x(z) \).

**Proof:** Using Lemma 4 we observe that \( y \Longrightarrow_k z \) if and only if \( y = z \) (in which case \( \psi_x(y) = \psi_x(z) \)) or
\[
\psi_x(z) = \psi_x(y) + \sum_{u=1}^t e_{j_u}
\]
for some unit vectors \( e_{j_1}, \ldots, e_{j_t} \in \mathbb{N}^{m+1} \). The claim follows.

### Lemma 6
\( \psi_x \) is a poset isomorphism from \( (D_k^1(x), \Longrightarrow_k) \) to \( (\mathbb{N}^{m+1}, \preceq) \).

**Proof:** Using Corollary 5 and the fact that \( (\mathbb{N}^{m+1}, \preceq) \) is a partially ordered set we observe that \( (D_k^1(x), \Longrightarrow_k) \) is also a poset, and that \( \psi_x \) is a poset homomorphism. We have already noted that it is injective (as an isometry).

Finally, note that \( \psi_x(x) = 0^{m+1} \). Every element of \( \mathbb{N}^{m+1} \) can be decomposed into
\[
\sum_{u=1}^t e_{j_u} = \psi_x(x) + \sum_{u=1}^t e_{j_u}
\]
Lemma 8

\[ \psi_z(y_t) = \sum_{t=1}^k e_{j_t}, \quad \text{thus } \psi_x \text{ is also surjective.} \]

Thus, \( \xrightarrow{k} \) endows \( D^*_k(x) \) with a lattice structure; We denote the join of \( y, z \in D^*_k(x) \) as \( y \lor z \), and their meet \( y \land z \). We have the following immediate results:

**Corollary 7** For all \( y, z \in D^*_k(x) \),
\[ D^*_k(y) \cap D^*_k(z) = D^*_k(y \lor z). \]

**Lemma 8** \[ |D^*_k(x)| = \binom{(t+m(x))}{m(x)}. \]

**Proof:** By Lemma 4 we know that
\[ D^*_k(x) = \{ y \in D^*_k(x) \mid \|\psi_x(y)\|_1 = t \}. \]

Since \( \psi_x : D^*_k(x) \to \mathbb{N}^{(m(x))} \) is bijective, \( |D^*_k(x)| \) equals the number of distinct integer solutions to \( \sum_{j=1}^{m(x)+1} x_j = t \), where \( x_1, \ldots, x_{m(x)+1} \geq 0 \) (equivalently, the number of distinct ways to distribute \( t \) identical balls into \( m(x)+1 \) bins).

**B. Reconstruction from uniform tandem-duplication errors**

We start by rephrasing the properties of descendant cones as seen in the previous section:

**Corollary 9** Suppose that \( x, x' \in \text{Irr}_k \). Then the following conditions are equivalent:

1. \( m(x') = m(x) \).
2. For all \( y' \in D^*_k(x') \) and \( y \in D^*_k(x) \), it holds that \( D^*_k(y') = D^*_k(y) \).
3. For all \( t > 0 \), \( y' \in D^*_k(x') \) and \( y \in D^*_k(x) \), it holds that \( |D^*_k(y')| = |D^*_k(y)| \).
4. There exist some \( t > 0 \), \( y' \in D^*_k(x') \) and \( y \in D^*_k(x) \) such that \( |D^*_k(y')| = |D^*_k(y)| \).

**Proof:** That 1) \( \implies \) 2) follows from Lemma 6. Implications 2) \( \implies \) 3) \( \implies \) 4) follow trivially. To show that 4) \( \implies \) 1), note by previous parts that \( D^*_k(y') \equiv D^*_k(x') \) and \( D^*_k(y) \equiv D^*_k(x) \). In particular, we have that \( |D^*_k(x')| = |D^*_k(x)| \). Lemma 8 now implies 1.

These observations allow us to classify the intersection size of descendant cones.

**Lemma 10** For \( n \geq k \), \( t \geq 0 \) and \( y_1, y_2 \in \mathbb{Z}_q^n \),
\[ |D^*_k(y_1) \cap D^*_k(y_2)| = \left| D^*_k(y_1) \cap D^*_k(y_2) \right| \]
if \( y_1 \sim_k y_2 \) and \( t \geq d_k(y_1, y_2) \), or \( D^*_k(y_1) \cap D^*_k(y_2) = \emptyset \) otherwise.

**Proof:** As already noted, if \( y_1 \neq y_2 \) or \( t < d_k(y, z) \) we have \( D^*_k(y) \cap D^*_k(z) = \emptyset \). Otherwise, by Corollary 7 we have
\[ D^*_k(y_1) \cap D^*_k(y_2) = D^*_k(y_1 \lor y_2). \]

Note, then, that if \( z \in D^*_k(y_1) \cap D^*_k(y_2) \) then
\[ y_1 \lor y_2 \frac{t-d_k(y_1, y_2)}{k} z, \]
therefore
\[ D^*_k(y_1) \cap D^*_k(y_2) = D^*_k(y_1 \lor y_2). \]

and by Corollary 9 we have
\[ D^*_k(y_1 \lor y_2) \equiv D^*_k(y_1 \lor y_2) \]

We can now state the main result of this section:

**Theorem 11** Take \( x \in \mathbb{Z}_q^n \), \( n \geq |x| \). Then \( C \subseteq D^*_k(x) \cap \mathbb{Z}_q^n \) is an \((N, t, k)_q\)-UTR code if and only if
\[ \min\{d_k(c, c') \mid c, c' \in C, c \neq c'\} \geq d_{N,t}(m(x)), \]
where we make the notation
\[ d_{N,t}(m) \triangleq \min\left\{ \delta \in \mathbb{N} \mid \left( t - \delta + m(x) \right) \leq N \right\}. \]

**Proof:** The claim follows from Lemma 8, Lemma 10.

In other words, the intersection of a uniform-tandem-duplication reconstruction code \( C \) with the descendant cone of any irreducible word \( D^*_k(x) \) is simply an error-correcting code with a suitable minimal distance. We note, however, that this does not hold for \( C \) in general: not only is the minimal distance dependent on \( x \), but \( D^*_k(x) \cap \mathbb{Z}_q^n \) also depends on \(|x|\).

