# GOLDIE RANKS OF PRIMITIVE IDEALS AND INDEXES OF EQUIVARIANT AZUMAYA ALGEBRAS 

IVAN LOSEV AND IVAN PANIN

#### Abstract

Let $\mathfrak{g}$ be a semisimple Lie algebra. We establish a new relation between the Goldie rank of a primitive ideal $\mathcal{J} \subset U(\mathfrak{g})$ and the dimension of the corresponding irreducible representation $V$ of an appropriate finite W -algebra. Namely, we show that $\operatorname{Grk}(\mathcal{J}) \leqslant \operatorname{dim} V / d_{V}$, where $d_{V}$ is the index of a suitable equivariant Azumaya algebra on a homogeneous space. We also compute $d_{V}$ in representation theoretic terms.

## 1. Introduction

In this paper we find a new relation between the Goldie ranks of primitive ideals and the dimensions of finite dimensional irreducible modules over finite W -algebras.

Let $\mathfrak{g}$ be a semisimple Lie algebra over $\mathbb{C}$, and let $\mathcal{U}$ denote its universal enveloping algebra. Recall that by a primitive ideal in $\mathcal{U}$ one means the annihilator of an irreducible module. Let $\mathcal{J}$ be a primitive ideal. Then $\mathcal{U} / \mathcal{J}$ is a prime Noetherian algebra and so, by the Goldie theorem (see, e.g., [MR, Chapter 2]), it has the full fraction $\operatorname{ring}, \operatorname{Frac}(\mathcal{U} / \mathcal{J})$ that is a matrix algebra over a skew-field. The rank of this matrix algebra is called the Goldie rank of $\mathcal{J}$ and is denoted by $\operatorname{Grk}(\mathcal{J})$. For example, when $\mathcal{J}$ is the annihilator of a finite dimensional irreducible representation, then the Goldie rank is the dimension of that representation. Finding a formula for $\operatorname{Grk}(\mathcal{J})$ in the general case is a well-known open problem in Lie representation theory.

Recall that to the primitive ideal $\mathcal{J}$ one can assign a nilpotent orbit in $\mathfrak{g}$ : the unique dense orbit in the subvariety $\mathrm{V}(\mathcal{J}) \subset \mathfrak{g}$ defined by gr $\mathcal{J}$. Let $\mathbb{O}$ denote this orbit. From $(\mathfrak{g}, \mathbb{O})$ one can construct an associative algebra known as the finite W-algebra, see [Pr1, L1]. We denote this algebra by $\mathcal{W}$. According to [L2, Section 1.2], to $\mathcal{J}$ one can assign an irreducible representation of $\mathcal{W}$ defined up to twisting with an outer automorphism. More precisely, pick $e \in \mathbb{O}$ and include it into an $\mathfrak{s l}_{2}$-triple $(e, h, f)$. Let $G$ be the simply connected group with Lie algebra $\mathfrak{g}$. Set $Q:=Z_{G}(e, h, f)$, it is the reductive part of $Z_{G}(e)$. The group $Q$ acts on $\mathcal{W}$ by algebra automorphisms, moreover, the action is Hamiltonian meaning that there is a compatible Lie algebra homomorphism (in fact, an inclusion) $\mathfrak{q} \hookrightarrow \mathcal{W}$. So the component group $\Gamma:=Q / Q^{\circ}$ acts on the set $\operatorname{Irr}_{f i n}(\mathcal{W})$ of isomorphism classes of irreducible representations. The main result of [L2] is that the orbit set $\operatorname{Irr}_{f i n}(\mathcal{W}) / \Gamma$ is naturally identified with the set $\operatorname{Prim}_{\mathscr{O}}(\mathcal{U})$ of primitive ideals in $\mathcal{U}$ corresponding to the orbit $\mathbb{O}$. The papers $[\mathrm{LO}, \mathrm{BL}]$ explain how to compute the $A$-orbits corresponding to the primitive ideals, see [LO, Theorem 1.1] for the case of integral central character and and [BL, Theorem 5.2, Corollary 5.3] for the full generality.
1.1. Known results. In particular, to $\mathcal{J}$ we can assign another numerical invariant, the dimension of the corresponding finite dimensional irreducible representation of $\mathcal{W}$, denote

[^0]this representation by $V$. There is a lot of evidence that $\operatorname{dim} V$ and $\operatorname{Grk}(\mathcal{J})$ are closely related. For example, it was shown in [1] that $\operatorname{Grk}(\mathcal{J}) \leqslant \operatorname{dim} V$. Premet improved this result in [Pr2], where he proved that $\operatorname{dim} V$ is divisible by $\operatorname{Grk}(\mathcal{J})$. On the other hand, in [L6, Corollary 1.2] the first named author proved that $\operatorname{Grk}(\mathcal{J})=\operatorname{dim} V$ provided $\mathcal{J}$ has integral central character for all orbits but one in type $E_{8}$ (and whether the equality holds for the remaining orbit is not known). One also has $\operatorname{Grk}(\mathcal{J})=\operatorname{dim} V$ when $\mathfrak{g}=\mathfrak{s l}_{n}$, see [Pr2] and [B]. Another main result of [L5] is a Kazhdan-Lusztig type formula for $\operatorname{dim} V$ (for $V$ with integral central character). So the equality $\operatorname{Grk}(\mathcal{J})=\operatorname{dim} V$ yields a formula for $\operatorname{Grk}(\mathcal{J})$.

