# QUALITATIVE PROPERTIES OF SINGULAR SOLUTIONS TO SEMILINEAR ELLIPTIC PROBLEMS 

F. ESPOSITO*, A.FARINA ${ }^{+}$AND B. SCIUNZI*

#### Abstract

We consider positive singular solutions to semilinear elliptic problems with possibly singular nonlinearity. We deduce symmetry and monotonicity properties of the solutions via the moving plane procedure.

## 1. INTRODUCTION

The aim of the paper is to investigate symmetry and monotonicity properties of singular solutions to semilinear elliptic equations. We address the issue of problems involving singular nonlinearity. More precisely let us consider the problem

$$
\begin{cases}-\Delta u=f(x, u) & \text { in } \Omega \backslash \Gamma  \tag{1.1}\\ u>0 & \text { in } \Omega \backslash \Gamma \\ u=0 & \text { on } \partial \Omega\end{cases}
$$

where $\Omega$ is a bounded smooth domain of $\mathbb{R}^{n}$ with $n \geq 2$. Our results will be obtained by means of the moving plane technique, see $[1,2,13,19]$. Such a technique can be performed in general domains providing partial monotonicity results near the boundary and symmetry when the domain is convex and symmetric. For semplicity of exposition we assume directly in all the paper that $\Omega$ is a convex domain which is symmetric with respect to the hyperplane $\left\{x_{1}=0\right\}$. The solution has a possible singularity on the critical set $\Gamma \subset \Omega$. Furthermore in all the paper the nonlinearity $f$ will be assumed to be uniformly locally Lipschitz continuous from above far from the singular set. More precisely we state the following:
Definition $1.1\left(h_{f}\right)$. We say that $f$ fulfills the condition $\left(h_{f}\right)$ if $f: \bar{\Omega} \backslash \Gamma \times(0,+\infty) \rightarrow \mathbb{R}$ is a continuous function such that for $0<t \leq s \leq M$ and for any compact set $K \subset \bar{\Omega} \backslash \Gamma$, it holds

$$
f(x, s)-f(x, t) \leq C(K, M)(s-t) \quad \text { for any } \quad x \in K
$$

where $C(K, M)$ is a positive constant depending on $K$ and $M$. Furthermore $f(\cdot, s)$ is nondecreasing in the $x_{1}$-direction in $\Omega \cap\left\{x_{1}<0\right\}$ and symmetric with respect to the hyperplane $\left\{x_{1}=0\right\}$.

A typical example is provided by positive solutions to

$$
\begin{equation*}
-\Delta u=\frac{1}{u^{\alpha}}+g(u) \quad \text { in } \quad \Omega \backslash \Gamma \tag{1.2}
\end{equation*}
$$

where $\alpha>0$ and $g$ is locally Lipschitz continuous. Such a problem, in the case $\Gamma=\emptyset$, as been widely investigated in the literature. We refer the readers to the pioneering work [11]

[^0]and to $[3,6,7,9,10,15,21,17]$. In particular, by [15], it is known that solutions generally have no $H^{1}$-regularity up to the boundary. Therefore, having this example in mind, the natural assumption in our paper is
$$
u \in H_{l o c}^{1}(\Omega \backslash \Gamma) \cap C(\bar{\Omega} \backslash \Gamma)
$$
and thus the equation is understood in the following sense:
\[

$$
\begin{equation*}
\int_{\Omega} \nabla u \nabla \varphi d x=\int_{\Omega} f(x, u) \varphi d x \quad \forall \varphi \in C_{c}^{1}(\Omega \backslash \Gamma) \tag{1.3}
\end{equation*}
$$

\]

Remark 1.2. Note that, by the assumption $\left(h_{f}\right)$, the right hand side in the equation of (1.1) is locally bounded. Therefore, by standard elliptic regularity theory, it follows that

$$
u \in C_{l o c}^{1, \alpha}(\Omega \backslash \Gamma)
$$

where $0<\alpha<1$.
Let us now state our main result
Theorem 1.3. Let $\Omega$ be a convex domain which is symmetric with respect to the hyperplane $\left\{x_{1}=0\right\}$ and let $u \in H_{l o c}^{1}(\Omega \backslash \Gamma) \cap C(\bar{\Omega} \backslash \Gamma)$ be a solution to (1.1). Assume that $f$ fulfills $\left(h_{f}\right)$ (see Definition 1.1). Assume also that $\Gamma$ is a point if $n=2$ while $\Gamma$ is closed and such that

$$
\underset{\mathbb{R}^{n}}{\operatorname{Cap}_{2}}(\Gamma)=0,
$$

if $n \geq 3$. Then, if $\Gamma \subset\left\{x_{1}=0\right\}$, it follows that $u$ is symmetric with respect to the hyperplane $\left\{x_{1}=0\right\}$ and increasing in the $x_{1}$-direction in $\Omega \cap\left\{x_{1}<0\right\}$. Furthermore

$$
u_{x_{1}}>0 \quad \text { in } \quad \Omega \cap\left\{x_{1}<0\right\} .
$$

Remark 1.4. Theorem 1.3 is proved for convex domains. It will be clear from the proofs that this is only used to prove that $\partial \Omega \cap\left\{x_{1}=\lambda\right\}$ is discrete in dimension two while $\partial \Omega \cap\left\{x_{1}=\lambda\right\}$ has zero capacity for $n \geq 3$. Therefore the result holds true more generally once that such an information is available. In all this cases we could assume that $\Omega$ is convex only in the $x_{1}$-direction.

First results regarding the applicability of the moving plane procedure to the case of singular solutions go back to [5] (see also [22]) where the case when the singular set is a single point is considered. We follow and improve here the technique in [18], where the case of a smooth ( $n-2$ )-dimensional singular set was considered in the case of locally Lipschitz continuous nonlinearity. Let us mention that the technique introduced in [18] also works in the nonlocal context, see [16].
On the other hand, in the case $\Gamma=\emptyset$, symmetry and monotonicity properties of solutions to semilinear elliptic problems involving singular nonlinearities, have been studied in $[7,8]$. Also in this direction our result is new and more general. In fact, while in [7, 8] it is necessary to restrict the attention to problems of the form (1.2), here we only need to consider nonlinearities that are locally Lipschitz continuous from above. Actually, all the nonlinearities of the form

$$
f(x, s):=a_{1}(x) f_{1}(s)+a_{2}(x) f_{2}(s)
$$

where $f_{1}$ is an increasing continuous function in $[0, \infty), f_{2}(\cdot)$, is locally Lipschitz continuous in $[0, \infty)$ and $a_{1}, a_{2} \in C^{0}(\bar{\Omega}), a_{1} \geq 0$ on $\bar{\Omega}$, satisfy our assumptions.

The technique, as showed in [18], can be applied to study singular solutions to the following Sobolev critical equation in $\mathbb{R}^{n}, n \geq 3$,

$$
\left\{\begin{array}{lll}
-\Delta u=u^{2^{*}-1} & \text { in } & \mathbb{R}^{n} \backslash \Gamma  \tag{1.4}\\
u>0 & \text { in } & \mathbb{R}^{n} \backslash \Gamma
\end{array}\right.
$$

In [18] it was considered the case of a closed critical set $\Gamma$ contained in a compact smooth submanifold of dimension $d \leq n-2$ and a summability property of the solution at infinity was imposed (see also [22] for the special case in which the singular set $\Gamma$ is reduced to a single point). Here we remove both these restrictions and we prove the following:

Theorem 1.5. Let $n \geq 3$ and let $u \in H_{l o c}^{1}\left(\mathbb{R}^{n} \backslash \Gamma\right)$ be a solution to (1.4). Assume that the solution $u$ has a non-removable ${ }^{1}$ singularity in the singular set $\Gamma$, where $\Gamma$ is a closed and proper subset of $\left\{x_{1}=0\right\}$ such that

$$
\underset{\mathbb{R}^{n}}{\operatorname{Cap}_{2}}(\Gamma)=0
$$

Then, $u$ is symmetric with respect to the hyperplane $\left\{x_{1}=0\right\}$.
The same conclusion is true if the hyperplane $\left\{x_{1}=0\right\}$ is replaced by any affine hyperplane.

Some interesting consequences of the previous result are contained in the following
Corollary 1.6. Let $n \geq 3$ and let $u \in H_{l o c}^{1}\left(\mathbb{R}^{n} \backslash \Gamma\right)$ be a solution to (1.4) with a nonremovable singularity in the singular set $\Gamma$.
(i) If $\Gamma=\left\{x_{0}\right\}$, then $u$ is radially symmetric with respect to $x_{0}$.
(ii) If $\Gamma=\left\{x_{0}, x_{1}\right\}$, then $u$ has cylindrical symmetry with respect to the axis passing through $x_{0}$ and $x_{1}$.
More generally we have :
(iii) assume $1 \leq k \leq n-2$ and suppose that $\Gamma$ is a closed subset of an affine $k$-dimensional subspace of $\mathbb{R}^{n}$. Then, up to isometry, the solution $u$ has the form $u(x)=u\left(x_{1}, \ldots, x_{k},\left|x^{\prime}\right|\right)$, where $x^{\prime}:=\left(x_{k+1}, \ldots x_{n}\right)$ and $\left|x^{\prime}\right|:=\sqrt{x_{k+1}^{2}+\ldots+x_{n}^{2}}$.

The following example shows that Theorem 1.5 and item (iii) of Corollary 1.6 are sharp for $n \geq 5$ and also that singular solutions exhibiting un unbounded critical set $\Gamma$ exist.

For $n \geq 5$ and $1 \leq k<\frac{n-2}{2}, k$ integer, we set $p=p(n)=\frac{n+2}{n-2}>1$ and $A=A(n, k)=$ $\left[\left(\frac{n}{2}-k-1\right) \frac{n}{2}\right]^{\frac{n-2}{4}}>0$. Then, the function $v(r)=A r^{-\frac{2}{p(n)-1}}$ is a singular positive radial solution of $-\Delta v=v^{p(n)}$ in $\mathbb{R}^{n-k} \backslash\left\{0^{\prime}\right\}$, which is smooth in $\mathbb{R}^{n-k} \backslash\left\{0^{\prime}\right\}$. Hence $u=u\left(x_{1}, \ldots, x_{n}\right):=v\left(\left|x^{\prime}\right|\right)$ is a singular solution to (1.4) in $\mathbb{R}^{n} \backslash \Gamma$, with $\Gamma$ given by the $k$-dimensional subspace $\left\{x_{1}=\ldots=x_{k}=0\right\} \subset \mathbb{R}^{n}$, moreover $u \in C^{\infty}\left(\mathbb{R}^{n} \backslash \Gamma\right)$.
The remaining part of the paper is devoted to the proofs of our results.