**C. Size of reconstruction codes**

In this section we aim to estimate the maximal size of \((N, t, k)_q\)-UTR codes.

**Definition 12** For \( m, r > 0 \) we denote the \((m, r)\)-simplex
\[ \Delta^m_r \triangleq \left\{ (x_i)_{i=1}^{m+1} \in \mathbb{N}^{m+1} \mid \sum_{j=1}^{m+1} x_j = r \right\}. \]

**Theorem 13** We take positive integers \( N, t \) and \( n > k \). For \( C \subseteq \mathbb{Z}_q^n \) and \( x \in \text{Irr}_k \) we partition \( C_x \triangleq C \cap D^*_k(x) \) and define \( r(x) \triangleq \frac{n-|x|}{k} \).

If \( C_x \neq \emptyset \) then \( r(x) \in \mathbb{N} \) and \( r(x) < \left\lfloor \frac{n}{k} \right\rfloor \). Moreover, \( C \) is an \((N, t, k)_q\)-UTR code if and only if for all \( x \in \text{Irr}_k \) such that \( C_x \neq \emptyset \), the image \( \psi_x (C_x) \) \( \subseteq \Delta^m_r \) satisfies
\[ \min\left\{ \frac{1}{2} \| c - c' \|_1 \mid c \neq c' \in \psi_x (C_x) \right\} \geq d_{N,t}(m(x)). \]

**Proof:** If \( C \cap D^*_k(x) \neq \emptyset \) then it follows from the definitions that for some \( r \in \mathbb{N} \) we have \(|x| + rk = n\); since \(|x| \geq k \), necessarily \( r = r(x) < \left\lfloor \frac{n}{k} \right\rfloor \). Furthermore, \( C \cap D^*_k(x) = C \cap D^*_k(x') \), hence we have seen in the proof of Lemma 6 that for all \( y \in D^*_k(x) \) we have \( \psi_x(y) = \sum_{y=1}^r e_{j_x} \in \Delta^m_r \).

To conclude the proof, we recall that for \( x, x' \in \text{Irr}_k \) we have \( D^*_k(x) \cap D^*_k(x') = \emptyset \), and that \( \psi_x \) is a bijective isometry into \((\mathbb{N}^{m(x)} + 1, \frac{1}{2} \| \cdot \|_1)\).

The rest now follows from Theorem 13.

n \leq k - n \leq \frac{n^2}{4},
\begin{align*}
|C| &= \frac{|n|}{k} \sum_m M(m, r, d) \\
&= \sum_{r=0}^{\frac{n}{d}} M(m, r, d) m.
\end{align*}

IV. CODES ON THE SIMPLEX WITH THE MANHATTAN METRIC

Lemma 17 For integers 0 < k < n it holds that
\[ nH\left(\frac{k}{n}\right) - \frac{1}{2} \log_2(2\pi n) \leq \log_2 \left(\frac{n}{k}\right) < nH\left(\frac{k}{n}\right). \]

Proof: For all 0 < k < n we have n - 1 \leq k(n - k) \leq \frac{n^2}{4}, hence
\[ \frac{n}{2\pi k(n - k)} \leq \frac{1}{2\pi} \left(1 + \frac{1}{n - 1}\right) \leq \frac{1}{\pi} < 1, \]
\[ \frac{n}{8\pi k(n - k)} \geq \frac{1}{2\pi}. \]

Thus the claim trivially follows from Lemma 16.

Definition 18 For 0 < m \in \mathbb{N} and r \in \mathbb{Z}, we denote the hyperplane
\[ A_m^m \triangleq \left\{ (x_i)_{i=1}^{m+1} \in \mathbb{Z}^{m+1} \mid \sum_{i=1}^{m+1} x_i = r \right\}, \]
and omit r = 0 in A_m^m \triangleq A_0^m.

We also denote the ball of radius d \geq 0 about x \in A_m^m as
\[ B_r^d(x) \triangleq \left\{ y \in A_m^m \mid \frac{1}{2} |||y - x||_1 \leq d \right\}, \]

since the size of each ball is invariant in r, x, we also denote B_m^d = B_0^d(0) for ease of notation.