On the other hand, Premet in [Pr2, Remark 4.3] found a series of examples of primitive ideals $\mathcal{J}$, where the Goldie rank is always 1 , while the dimension can be arbitrarily large. We will revisit that example in our paper.
1.2. Main result. The main result of this paper is the inequality $\operatorname{Grk}(\mathcal{J}) \leqslant \operatorname{dim} V / d_{V}$, where $d_{V}$ is a positive integer determined as follows. Let $Q_{V}$ denote the stabilizer of (the isomorphism class of) $V$ in $Q$. Note that $Q_{V}$ is a finite index subgroup in $Q$ because $Q^{\circ}$ acts trivially on the set of isomorphism classes of finite dimensional irreducible $\mathcal{W}$-modules. Since $Q$ acts on $\mathcal{W}$ by automorphisms and $V$ is an irreducible $\mathcal{W}$-module, we see that $V$ is a projective representation of $Q_{V}$, let $\psi$ denote the Schur multiplier, the class in $H^{2}\left(Q_{V}, \mathbb{C}^{\times}\right)$ measuring the failure of $V$ to be a genuine representation.

Definition 1.1. Define $d_{V}$ as the GCD of the dimensions of the projective representations of $Q_{V}$ with Schur multiplier $\psi$.

Theorem 1.2. We have $\operatorname{Grk}(\mathcal{J}) \leqslant \operatorname{dim} V / d_{V}$.
Conjecture 1.3. We have $\operatorname{Grk}(\mathcal{J})=\operatorname{dim} V / d_{V}$, at least for classical Lie algebras.
Let us make a few remarks about $d_{V}$. In type A, we have $d_{V}=\{1\}$, this is easily seen once one knows that $\operatorname{Grk}(\mathcal{J})=\operatorname{dim} V$ but can also be seen directly. In types $B, C, D, Q_{V}$ is a finite index subgroup in the product of orthogonal and symplectic groups. One can show that $d_{V}$ is a power of 2 , compare with the computations in Sections 2.6.

A current work in progress of the first named author and Bezrukavnikov should produce Kazhdan-Lusztig type formulas for $\operatorname{dim} V$ (for $V$ with an arbitrary central character). Together with Conjecture 1.3 this should give Kazhdan-Lusztig type formulas for Goldie ranks.
1.3. Ideas of proof and structure of the paper. Let us explain how Theorem 1.2 is proved.

The first step is as follows. Let $H$ denote the preimage of $Q_{V}$ under the natural epimorphism $Z_{G}(e) \rightarrow Q$. For a projective $H$-module $V^{\prime}$ with Schur multiplier $\psi$, we can form the equivariant Azumaya algebra $A=G \times{ }^{H} \operatorname{End}\left(V^{\prime}\right)$ on $G / H$. Our first important result is to show that the index $\operatorname{ind}(A)$ of $A$ (we recall the definition of the index in Section 2.1) coincides with $d_{V^{\prime}}$.

The second step is as follows. We can view $V$ as a projective $H$-representation with Schur multiplier $\psi$, where the action of $H$ is inflated from $Q_{V}$. Our second step is to produce a $G$-equivariant sheaf of $\mathbb{C}[[\hbar]]$-algebras $\mathcal{A}_{\hbar}$ on $G / H$ (that is, in a suitable sense, the microlocalization of the Rees algebra of $\mathcal{U} / \mathcal{J})$ that modulo $\hbar$ reduces to the equivariant Azumaya algebra $A:=G \times{ }^{H} \operatorname{End}(V)$.

In the third and final step we use the sheaf $\mathcal{A}_{\hbar}$ to show that $\operatorname{Grk}(\mathcal{J})$ cannot exceed the Goldie rank of $A$ that equals $\operatorname{dim} V / d_{V}$.

The paper is organized as follows. In Section 2 we complete step 1 above computing the index of an equivariant Azumaya algebra on a homogeneous space. In Section 3 we complete the proof of Theorem 1.2. Then in Section 4 we revisit Premet's example mentioned above.

## 2. Indexes of equivariant Azumaya algebras

2.1. Main result on indexes. Let $G$ be a simply connected algebraic group over $\mathbb{C}$ and $H \subset G$ an algebraic subgroup.

Let $X$ be an algebraic variety. Recall that an Azumaya algebra on $X$ is a coherent sheaf of algebras on $X$ subject to the following two properties: it is a vector bundle and every fiber is a matrix algebra. If $G$ acts on $X$ then we can talk about $G$-equivariant Azumaya algebras: these are $G$-equivariant vector bundles where $G$ acts by isomorphisms of sheaves of algebras.