[^1]
## 2. Notations and preliminary results

For a real number $\lambda$ we set

$$
\begin{gather*}
\Omega_{\lambda}=\left\{x \in \Omega: x_{1}<\lambda\right\}  \tag{2.5}\\
x_{\lambda}=R_{\lambda}(x)=\left(2 \lambda-x_{1}, x_{2}, \ldots, x_{n}\right) \tag{2.6}
\end{gather*}
$$

which is the reflection through the hyperplane $T_{\lambda}:=\left\{x_{1}=\lambda\right\}$. Also let

$$
\begin{equation*}
a=\inf _{x \in \Omega} x_{1} . \tag{2.7}
\end{equation*}
$$

Since $\Gamma$ is compact and of zero capacity, $u$ is defined a.e. on $\Omega$ and Lebesgue measurable on $\Omega$. Therefore the function

$$
\begin{equation*}
u_{\lambda}:=u \circ R_{\lambda} \tag{2.8}
\end{equation*}
$$

is Lebesgue measurable on $R_{\lambda}(\Omega)$. Similarly, $\nabla u$ and $\nabla u_{\lambda}$ are Lebesgue measurable on $\Omega$ and $R_{\lambda}(\Omega)$ respectively.
It is easy to see that, if $\underset{\mathbb{R}^{n}}{\mathrm{Cap}_{2}}(\Gamma)=0$, then $\underset{\mathbb{R}^{n}}{\operatorname{Cap}_{2}}\left(R_{\lambda}(\Gamma)\right)=0$. Another consequence of our assumptions is that $\operatorname{Cap}_{2}\left(R_{\lambda}(\Gamma)\right)=0$ for any open neighborhood $\mathcal{B}_{\epsilon}^{\lambda}$ of $R_{\lambda}(\Gamma)$. Indeed, recalling that $\Gamma$ is a point if $n=2$ while $\Gamma$ is closed with $\operatorname{Cap}_{\mathbb{R}^{n}}(\Gamma)=0$ if $n \geq 3$ by assumption, it follows that

$$
\underset{\mathcal{B}_{\epsilon}^{\lambda}}{\operatorname{Cap}_{2}}\left(R_{\lambda}(\Gamma)\right):=\inf \left\{\int_{\mathcal{B}_{\epsilon}^{\lambda}}|\nabla \varphi|^{2} d x<+\infty: \varphi \geq 1 \text { in } \mathcal{B}_{\delta}^{\lambda}, \varphi \in C_{c}^{\infty}\left(\mathcal{B}_{\epsilon}^{\lambda}\right)\right\}=0,
$$

for some neighborhood $\mathcal{B}_{\delta}^{\lambda} \subset \mathcal{B}_{\varepsilon}^{\lambda}$ of $R_{\lambda}(\Gamma)$. From this, it follows that there exists $\varphi_{\varepsilon} \in$ $C_{c}^{\infty}\left(\mathcal{B}_{\epsilon}^{\lambda}\right)$ such that $\varphi_{\varepsilon} \geq 1$ in $\mathcal{B}_{\delta}^{\lambda}$ and $\int_{\mathcal{B}_{\varepsilon}^{\lambda}}^{\lambda}\left|\nabla \varphi_{\varepsilon}\right|^{2} d x<\varepsilon$.
Now we construct a function $\psi_{\varepsilon} \in C^{0,1}\left(\mathbb{R}^{n},[0,1]\right)$ such that $\psi_{\varepsilon}=1$ outside $\mathcal{B}_{\varepsilon}^{\lambda}, \psi_{\varepsilon}=0$ in $\mathcal{B}_{\delta}^{\lambda}$ and

$$
\int_{\mathbb{R}^{n}}\left|\nabla \psi_{\varepsilon}\right|^{2} d x=\int_{\mathcal{B}_{\epsilon}^{\lambda}}\left|\nabla \psi_{\varepsilon}\right|^{2} d x<4 \varepsilon .
$$

To this end we consider the following Lipschitz continuous function

$$
T_{1}(s)=\left\{\begin{array}{lll}
1 & \text { if } & s \leq 0 \\
-2 s+1 & \text { if } & 0 \leq s \leq \frac{1}{2} \\
0 & \text { if } & s \geq \frac{1}{2}
\end{array}\right.
$$

and we set

$$
\begin{equation*}
\psi_{\varepsilon}:=T_{1} \circ \varphi_{\varepsilon} \tag{2.9}
\end{equation*}
$$

where we have extended $\varphi_{\varepsilon}$ by zero outside $\mathcal{B}_{\varepsilon}^{\lambda}$. Clearly $\psi_{\varepsilon} \in C^{0,1}\left(\mathbb{R}^{n}\right), 0 \leq \psi_{\varepsilon} \leq 1$ and

$$
\int_{\mathcal{B}_{\varepsilon}^{\lambda}}\left|\nabla \psi_{\varepsilon}\right|^{2} d x \leq 4 \int_{\mathcal{B}_{\varepsilon}^{\lambda}}\left|\nabla \varphi_{\varepsilon}\right|^{2} d x<4 \varepsilon .
$$

Now we set $\gamma_{\lambda}:=\partial \Omega \cap T_{\lambda}$. Recalling that $\Omega$ is convex, it is easy to deduce that $\gamma_{\lambda}$ is made of two points in dimension two. If else $n \geq 3$ then it follows that $\gamma_{\lambda}$ is a smooth manifold of dimension $n-2$. Note in fact that locally $\partial \Omega$ is the zero level set of a smooth function $g(\cdot)$ whose gradient is not parallel to the $x_{1}$-direction since $\Omega$ is convex. Then it is sufficient to observe that locally $\partial \Omega \cap T_{\lambda} \equiv\left\{g\left(\lambda, x^{\prime}\right)=0\right\}$ and use the implicit function theorem exploiting the fact that $\nabla_{x^{\prime}} g\left(\lambda, x^{\prime}\right) \neq 0$. This implies that $\underset{\mathbb{R}^{n}}{\operatorname{Cap}_{2}}\left(\gamma_{\lambda}\right)=0$, see e.g. [12]. So, as before, $\operatorname{Cap}_{\mathcal{I}_{2}}\left(\gamma_{\lambda}\right)=0$ for any open neighborhood of $\gamma_{\lambda}$ and then there exists $\varphi_{\tau} \in C_{c}^{\infty}\left(\mathcal{I}_{\tau}^{\lambda}\right)$ such that $\varphi_{\tau} \geq 1$ in a neighborhood $\mathcal{I}_{\sigma}^{\lambda}$ with $\gamma_{\lambda} \subset \mathcal{I}_{\sigma}^{\lambda} \subset \mathcal{I}_{\tau}^{\lambda}$. As above, we set

$$
\begin{equation*}
\phi_{\tau}:=T_{1} \circ \varphi_{\tau} \tag{2.10}
\end{equation*}
$$

where we have extended $\varphi_{\tau}$ by zero outside $\mathcal{I}_{\tau}^{\lambda}$. Then, $\phi_{\tau} \in C^{0,1}\left(\mathbb{R}^{n}\right), 0 \leq \phi_{\tau} \leq 1, \phi_{\tau}=1$ outside $\mathcal{I}_{\tau}^{\lambda}, \phi_{\tau}=0$ in $\mathcal{I}_{\sigma}^{\lambda}$ and

$$
\int_{\mathbb{R}^{n}}\left|\nabla \phi_{\tau}\right|^{2} d x=\int_{\mathcal{I}_{\tau}^{\lambda}}\left|\nabla \phi_{\tau}\right|^{2} d x \leq 4 \int_{\mathcal{I}_{\tau}^{\lambda}}\left|\nabla \varphi_{\tau}\right|^{2} d x<4 \tau .
$$

## 3. Proof of Theorem 1.3

In the following we will exploit the fact that $u_{\lambda}$ is a solution to:

$$
\begin{equation*}
\int_{R_{\lambda}(\Omega)} \nabla u_{\lambda} \nabla \varphi d x=\int_{R_{\lambda}(\Omega)} f\left(x_{\lambda}, u_{\lambda}\right) \varphi d x \quad \forall \varphi \in C_{c}^{1}\left(R_{\lambda}(\Omega) \backslash R_{\lambda}(\Gamma)\right) \tag{3.11}
\end{equation*}
$$

and we also observe that, for any $a<\lambda<0$, the function $w_{\lambda}:=u-u_{\lambda}$ satisfies $0 \leq w_{\lambda}^{+} \leq u$ a.e. on $\Omega_{\lambda}$ and so $w_{\lambda}^{+} \in L^{2}\left(\Omega_{\lambda}\right)$, since $u \in C^{0}\left(\overline{\Omega_{\lambda}}\right)$. To proceed further, we need the following two results

Lemma 3.1. Let $\lambda \in(a, 0)$ be such that $R_{\lambda}(\Gamma) \cap \bar{\Omega}=\emptyset$ and consider the function

$$
\varphi:=\left\{\begin{array}{lll}
w_{\lambda}^{+} \phi_{\tau}^{2} & \text { in } \Omega_{\lambda}, \\
0 & \text { in } & \mathbb{R}^{n} \backslash \Omega_{\lambda}
\end{array}\right.
$$

where $\phi_{\tau}$ is as in (2.10). Then, $\varphi \in C_{c}^{0,1}(\Omega) \cap C_{c}^{0,1}\left(R_{\lambda}(\Omega)\right)$, $\varphi$ has compact support contained in $(\Omega \backslash \Gamma) \cap\left(R_{\lambda}(\Omega) \backslash R_{\lambda}(\Gamma)\right) \cap\left\{x_{N} \leq \lambda\right\}$ and

$$
\begin{equation*}
\nabla \varphi=\phi_{\tau}^{2}\left(\nabla w_{\lambda} \chi_{\text {supp }\left(w_{\lambda}^{+}\right) \cap \operatorname{supp}(\varphi)}\right)+2 \phi_{\tau}\left(w_{\lambda}^{+} \chi_{\operatorname{supp}(\varphi)}\right) \nabla \phi_{\tau} \quad \text { a.e. on } \Omega \cup R_{\lambda}(\Omega) . \tag{3.12}
\end{equation*}
$$

If $\lambda \in(a, 0)$ is such that $R_{\lambda}(\Gamma) \cap \bar{\Omega} \neq \emptyset$, the same conclusions hold true for the function

$$
\varphi:=\left\{\begin{array}{lll}
w_{\lambda}^{+} \psi_{\varepsilon}^{2} \phi_{\tau}^{2} & \text { in } & \Omega_{\lambda}, \\
0 & \text { in } & \mathbb{R}^{n} \backslash \Omega_{\lambda},
\end{array}\right.
$$

where $\psi_{\varepsilon}$ is defined as in (2.9) and $\phi_{\tau}$ as in (2.10). Furthermore, a.e. on $\Omega \cup R_{\lambda}(\Omega)$,

$$
\begin{equation*}
\nabla \varphi=\psi_{\varepsilon}^{2} \phi_{\tau}^{2}\left(\nabla w_{\lambda} \chi_{\operatorname{supp}\left(w_{\lambda}^{+}\right) \cap \operatorname{supp}(\varphi)}\right)+2\left(w_{\lambda}^{+} \chi_{\operatorname{supp}(\varphi)}\right)\left(\psi_{\varepsilon}^{2} \phi_{\tau} \nabla \phi_{\tau}+\psi_{\varepsilon} \phi_{\tau}^{2} \nabla \psi_{\varepsilon}\right) \tag{3.13}
\end{equation*}
$$

In particular, $\varphi \in C^{0,1}\left(\overline{\Omega_{\lambda}}\right), \varphi_{\partial \Omega_{\lambda}}=0$ and so $\varphi \in H_{0}^{1}\left(\Omega_{\lambda}\right)$.

Proof. Let us consider the case when $\lambda \in(a, 0)$ is such that $R_{\lambda}(\Gamma) \cap \bar{\Omega} \neq \emptyset$ (the other case being similar and easier). We first prove that for every $x \in \Omega$ there is an open ball $B_{x}$ centered at $x$, such that $\overline{B_{x}} \subset \Omega$ and $\varphi \in C^{0,1}\left(\overline{B_{x}}\right)$, and then that there exists $\eta>0$ such that $\operatorname{supp}(\varphi)$ is contained in the compact set $\{x \in \Omega: \operatorname{dist}(x, \partial \Omega) \geq \eta\} \cap\left\{x_{N} \leq\right.$ $\lambda\} \cap\left(\mathbb{R}^{n} \backslash V\right) \subset(\Omega \backslash \Gamma) \cap\left(R_{\lambda}(\Omega) \backslash R_{\lambda}(\Gamma)\right)$, where $V$ is any open set contained in the neighborhood $\mathcal{B}_{\delta}^{\lambda}$ appearing in the construction of $\psi_{\varepsilon}$.