Lemma 19 For d, m > 0 denote
\[ B_m^d \triangleq \sum_{k=1}^{\min(d, m)} \left(\begin{array}{c} m + 1 \\ k \end{array}\right) \left(\begin{array}{c} d - 1 \\ k - 1 \end{array}\right) \left(\begin{array}{c} m - k + d \\ d \end{array}\right). \]

then
\[ B_m^d \leq |B_m^d| \leq d \cdot B_m^d. \]

Proof: We may count |B_m^d| in the following manner:
\begin{itemize}
\item Partition by distance from the origin \frac{1}{2} ||x||_1 = r; then for each 0 \neq x \in B_m^d we have 1 \leq r \leq d.
\item Further partition by the number k of strictly positive coordinates x_i > 0; then 1 \leq k \leq \min(r, m).
\item Choose positive coordinates, which may be done in \binom{m+1}{k} distinct ways.
\item Find the number of solutions to \sum_{j=1}^{k} x_{i_j} = r such that each x_{i_j} > 0. That is \binom{k}{r}.\]
\item The remaining m - 1 - k coordinates are non-positive, and their sum is -r. There are \binom{m - 1 - k + r}{r} such distinct distributions.
\end{itemize}

Thus, |B_m^d| = 1 + \sum_{r=1}^{d} B_m^r(r), and it now suffices to note that B_m^r(r) is a strictly increasing function of r, hence the claim is satisfied.

In the following lemma we make an asymptotic evaluation of |B_m^d|:

Lemma 20 Take \mu \in (0, 1) and fix d > 0. Suppose we are given a sequence of dimensions (m_n)_{n \geq 0} such that \lim_{n \to \infty} \frac{m_n}{n} = \mu. Then \lim_{n \to \infty} \frac{1}{n} \log_2|B_m^d| = 0.
Proof: For sufficiently large \( n \) we find that
\[
\mathcal{B}^m_n(d) = \sum_{k=1}^{d} \binom{m_n+1}{k} \binom{d-1}{k-1} \binom{m_n-k+d}{d}
\]
\[
\leq d \cdot \binom{m_n+1}{d}^{d-1} \binom{m_n-1+d}{d}.
\]
Thus, using Lemma 17 it is straightforward to show that
\[
\lim_{n \to \infty} \frac{1}{n} \log_2 \mathcal{B}^m_n(d) = 0.
\]
Recalling that by Lemma 19 we have \(|B^m_n(d)| \leq d \cdot B^m_n(d)\), the proof is completed.

We can now quickly state the Gilbert-Varshamov bounds on \( M(m,r,d) \):

**Lemma 21** For \( m, r, d > 0 \) we have
\[
M(m,r,d) \geq \left( \frac{r+m}{m} \right) / |B^m(d-1)|.
\]

**Proof:** The proof is an application of Lemma 8 and the typical GV argument: if \( C \subseteq \Delta^m_r \) is a maximal code such that for all \( x \neq y \in C \) we have \( \frac{1}{2} \|x-y\|_1 \geq d \), then \( \Delta^m_r \subseteq \bigcup_{x \in C} B_m(d-1; x) \).

Thus, we have the following:

**Theorem 22** Take \( \mu \in (0,1), \rho > 0 \) and integer sequences \((m_n)_{n>0}, (r_n)_{n>0}\) such that \( \lim_{n \to \infty} \frac{m_n}{n} = \mu \) and \( \lim_{n \to \infty} \frac{r_n}{n} = \rho \). Also take a fixed \( d > 0 \). Then
\[
\lim_{n \to \infty} \frac{1}{n} \log_2 M(m_n, r_n, d) = (\mu + \rho) H \left( \frac{1}{1+\frac{d}{\mu}} \right).
\]

**Proof:** We use Lemma 21 to find
\[
\liminf_{n \to \infty} \frac{1}{n} \log_2 M(m_n, r_n, d) \geq \limsup_{n \to \infty} \left[ \frac{1}{n} \log_2 \left( \frac{r_n+m_n}{m_n} \right) - \frac{1}{n} \log_2 |B^m_n(d-1)| \right]
\]
Using Lemma 20 we know that
\[
\lim_{n \to \infty} \frac{1}{n} \log_2 |B^m_n(d-1)| = 0.
\]
On the other hand, since \( M(m_n, r_n, d) \leq |\Delta^m_{r_n}| = (\frac{r_n+m_n}{m_n}) \), Lemma 17 implies the reverse inequality.

**B. Minimal distance of reconstruction codes**

Next, given \( N, t > 0 \) and \( m > 0 \), we establish bounds on
\[
d_{N,t}(m) \triangleq \min \left\{ \delta \in \mathbb{N} \ \middle| \ \frac{t-\delta + m}{m} \leq N \right\}
\]
seen in Theorem 11.

For ease of notation in what follows, we make the notation, for \( 1 \leq x \in \mathbb{R} \):
\[
\mathcal{H}(x) \triangleq x H \left( \frac{1}{x} \right).
\]

**Lemma 23** If \( N \leq m \) then \( d_{N,t}(m) = t \).

**Proof:** We may verify by substitution that \( \delta = t \) satisfies \( (t-\delta + m) \leq N \), while \( \delta = t - 1 \) does not. Using the strict monotonicity of \( s \mapsto (s+\frac{m}{m}) \), we are done. In order to find a practical bound for \( d_{N,t}(m) \) when \( N > m \), we first require the following two lemmas:

**Lemma 24** For \( N > m > 0 \) and \( t > 0 \) it holds that
\[
d_{N,t}(m) \leq \min \left\{ \delta \in \mathbb{N} \ \middle| \ \mathcal{H} \left( \frac{1 + \frac{t-\delta + m}{m}}{m} \right) \leq \frac{\log_2 N}{m} \right\}.
\]

**Proof:** Under the assumption, \( \delta = t - 1 \) satisfies the inequality \( (t-\delta + m) \leq N \). Therefore we may restrict the minimum to \( \delta < t \), giving \( 0 < m < (t-\delta) + m \). Now, Lemma 17 implies
\[
\log_2 \left( \frac{t-\delta + m}{m} \right) \leq \log_2 \left( 1 + \frac{t-\delta + m}{m} \right) \leq \log_2 \left( 1 + \frac{t-\delta + m}{m} - \frac{\log_2 N}{m} \right),
\]
which completes the proof.