Let $A$ be a $G$-equivariant Azumaya algebra on $X:=G / H$. Recall that the specialization $A_{\mathbb{C}(X)}$ of $A$ to the generic point of $X$ is a central simple algebra, hence a matrix algebra over a skew-field. We are interested in computing the index ind $(A)$. Recall that, for an Azumaya algebra $A$ on an integral scheme $X$, by the index of $A$ we mean $\sqrt{\operatorname{dim}_{\mathbb{C}(X)} D}$, where $D$ is a skew-field such that the specialization $A_{\mathbb{C}(X)}$ of $A$ to the generic point of $X$ is a matrix algebra over $D$.

Since $A$ is $G$-equivariant, it is a homogeneous vector bundle on $G / H$. Since $A$ is a sheaf of algebras, the fiber over $1 H / H$ is an algebra with an action of $H$ by automorphisms. And since $A$ is Azumaya, this fiber is of the form $\operatorname{End}(V)$, where $V$ is a vector space such that $H$ acts on $\operatorname{End}(V)$ by algebra automorphisms. In other words, $V$ is a projective representation with Schur multiplier, say, $-\psi \in H^{2}\left(H, \mathbb{C}^{\times}\right)$. Let $\operatorname{Rep}^{\psi}(H)$ denote the category of projective representations of $H$ with Schur multiplier $\psi$ and let $d(\psi)$ denote the GCD of the dimensions of the representations in $\operatorname{Rep}^{\psi}(H)$. We also write $d_{V}$ for $d(\psi)$.

The main result of this section is as follows.
Theorem 2.1. In the notation above, we have ind $(A)=d(\psi)$.
The proof occupies Sections [2.2-2.5. In Section [2.6 we provide some examples of computation that will become relevant for us in Section 4.
2.2. K-theoretic definition of the index. Let us recall an equivalent definition of the index. Let $A^{\prime}$ be a central simple algebra over a field $\mathbb{K}$. Let $\tilde{\mathbb{K}}$ be an extension of $\mathbb{K}$ such that the base change $\widetilde{A^{\prime}}:=\tilde{\mathbb{K}} \otimes_{\mathbb{K}} A^{\prime}$ splits (note that we do not require that $\tilde{\mathbb{K}}$ is an algebraic extension $)$. Then we have the base change map $K_{0}\left(A^{\prime}-\bmod \right) \rightarrow K_{0}\left(\widetilde{A^{\prime}}-\bmod \right)$. Note that both $K_{0}$ groups are isomorphic to $\mathbb{Z}$ (since $A^{\prime}$ is a central simple algebra, we have $A^{\prime}=\operatorname{Mat}_{n}(D)$, where $D$ is a skew-field; then $A^{\prime}$-mod is equivalent to the category of right vector spaces over $D$, whose $K_{0}$ is $\mathbb{Z}$ ).

The following lemma is classical, but we provide a proof for readers convenience.
Lemma 2.2. The image of $K_{0}\left(A^{\prime}-\bmod \right)$ in $K_{0}\left(\widetilde{A^{\prime}}-\bmod \right) \cong \mathbb{Z}$ is $\operatorname{ind}\left(A^{\prime}\right) \mathbb{Z}$.
Proof. Let $\widetilde{A^{\prime}}=\operatorname{Mat}_{m}(\tilde{\mathbb{K}})$ so that $m^{2}=n^{2} \operatorname{dim}_{\mathbb{K}} D$. The group $K_{0}\left(A^{\prime}-\bmod \right)$ is generated by $D^{n}$, while $K_{0}\left(\widetilde{A}^{\prime}\right.$-mod) is generated by $\tilde{\mathbb{K}}^{m}$. So the image of interest is the subgroup $k \mathbb{Z}$,
where

$$
k=\operatorname{dim}_{\tilde{\mathbb{K}}} \tilde{\mathbb{K}} \otimes_{\mathbb{K}} D^{n} / m=\frac{n}{m} \operatorname{dim}_{\mathbb{K}} D=\sqrt{\operatorname{dim}_{\mathbb{K}} D}=\operatorname{ind}\left(A^{\prime}\right) .
$$

Let us return to the situation when we have an equivariant Azumaya algebra $A$ over $G / H$, $\mathbb{K}=\mathbb{C}(G / H)$ and $A^{\prime}=A_{\mathbb{C}(G / H)}$. Let us explain our choice of $\tilde{\mathbb{K}}$. Let $\pi$ denote the projection $G \rightarrow G / H$.

Lemma 2.3. The pull-back $\pi^{*} A$ (an Azumaya algebra on $G$ ) splits. In particular, for $\tilde{\mathbb{K}}:=$ $\mathbb{C}(G)$, the algebra $\widetilde{A}^{\prime}$ splits.
Proof. The pullback $\pi^{*} A$ is the equivariant Azumaya algebra over $G$ with fiber $\operatorname{End}(V)$ over 1 in $G$. So it is the trivial Azumaya algebra.