If $x \in \Omega \cap\left\{x_{N}>\lambda\right\}$ then $\varphi \equiv 0$ in an open neighbourhood of $x$ and so $\varphi \in C^{0,1}\left(\overline{B_{x}}\right)$ for a suitable ball $B_{x}$. If $x \in \Omega \cap T_{\lambda}$ then we can find a small open ball $B_{x} \subset \Omega$ such that $B_{x} \cap\left(\partial \Omega \cup R_{\lambda}(\Gamma)\right)=\emptyset$. Therefore, both $u$ and $u_{\lambda}$ belong to $C^{1}\left(\overline{B_{x}} \cap\left\{x_{N} \leq \lambda\right\}\right)$ and so, $\varphi \in C^{0,1}\left(\overline{B_{x}} \cap\left\{x_{N} \leq \lambda\right\}\right)$, thanks to the lipschitz character of $\phi_{\tau}$ and $\psi_{\varepsilon}$. On the other hand we also have that $\varphi \equiv 0$ on $\overline{B_{x}} \cap T_{\lambda}$, by definition of $w_{\lambda}$. Thus $\varphi \in C^{0,1}\left(\overline{B_{x}}\right)$ and we are done also in this case. If $x \in R_{\lambda}(\Gamma) \cap \Omega$ then $\varphi \equiv 0$ in an open neighbourhood of $x$ by definition of $\psi_{\varepsilon}$ and so $\varphi \in C^{0,1}\left(\overline{B_{x}}\right)$ for a suitable ball $B_{x}$. Finally, if $x \in \Omega_{\lambda} \backslash R_{\lambda}(\Gamma)$ then, as before, we can find a small open ball $B_{x}$ such that $\overline{B_{x}} \subset \Omega_{\lambda} \backslash R_{\lambda}(\Gamma)$. In this case, both $u$ and $u_{\lambda}$ belong to $C^{1}\left(\overline{B_{x}}\right)$. This yields $w_{\lambda} \in C^{0,1}(\bar{B})$ and so is $\varphi$, again thanks to the lipschitz character of $\phi_{\tau}$ and $\psi_{\varepsilon}$.
To prove the second part of the claim we observe that $\varphi \equiv 0$ on $\Omega \backslash \Omega_{\lambda}$ and that, for any point $x$ of the compact set $(\partial \Omega) \cap\left\{x_{N} \leq \lambda\right\}$ there is a small open ball $B_{x}$, centered at $x$, such that $\varphi=0$ on $B_{x} \cap \Omega$. The latter clearly holds for any point of $\gamma_{\lambda}$, by definition of $\phi_{\tau}$, and for any point of $\partial \Omega \cap R_{\lambda}(\Gamma)$, by definition of $\psi_{\varepsilon}$. It is also true for any $x \in(\partial \Omega) \cap\left\{x_{N}<\lambda\right\}$, since $u-u_{\lambda}$ is well-defined, continuous and negative on the set $\left[(\partial \Omega) \cap\left\{x_{N}<\lambda\right\}\right] \backslash R_{\lambda}(\Gamma)$. The arguments above immediately yield that $\varphi \in C_{c}^{0,1}(\Omega)$ and the formula (3.13). A similar argument also shows that $\varphi \in C_{c}^{0,1}\left(R_{\lambda}(\Omega)\right)$.
To compute $\nabla \varphi$ we also took into consideration the Remark 1.2.

Lemma 3.2. Under the assumptions of Theorem 1.3, let $a<\lambda<0$. Then $w_{\lambda}^{+} \in H_{0}^{1}\left(\Omega_{\lambda}\right)$ and

$$
\int_{\Omega_{\lambda}}\left|\nabla w_{\lambda}^{+}\right|^{2} d x \leq c\left(f,|\Omega|,\|u\|_{L^{\infty}\left(\Omega_{\lambda}\right)}\right)
$$

where $|\Omega|$ denotes the $n$-dimensional Lebesgue measure of $\Omega$.

Proof. We first prove that $\nabla w_{\lambda} \chi_{\operatorname{supp}\left(w_{\lambda}^{+}\right)} \in L^{2}\left(\Omega_{\lambda}\right)$ and then that the distributional gradient of $w_{\lambda}^{+}$is given by $\nabla w_{\lambda} \chi_{\operatorname{supp}\left(w_{\lambda}^{+}\right)}$. We do this only for the case in which $\lambda$ is such that $R_{\lambda}(\Gamma) \cap \bar{\Omega} \neq \emptyset$, the other case being similar and easier. For $\psi_{\varepsilon}$ as in (2.9) and $\phi_{\tau}$ as in (2.10), we consider the function $\varphi$ defined in Lemma 3.1. In view of the properties of $\varphi$, stated in Lemma 3.1, and a standard density argument, we can use $\varphi$ as test function in (1.3) and (3.11) so that, subtracting, we get

$$
\begin{aligned}
\int_{\Omega_{\lambda}}\left|\nabla w_{\lambda} \chi_{\text {supp }\left(w_{\lambda}^{+}\right)}\right|^{2} \psi_{\varepsilon}^{2} \phi_{\tau}^{2} d x & =-2 \int_{\Omega_{\lambda}} \nabla w_{\lambda} \nabla \psi_{\varepsilon} w_{\lambda}^{+} \psi_{\varepsilon} \phi_{\tau}^{2} d x-2 \int_{\Omega_{\lambda}} \nabla w_{\lambda} \nabla \phi_{\tau} w_{\lambda}^{+} \psi_{\varepsilon}^{2} \phi_{\tau} d x \\
& +\int_{\Omega_{\lambda}}\left(f(x, u)-f\left(x_{\lambda}, u_{\lambda}\right)\right) w_{\lambda}^{+} \psi_{\varepsilon}^{2} \phi_{\tau}^{2} d x \\
& \leq-2 \int_{\Omega_{\lambda}} \nabla w_{\lambda} \nabla \psi_{\varepsilon} w_{\lambda}^{+} \psi_{\varepsilon} \phi_{\tau}^{2} d x-2 \int_{\Omega_{\lambda}} \nabla w_{\lambda} \nabla \phi_{\tau} w_{\lambda}^{+} \psi_{\varepsilon}^{2} \phi_{\tau} d x \\
& +\int_{\Omega_{\lambda}}\left(f(x, u)-f\left(x, u_{\lambda}\right)\right) w_{\lambda}^{+} \psi_{\varepsilon}^{2} \phi_{\tau}^{2} d x
\end{aligned}
$$

Here we also used the monotonicity properties of $f(\cdot, s)$, see $\left(h_{f}\right)$. Exploiting Young's inequality we get that

$$
\begin{align*}
\int_{\Omega_{\lambda}}\left|\nabla w_{\lambda} \chi_{\text {supp }\left(w_{\lambda}^{+}\right)}\right|^{2} \psi_{\varepsilon}^{2} \phi_{\tau}^{2} d x & \leq \frac{1}{4} \int_{\Omega_{\lambda}}\left|\nabla w_{\lambda} \chi_{\operatorname{supp}\left(w_{\lambda}^{+}\right)}\right|^{2} \psi_{\varepsilon}^{2} \phi_{\tau}^{2} d x+4 \int_{\Omega_{\lambda}}\left|\nabla \psi_{\varepsilon}\right|^{2}\left(w_{\lambda}^{+}\right)^{2} \phi_{\tau}^{2} d x  \tag{3.14}\\
& +\frac{1}{4} \int_{\Omega_{\lambda}}\left|\nabla w_{\lambda} \chi_{\operatorname{supp}\left(w_{\lambda}^{+}\right)}\right|^{2} \psi_{\varepsilon}^{2} \phi_{\tau}^{2} d x+4 \int_{\Omega_{\lambda}}\left|\nabla \phi_{\tau}\right|^{2}\left(w_{\lambda}^{+}\right)^{2} \psi_{\varepsilon}^{2} d x \\
& +\int_{\Omega_{\lambda}}\left(f(x, u)-f\left(x, u_{\lambda}\right)\right) w_{\lambda}^{+} \psi_{\varepsilon}^{2} \phi_{\tau}^{2} d x
\end{align*}
$$

Now we observe that the last integral is actually computed on the set $\left\{x \in \Omega_{\lambda} \backslash R_{\lambda}(\Gamma)\right.$ : $\left.u(x)>u_{\lambda}(x)>0\right\} \subset \overline{\Omega_{\lambda}} \subset \bar{\Omega} \backslash \Gamma$ and so, we can apply condition $\left(h_{f}\right)$ with the compact set $K=\overline{\Omega_{\lambda}}$ and $M=\|u\|_{L^{\infty}\left(\Omega_{\lambda}\right)}$. We get therefore that

$$
\begin{equation*}
\int_{\Omega_{\lambda}}\left(f(x, u)-f\left(x, u_{\lambda}\right)\right) w_{\lambda}^{+} \psi_{\varepsilon}^{2} \phi_{\tau}^{2} d x \leq c\left(f,\|u\|_{L^{\infty}\left(\Omega_{\lambda}\right)}\right) \int_{\Omega_{\lambda}}\left(w_{\lambda}^{+}\right)^{2} \psi_{\varepsilon}^{2} \phi_{\tau}^{2} d x \tag{3.15}
\end{equation*}
$$

and so, from (3.14), we infer that

$$
\begin{align*}
\int_{\Omega_{\lambda}}\left|\nabla w_{\lambda} \chi_{\operatorname{supp}\left(w_{\lambda}^{+}\right)}\right|^{2} \psi_{\varepsilon}^{2} \phi_{\tau}^{2} d x & \leq 8 \int_{\Omega_{\lambda}}\left|\nabla \psi_{\varepsilon}\right|^{2}\left(w_{\lambda}^{+}\right)^{2} \phi_{\tau}^{2} d x+8 \int_{\Omega_{\lambda}}\left|\nabla \phi_{\tau}\right|^{2}\left(w_{\lambda}^{+}\right)^{2} \psi_{\varepsilon}^{2} d x  \tag{3.16}\\
& +2 c\left(f,\|u\|_{L^{\infty}\left(\Omega_{\lambda}\right)}\right) \int_{\Omega_{\lambda}}\left(w_{\lambda}^{+}\right)^{2} \psi_{\varepsilon}^{2} \phi_{\tau}^{2} d x
\end{align*}
$$

Taking into account the properties of $\psi_{\varepsilon}$ and $\phi_{\tau}$, we see that

$$
\begin{align*}
& \int_{\Omega_{\lambda}}\left|\nabla \psi_{\varepsilon}\right|^{2} d x=\int_{\Omega_{\lambda} \cap\left(\mathcal{B}_{\varepsilon}^{\lambda} \backslash \mathcal{B}_{\delta}^{\lambda}\right)}\left|\nabla \psi_{\varepsilon}\right|^{2} d x<4 \varepsilon,  \tag{3.17}\\
& \int_{\Omega_{\lambda}}\left|\nabla \phi_{\tau}\right|^{2} d x=\int_{\Omega_{\lambda} \cap\left(\mathcal{I}_{\tau}^{\lambda} \backslash \mathcal{I}_{\sigma}^{\lambda}\right)}\left|\nabla \phi_{\tau}\right|^{2} d x<4 \tau, \tag{3.18}
\end{align*}
$$

which combined with $0 \leq w_{\lambda}^{+} \leq u$, immediately lead to

$$
\int_{\Omega_{\lambda}}\left|\nabla w_{\lambda} \chi_{s u p p\left(w_{\lambda}^{+}\right)}\right|^{2} \psi_{\varepsilon}^{2} \phi_{\tau}^{2} d x \leq 32(\varepsilon+\tau)\|u\|_{L^{\infty}\left(\Omega_{\lambda}\right)}^{2}+2 c\left(f,\|u\|_{L^{\infty}\left(\Omega_{\lambda}\right)}\right)\|u\|_{L^{\infty}\left(\Omega_{\lambda}\right)}^{2}|\Omega| .
$$

By Fatou Lemma, as $\varepsilon$ and $\tau$ tend to zero, we deduce that $\nabla w_{\lambda} \chi_{\operatorname{supp}\left(w_{\lambda}^{+}\right)} \in L^{2}\left(\Omega_{\lambda}\right)$. To conclude we note that $\varphi \rightarrow w_{\lambda}^{+}$in $\mathrm{E}^{2}(\Omega)$, as $\varepsilon$ and $\tau$ tend to zero, by definition of $\varphi$. Also, $\nabla \varphi \rightarrow \nabla w_{\lambda} \chi_{\operatorname{supp}\left(w_{\lambda}^{+}\right)}$in $L^{2}\left(\Omega_{\lambda}\right)$, by (3.13). Therefore, $\nabla w_{\lambda} \chi_{\operatorname{supp}\left(w_{\lambda}^{+}\right)}$is the distributional
gradient of $\nabla w_{\lambda}^{+}$and $w_{\lambda}^{+}$in $H_{0}^{1}\left(\Omega_{\lambda}\right)$, since $\varphi \in H_{0}^{1}\left(\Omega_{\lambda}\right)$ again by Lemma 3.1. Which concludes the proof.