**Lemma 25** For \( x \geq 1 \) it holds that \( \mathcal{H}(x) \leq 2 \sqrt{x - 1} \).

**Proof:** The claim can be restated by the substitution \( p = \frac{1}{x} \) as the known inequality \( H(p)^2 \leq 4p(1-p) \) (its proof follows elementary calculus, and is omitted here).

Finally,

**Theorem 26** Take \( N > m > 0 \). Then
\[
d_{N,t}(m) \leq \max \left\{ 1, t - \left[ \frac{\log_2 N}{4m} \right]^2 \right\}.
\]

**Proof:** Using Lemma 25 we may bound \( \mathcal{H} \left( 1 + \frac{\log_2 N}{4m} \right) \leq 2 \sqrt{1 - \frac{\log_2 N}{4m}} \). Lemma 24 therefore implies that it suffices to require
\[
2 \sqrt{1 - \frac{\log_2 N}{4m}} \leq \log_2 N \]
and reordering the inequality we get \( \delta \geq t - \frac{\log_2 N}{4m} \), yielding the claim.

**V. Capacity of reconstruction codes**

**Definition 27** We define the rate of a code \( C \subseteq \mathbb{Z}_q^n \) as
\[
R(C) \triangleq \frac{1}{n} \log_2 |C^n|,
\]
and the capacity of a system \( C \subseteq \mathbb{Z}_q^n \) as
\[
\cap(C) \triangleq \limsup_{n \to \infty} \frac{1}{n} \log_2 |C \cap \mathbb{Z}_q^n|.
\]
We are interested in \( \sup \{ \cap(C) \} \), where \( C \) is any family of reconstruction codes (i.e., \( C \cap \mathbb{Z}_q^n \) is an \((N_n, t_n, k)_q\)-code for all \( n \)).

The purpose of this section is to determine that optimal capacity in two asymptotic regimes:

**Regime I** When \( N_n = o(n) \) and \( t_n = t \) is fixed.

**Regime II** When \( N_n = 2^{\alpha n} \) and \( t_n = \beta n \) for constants \( \alpha, \beta > 0 \) (such that \( N_n, t_n \in \mathbb{N} \) for some, hence infinitely many, indices).

In practical applications, Regime I is likely to apply, since we may indeed expect the number of duplications \( t \), which
is dependent on the period of time before data is read, to be fixed w.r.t. $n$. The allowed uncertainty $N_n$ will also likely be bounded. Regime II requires Theorem 26 (and some restrictions over the values of $\alpha, \beta$), but allows us to calculate capacity in much the same way, which we do after presenting the first.

Note, since [17] showed that $\text{Irr}_k(n)$ can correct any number of tandem-duplication errors, they are trivially $(N, t, k)_q$-codes for all $N, t$ (more precisely, they are $(0, t, k)_q$-codes for all $t$). It is our purpose, then, to prove that families of reconstruction codes exist which have strictly higher capacity than $\text{Irr}_k$.

First, we denote for any $n, r \in \mathbb{N}$ such that $n \geq k$ and $r < \left\lfloor \frac{n}{k} \right\rfloor$, and any $N, t \in \mathbb{N}$

$$\mathcal{M}_{N,t}(n, r) \triangleq \sum_{m} M(m, r, d_{N,t}(m)) \cdot \left\{ b \in \mathbb{Z}_q^{n-(r+1)k} \mid b \text{ is } (0, k-1)_q \text{-RLL} \right\}.$$ \hspace{1cm} (30)

We recall for all $n$, if $r_n = \arg \max_r \mathcal{M}_{N,t}(n, r)$, that by Corollary 15 we have an $(N, t, k)_q$-code $C \subseteq \mathbb{Z}_q^n$ with $|C| \geq q^k \mathcal{M}_{N,t}(n, r_n)$. Corollary 15 also implies that for all $C \subseteq \mathbb{Z}_q^n$ it holds that $|C| \leq \frac{1}{q} q^k \mathcal{M}_{N,t}(n, r_n)$. We therefore focus on maximizing $\limsup_{n \rightarrow \infty} \frac{1}{n} \log q \mathcal{M}_{N,t}(n, r_n)$ by choice of $r_n$.

In what follows, we take $\gamma \in (0, 1)$ and set $r_n = \frac{1}{\lambda} n - 1$ for any $n \in \mathbb{N}$ for which $r_n \in \mathbb{N}$; we shall assume that such $n$ exist (hence, infinitely many exist), and refer only to such indices.

For all $x \in \text{Irr}_k(n - r_n, k) = \text{Irr}_k(k + \gamma n)$, recall that we denoted $\phi_k(x) = (a, b)$ with $b \in \mathbb{Z}_q^{n-1}$ in $(0, k-1)_q$-RLL. We shall build a reconstruction code in the descendant cone of only such $x$, which we denote $C_{\gamma}$.

**Lemma 28** There exists a system $S \subseteq (0, k-1)_q \cdot \text{RLL}$ and $\theta \in (0, 1)$ such that

$$\text{cap}(S) = \lim_{n \rightarrow \infty} \frac{1}{n} \log q \text{cap}(S \cap \mathbb{Z}_q^l) = \text{cap}(0, k-1)_q \cdot \text{RLL}$$

and for all $b \in S$ it holds that $\text{wt}_H(b) \geq \theta |b|$.