Consider the categories $\operatorname{Coh}(G / H, A), \operatorname{Coh}\left(G, \pi^{*} A\right)$ of coherent sheaves of modules over the corresponding Azumaya algebras. We have the pull-back map $\pi^{*}: K_{0}(\operatorname{Coh}(G / H, A)) \rightarrow$ $K_{0}\left(\operatorname{Coh}\left(G, \pi^{*} A\right)\right)$. The following statement, that should be thought of as a global analog of Lemma 2.2, is an important part of our proof of Theorem 2.1.

Proposition 2.4. We have $K_{0}\left(\operatorname{Coh}\left(G, \pi^{*} A\right)\right) \cong \mathbb{Z}$ and $\operatorname{im} \pi^{*}=\operatorname{ind}(A) \mathbb{Z}$.
Proof. We have the following commutative diagram, where the horizontal maps are pullbacks and the vertical maps are the specializations to the generic points. As before, we write $A^{\prime}:=A_{\mathbb{K}}$ and $\widetilde{A^{\prime}}:=\widetilde{\mathbb{K}} \otimes_{\mathbb{K}} A^{\prime}$.

The claim of the proposition will immediately follow from Lemma 2.2 once we know that
(1) the map $K_{0}(\operatorname{Coh}(G / H, A)) \rightarrow K_{0}\left(A^{\prime}\right.$-mod) corresponding to the localization to the generic point is surjective,
(2) and the map $K_{0}\left(\operatorname{Coh}\left(G, \pi^{*} A\right)\right) \rightarrow K_{0}\left(\tilde{A}^{\prime}-\bmod \right)$ is an isomorphism.
(1) is straightforward. Let us explain why (2) holds.

Since the Azumaya algebra $\pi^{*} A$ splits, (2) boils down to showing the map $K_{0}(\operatorname{Coh}(G)) \rightarrow$ $\mathbb{Z}$ (sending the class of a coherent sheaf on $G$ to the dimension of its fiber at the generic point) is an isomorphism. This follows because $G$ is simply connected as will be explained after Proposition 2.6.
2.3. Equivariant $K_{0}$-groups. We can also consider the categories $\operatorname{Coh}^{G}(G / H, A)$ and $\operatorname{Coh}^{G}\left(G, \pi^{*} A\right)$ of $G$-equivariant sheaves of $A$ - and $\pi^{*} A$-modules. We still have the pullback functor $\pi^{*}: \operatorname{Coh}^{G}(G / H, A) \rightarrow \operatorname{Coh}^{G}\left(G, \pi^{*} A\right)$. This gives rise to the pull-back map on the level of $K_{0}$-groups that will be denoted by $\pi^{*}$ as well. We will need to describe the image.

Proposition 2.5. We have identifications

$$
K_{0}\left(\operatorname{Coh}^{G}(G / H, A)\right) \xrightarrow{\sim} K_{0}\left(\operatorname{Rep}^{\psi}(H)\right), K_{0}\left(\operatorname{Coh}^{G}\left(G, \pi^{*} A\right)\right) \xrightarrow{\sim} \mathbb{Z}
$$

so that the map $\pi^{*}$ sends the class of $U \in \operatorname{Rep}^{\psi}(H)$ to $\operatorname{dim} U$.

Proof. For any algebraic subgroup $H^{1} \subset G$ and any $G$-equivariant Azumaya algebra $A^{1}$ on $G / H^{1}$, the algebra $A^{1}$ is the homogeneous bundle on $G / H^{1}$ with fiber $A_{1}^{1}$ at the point $1 H^{1} / H^{1} \in G / H^{1}$. We have a category equivalence $\operatorname{Coh}^{G}\left(G / H^{1}, A^{1}\right) \rightarrow A_{1}^{1}-\bmod ^{H^{1}}$, where the notation $\bmod ^{H^{1}}$ means the category of $H^{1}$-equivariant modules. This equivalence is given by taking the fiber at $1 H^{1} / H^{1}$, its quasi-inverse sends an $A_{1}^{1}$-module $V^{1}$ to the homogeneous bundle on $G / H^{1}$ with fiber $V^{1}$.

Applying this to $H^{1}:=\{1\}, A^{1}:=\pi^{*} A$, we get an equivalence $\operatorname{Coh}^{G}\left(G, \pi^{*} A\right) \cong\left(\pi^{*} A\right)_{1}$-mod. Recall that $\left(\pi^{*} A\right)_{1}=\operatorname{End}(V)$, where $V$ is a projective representation of $H$ with Schur multiplier $-\psi$. Then Vect $\xrightarrow{\sim} \operatorname{End}(V)-\bmod$ via $U \mapsto V \otimes U$.

Similarly, for $H^{1}:=H, A^{1}:=A$, we get $\operatorname{Coh}^{G}(G / H, A) \cong A_{1}-\bmod ^{H}$. And we get the equivalence $\operatorname{Rep}^{\psi}(H) \xrightarrow{\sim} A_{1}-\bmod ^{H}$ by $U \mapsto V \otimes U$ (since the Schur multipliers of $U$ and $V$ are opposite, $V \otimes U$ is a genuine linear representation of $H$ ).