Proof of Theorem 1.3. We define

$$
\Lambda_{0}=\left\{a<\lambda<0: u \leq u_{t} \text { in } \Omega_{t} \backslash R_{t}(\Gamma) \text { for all } t \in(a, \lambda]\right\}
$$

and to start with the moving plane procedure, we have to prove that
Step 1: $\Lambda_{0} \neq \emptyset$. Fix a $\lambda_{0} \in(a, 0)$ such that $R_{\lambda_{0}}(\Gamma) \subset \Omega^{c}$, then for every $a<\lambda<\lambda_{0}$, we also have that $R_{\lambda}(\Gamma) \subset \Omega^{c}$. For any $\lambda$ in this set we consider, on the domain $\Omega$, the function $\varphi:=w_{\lambda}^{+} \phi_{\tau}^{2} \chi_{\Omega_{\lambda}}$, where $\phi_{\tau}$ is as in (2.10) and we proceed as in the proof of Lemma 3.2. That is, by Lemma 3.1 and a density argument, we can use $\varphi$ as test function in (1.3) and (3.11) so that, subtracting, we get

$$
\begin{aligned}
\int_{\Omega_{\lambda}}\left|\nabla w_{\lambda}^{+}\right|^{2} \phi_{\tau}^{2} d x & =-2 \int_{\Omega_{\lambda}} \nabla w_{\lambda}^{+} \nabla \phi_{\tau} w_{\lambda}^{+} \phi_{\tau} d x+\int_{\Omega_{\lambda}}\left(f(x, u)-f\left(x_{\lambda}, u_{\lambda}\right)\right) w_{\lambda}^{+} \phi_{\tau}^{2} d x \\
& \leq-2 \int_{\Omega_{\lambda}} \nabla w_{\lambda}^{+} \nabla \phi_{\tau} w_{\lambda}^{+} \phi_{\tau} d x+\int_{\Omega_{\lambda}}\left(f(x, u)-f\left(x, u_{\lambda}\right)\right) w_{\lambda}^{+} \phi_{\tau}^{2} d x
\end{aligned}
$$

Exploiting Young's inequality and the assumption $\left(h_{f}\right)$, with $K=\overline{\Omega_{\lambda_{0}}}$ and $M=\|u\|_{L^{\infty}\left(\Omega_{\lambda_{0}}\right)}^{2}$, we then get that

$$
\begin{aligned}
\int_{\Omega_{\lambda}}\left|\nabla w_{\lambda}^{+}\right|^{2} \phi_{\tau}^{2} d x & \leq \frac{1}{2} \int_{\Omega_{\lambda}}\left|\nabla w_{\lambda}^{+}\right|^{2} \phi_{\tau}^{2} d x+2 \int_{\Omega_{\lambda}}\left|\nabla \phi_{\tau}\right|^{2}\left(w_{\lambda}^{+}\right)^{2} d x \\
& +c\left(f,\|u\|_{L^{\infty}\left(\Omega_{\lambda_{0}}\right)}\right) \int_{\Omega_{\lambda}}\left(w_{\lambda}^{+}\right)^{2} \phi_{\tau}^{2} d x .
\end{aligned}
$$

Taking into account the properties of $\phi_{\tau}$, we see that

$$
\begin{equation*}
\int_{\Omega_{\lambda}}\left|\nabla \phi_{\tau}\right|^{2}\left(w_{\lambda}^{+}\right)^{2} d x \leq\|u\|_{L^{\infty}\left(\Omega_{\lambda}\right)}^{2} \int_{\Omega_{\lambda} \cap\left(\mathcal{I}_{\tau}^{\lambda} \backslash \mathcal{I}_{\sigma}^{\lambda}\right)}\left|\nabla \phi_{\tau}\right|^{2} d x \leq 4\|u\|_{L^{\infty}\left(\Omega_{\lambda}\right)}^{2} \cdot \tau . \tag{3.19}
\end{equation*}
$$

We therefore deduce that

$$
\int_{\Omega_{\lambda}}\left|\nabla w_{\lambda}^{+}\right|^{2} \phi_{\tau}^{2} d x \leq 16\|u\|_{L^{\infty}\left(\Omega_{\lambda}\right)} \cdot \tau+2 c\left(f,\|u\|_{L^{\infty}\left(\Omega_{\lambda_{0}}\right)}\right) \int_{\Omega_{\lambda}}\left(w_{\lambda}^{+}\right)^{2} \phi_{\tau}^{2} d x .
$$

By Fatou Lemma, as $\tau$ tend to, zero we have

$$
\begin{align*}
\int_{\Omega_{\lambda}}\left|\nabla w_{\lambda}^{+}\right|^{2} d x & \leq 2 c\left(f,\|u\|_{L^{\infty}\left(\Omega_{\lambda_{0}}\right)}\right) \int_{\Omega_{\lambda}}\left(w_{\lambda}^{+}\right)^{2} d x  \tag{3.20}\\
& \leq 2 c\left(f,\|u\|_{L^{\infty}\left(\Omega_{\lambda_{0}}\right)}\right) c_{p}^{2}\left(\Omega_{\lambda}\right) \int_{\Omega_{\lambda}}\left|\nabla w_{\lambda}^{+}\right|^{2} d x
\end{align*}
$$

where $c_{p}(\cdot)$ is the Poincaré constant (in the Poincaré inequality in $H_{0}^{1}\left(\Omega_{\lambda}\right)$ ). Since $c_{p}^{2}\left(\Omega_{\lambda}\right) \rightarrow$ 0 as $\lambda \rightarrow a$, we can find $\lambda_{1} \in\left(a, \lambda_{0}\right)$, such that

$$
\forall \lambda \in\left(a, \lambda_{1}\right) \quad 2 c\left(f,\|u\|_{L^{\infty}\left(\Omega_{\lambda_{0}}\right)}\right) c_{p}^{2}\left(\Omega_{\lambda}\right)<\frac{1}{2},
$$

so that by (3.20), we deduce that

$$
\forall \lambda \in\left(a, \lambda_{1}\right) \quad \int_{\Omega_{\lambda}}\left|\nabla w_{\lambda}^{+}\right|^{2} d x \leq 0
$$

proving that $u \leq u_{\lambda}$ in $\Omega_{\lambda} \backslash R_{\lambda}(\Gamma)$ for $\lambda$ close to $a$, which implies the desired conclusion $\Lambda_{0} \neq \emptyset$.

Now we can set

$$
\lambda_{0}=\sup \Lambda_{0}
$$

Step 2: here we show that $\lambda_{0}=0$. To this end we assume that $\lambda_{0}<0$ and we reach a contradiction by proving that $u \leq u_{\lambda_{0}+\nu}$ in $\Omega_{\lambda_{0}+\nu} \backslash R_{\lambda_{0}+\nu}(\Gamma)$ for any $0<\nu<\bar{\nu}$ for some small $\bar{\nu}>0$. By continuity we know that $u \leq u_{\lambda_{0}}$ in $\Omega_{\lambda_{0}} \backslash R_{\lambda_{0}}(\Gamma)$. Since $\Omega$ is convex in the $x_{1}$-direction and the set $R_{\lambda_{0}}(\Gamma)$ lies in the hyperplane of equation $\left\{x_{1}=-2 \lambda_{0}\right\}$, we see that $\Omega_{\lambda_{0}} \backslash R_{\lambda_{0}}(\Gamma)$ is open and connected. Therefore, by the strong maximum principle we deduce that $u<u_{\lambda_{0}}$ in $\Omega_{\lambda_{0}} \backslash R_{\lambda_{0}}(\Gamma)$ (here we have also used that $u, u_{\lambda_{0}} \in C^{1}\left(\Omega_{\lambda_{0}} \backslash R_{\lambda_{0}}(\Gamma)\right.$ ) by Remark 1.2, as well as the assumption $\left(h_{f}\right)$.)
Now, note that for $K \subset \Omega_{\lambda_{0}} \backslash R_{\lambda_{0}}(\Gamma)$, there is $\nu=\nu\left(K, \lambda_{0}\right)>0$, sufficiently small, such that $K \subset \Omega_{\lambda} \backslash R_{\lambda}(\Gamma)$ for every $\lambda \in\left[\lambda_{0}, \lambda_{0}+\nu\right]$. Consequently $u$ and $u_{\lambda}$ are well defined on $K$ for every $\lambda \in\left[\lambda_{0}, \lambda_{0}+\nu\right]$. Hence, by the uniform continuity of the function $g(x, \lambda):=u(x)-u\left(2 \lambda-x_{1}, x^{\prime}\right)$ on the compact set $K \times\left[\lambda_{0}, \lambda_{0}+\nu\right]$ we can ensure that $K \subset \Omega_{\lambda_{0}+\nu} \backslash R_{\lambda_{0}+\nu}(\Gamma)$ and $u<u_{\lambda_{0}+\nu}$ in $K$ for any $0 \leq \nu<\bar{\nu}$, for some $\bar{\nu}=\bar{\nu}\left(K, \lambda_{0}\right)>0$ small. Clearly we can also assume that $\bar{\nu}<\frac{\left|\lambda_{0}\right|}{4}$.
Let us consider $\psi_{\varepsilon}$ constructed in such a way that it vanishes in a neighborhood of $R_{\lambda_{0}+\nu}(\Gamma)$ and $\phi_{\tau}$ constructed in such a way it vanishes in a neighborhood of $\gamma_{\lambda_{0}+\nu}=\partial \Omega \cap T_{\lambda_{0}+\nu}$. As swown in the proof of lemma 3.2, the functions

$$
\varphi:=\left\{\begin{array}{lll}
w_{\lambda_{0}+\nu}^{+} \psi_{\varepsilon}^{2} \phi_{\tau}^{2} & \text { in } \Omega_{\lambda_{0}+\nu} \\
0 & \text { in } \mathbb{R}^{n} \backslash \Omega_{\lambda_{0}+\nu}
\end{array}\right.
$$

are such that $\varphi \rightarrow w_{\lambda_{0}+\nu}^{+}$in $H_{0}^{1}\left(\Omega_{\lambda_{0}+\nu}\right)$, as $\varepsilon$ and $\tau$ tend to zero. Moreover, $\varphi \in C^{0,1}\left(\overline{\Omega_{\lambda_{0}+\nu}}\right)$ and $\varphi_{\partial \Omega_{\lambda_{0}+\nu}}=0$, by Lemma 3.1, and $\varphi=0$ on an open neighborhood of $K$, by the above argument. Therefore, $\varphi \in H_{0}^{1}\left(\Omega_{\lambda_{0}+\nu} \backslash K\right)$ and thus, also $w_{\lambda_{0}+\nu}^{+}$belongs to $H_{0}^{1}\left(\Omega_{\lambda_{0}+\nu} \backslash K\right)$. We also note that $\nabla w_{\lambda_{0}+\nu}^{+}=0$ on an open neighborhood of $K$.
Now we argue as in Lemma 3.2 and we plug $\varphi$ as test function in (1.3) and (3.11) so that, by subtracting, we get

$$
\begin{aligned}
\int_{\Omega_{\lambda_{0}+\nu}}\left|\nabla w_{\lambda_{0}+\nu}^{+}\right|^{2} \psi_{\varepsilon}^{2} \phi_{\tau}^{2} d x & \leq-2 \int_{\Omega_{\lambda_{0}+\nu}} \nabla w_{\lambda_{0}+\nu} \nabla \psi_{\varepsilon} w_{\lambda_{0}+\nu}^{+} \psi_{\varepsilon} \phi_{\tau}^{2} d x \\
& -2 \int_{\Omega_{\lambda_{0}+\nu}} \nabla w_{\lambda_{0}+\nu} \phi_{\tau} w_{\lambda_{0}+\nu}^{+} \psi_{\varepsilon}^{2} \phi_{\tau} d x \\
& +\int_{\Omega_{\lambda_{0}+\nu}}\left(f(x, u)-f\left(x, u_{\lambda}\right)\right) w_{\lambda_{0}+\nu}^{+} \psi_{\varepsilon}^{2} \phi_{\tau}^{2} d x
\end{aligned}
$$

where we also use the monotonicity of $f(\cdot, s)$ in the $x_{1}$-direction. Therefore, taking into account the properties of $w_{\lambda_{0}+\nu}^{+}$and $\nabla w_{\lambda_{0}+\nu}^{+}$we also have

$$
\begin{aligned}
\int_{\Omega_{\lambda_{0}+\nu} \backslash K}\left|\nabla w_{\lambda_{0}+\nu}^{+}\right|^{2} \psi_{\varepsilon}^{2} \phi_{\tau}^{2} d x & \leq-2 \int_{\Omega_{\lambda_{0}+\nu} \backslash K} \nabla w_{\lambda_{0}+\nu}^{+} \nabla \psi_{\varepsilon} w_{\lambda_{0}+\nu}^{+} \psi_{\varepsilon} \phi_{\tau}^{2} d x \\
& -2 \int_{\Omega_{\lambda_{0}+\nu} \backslash K} \nabla w_{\lambda_{0}+\nu}^{+} \nabla \phi_{\tau} w_{\lambda_{0}+\nu}^{+} \psi_{\varepsilon}^{2} \phi_{\tau} d x \\
& +\int_{\Omega_{\lambda_{0}+\nu} \backslash K}\left(f(x, u)-f\left(x, u_{\lambda}\right)\right) w_{\lambda_{0}+\nu}^{+} \psi_{\varepsilon}^{2} \phi_{\tau}^{2} d x .
\end{aligned}
$$