**Proof:** Let $G_q(k-1)$ be the strongly connected deterministic digraph representing the $(0, k-1)_q$-RLL system, seen in Figure 1, whose adjacency matrix is

$$T_q(k-1) = \begin{pmatrix}
q - 1 & 1 & 0 & \cdots & 0 \\
q - 1 & 0 & 1 & \cdots & 0 \\
 \vdots & \vdots & \ddots & \ddots & \vdots \\
q - 1 & 0 & \cdots & 0 & 1 \\
q - 1 & 0 & \cdots & \cdots & 0
\end{pmatrix}.$$ \hspace{1cm} (31)

As is well known for the case of $q = 2$ (see, e.g., [15, [41]), its characteristic polynomial is

$$p_{q(k-1)}(x) = x^k - (q - 1) \sum_{j=0}^{k-1} x^j = \frac{x^{k+1} - qx^k + (q - 1)}{x - 1},$$

hence the Perron eigenvalue $\lambda$ of $T_q(k-1)$ is the unique positive root of $p_{q(k-1)}(x) = x^{k+1} - qx^k + (q - 1) > 1$ (in fact, $\lambda \in (q - 1, q)$, which can readily be confirmed either using elementary calculus or by information-theoretic methods, since $(\mathbb{Z}_q \setminus \{0\})^* \subseteq (0, k-1)_q \cdot \text{RLL} \subseteq \mathbb{Z}_q^*$).

Further, $T_q(k-1)$ has positive right- and left-eigenvectors associated with $\lambda$, which we denote $\bar{v}, \bar{w}$ respectively; specifically,

$$\bar{v} = \left(1, \lambda - (q - 1), \lambda^{-1} - (q - 1) \sum_{i=0}^{k-2} \lambda^i, \ldots, \lambda^{-k+1} - (q - 1) \sum_{i=0}^{k-2} \lambda^i\right),$$

and we may verify that

$$v_k = \lambda^{-k+1} - (q - 1) \sum_{i=0}^{k-2} \lambda^i = \frac{1}{\lambda} \lambda^{-k+1} - (q - 1) \sum_{j=1}^{k-1} \lambda^j = q - 1 > 0$$

and $v_j = v_{j+1} + (q - 1)$, hence every entry of $\bar{v}$ is indeed positive.

Denoting $q_{i,j} = (T_q(k-1))_{i,j}$, it follows (see, e.g., [34][Sec. 3.5]) that $Q = (q_{i,j})_{1 \leq i,j \leq k}$ is stochastic, and represents a transition matrix of a stationary Markov chain $\mathcal{P}$ on $G_q(k-1)$ (a probability measure on its edges set $E_q(k-1)$) satisfying $\log \lambda = \text{cap}(0, k-1)_q \cdot \text{RLL}$. Further, the stationary distribution of the Markov chain, i.e., a positive $\pi = (\pi_1, \ldots, \pi_k)$ such that $\sum_{j=1}^{k} \pi_j = 1$ and $\pi^T Q = \pi^T$, is given by $\pi_j = \frac{\pi_{j+1}}{\pi_j}$, where $\pi$ is defined by $\pi_j = w_j v_j$. It holds for all $j$ that $\pi_j$ is the sum of probabilities $\pi(e)$ of edges terminating at the $j$’th node.

Note, then, that

$$\sum_{i=1}^{k} \pi_i = \lambda^{-k+1} + \sum_{i=2}^{k} \left( \lambda^{-k} - (q - 1) \frac{\lambda^{-k-1} - \lambda^{-k+1}}{\lambda - 1} \right)$$

$$= \lambda^{-k+1} \left[ 1 + (k - 1) \frac{q - 1}{\lambda - 1} \right] + \frac{q - 1}{\lambda - 1} \sum_{i=2}^{k} \lambda^{-k-i}$$

$$= \lambda^{-k} \left[ k - (k - 1)q - 1 \right] + \frac{q - 1}{\lambda - 1} \sum_{j=0}^{k-2} \lambda^j$$

$$= \lambda^{-k} \left[ k - (k - 1)q - 1 \right] + \frac{\lambda - (q - 1) \lambda^{k-1}}{\lambda - 1}$$

and in particular $\pi_1 = \frac{\lambda^{-1} - \lambda^{-k}}{\lambda - (q - 1)}$. (Incidentally, it follows from $\pi_1 \in (0, 1)$ that $1 < k(q - \lambda) < \lambda$, that is, $q - \frac{q}{k+1} < \lambda < \frac{q}{k+1}$.)

Next, recall that for a given $\epsilon > 0$, a $(\mathcal{P}, \epsilon)$-strongly-typical path in $G$ is a path $\gamma = (e_1, e_2, \ldots, e_l)$ (denoted by its edges $\{e_1, e_2, \ldots, e_l\} \subseteq E_q(k-1)$) such that each $e \in E_q(k-1)$ appears in the path $l \cdot \tau$ times, for some $\tau$ satisfying $|\tau - \mathcal{P}(e)| \leq \epsilon$. If we let $S_\epsilon \subseteq \mathbb{Z}_q^l$ be the system induced by $(\mathcal{P}, \epsilon)$-strongly-typical paths, then it is well known that $\text{cap}(S_\epsilon) = \text{cap}(0, k-1)_q \cdot \text{RLL}$. Note,
for $b \in S_0$ of length $|b| = l$, which is generated by the path $\gamma = (e_1, \ldots, e_l)$, $\text{wt}_B(b)$ is precisely the number of edges which terminate at the first node; since $\gamma$ is $(P, \frac{\varepsilon}{k(q-1)})$-strongly-typical,  
\[
\text{wt}_B(b) \geq \sum_l l \cdot \left( P(e) - \frac{\varepsilon}{k(q-1)} \right) = l(\pi_1 - \varepsilon)
\]
To conclude the proof, note  
\[
\lambda + k(q - \lambda) = q + (k - 1)(q - \lambda) > q \geq 2 
\implies \lambda > 2 - k(q - \lambda)
\implies 2(\lambda - 1) > \lambda - k(q - \lambda) \implies \pi_1 > \frac{1}{2}
\]
Hence we can take any $0 < \varepsilon < \pi_1 - \frac{1}{2}$, and observe that $S = S_0$, $\theta = \pi_1 - \varepsilon$ satisfy the proposition.