Now we claim that, under the resulting identifications, $\operatorname{Coh}^{G}\left(G, \pi^{*} A\right) \xrightarrow{\sim} \operatorname{Vect}$ and $\operatorname{Coh}^{G}(G / H, A) \xrightarrow{\sim}$ $\operatorname{Rep}^{\psi}(H)$ the pull-back functor $\pi^{*}: \operatorname{Coh}^{G}(G / H, A) \rightarrow \operatorname{Coh}^{G}\left(G, \pi^{*} A\right)$ becomes the forgetful functor $\operatorname{Rep}^{\psi}(H) \rightarrow$ Vect. Indeed, the pull-back functor sends the homogeneous bundle on $G / H$ with fiber $V$ to the homogeneous bundle on $G$ with fiber $V$. The claim of the proposition follows.

### 2.4. Forgetful map. The goal of this section is to prove the following proposition.

Proposition 2.6. Let $X$ be a smooth algebraic variety and $G$ be a simply connected algebraic group acting on $X$. Let $A$ be a $G$-equivariant Azumaya algebra on $X$. Then the forgetful map $K_{0}\left(\operatorname{Coh}^{G}(X, A)\right) \rightarrow K_{0}(\operatorname{Coh}(X, A))$ is surjective.

We remark that for $A=\mathcal{O}_{X}$, this is a theorem of Merkurjev, [Me, Thm.40]. This, in particular, implies that $K_{0}(\operatorname{Coh}(G)) \xrightarrow{\sim} \mathbb{Z}$ via taking the generic rank (this has been already used in the proof of Proposition (2.4): indeed, the inverse map is given by the forgetful map $\mathbb{Z} \xrightarrow{\sim} K_{0}\left(\operatorname{Coh}^{G}(G)\right) \rightarrow K_{0}(\operatorname{Coh}(G))$.

We will reduce the proof of Proposition [2.6 to the case of $A=\mathcal{O}_{X}$ using the Severi-Brauer variety of $A$. Recall that this is a variety $\mathrm{SB}_{X}(A)$ whose $\mathbb{C}$-points are pairs $(x, J)$, where $x \in X, J \subset A_{x}$ is a minimal left ideal of $A_{x}$. It is closed subvariety in the total space of the bundle over $X$ whose fiber over $x \in X$ is $\operatorname{Gr}\left(k, A_{x}\right)$, where $k=\sqrt{\operatorname{dim} A_{x}}$ (note that this bundle is locally trivial in the Zariski topology). $\mathrm{So}_{\mathrm{SB}_{X}}(A)$ comes with a natural projection $p: \mathrm{SB}_{X}(A) \rightarrow X$ and with the tautological vector bundle $\mathcal{J}$ whose fiber over a point $(x, J)$ is $J$.

Since $J$ is an $A_{x}$-module, we see that $\mathcal{J}$ is a module over the Azumaya algebra $p^{*} A$. Since $\operatorname{rk} J=\sqrt{\operatorname{rk} A}$, we see that $p^{*} A$ splits: $p^{*} A=\mathcal{E} n d_{\mathcal{O}}(\mathcal{J})$, here we write $\mathcal{O}$ for the structure sheaf of $\mathrm{SB}_{X}(A)$. Also, $p: \mathrm{SB}_{X}(A) \rightarrow X$ is a projective bundle (that is locally trivial in the étale topology). In particular, $\mathrm{SB}_{X}(A)$ is smooth.

Now if $G$ is an algebraic group acting on $X$ and $A$ is $G$-equivariant, then we have a natural action of $G$ on $\mathrm{SB}_{X}(A), p$ is $G$-equivariant and $\mathcal{J}$ is a $G$-equivariant vector bundle on $\mathrm{SB}_{X}(A)$.

Proof of Proposition 2.6. To simplify the notation, let us write $S$ for $\mathrm{SB}_{X}(A)$. It is wellknown that $K_{0}(\operatorname{Coh}(X, A))$ splits as a direct summand of $K_{0}(\operatorname{Coh}(S))$, Pa1, Remark 3.3,Examples 3.6(c)], Pa 2 .

Let us recall how this works. Let us produce maps $\alpha: K_{0}(\operatorname{Coh}(X, A)) \rightleftarrows K_{0}(\operatorname{Coh}(S)): \beta$ with $\beta \circ \alpha=$ id. Namely, $\alpha$ is induced by the (exact) functor $\mathcal{F} \mapsto \mathcal{J}^{*} \otimes_{p^{*} A} p^{*} \mathcal{F}: \operatorname{Coh}(X, A) \rightarrow$
$\operatorname{Coh}(S)$, while $\beta$ is induced by $\mathcal{G} \mapsto R p_{*}\left(\mathcal{J} \otimes_{\mathcal{O}_{S}} \mathcal{G}\right): D^{b}(\operatorname{Coh}(S)) \rightarrow D^{b}(\operatorname{Coh}(X, A))$. Now observe that the composition $D^{b}(\operatorname{Coh}(X, A)) \rightarrow D^{b}(\operatorname{Coh}(S)) \rightarrow D^{b}(\operatorname{Coh}(X, A))$ is isomorphic to the identity functor. Indeed, since $p^{*} A=\mathcal{J} \otimes_{\mathcal{O}_{S}} \mathcal{J}^{*}$, the composition is