Furthermore, since $f$ is locally uniformly Lipschitz continuous from above, we deduce that

$$
\begin{align*}
\int_{\Omega_{\lambda_{0}+\nu} \backslash K}\left|\nabla w_{\lambda_{0}+\nu}^{+}\right|^{2} \psi_{\varepsilon}^{2} \phi_{\tau}^{2} d x & \leq 2 \int_{\Omega_{\lambda_{0}+\nu} \backslash K}\left|\nabla w_{\lambda_{0}+\nu}^{+}\right|\left|\nabla \psi_{\varepsilon}\right| w_{\lambda_{0}+\nu}^{+} \psi_{\varepsilon} \phi_{\tau}^{2} d x \\
& +2 \int_{\Omega_{\lambda_{0}+\nu} \backslash K}\left|\nabla w_{\lambda_{0}+\nu}^{+}\right|\left|\nabla \phi_{\tau}\right| w_{\lambda_{0}+\nu}^{+} \psi_{\varepsilon}^{2} \phi_{\tau} d x  \tag{3.21}\\
& +c\left(f,\|u\|_{L^{\infty}\left(\Omega_{\lambda_{0}+\frac{1 \lambda_{0} \mid}{}}^{4}\right)}\right) \int_{\Omega_{\lambda_{0}+\nu} \backslash K}\left(w_{\lambda_{0}+\nu}^{+}\right)^{2} \psi_{\varepsilon}^{2} \phi_{\tau}^{2} d x .
\end{align*}
$$

Now, as in the proof of Lemma 3.2, we use Young's inequality to deduce that

$$
\begin{align*}
\int_{\Omega_{\lambda_{0}+\nu} \backslash K}\left|\nabla w_{\lambda_{0}+\nu}^{+}\right|^{2} \psi_{\varepsilon}^{2} \phi_{\tau}^{2} d x & \leq 8 \int_{\Omega_{\lambda_{0}+\nu \backslash K}}\left|\nabla \psi_{\varepsilon}\right|^{2}\left(w_{\lambda_{0}+\nu}^{+}\right)^{2} \phi_{\tau}^{2} d x \\
& +8 \int_{\Omega_{\lambda_{0}+\nu} \backslash K}\left|\nabla \phi_{\tau}\right|^{2}\left(w_{\lambda_{0}+\nu}^{+}\right)^{2} \psi_{\varepsilon}^{2} d x  \tag{3.22}\\
& +2 c\left(f,\|u\|_{L^{\infty}\left(\Omega_{\lambda_{0}+\frac{\left|\lambda_{0}\right|}{}}^{4}\right)}\right) \int_{\Omega_{\lambda_{0}+\nu} \backslash K}\left(w_{\lambda}^{+}\right)^{2} \psi_{\varepsilon}^{2} \phi_{\tau}^{2} d x,
\end{align*}
$$

which in turns yields

$$
\begin{align*}
\int_{\Omega_{\lambda_{0}+\nu} \backslash K}\left|\nabla w_{\lambda_{0}+\nu}^{+}\right|^{2} \psi_{\varepsilon}^{2} \phi_{\tau}^{2} d x & \leq 32\|u\|_{L^{\infty}\left(\Omega_{\lambda_{0}+\bar{\nu}}\right)}^{2}(\epsilon+\tau)  \tag{3.23}\\
& +2 c\left(f,\|u\|_{L^{\infty}\left(\Omega_{\lambda_{0}+\frac{\left|\lambda_{0}\right|}{}}^{4}\right)}\right) \int_{\Omega_{\lambda_{0}+\nu} \backslash K}\left(w_{\lambda}^{+}\right)^{2} \psi_{\varepsilon}^{2} \phi_{\tau}^{2} d x .
\end{align*}
$$

Passing to the limit, as $(\epsilon, \tau) \rightarrow(0,0)$, in the latter we get

$$
\begin{align*}
& \int_{\Omega_{\lambda_{0}+\nu} \backslash K}\left|\nabla w_{\lambda_{0}+\nu}^{+}\right|^{2} d x \leq 2 c\left(f,\|u\|_{L^{\infty}\left(\Omega_{\left.\lambda_{0}+\frac{\left|\lambda_{0}\right|}{} \right\rvert\,}^{4}\right.}\right) \int_{\Omega_{\lambda_{0}+\nu} \backslash K}\left(w_{\lambda_{0}+\nu}^{+}\right)^{2} d x  \tag{3.24}\\
& \leq 2 c\left(f,\|u\|_{L^{\infty}\left(\Omega_{\lambda_{0}+}+\frac{\left|\lambda_{0}\right|}{4}\right)}\right) c_{p}^{2}\left(\Omega_{\lambda_{0}+\nu} \backslash K\right) \int_{\Omega_{\lambda_{0}+\nu} \backslash K}\left|\nabla w_{\lambda_{0}+\nu}^{+}\right|^{2} d x,
\end{align*}
$$

where $c_{p}(\cdot)$ is the Poincaré constant (in the Poincaré inequality in $H_{0}^{1}\left(\Omega_{\lambda_{0}+\nu} \backslash K\right)$ ). Now we recall that $c_{p}^{2}\left(\Omega_{\lambda_{0}+\nu} \backslash K\right) \leq Q(n)\left|\Omega_{\lambda_{0}+\nu} \backslash K\right|^{\frac{2}{N}}$, where $Q=Q(n)$ is a positive constant depending only on the dimension $n$, and therefore, by summarizing, we have proved that for every compact set $K \subset \Omega_{\lambda_{0}} \backslash R_{\lambda_{0}}(\Gamma)$ there is a small $\bar{\nu}=\bar{\nu}\left(K, \lambda_{0}\right) \in\left(0, \frac{\left|\lambda_{0}\right|}{4}\right)$ such that
for every $0 \leq \nu<\bar{\nu}$ we have

$$
\begin{equation*}
\int_{\Omega_{\lambda_{0}+\nu} \backslash K}\left|\nabla w_{\lambda_{0}+\nu}^{+}\right|^{2} d x \leq 2 c\left(f,\|u\|_{L^{\infty}\left(\Omega_{\lambda_{0}+\frac{\left|\lambda_{0}\right|}{4}}^{4}\right.}\right) Q(n)\left|\Omega_{\lambda_{0}+\nu} \backslash K\right|^{\frac{2}{N}} \int_{\Omega_{\lambda_{0}+\nu} \backslash K}\left|\nabla w_{\lambda_{0}+\nu}^{+}\right|^{2} d x \tag{3.25}
\end{equation*}
$$

Now we first fix a compact $K \subset \Omega_{\lambda_{0}} \backslash R_{\lambda_{0}}(\Gamma)$ such that

$$
\left|\Omega_{\lambda_{0}} \backslash K\right|^{\frac{2}{N}}<\left[20 c\left(f,\|u\|_{L^{\infty}\left(\Omega_{\lambda_{0}+\frac{\left|\lambda_{0}\right|}{4}}\right.}\right) Q(n)\right]^{-1}
$$

this is possible since $\left|R_{\lambda_{0}}(\Gamma)\right|=0$ by the assumption on $\Gamma$, and then we take $\bar{\nu}_{0}<\bar{\nu}$ such that for every $0 \leq \nu<\bar{\nu}_{0}$ we have $\left|\Omega_{\lambda_{0}+\nu} \backslash \Omega_{\lambda_{0}}\right|^{\frac{2}{N}}<\left[20 c\left(f,\|u\|_{L^{\infty}\left(\Omega_{\lambda_{0}+\frac{\left|\lambda_{0}\right|}{4}}\right)}\right) Q(n)\right]^{-1}$. Inserting those informations into (3.25) we immediately get that

$$
\begin{equation*}
\int_{\Omega_{\lambda_{0}+\nu} \backslash K}\left|\nabla w_{\lambda_{0}+\nu}^{+}\right|^{2} d x<\frac{1}{2} \int_{\Omega_{\lambda_{0}+\nu} \backslash K}\left|\nabla w_{\lambda_{0}+\nu}^{+}\right|^{2} d x \tag{3.26}
\end{equation*}
$$

and so $\nabla w_{\lambda_{0}+\nu}^{+}$on $\Omega_{\lambda_{0}+\nu} \backslash K$ for every $0 \leq \nu<\bar{\nu}_{0}$. On the other hand, we recall that $\nabla w_{\lambda_{0}+\nu}^{+}$on an open neighbourhood of $K$ for every $0 \leq \nu<\bar{\nu}$, thus $\nabla w_{\lambda_{0}+\nu}^{+}$on $\Omega_{\lambda_{0}+\nu}$ for every $0 \leq \nu<\bar{\nu}_{0}$. The latter proves that $u \leq u_{\lambda_{0}+\nu}$ in $\Omega_{\lambda_{0}+\nu} \backslash R_{\lambda_{0}+\nu}(\Gamma)$ for every $0<\nu<\bar{\nu}_{0}$. Such a contradiction shows that

$$
\lambda_{0}=0
$$

Step 3: conclusion. Since the moving plane procedure can be performed in the same way but in the opposite direction, then this proves the desired symmetry result. The fact that the solution is increasing in the $x_{1}$-direction in $\left\{x_{1}<0\right\}$ is implicit in the moving plane procedure. Since $u$ has $C^{1}$ regularity, see Remark 1.2 , the fact that $u_{x_{1}}$ is positive for $x_{1}<0$ follows by the maximum principle, the Höpf lemma and the assumption $\left(h_{f}\right)$.

## 4. Proof of Theorem 1.5 and Corollary 1.6

Proof of Theorem 1.5. We first note that, thanks to a well-known result of Brezis and Kato [4] and standard elliptic estimates (see also [20]), the solution $u$ is smooth in $\mathbb{R}^{n} \backslash \Gamma$. Furthermore we observe that it is enough to prove the theorem for the special case in which the origin does not belong to $\Gamma$. Indeed, if the result is true in this special case, then we can apply it to the function $u_{z}(x):=u(x+z)$, where $z \in\left\{x_{1}=0\right\} \backslash \Gamma \neq \emptyset$, which satisfies the equation (1.4) with $\Gamma$ replaced by $-z+\Gamma$ (note that $-z+\Gamma$ is a closed and proper subset of $\left\{x_{1}=0\right\}$ with $\operatorname{Cap}_{\mathbb{R}^{n}}(-z+\Gamma)=0$ and such that the origin does not belong to it).
Under this assumption, we consider the map $K: \mathbb{R}^{n} \backslash\{0\} \longrightarrow \mathbb{R}^{n} \backslash\{0\}$ defined by $K=$ $K(x):=\frac{x}{|x|^{2}}$. Given $u$ solution to (1.4), its Kelvin transform is given by

$$
\begin{equation*}
v(x):=\frac{1}{|x|^{n-2}} u\left(\frac{x}{|x|^{2}}\right), \quad x \in \mathbb{R}^{n} \backslash\left\{\Gamma^{*} \cup\{0\}\right\} \tag{4.27}
\end{equation*}
$$

where $\Gamma^{*}=K(\Gamma)$. It follows that $v$ weakly satisfies (1.4) in $\mathbb{R}^{n} \backslash\left\{\Gamma^{*} \cup\{0\}\right\}$ and that $\Gamma^{*} \subset\left\{x_{1}=0\right\}$ since, by assumption, $\Gamma \subset\left\{x_{1}=0\right\}$. Furthermore, we also have that $\Gamma^{*}$ is bounded (not necessarily closed) since we assumed that $0 \notin \Gamma$.