Lemma 28 implies that there exists a subset $S_k \subseteq \text{Irr}_\gamma$ such that $\text{cap}(S_k) = \text{cap}(\text{Irr}_\gamma)$, and for every $x \in S_k$ of length $|x| = k + \gamma n$ we have $m(x) \geq [\theta \cdot \gamma n]$. For the rest of this section we only build codes $C^n_\gamma$ in the descendant cones of roots in $S_k$. Note, then, that if we denote $m_n = [\theta \cdot \gamma n]$ and $C_\gamma = \bigcup C^n_\gamma$, then 
\[
\text{cap}(C_\gamma) \geq \limsup_{n \to \infty} \frac{1}{n} \log_q \left[ \left( \text{Irr}_\gamma(k + \gamma n) \right) \cdot M(m_n, r_n, d_{N,T}(m_n)) \right]
\]
\[
= \gamma \text{cap}(\text{Irr}_\gamma) + 
\limsup_{n \to \infty} \frac{1}{n} \log_q M(m_n, r_n, d_{N,T}(m_n)) \tag{2}
\]
We evaluate the second addend in the following theorem:

Theorem 29 As before, we denote $r_n = \frac{1-\alpha}{k} n - 1$ and $m_n = [\theta \cdot \gamma n]$. Then 
\[
\lim_{n \to \infty} \frac{1}{n} \log_q M(m_n, r_n, d_{N,T}(m_n)) = 
\frac{\theta \gamma}{\log_2 q} \cdot H \left( 1 + \frac{1 - \gamma}{k \theta \gamma} \right)
\]
in both of the aforementioned two regimes:  
1) Regime I: when $N_n = o(n)$ and $t_n = t$ is fixed.  
2) Regime II: when $N_n = 2\alpha n$ and $t_n = \beta n$, if we additionally require $\frac{\alpha}{\beta} > 4 \theta \gamma$.

Proof:  
1) Note, for sufficiently large $n$, that $N_n < \theta \cdot \gamma n \leq m_n$, resulting by Lemma 23 in $d_{N_n,T}(m_n) = t$. We note that $\lim_{n \to \infty} \frac{\alpha_n}{t_n} = \frac{1-\gamma}{k}$ and $\lim_{n \to \infty} \frac{m_n}{n} = \theta \gamma$, hence by Theorem 22 the claim is proven when $t$ is fixed.

2) By Theorem 26:  
\[
d_{N_n,T}(m_n) \leq \max \{ 1, \beta n - \left\lfloor \frac{\alpha^2 n}{4(\theta \cdot \gamma n)} \right\rfloor \}
\]
\[
= \max \{ 1, \left\lfloor \left( \beta - \frac{\alpha^2 n}{4(\theta \cdot \gamma n)} \right) \right\rfloor \}
\]
If $\frac{\alpha^2}{\beta} > 4 \theta \gamma$ then for sufficiently large $n$ we have $\beta < \frac{\alpha^2}{4 \theta \gamma}$, hence $d_{N_n,T}(m_n) = 1$. Since it is fixed, we may now apply the same argument used in the previous part.

Going forward, we shall view the lower bound to $\text{cap}(C_\gamma)$, 
\[
R(\gamma) \triangleq \gamma \text{cap}(\text{Irr}_\gamma) + \frac{\theta \gamma}{\log_2 q} \cdot H \left( 1 + \frac{1 - \gamma}{k \theta \gamma} \right),
\]
as a function of $\gamma$. Before moving on to show that it may be made to exceed $\text{cap}(\text{Irr}_\gamma)$ by a careful choice of $\gamma$, we look at the following example.

Example 30 Set $q = k = 2$. Then the Perron eigenvalue of $T_2(1)$ is $\lambda = \frac{1 + \sqrt{3}}{2}$, and
\[
\text{cap}(\text{Irr}_2) = \log_2(\lambda) = \log_2 \left( \frac{1 + \sqrt{3}}{2} \right) \approx 0.6942.
\]
In addition, any $\theta$ which is less than $\pi_1 = \frac{1}{2} \left( 1 + \frac{1}{\sqrt{3}} \right) \approx 0.7236$ satisfies Lemma 28.

Alternatively, we may set $q = 4$ (for the special case of human DNA) and duplication-length $k = 2$. Now the Perron eigenvalue of $T_4(1)$ is given by $\lambda = \frac{3 + \sqrt{21}}{2}$, hence
\[
\text{cap}(\text{Irr}_2) = \log_4(\lambda) = \log_4 \left( \frac{3 + \sqrt{21}}{2} \right) \approx 0.9613.
\]
Further, we may choose any $\theta$ which is less than $\pi_1 = \frac{1}{2} \left( 1 + \frac{3}{\sqrt{7}} \right) \approx 0.8273$.