$$
R p_{*}\left(\mathcal{J} \otimes_{\mathcal{O}_{S}} \mathcal{J}^{*} \otimes_{p^{*} A} p^{*}(\bullet)\right)=R p_{*}\left(p^{*}(\bullet)\right)=R p_{*}\left(p^{*} \mathcal{O}_{X}\right) \otimes_{\mathcal{O}_{X}}^{L} \bullet
$$

where the last equality is the projection formula. Of course, $p^{*} \mathcal{O}_{X}=\mathcal{O}_{S}$. Since $p: S \rightarrow X$ is a projective bundle, we see that $R p_{*}\left(\mathcal{O}_{S}\right)=\mathcal{O}_{X}$. This proves that $\beta \circ \alpha=\mathrm{id}$.

Similarly, we have maps $\alpha_{G}: K_{0}\left(\operatorname{Coh}^{G}(X, A)\right) \rightleftarrows K_{0}\left(\operatorname{Coh}^{G}(S)\right): \beta_{G}$ with $\beta_{G} \circ \alpha_{G}=$ id. Note that the forgetful maps $K_{0}\left(\operatorname{Coh}^{G}(X, A)\right) \rightarrow K_{0}(\operatorname{Coh}(X, A))$ and $K_{0}\left(\operatorname{Coh}^{G}(S)\right) \rightarrow$ $K_{0}(\operatorname{Coh}(S))$ intertwine $\alpha_{G}$ with $\alpha$ and $\beta_{G}$ with $\beta$. The forgetful map $K_{0}\left(\operatorname{Coh}^{G}(S)\right) \rightarrow$ $K_{0}(\operatorname{Coh}(S))$ is surjective as was explained after the statement of the proposition. Being a retraction of a surjective map, the forgetful map $K_{0}\left(\operatorname{Coh}^{G}(X, A)\right) \rightarrow K_{0}(\operatorname{Coh}(X, A))$ is surjective as well.

### 2.5. Completion of the proof. Let us finish the proof.

Proof of Theorem 2.1. We have the following commutative diagram, where the vertical maps $F_{G / H}, F_{G}$ are the forgetful ones.

First, let us show that $F_{G}: K_{0}\left(\operatorname{Coh}^{G}\left(G, \pi^{*} A\right)\right) \rightarrow K_{0}\left(\operatorname{Coh}\left(G, \pi^{*} A\right)\right)$ is an isomorphism. Indeed, since $\pi^{*} A$ splits in a $G$-equivariant way - i.e., it is the endomorphism sheaf of a $G$-equivariant vector bundle, we reduce to showing that the forgetful map $K_{0}\left(\operatorname{Coh}^{G}(G)\right) \rightarrow$ $K_{0}(\operatorname{Coh}(G))$ is an isomorphism. This was established after Proposition 2.6. The isomorphism sends the class of any vector bundle to its rank. So $F_{G}$ is an isomorphism as well.

By Proposition 2.6, $F_{G / H}$ is surjective. So the image of $K_{0}(\operatorname{Coh}(G / H, A))$ in $K_{0}\left(\operatorname{Coh}\left(G, \pi^{*} A\right)\right)=$ $\mathbb{Z}$ coincides with the image of $K_{0}\left(\operatorname{Rep}^{\psi}(H)\right)$ in $K_{0}\left(\operatorname{Coh}^{G}\left(G, \pi^{*} A\right)\right)=\mathbb{Z}$. The latter is $d(\psi) \mathbb{Z}$ by Proposition 2.5. The former is $\operatorname{ind}(A) \mathbb{Z}$ by Proposition [2.4. The equality ind $(A)=d(\psi)$ follows.
2.6. Examples of computations of $d_{V}$. Let us provide two examples that will be relevant for what follows.

Example 2.7. Let $H$ be an algebraic group with reductive part $\mathrm{SO}_{2 n+1}$ and $V$ be the spinor representation (of dimension $2^{n}$ ) of $\mathrm{SO}_{2 n+1}$ (hence of $H$ ), which is the irreducible $\mathfrak{h}$-module with highest weight $\omega_{n}=\frac{1}{2}\left(\epsilon_{1}+\ldots+\epsilon_{n}\right)$ (in the standard notation). We claim that the dimension of any $H$-module with the same Schur multiplier is divisible by $2^{n}$ (and so $d_{V}=2^{n}$ ). This is equivalent to saying that the dimension of any irreducible $\mathfrak{h}$-module $V(\lambda)$ such that $\lambda-\omega_{n}$ is in the root lattice is divisible by $2^{n}$. This will follow if we check that the cardinalities of the Weyl group orbits of dominant weights $\lambda^{\prime}$ with $\lambda^{\prime}-\omega_{n}$ in the root lattice are divisible by $2^{n}$. We have $\lambda^{\prime}=\sum_{i=1}^{n}\left(m_{i}+\frac{1}{2}\right) \epsilon_{i}$, where $m_{1} \geqslant m_{2} \geqslant \ldots \ldots m_{n} \geqslant 0$ are integers. The stabilizer $W_{\lambda^{\prime}}$ is included into $S_{n} \subset W$ so $\left|W \lambda^{\prime}\right|$ is indeed divisible by $|W| /\left|S_{n}\right|=2^{n}$.