The proceed further we need the following lemmata
Lemma 4.1. Let $F: \mathbb{R}^{n} \backslash\{0\} \longrightarrow \mathbb{R}^{n} \backslash\{0\}$ be a $C^{1}$-diffeomorphism and let $A$ be a bounded open set of $\mathbb{R}^{n} \backslash\{0\}$. If $C \subset A$ is a compact set such that

$$
\begin{equation*}
\mathrm{Cap}_{A}(C)=0, \tag{4.28}
\end{equation*}
$$

then

$$
\begin{equation*}
\underset{F(A)}{\operatorname{Cap}_{2}}(F(C))=0 . \tag{4.29}
\end{equation*}
$$

Proof. By hypothesis (4.28) and by definition of 2-capacity, for every $\varepsilon>0$ let $\varphi_{\varepsilon} \in C_{c}^{\infty}(A)$ such that
a. $\int_{A}\left|\nabla \varphi_{\varepsilon}\right|^{2} d x<\varepsilon$
b. $\varphi_{\varepsilon} \geq 1$ in a neighborhood $\mathcal{B}_{\varepsilon}$ of $C$.

Let $\psi_{\varepsilon}:=\varphi_{\varepsilon} \circ G$, where $G:=F^{-1}$. By definition of $\psi_{\varepsilon}$, we immediately have that $\psi_{\varepsilon} \geq 1$ in a neighborhood $\mathcal{B}_{\varepsilon}^{\prime}$ of the compact set $F(C)$. Moreover

$$
\begin{aligned}
\int_{F(A)}\left|\nabla \psi_{\varepsilon}(y)\right|^{2} d y & =\int_{F(A)}\left|J G\left(y_{1}, \ldots, y_{n}\right) \cdot \nabla \varphi_{\varepsilon}\left(G_{1}\left(y_{1}\right), \ldots, G_{N}\left(y_{n}\right)\right)\right|^{2} d y_{1} \cdots d y_{n} \\
& \leq \int_{F(A)}\|J G\|_{\infty, \overline{F(A)} \mid}\left|\nabla \varphi_{\varepsilon}\left(G_{1}\left(y_{1}\right), \ldots, G_{N}\left(y_{n}\right)\right)\right|^{2} d y_{1} \cdots d y_{n} \\
& \leq C(F, A) \int_{F(A)}\left|\nabla \varphi_{\varepsilon}\left(G_{1}\left(y_{1}\right), \ldots, G_{N}\left(y_{n}\right)\right)\right|^{2} d y_{1} \cdots d y_{n} \\
& =C(F, A) \int_{A}\left|\nabla \varphi_{\varepsilon}\left(x_{1}, \ldots, x_{n}\right)\right|^{2}\left|\operatorname{det}\left(J F\left(x_{1}, \ldots, x_{n}\right)\right)\right| d x_{1} \cdots d x_{n} \\
& \leq \tilde{C}(F, A) \int_{A}\left|\nabla \varphi_{\varepsilon}\right|^{2} d x<\tilde{C}(F, A) \varepsilon
\end{aligned}
$$

Since $\tilde{C}(F, A)$ is independent of $\varepsilon$, the desired conclusion follows at once.

Lemma 4.2. Let $\Gamma$ be a closed subset of $\mathbb{R}^{n}$, with $n \geq 3$. Also suppose that $0 \notin \Gamma$ and

$$
\begin{equation*}
\operatorname{Cap}_{\mathbb{R}^{n}}(\Gamma)=0 . \tag{4.30}
\end{equation*}
$$

Then

$$
\begin{equation*}
\underset{\mathbb{R}^{n}}{\mathrm{Cap}_{2}}\left(\Gamma^{*}\right)=0 \tag{4.31}
\end{equation*}
$$

Proof. Since 0 belongs to the open set $\mathbb{R}^{n} \backslash \Gamma$, there exists $r_{0} \in(0,1)$ such that $B_{r_{0}}(0) \cap \Gamma=\emptyset$.
Therefore, $\Gamma=\bigcup_{m=1}^{+\infty}\left[\Gamma \cap\left(\overline{B_{m}(0)} \backslash B_{r_{0}}(0)\right)\right]$ and so

$$
\underset{\mathbb{R}^{n}}{\mathrm{Cap}_{2}}\left[\Gamma \cap\left(\overline{B_{m}(0)} \backslash B_{r_{0}}(0)\right)\right]=0, \quad \forall m \in \mathbb{N},
$$

since (4.30) is in force. The latter and $n \geq 3$ imply that

$$
\mathrm{Cap}_{A_{m}}\left[\Gamma \cap\left(\overline{B_{m}(0)} \backslash B_{r_{0}}(0)\right)\right]=0, \quad \forall m \in \mathbb{N}
$$

where $A_{m}:=B_{m+1}(0) \backslash \overline{\left.B_{\frac{r_{0}}{2}}(0)\right)}$ is an open and bounded set for every $m \geq 1$. An application of lemma 4.1 with $F=K$, the inversion $x \rightarrow \frac{x}{|x|^{2}}, A=A_{m}$ and $C=\Gamma \cap\left(\overline{B_{m}(0)} \backslash B_{r_{0}}(0)\right)$ yields

$$
\underset{K\left(A_{m}\right)}{\operatorname{Cap}_{2}} K\left(\Gamma \cap\left(\overline{B_{m}(0)} \backslash B_{r_{0}}(0)\right)\right)=0, \quad \forall m \in \mathbb{N}
$$

and so

$$
\underset{\mathbb{R}^{n}}{\mathrm{Cap}_{2}} K\left(\Gamma \cap\left(\overline{B_{m}(0)} \backslash B_{r_{0}}(0)\right)\right)=0, \quad \forall m \in \mathbb{N} .
$$

But $\Gamma^{*}=K(\Gamma)=K\left(\bigcup_{m=1}^{+\infty}\left[\Gamma \cap\left(\overline{B_{m}(0)} \backslash B_{r_{0}}(0)\right)\right]\right)=\bigcup_{m=1}^{+\infty} K\left(\Gamma \cap\left(\overline{B_{m}(0)} \backslash B_{r_{0}}(0)\right)\right)$ and the 2-capacity is an exterior measure (see e.g. [12]), so the desired conclusion (4.31) follows.

Let us now fix some notations. We set

$$
\begin{equation*}
\Sigma_{\lambda}=\left\{x \in \mathbb{R}^{n}: x_{1}<\lambda\right\} . \tag{4.32}
\end{equation*}
$$

As above $x_{\lambda}=\left(2 \lambda-x_{1}, x_{2}, \ldots, x_{n}\right)$ is the reflection of $x$ through the hyperplane $T_{\lambda}=\{x=$ $\left.\left(x_{1}, \ldots, x_{n}\right) \in \mathbb{R}^{n} \mid x_{1}=\lambda\right\}$. Finally we consider the Kelvin transform $v$ of $u$ defined in (4.27) and we set

$$
\begin{equation*}
w_{\lambda}(x)=v(x)-v_{\lambda}(x)=v(x)-v\left(x_{\lambda}\right) \tag{4.33}
\end{equation*}
$$

Note that $v$ weakly solves

$$
\begin{equation*}
\int_{\mathbb{R}^{n}} \nabla v \nabla \varphi d x=\int_{\mathbb{R}^{n}} v^{2^{*}-1} \varphi d x \quad \forall \varphi \in C_{c}^{1}\left(\mathbb{R}^{n} \backslash \Gamma^{*} \cup\{0\}\right) \tag{4.34}
\end{equation*}
$$

and $v_{\lambda}$ weakly solves

$$
\begin{equation*}
\int_{\mathbb{R}^{n}} \nabla v_{\lambda} \nabla \varphi d x=\int_{\mathbb{R}^{n}} v_{\lambda}^{2^{*}-1} \varphi d x \quad \forall \varphi \in C_{c}^{1}\left(\mathbb{R}^{n} \backslash R_{\lambda}\left(\Gamma^{*} \cup\{0\}\right)\right) \tag{4.35}
\end{equation*}
$$

The properties of the Kelvin transform, the fact that $0 \notin \Gamma$ and the regularity of $u$ imply that $|v(x)| \leq C|x|^{2-N}$ for every $x \in \mathbb{R}^{n}$ such that $|x| \geq R$, where $C$ and $R$ are positive constants (depending on $u$ ). In particular, for every $\lambda<0$, we have

$$
\begin{equation*}
v \in L^{2^{*}}\left(\Sigma_{\lambda}\right) \cap L^{\infty}\left(\Sigma_{\lambda}\right) \cap C^{0}\left(\overline{\Sigma_{\lambda}}\right) . \tag{4.36}
\end{equation*}
$$

Lemma 4.3. Under the assumption of Theorem 1.5, for every $\lambda<0$, we have that $w_{\lambda}^{+} \in$ $L^{2^{*}}\left(\Sigma_{\lambda}\right), \nabla w_{\lambda}^{+} \in L^{2}\left(\Sigma_{\lambda}\right)$ and

$$
\begin{equation*}
\left\|w_{\lambda}^{+}\right\|_{L^{2^{*}}\left(\Sigma_{\lambda}\right)}^{2} \leq C_{S}^{2} \int_{\Sigma_{\lambda}}\left|\nabla w_{\lambda}^{+}\right|^{2} d x \leq 2 C_{S}^{2} \frac{n+2}{n-2}\|v\|_{L^{2^{*}}\left(\Sigma_{\lambda}\right)}^{2^{*}}, \tag{4.37}
\end{equation*}
$$

where $C_{S}$ denotes de best constant in Sobolev embedding.

Proof. We immediately see that $w_{\lambda}^{+} \in L^{2^{*}}\left(\Sigma_{\lambda}\right)$, since $0 \leq w_{\lambda}^{+} \leq v \in L^{2^{*}}\left(\Sigma_{\lambda}\right)$. The rest of the proof follows the lines of the one of lemma 3.2. Arguing as in section 2 , for every $\varepsilon>0$, we can find a function $\psi_{\varepsilon} \in C^{0,1}\left(\mathbb{R}^{N},[0,1]\right)$ such that

$$
\int_{\Sigma_{\lambda}}\left|\nabla \psi_{\varepsilon}\right|^{2}<4 \varepsilon
$$

and $\psi_{\varepsilon}=0$ in an open neighborhood $\mathcal{B}_{\varepsilon}$ of $R_{\lambda}\left(\left\{\Gamma^{*} \cup\{0\}\right\}\right)$, with $\mathcal{B}_{\varepsilon} \subset \Sigma_{\lambda}$.
Fix $R_{0}>0$ such that $R_{\lambda}\left(\left\{\Gamma^{*} \cup\{0\}\right) \subset B_{R_{0}}\right.$ and, for every $R>R_{0}$, let $\varphi_{R}$ be a standard cut off function such that $0 \leq \varphi_{R} \leq 1$ on $\mathbb{R}^{n}, \varphi_{R}=1$ in $B_{R}, \varphi_{R}=0$ outside $B_{2 R}$ with $\left|\nabla \varphi_{R}\right| \leq 2 / R$, and consider

$$
\varphi:=\left\{\begin{array}{lll}
w_{\lambda}^{+} \psi_{\varepsilon}^{2} \varphi_{R}^{2} & \text { in } \quad \Sigma_{\lambda}, \\
0 & \text { in } & \mathbb{R}^{n} \backslash \Sigma_{\lambda}
\end{array}\right.
$$

Now, as in Lemma 3.1 we see that $\varphi \in C_{c}^{0,1}\left(\mathbb{R}^{n}\right)$ with $\operatorname{supp}(\varphi)$ contained in $\overline{\Sigma_{\lambda} \cap B_{2 R}} \backslash$ $R_{\lambda}\left(\left\{\Gamma^{*} \cup\{0\}\right\}\right)$ and

$$
\begin{equation*}
\nabla \varphi=\psi_{\varepsilon}^{2} \varphi_{R}^{2}\left(\nabla w_{\lambda} \chi_{\operatorname{supp}\left(w_{\lambda}^{+}\right) \operatorname{supp}(\varphi)}\right)+2\left(w_{\lambda}^{+} \chi_{\operatorname{supp}(\varphi)}\right)\left(\psi_{\varepsilon}^{2} \varphi_{R} \nabla \varphi_{R}+\psi_{\varepsilon} \varphi_{R}^{2} \nabla \psi_{\varepsilon}\right) \tag{4.38}
\end{equation*}
$$