$R(\gamma)$ is shown for both cases in Figure 2, under the assumptions of asymptotic regime made in Theorem 29.
We now attempt to maximize \( R(\gamma) \) by a proper choice of \( \gamma \in (0, 1) \). Analysis of \( R(\gamma) \) is simpler using the following change of variable:

**Definition 31** Define \( x : (0, 1) \rightarrow (0, \infty) \) by \( x(\gamma) = \frac{1 - \gamma}{\gamma} \).

We observe that \( x(\gamma) \) is a decreasing diffeomorphism, and \( \gamma = \frac{1}{1 + x(\gamma)/y} \).

**Lemma 32** One has

\[
R(\gamma) = \gamma \text{cap(Irr}_k) + \theta \gamma \left( 1 + \frac{x(\gamma)}{q^\gamma} \right) \log_q \left( 1 + \frac{x(\gamma)}{k \theta \gamma} \right) - \frac{x(\gamma)}{k \theta} \log_q \left( \frac{x(\gamma)}{k \theta} \right)
\]

**Proof:** We observe that for all \( x > 0 \), \( \log(1 + \frac{1}{x}) = \log(\frac{x+1}{x}) = \log(x+1) - \log x \); in particular

\[
\log_q \left( 1 + \frac{k \theta \gamma}{1 - \gamma} \right) = \log_q \left( 1 + \frac{1 - \gamma}{k \theta \gamma} \right) - \log_q \left( \frac{1 - \gamma}{k \theta \gamma} \right).
\]

Hence,

\[
R(\gamma) = \gamma \text{cap(Irr}_k) + \frac{\theta \gamma}{\log_2 q} \cdot H \left( 1 + \frac{1 - \gamma}{k \theta \gamma} \right) - \frac{x(\gamma)}{k \theta} \log_q \left( \frac{x(\gamma)}{k \theta} \right)
\]

We can now show that there always exists a choice of \( \gamma \) for which we get \( R(C^n_m) > \text{cap(Irr}_k) \):

**Theorem 33** \( \max_{\gamma \in (0, 1)} R(\gamma) > \text{cap(Irr}_k) \).

**Proof:** Observe that \( R(\gamma) \) is continuously differentiable and satisfies \( \lim_{\gamma \to 0} R(\gamma) = 0 \), \( \lim_{\gamma \to 1} R(\gamma) = \text{cap(Irr}_k) \). We find \( R'(\gamma) \) in Eq. (3); Thus, We can show that \( R'(\gamma) = 0 \) if and only if

\[
q^{-k \text{cap(Irr}_k} = \left( 1 + \frac{x(\gamma)}{k \theta} \right)^{k\theta-1} \cdot \frac{x(\gamma)}{k \theta} \]

This equation has a unique solution \( x_0 = x(\gamma_0) \), since the RHS is a monotonic increasing function of \( x \), vanishing at \( x = 0 \) and unbounded as \( x \) grows. Moreover, \( 0 < x_0 < k \theta \), since \( k \theta > 1 \), hence the RHS is greater than 1 at \( x = k \theta \). Thus \( R(\gamma) \) has a unique local extremum in \((0, 1)\).

It now suffices to show that \( R(\gamma) \) is concave, hence the extremum is a maximum. Indeed,

\[
R''(\gamma) = \frac{1}{k \theta} \cdot \frac{d}{dx} \left[ (k \theta - 1) \log_q \left( 1 + \frac{x(\gamma)}{k \theta} \right) + \log_q \left( \frac{x(\gamma)}{k \theta} \right) \right]
\]

\[
= -\frac{1}{k \theta^2 q^{\text{cap(Irr}_k}}} \left[ \frac{k \theta - 1}{k \theta + x(\gamma)} + \frac{1}{x(\gamma)} \right] < 0
\]

It follows that \( R(\gamma_0) = \lim_{\gamma \to 1} R(\gamma) = \text{cap(Irr}_k) \).

Thus, the main result of this paper is established. In what remains of this section we show that we can bound \( \gamma_0 \) which maximizes \( R(\gamma) \), in practice, to any desired level of accuracy. We begin by establishing bounds in the following lemma.

**Lemma 34** Let \( \gamma_0 \in (0, 1) \) be the unique maximum of \( R(\gamma) \), and denote \( x_0 = x(\gamma_0) \). Then

\[
x_0 \geq \frac{k \theta}{(2q^{\text{cap(Irr}_k}})^k} - 1
\]

and

\[
x_0 \leq \frac{1}{2} \left[ \sqrt{(1 - q^{-k \text{cap(Irr}_k})^2 + k \theta q^{2 \text{cap(Irr}_k}}) - (1 - q^{-k \text{cap(Irr}_k})^2} \right] \leq \frac{k \theta q^{2 \text{cap(Irr}_k}}}{4(q^{\text{cap(Irr}_k})^k - 1)}
\]

**Proof:** For fixed \( x \in [0, \infty) \) define \( g_x : (0, \infty) \rightarrow \mathbb{R} \) by \( g_x(y) = y \ln \left( 1 + \frac{x}{y} \right) \). Then

\[
g'_x(y) = \ln \left( 1 + \frac{x}{y} \right) + \frac{y}{1 + \frac{x}{y}} \cdot \frac{x}{y^2} = \ln \left( 1 + \frac{x}{y} \right) - \frac{x}{y + x}
\]

\[
\leq - \frac{x}{x + y} - \frac{x}{y + x} \geq 0.
\]
Indeed, recalling \( a, b > 0 \) and which proves the lower bound.