Example 2.8. Now let the reductive part be $\mathrm{SO}_{2 n}$ and $V$ be one of the half-spinor representations (of dimension $2^{n-1}$ ). Similarly to the previous example, we see that $d_{V}=2^{n-1}$.

Note that, in general, it is not true that $d_{V}=\operatorname{dim} V$ for a minuscule representation of $\mathfrak{h}$. For example, for $\mathfrak{h}=\mathfrak{s l}_{n}$, the dimension of $S^{2}\left(\mathbb{C}^{n}\right)$ is not divisible by that of the corresponding minuscule representation $\Lambda^{2}\left(\mathbb{C}^{n}\right)$.

## 3. Inequality on Goldie ranks

3.1. W-algebras. Let us recall some results about W-algebras, see [Pr1, L2].

Let $G$ be a simply connected semisimple algebraic group, $\mathfrak{g}$ its Lie algebra, $\mathbb{O} \subset \mathfrak{g}$ a nilpotent orbit, $e \in \mathbb{O}$. We will write $Q$ for $Z_{G}(e, h, f)$.

Pick an $\mathfrak{s l}_{2}$-triple $(e, h, f)$. Set $S=e+\mathfrak{z}_{\mathfrak{g}}(f)$, this is a transverse slice to $\mathbb{O}$. The group $Q$ naturally acts on $S$. Also we have a $\mathbb{C}^{\times}$-action on $S$. Namely, we introduce a grading on $\mathfrak{g}, \mathfrak{g}=\bigoplus_{i} \mathfrak{g}(i)$ by eigenvalues of $[h, \cdot]$. We define a $\mathbb{C}^{\times}$-action on $\mathfrak{g}$ by $t . x:=t^{i-2} x$ for $x \in \mathfrak{g}(i)$. Clearly, the action fixes $S$ giving rise to a grading on $\mathbb{C}[S]$. The algebra $\mathbb{C}[S]$ admits a Poisson bracket of degree -2 , see, e.g., [GG, Section 3].

A finite W -algebra $\mathcal{W}$ as constructed by Premet in [Pr1] (see also [L1] for an equivalent alternative definition) is a filtered quantization of the graded Poisson algebra $\mathbb{C}[S]$, i.e., $\mathcal{W}$ is a $\mathbb{Z}_{\geqslant 0}$-filtered associative algebra and we have an isomorphism $\operatorname{gr} \mathcal{W} \cong \mathbb{C}[S]$ of graded Poisson algebras. The group $Q$ acts on $\mathcal{W}$ by filtered algebra automorphisms and this action is Hamiltonian: we have a $Q$-equivariant inclusion $\mathfrak{q} \hookrightarrow \mathcal{W}$ such that the adjoint action of $\mathfrak{q}$ on $\mathcal{W}$ coincides with the differential of the $Q$-action.

In what follows we will need an isomorphism of completions from [L1, L2] that connects $\mathcal{U}$ and $\mathcal{W}$. Namely, consider the Rees algebra $\mathcal{U}_{\hbar}$ of $\mathcal{U}$ with $\operatorname{deg} \mathfrak{g}=2$. Let $\chi \in \mathfrak{g}^{*}$ be the image of $e$ under the isomorphism $\mathfrak{g} \cong \mathfrak{g}^{*}$ coming from the Killing form. The element $\chi$ gives rise to the composed homomorphism $\mathcal{U}_{\hbar} \rightarrow \mathbb{C}\left[\mathfrak{g}^{*}\right] \rightarrow \mathbb{C}$ that we also denote by $\chi$. Consider the completion $\mathcal{U}_{\hbar}^{\wedge \chi}:=\lim _{n \rightarrow \infty} \mathcal{U}_{\hbar} /(\operatorname{ker} \chi)^{n}$. This is a complete and separated topological $\mathbb{C}[[\hbar]]-$ algebra that is flat over $\mathbb{C}[[\hbar]]$. Note that it carries an action of $H$ by algebra automorphisms and this action is Hamiltonian in the sense that the differential of the $H$-action coincides with the map $x \mapsto \hbar^{-2}[x, \cdot]: \mathfrak{h} \rightarrow \operatorname{Der}\left(\mathcal{U}_{\hbar}^{\wedge \chi}\right)$. There is also a $\mathbb{C}^{\times}$-action on $\mathcal{U}_{\hbar}^{\wedge \chi}$ coming from the grading on $\mathfrak{g}$ with $\operatorname{deg} \mathfrak{g}(i)=i+2$.