Therefore, by a standard density argument, we can use $\varphi$ as test function in (4.34) and in (4.35) so that, subtracting we get

$$
\begin{align*}
\int_{\Sigma_{\lambda}}\left|\nabla w_{\lambda} \chi_{\operatorname{supp}\left(w_{\lambda}^{+}\right)}\right|^{2} \psi_{\varepsilon}^{2} \varphi_{R}^{2} d x & =-2 \int_{\Sigma_{\lambda}} \nabla w_{\lambda} \nabla \psi_{\varepsilon} w_{\lambda}^{+} \psi_{\varepsilon} \varphi_{R}^{2} d x-2 \int_{\Sigma_{\lambda}} \nabla w_{\lambda} \nabla \varphi_{R} w_{\lambda}^{+} \varphi_{R} \psi_{\varepsilon}^{2} d x  \tag{4.39}\\
& +\int_{\Sigma_{\lambda}}\left(v^{2^{*}-1}-v_{\lambda}^{2^{*}-1}\right) w_{\lambda}^{+} \psi_{\varepsilon}^{2} \varphi_{R}^{2} d x \\
& =: I_{1}+I_{2}+I_{3}
\end{align*}
$$

Exploiting also Young's inequality and recalling that $0 \leq w_{\lambda}^{+} \leq v$, we get that

$$
\begin{align*}
\left|I_{1}\right| & \leq \frac{1}{4} \int_{\Sigma_{\lambda}}\left|\nabla w_{\lambda} \chi_{\operatorname{supp}\left(w_{\lambda}^{+}\right)}\right|^{2} \psi_{\varepsilon}^{2} \varphi_{R}^{2} d x+4 \int_{\Sigma_{\lambda}}\left|\nabla \psi_{\varepsilon}\right|^{2}\left(w_{\lambda}^{+}\right)^{2} \varphi_{R}^{2} d x \\
& \leq \frac{1}{4} \int_{\Sigma_{\lambda}}\left|\nabla w_{\lambda} \chi_{\operatorname{supp}\left(w_{\lambda}^{+}\right)}\right|^{2} \psi_{\varepsilon}^{2} \varphi_{R}^{2} d x+16 \varepsilon\|v\|_{L^{\infty}\left(\Sigma_{\lambda}\right)}^{2} . \tag{4.40}
\end{align*}
$$

Furthermore we have that

$$
\begin{align*}
\left|I_{2}\right| & \leq \frac{1}{4} \int_{\Sigma_{\lambda}}\left|\nabla w_{\lambda} \chi_{\text {supp }\left(w_{\lambda}^{+}\right)}\right|^{2} \psi_{\varepsilon}^{2} \varphi_{R}^{2} d x+4 \int_{\Sigma_{\lambda} \cap\left(B_{2 R} \backslash B_{R}\right)}\left|\nabla \varphi_{R}\right|^{2}\left(w_{\lambda}^{+}\right)^{2} \psi_{\varepsilon}^{2} d x \\
& \leq \frac{1}{4} \int_{\Sigma_{\lambda}}\left|\nabla w_{\lambda} \chi_{\operatorname{supp}\left(w_{\lambda}^{+}\right)}\right|^{2} \psi_{\varepsilon}^{2} \varphi_{R}^{2} d x \\
& +4\left(\int_{\Sigma_{\lambda} \cap\left(B_{2 R} \backslash B_{R}\right)}\left|\nabla \varphi_{R}\right|^{n} d x\right)^{\frac{2}{n}}\left(\int_{\Sigma_{\lambda} \cap\left(B_{2 R} \backslash B_{R}\right)} v^{2^{*}} d x\right)^{\frac{n-2}{n}}  \tag{4.41}\\
& \leq \frac{1}{4} \int_{\Sigma_{\lambda}}\left|\nabla w_{\lambda} \chi_{\operatorname{supp}\left(w_{\lambda}^{+}\right)}\right|^{2} \psi_{\varepsilon}^{2} \varphi_{R}^{2} d x+c(n)\left(\int_{\Sigma_{\lambda} \cap\left(B_{2 R} \backslash B_{R}\right)} v^{2^{*}} d x\right)^{\frac{n-2}{n}}
\end{align*}
$$

where $c(n)$ is a positive constant depending only on the dimension $n$.

Let us now estimate $I_{3}$. Since $v(x), v_{\lambda}(x)>0$, by the convexity of $t \rightarrow t^{2^{*}-1}$, for $t>0$, we obtain $v^{2^{*}-1}(x)-v_{\lambda}^{2^{*}-1}(x) \leq \frac{n+2}{n-2} v_{\lambda}^{2^{*}-2}(x)\left(v(x)-v_{\lambda}(x)\right)$, for every $x \in \Sigma_{\lambda}$. Thus, by making use of the monotonicity of $t \rightarrow t^{2^{*}-2}$, for $t>0$ and the definition of $w_{\lambda}^{+}$we get $\left(v^{2^{*}-1}-v_{\lambda}^{2^{*}-1}\right) w_{\lambda}^{+} \leq \frac{n+2}{n-2} v_{\lambda}^{2^{*}-2}\left(v-v_{\lambda}\right) w_{\lambda}^{+} \leq \frac{n+2}{n-2} v^{2^{*}-2}\left(w_{\lambda}^{+}\right)^{2}$. Therefore

$$
\begin{align*}
I_{3} & \leq \frac{n+2}{n-2} \int_{\Sigma_{\lambda}} v^{2^{*}-2}\left(w_{\lambda}^{+}\right)^{2} \psi_{\varepsilon}^{2} \varphi_{R}^{2} d x \\
& \leq \frac{n+2}{n-2} \int_{\Sigma_{\lambda}} v^{2^{*}-2} v^{2} d x=\frac{n+2}{n-2} \int_{\Sigma_{\lambda}} v^{2^{*}} d x=\frac{n+2}{n-2}\|v\|_{L^{2^{*}}\left(\Sigma_{\lambda}\right)}^{2^{*}} \tag{4.42}
\end{align*}
$$

where we also used that $0 \leq w_{\lambda}^{+} \leq v$. Taking into account the estimates on $I_{1}, I_{2}$ and $I_{3}$, by (4.39) we deduce that

$$
\begin{align*}
\int_{\Sigma_{\lambda}}\left|\nabla w_{\lambda} \chi_{\operatorname{supp}\left(w_{\lambda}^{+}\right)}\right|^{2} \varphi_{\varepsilon}^{2} \varphi_{R}^{2} d x & \leq 32 \varepsilon\|v\|_{L^{\infty}\left(\Sigma_{\lambda}\right)}^{2} \\
& +2 c(n)\left(\int_{\Sigma_{\lambda} \cap\left(B_{2 R} \backslash B_{R}\right)} v^{2^{*}} d x\right)^{\frac{n-2}{n}}  \tag{4.43}\\
& +2 \frac{n+2}{n-2}\|v\|_{L^{2^{*}}\left(\Sigma_{\lambda}\right)}^{2^{*}} .
\end{align*}
$$

By Fatou Lemma, as $\varepsilon$ tends to zero and $R$ tends to infinity, we deduce that $\nabla w_{\lambda} \chi_{\operatorname{supp}\left(w_{\lambda}^{+}\right)} \in$ $L^{2}\left(\Sigma_{\lambda}\right)$. We also note that $\varphi \rightarrow w_{\lambda}^{+}$in $L^{2^{*}}\left(\Sigma_{\lambda}\right)$, by definition of $\varphi$, and that $\nabla \varphi \rightarrow$ $\nabla w_{\lambda} \chi_{\operatorname{supp}\left(w_{\lambda}^{+}\right)}$in $L^{2}\left(\Sigma_{\lambda}\right)$, by (4.38) and the fact that $w_{\lambda}^{+} \in L^{2^{*}}\left(\Sigma_{\lambda}\right)$. Therefore, $\nabla w_{\lambda} \chi_{\text {supp }\left(w_{\lambda}^{+}\right)}$ is the distributional gradient of $\nabla w_{\lambda}^{+}$and so $\nabla w_{\lambda}^{+}$in $L^{2}\left(\Sigma_{\lambda}\right)$ with (taking limit in (4.43))

$$
\begin{equation*}
\int_{\Sigma_{\lambda}}\left|\nabla w_{\lambda}\right|^{2} d x \leq 2 \frac{n+2}{n-2}\|v\|_{L^{2^{*}}\left(\Sigma_{\lambda}\right)}^{2^{*}} \tag{4.44}
\end{equation*}
$$

Since $\varphi \in C_{c}^{0,1}\left(\mathbb{R}^{n}\right)$ we also have

$$
\begin{equation*}
\left(\int_{\Sigma_{\lambda}} \varphi^{2^{*}}\right)^{\frac{2}{2^{*}}} \leq C_{S}^{2} \int_{\Sigma_{\lambda}}|\nabla \varphi|^{2} \tag{4.45}
\end{equation*}
$$

where $C_{S}$ denotes de best constant in Sobolev embedding. Thus, passing to the limit in (4.45) and using the above convergence results, we get the desired conclusion (4.37).

We can now complete the proof of Theorem 1.5. As for the proof of Theorem 1.3, we split the proof into three steps and we start with
Step 1: there exists $M>1$ such that $v \leq v_{\lambda}$ in $\Sigma_{\lambda} \backslash R_{\lambda}\left(\Gamma^{*} \cup\{0\}\right)$, for all $\lambda<-M$.
Arguing as in the proof of Lemma 4.3 and using the same notations and the same construction for $\psi_{\varepsilon}, \varphi_{R}$ and $\varphi$, we get

$$
\begin{align*}
\int_{\Sigma_{\lambda}}\left|\nabla w_{\lambda}^{+}\right|^{2} \varphi_{\varepsilon}^{2} \varphi_{R}^{2} d x & =-2 \int_{\Sigma_{\lambda}} \nabla w_{\lambda}^{+} \nabla \varphi_{\varepsilon} w_{\lambda}^{+} \varphi_{\varepsilon} \varphi_{R}^{2} d x-2 \int_{\Sigma_{\lambda}} \nabla w_{\lambda}^{+} \nabla \varphi_{R} w_{\lambda}^{+} \varphi_{R} \varphi_{\varepsilon}^{2} d x \\
& +\int_{\Sigma_{\lambda}}\left(v^{2^{*}-1}-v_{\lambda}^{2^{*}-1}\right) w_{\lambda}^{+} \varphi_{\varepsilon}^{2} \varphi_{R}^{2} d x  \tag{4.46}\\
& =: I_{1}+I_{2}+I_{3},
\end{align*}
$$

where $I_{1}, I_{2}$ and $I_{3}$ can be estimated exactly as in (4.40), (4.41) and (4.42). The latter yield

$$
\begin{aligned}
\int_{\Sigma_{\lambda}}\left|\nabla w_{\lambda}^{+}\right|^{2} \varphi_{\varepsilon}^{2} \varphi_{R}^{2} d x & \leq 32 \varepsilon\|v\|_{L^{\infty}\left(\Sigma_{\lambda}\right)}^{2} \\
& +2 c(n)\left(\int_{\Sigma_{\lambda} \cap\left(B_{2 R} \backslash B_{R}\right)} v^{2^{*}} d x\right)^{\frac{n-2}{n}} \\
& +2 \frac{n+2}{n-2} \int_{\Sigma_{\lambda}} v^{2^{*}-2}\left(w_{\lambda}^{+}\right)^{2} \psi_{\varepsilon}^{2} \varphi_{R}^{2} .
\end{aligned}
$$