Therefore, \( f_\varepsilon(z) = e^{\theta \varepsilon(z)} \left( 1 + \frac{\varepsilon}{\theta} \right)^v \) satisfies \( 1 + x = f_\varepsilon(1) \leq f_\varepsilon(y) = \left( 1 + \frac{\varepsilon}{\theta} \right)^v \) for all \( y \geq 1 \). In our case \( k\theta > 1 \) and \( x_0 \) satisfies Eq. (4), hence

\[
q^{-\text{cap}(\text{Irr}_k)^k} = \left( 1 + x_0 \right)^{k\theta - 1} \frac{x_0}{k\theta} \geq \frac{2k^\theta}{1 + \frac{x_0}{k\theta}} \cdot \frac{x_0}{k\theta} = \frac{x_0 + x_0^2}{k\theta + x_0}
\]

which simplifies to \( 0 \geq x_0^2 + \left( 1 - q^{-\text{cap}(\text{Irr}_k)^k} \right) x_0 - k\theta q^{-\text{cap}(\text{Irr}_k)^k} \). Thus, the first upper bound is proven. For the second, we require only that for \( a, b > 0 \) it holds that \( \sqrt{a + b^2} - b \leq \frac{a}{b} \), which is readily shown by differentiation.

On the other hand, Eq. (4) implies that \( x_0 \leq k\theta \). Therefore

\[
q^{-\text{cap}(\text{Irr}_k)^k} = \left( 1 + x_0 \right)^{k\theta - 1} \frac{x_0}{k\theta} \leq \frac{2k^\theta}{1 + \frac{x_0}{k\theta}} \cdot \frac{x_0}{k\theta} \leftrightarrow k\theta q^{-\text{cap}(\text{Irr}_k)^k} \leq \left( 2k^\theta - q^{-\text{cap}(\text{Irr}_k)^k} \right) x_0
\]

which proves the lower bound.

Next, we show that we may tighten the bounds we derived in the previous lemma.

**Lemma 35** Let \( x_0 > 0 \) be the unique solution to Eq. (4), and denote \( z_0 = \frac{x_0}{k\theta} \). If \( \frac{a}{b} \leq z_0 \leq \frac{b}{a} \) then \( F(z) \leq z_0 \leq F(\pi) \), where

\[
F(z) \triangleq \frac{q^{-\text{cap}(\text{Irr}_k)^k}}{1 + q^{-\text{cap}(\text{Irr}_k)^k}} \left( 1 + \frac{z}{1 + z} \right)^{k\theta - 1}.
\]

**Proof:** By assumption we have \( \frac{q^{-\text{cap}(\text{Irr}_k)^k}}{1 + z_0} \leq z_0 \), hence \( q^{-\text{cap}(\text{Irr}_k)^k} \leq \left( 1 + z_0 \right)^{k\theta - 1} \cdot z_0 \), implying that \( z_0 \geq G(\pi) \) where \( G(z) = \frac{z}{1 + z} \). Similarly, \( z_0 \leq G(z) \). The proposition now trivially follows for \( F(z) = G(G(z)) \).

Finally, we can show that \( x_0 \) may be found by the following limiting process:

**Theorem 36** The unique solution to Eq. (4) is given by \( x_0 = k\theta \lim_{n \to \infty} F^n(z_1) \), for all \( z_1 \in [0, 1] \).

**Proof:** As before, we denote the unique solution \( x_0 > 0 \), and take \( z_0 = \frac{x_0}{k\theta} \).

Note that Lemma 35 implies that \( z_0 = F(z_0) \). We will prove that \( F : [0, 1] \to [0, 1] \) is a contraction; that is, for all \( z_1, z_2 \in [0, 1] \) we have \( |F(z_1) - F(z_2)| \leq c |z_1 - z_2| \) for some \( c < 1 \). Indeed, recalling \( k\theta > 1 \) we find

\[
F'(z) = \frac{2 - 2q^{-\text{cap}(\text{Irr}_k)^k} (k\theta - 1)^2}{(1 + z)^k \cdot \left( 1 + q^{-\text{cap}(\text{Irr}_k)^k} \right)} \cdot (k\theta - 1)^2 \leq \frac{(k\theta - 1)^2}{(2q^{-\text{cap}(\text{Irr}_k)^k})} \leq \frac{9}{16} < 1,
\]

where the next to last inequality may be directly verified for all small \( k \).

Having done so, we utilize Banach’s fixed-point theorem to deduce that \( F \) has a unique fixed point (necessarily \( z_0 \)), and for all \( z_1 \in [0, 1] \), defining \( z_{n+1} = F(z_n) \) we get \( \lim_{n \to \infty} z_n = z_0 \).

**VI. CONCLUSION**

We have proposed that reconstruction codes can be applied to data-storage in the DNA of living organisms, due to the channel’s inherent property of data replication.

We have showed, under the assumption of uniform tandem-duplication noise, that any reconstruction code is partitioned into error-correcting codes for the Manhattan metric over a simplex, with minimal distances dependent on the reconstruction parameters. We then proved the existence of reconstruction codes with rates surpassing that of known tandem-duplication error-correcting codes (i.e., the case of reconstruction with zero uncertainty), which have been studied before. In particular, Theorem 36 allows us to bound the parameters required for code-design in any real application, such that the resulting code has optimal rate, to any degree of accuracy.

We believe that further research should focus on explicit code constructions. It is also desirable to examine the problem under broader noise models, such as bounded tandem-duplication, interspersed-duplication (perhaps complemented), as well as combinations of multiple error models.