Taking the limit in the latter, as $\varepsilon$ tends to zero and $R$ tends to infinity, leads to

$$
\begin{equation*}
\int_{\Sigma_{\lambda}}\left|\nabla w_{\lambda}^{+}\right|^{2} d x \leq 2 \frac{n+2}{n-2} \int_{\Sigma_{\lambda}} v^{2^{*}-2}\left(w_{\lambda}^{+}\right)^{2}<+\infty \tag{4.48}
\end{equation*}
$$

which combined with Lemma 4.3 gives

$$
\begin{align*}
\int_{\Sigma_{\lambda}}\left|\nabla w_{\lambda}^{+}\right|^{2} d x & \leq 2 \frac{n+2}{n-2} \int_{\Sigma_{\lambda}} v^{2^{*}-2}\left(w_{\lambda}^{+}\right)^{2} d x \\
& \leq 2 \frac{n+2}{n-2}\left(\int_{\Sigma_{\lambda}} v^{2^{*}} d x\right)^{\frac{2}{n}}\left(\int_{\Sigma_{\lambda}}\left(w_{\lambda}^{+}\right)^{2^{*}} d x\right)^{\frac{2}{2^{*}}}  \tag{4.49}\\
& \leq 2 \frac{n+2}{n-2} C_{S}^{2}\left(\int_{\Sigma_{\lambda}} v^{2^{*}} d x\right)^{\frac{2}{n}}\left(\int_{\Sigma_{\lambda}}\left|\nabla w_{\lambda}^{+}\right|^{2} d x\right) .
\end{align*}
$$

Recalling that $v \in L^{2^{*}}\left(\Sigma_{\lambda}\right)$, we deduce the existence of $M>1$ such that

$$
2 \frac{n+2}{n-2} C_{S}^{2}\left(\int_{\Sigma_{\lambda}} v^{2^{*}} d x\right)^{\frac{2}{n}}<1
$$

for every $\lambda<-M$. The latter and (4.49) lead to

$$
\int_{\Sigma_{\lambda}}\left|\nabla w_{\lambda}^{+}\right|^{2} d x=0
$$

This implies that $w_{\lambda}^{+}=0$ by Lemma 4.3 and the claim is proved.
To proceed further we define

$$
\Lambda_{0}=\left\{\lambda<0: v \leq v_{t} \text { in } \Sigma_{t} \backslash R_{t}\left(\Gamma^{*} \cup\{0\}\right) \text { for all } t \in(-\infty, \lambda]\right\}
$$

and

$$
\lambda_{0}=\sup \Lambda_{0} .
$$

Step 2: we have that $\lambda_{0}=0$. We argue by contradiction and suppose that $\lambda_{0}<0$. By continuity we know that $v \leq v_{\lambda_{0}}$ in $\Sigma_{\lambda_{0}} \backslash R_{\lambda_{0}}\left(\Gamma^{*} \cup\{0\}\right)$. By the strong maximum principle we deduce that $v<v_{\lambda_{0}}$ in $\Sigma_{\lambda_{0}} \backslash R_{\lambda_{0}}\left(\Gamma^{*} \cup\{0\}\right)$. Indeed, $v=v_{\lambda_{0}}$ in $\Sigma_{\lambda_{0}} \backslash R_{\lambda_{0}}\left(\Gamma^{*} \cup\{0\}\right)$ ) is
not possible if $\lambda_{0}<0$, since in this case $v$ would be singular somewhere on $R_{\lambda_{0}}\left(\Gamma^{*} \cup\{0\}\right)$. Now, for some $\bar{\tau}>0$, that will be fixed later on, and for any $0<\tau<\bar{\tau}$ we show that $v \leq v_{\lambda_{0}+\tau}$ in $\Sigma_{\lambda_{0}+\tau} \backslash R_{\lambda_{0}+\tau}\left(\Gamma^{*} \cup\{0\}\right)$ obtaining a contradiction with the definition of $\lambda_{0}$ and proving thus the claim. To this end we are going to show that, for every $\delta>0$ there are $\bar{\tau}\left(\delta, \lambda_{0}\right)>0$ and a compact set $K$ (depending on $\delta$ and $\lambda_{0}$ ) such that

$$
K \subset \Sigma_{\lambda} \backslash R_{\lambda}\left(\Gamma^{*} \cup\{0\}\right), \quad \int_{\Sigma_{\lambda} \backslash K} v^{2^{*}}<\delta, \quad \forall \lambda \in\left[\lambda_{0}, \lambda_{0}+\bar{\tau}\right] .
$$

To see this, we note that for every every $\delta>0$ there are $\tau_{1}\left(\delta, \lambda_{0}\right)>0$ and a compact set $K$ (depending on $\delta$ and $\lambda_{0}$ ) such that $\int_{\Sigma_{\lambda_{0}} \backslash K} v^{2^{*}}<\frac{\delta}{2}$ and $K \subset \Sigma_{\lambda} \backslash R_{\lambda}\left(\Gamma^{*} \cup\{0\}\right)$ for every $\lambda \in\left[\lambda_{0}, \lambda_{0}+\tau_{1}\right]$. Consequently $u$ and $u_{\lambda}$ are well defined on $K$ for every $\lambda \in\left[\lambda_{0}, \lambda_{0}+\tau_{1}\right]$. Hence, by the uniform continuity of the function $g(x, \lambda):=u(x)-u\left(2 \lambda-x_{1}, x^{\prime}\right)$ on the compact set $K \times\left[\lambda_{0}, \lambda_{0}+\tau_{1}\right]$ we can ensure that $K \subset \Sigma_{\lambda_{0}+\tau} \backslash R_{\lambda_{0}+\tau}\left(\Gamma^{*} \cup\{0\}\right)$ and $u<u_{\lambda_{0}+\tau}$ in $K$ for any $0 \leq \tau<\tau_{2}$, for some $\tau_{2}=\tau\left(\delta, \lambda_{0}\right) \in\left(0, \tau_{1}\right)$. Clearly we can also assume that $\tau_{2}<\frac{\left|\lambda_{0}\right|}{4}$. Finally, since $v^{2^{*}} \in L^{1}\left(\Sigma_{\lambda_{0}+\frac{\left|\lambda_{0}\right|}{4}}\right)$ and $\int_{\Sigma_{\lambda_{0}} \backslash K} v^{2^{*}}<\frac{\delta}{2}$, we obtain the existence of $\bar{\tau} \in\left(0, \tau_{2}\right)$ such that $\int_{\Sigma_{\lambda} \backslash K} v^{2^{*}}<\delta$ for all $\lambda \in\left[\lambda_{0}, \lambda_{0}+\bar{\tau}\right]$.
Now we repeat verbatim the arguments used in the proof of Lemma 4.3 but using the test function

$$
\varphi:=\left\{\begin{array}{lll}
w_{\lambda_{0}+\tau}^{+} \psi_{\varepsilon}^{2} \varphi_{R}^{2} & \text { in } & \Sigma_{\lambda_{0}+\tau} \\
0 & \text { in } & \mathbb{R}^{n} \backslash \Sigma_{\lambda_{0}+\tau}
\end{array}\right.
$$

Thus we recover the first inequality in (4.49), which immediately gives, for any $0 \leq \tau<\bar{\tau}$

$$
\begin{align*}
\int_{\Sigma_{\lambda_{0}+\tau} \backslash K}\left|\nabla w_{\lambda_{0}+\tau}^{+}\right|^{2} d x & \leq 2 \frac{n+2}{n-2} \int_{\Sigma_{\lambda_{0}+\tau} \backslash K} v^{2^{2^{*}-2}}\left(w_{\lambda_{0}+\tau}^{+}\right)^{2} d x \\
& \leq 2 \frac{n+2}{n-2}\left(\int_{\Sigma_{\lambda_{0}+\tau} \backslash K} v^{2^{*}} d x\right)^{\frac{2}{n}}\left(\int_{\Sigma_{\lambda_{0}+\tau} \backslash K}\left(w_{\lambda_{0}+\tau}^{+}\right)^{2^{*}} d x\right)^{\frac{2}{2^{*}}}  \tag{4.50}\\
& \leq 2 \frac{n+2}{n-2} C_{S}^{2}\left(\int_{\Sigma_{\lambda_{0}+\tau} \backslash K} v^{2^{*}} d x\right)^{\frac{2}{n}}\left(\int_{\Sigma_{\lambda_{0}+\tau} \backslash K}\left|\nabla w_{\lambda_{0}+\tau}^{+}\right|^{2} d x\right)
\end{align*}
$$

since $w_{\lambda_{0}+\tau}^{+}$and $\nabla w_{\lambda_{0}+\tau}^{+}$are zero in a neighbourhood of $K$, by the above construction. Now we fix $\delta<\frac{1}{2}\left[2 \frac{n+2}{n-2} C_{S}^{2}\right]^{-\frac{n}{2}}$ and we observe that with this choice we have

$$
2 \frac{n+2}{n-2} C_{S}^{2}\left(\int_{\Sigma_{\lambda_{0}+\tau} \backslash K} v^{2^{*}} d x\right)^{\frac{2}{n}}<\frac{1}{2}, \quad \forall 0 \leq \tau<\bar{\tau}
$$

which plugged into (4.50) implies that $\int_{\Sigma_{\lambda_{0}+\tau} \backslash K}\left|\nabla w_{\lambda_{0}+\tau}^{+}\right|^{2} d x=0$ for every $0 \leq \tau<\bar{\tau}$. Hence $\int_{\Sigma_{\lambda_{0}+\tau}}\left|\nabla w_{\lambda_{0}+\tau}^{+}\right|^{2} d x=0$ for every $0 \leq \tau<\bar{\tau}$, since $\nabla w_{\lambda_{0}+\tau}^{+}$is zero in a neighborhood of $K$. The latter and Lemma 4.3 imply that $w_{\lambda_{0}+\tau}^{+}=0$ on $\Sigma_{\lambda_{0}+\tau}$ for every $0 \leq \tau<\bar{\tau}$ and
thus $v \leq v_{\lambda_{0}+\tau}$ in $\Sigma_{\lambda_{0}+\tau} \backslash R_{\lambda_{0}+\tau}\left(\Gamma^{*} \cup\{0\}\right)$ for every $0 \leq \tau<\bar{\tau}$. Which proves the claim of Step 2.
Step 3: conclusion. The symmetry of the Kelvin transform $v$ follows now performing the moving plane method in the opposite direction. The fact that that $v$ is symmetric w.r.t. the hyperplane $\left\{x_{1}=0\right\}$ implies the symmetry of the solution $u$ w.r.t. the hyperplane $\left\{x_{1}=0\right\}$. The last claim then follows by the invariance of the considered problem with respect to isometries (translations and rotations).

Proof of Corollary 1.6. The function $v(x)=u\left(x+x_{0}\right)$ satisfies the assumptions of Theorem 1.5 with $\Gamma=\{0\}$. An application of Theorem 1.5 yields that $v$ is symmetric with respect to every hyperplane through the origin and so the original solution $u$ must be radially symmetric with respect to $x_{0}$. This proves item (i). Since item (ii) is a special case of item (iii) with $k=1$, we need only to prove item (iii). To this end we observe that, up to an isometry, we can suppose that the affine $k$-dimensional subspace is $\left\{x_{k+1}=\ldots=x_{n}=0\right\}$. Therefore, we can apply Theorem 1.5 to get that $u$ is symmetric with respect to each hyperplane of $\mathbb{R}^{n}$ containing $\left\{x_{k+1}=\ldots=x_{n}=0\right\}$; i.e., $u$ is invariant with respect to every rotation of $\mathbb{R}^{n}$ which leaves invariant the set $\left\{x_{k+1}=\ldots=x_{n}=0\right\}$. Note that we can apply Theorem 1.3 since any affine $k$-dimensional subspace of $\mathbb{R}^{n}$, with $1 \leq k \leq n-2$, has zero 2-capacity in $\mathbb{R}^{n}$ (and so $\left.\operatorname{Cap}_{\mathbb{R}}(\Gamma)=0\right)$.

[^0]:    Date: March 15, 2022.
    2000 Mathematics Subject Classification. 35J61,35B06,35B50.
    Key words and phrases. Semilinear elliptic equations, singular solutions, qualitative properties.

[^1]:    ${ }^{1}$ Here we mean that the solution $u$ does not admit a smooth extension all over the whole space. Namely it is not possible to find $\tilde{u} \in H_{l o c}^{1}\left(\mathbb{R}^{n}\right)$ with $u \equiv \tilde{u}$ in $\mathbb{R}^{n} \backslash \Gamma$.