Then, see, e.g., [L2, Section 2.3], there is a $Q \times \mathbb{C}^{\times}$-equivariant decomposition

$$
\begin{equation*}
\mathcal{U}_{\hbar}^{\wedge x} \cong \mathbb{A}_{\hbar}^{\wedge 0} \widehat{\otimes}_{\mathbb{C}[\hbar \hbar]]} \mathcal{W}_{\hbar}^{\wedge}, \tag{1}
\end{equation*}
$$

where the notation is as follows. We consider the vector space $[\mathfrak{g}, f]$. This space is symplectic with form $\omega\left(v_{1}, v_{2}\right):=\left\langle\chi,\left[v_{1}, v_{2}\right]\right\rangle$ so we can form its Weyl algebra $\mathbb{A}$. Let $\mathbb{A}_{\hbar}$ denote the Rees algebra of $\mathbb{A}$, and let $\mathbb{A}_{\hbar}^{\wedge_{0}}$ be the completion of $\mathbb{A}_{\hbar}$ at 0 . Similarly, $\mathcal{W}_{\hbar}$ is the Rees algebra of $\mathcal{W}$ and $\mathcal{W}_{\hbar}^{\wedge}$ is the completion of the former. The action of $Q \times \mathbb{C}^{\times}$on the right hand side of (11) is diagonal, we will not need a precise description of the action on $\mathbb{A}_{\hbar}^{\wedge_{0}}$.
 Namely, let $\mathcal{J}$ be a two-sided ideal in $\mathcal{U}$. We can consider the corresponding Rees ideal $\mathcal{J}_{\hbar}$ in $\mathcal{U}_{\hbar}$ and its closure $\mathcal{J}_{\hbar}^{\wedge}$ in $\mathcal{U}_{\hbar}^{\wedge}{ }^{\wedge}$. Then there is a unique two-sided ideal $\mathcal{J}_{\dagger} \subset \mathcal{W}$ such that

$$
\mathcal{J}_{\hbar}^{\wedge \chi} \cong \mathbb{A}_{\hbar}^{\wedge} 0 \widehat{\otimes}_{\mathbb{C}[\hbar \hbar]} \mathcal{J}_{\dagger, \hbar}^{\wedge \chi},
$$

see, e.g., [L1, Section 3.4] or [L2, Proposition 3.3.1]. If $\overline{\mathbb{O}}$ is an irreducible component of the associated variety of $\mathcal{J}$, then $\mathcal{J}_{\dagger}$ has finite codimension. If $\mathcal{J}$ is, in addition, primitive, then $\mathcal{J}_{\dagger}$ is a maximal $Q$-stable ideal of finite codimension in $\mathcal{W}$. Such ideals are in a natural
one-to-one correspondence with the $\Gamma$-orbits in $\operatorname{Irr}_{\text {fin }}(\mathcal{W})$. This gives rise to a bijection $\operatorname{Prim}_{\mathscr{O}}(\mathcal{U}) \xrightarrow{\sim} \operatorname{Irr}_{f i n}(\mathcal{W}) / \Gamma$ mentioned in the introduction.

Conversely, to a two-sided ideal $\mathcal{I} \subset \mathcal{W}$ we can assign a two-sided ideal $\mathcal{I}^{\dagger} \subset \mathcal{U}$ : the maximal two-sided ideal in $\mathcal{U}$ with the property that $\left(\mathcal{I}^{\dagger}\right)_{\dagger} \subset \mathcal{I}$, see [L1, Section 3.4].
3.2. Jet bundles. Here we will explain various constructions of jet bundles to be used in the construction of the sheaf of algebras $\mathcal{A}_{\hbar}$ on $G / H$ in the next section. Here the meaning of $H$ is the same as in the introduction: $H$ is a finite index subgroup of $Z_{G}(e)$.

Below for an algebraic variety $X$ we write $\mathcal{O}_{X}$ for its sheaf of regular functions and $\mathbb{C}[X]$ for its global sections.

Let us start with the usual jet bundle $\mathrm{J}^{\infty} \mathcal{O}_{X}$ of a smooth algebraic variety $X$. Let $\mathcal{I}_{\Delta} \subset$ $\mathcal{O}_{X \times X}$ be the sheaf of ideals of the diagonal in $X \times X$. Then, by definition, $\mathrm{J}^{\infty} \mathcal{O}_{X}$ is the formal completion of $\mathcal{O}_{X \times X}$ with respect to $\mathcal{I}_{\Delta}$. We view $J^{\infty} \mathcal{O}_{X}$ as a sheaf on $X$ via pushforward with respect to the projection $p_{1}: X \times X \rightarrow X$ to the first copy. This sheaf is pro-coherent (the inverse limit of coherent sheaves), namely, $\mathrm{J}^{\infty} \mathcal{O}_{X}=\lim _{\leftarrow} p_{1 *}\left(\mathcal{O}_{X \times X} / I_{\Delta}^{n}\right)$. Note that the fiber of $J^{\infty} \mathcal{O}_{X}$ over $x \in X$ is the formal completion of the stalk $\mathcal{O}_{X, x}$. The tangent sheaf of Lie algebras $T_{X}$ acts on $\mathcal{O}_{X \times X}$ via differentiation in the first copy. This gives rise to a flat connection on $\mathrm{J}^{\infty} \mathcal{O}_{X}$. The sheaf of flat sections $\left(J^{\infty} \mathcal{O}_{X}\right)^{\nabla}$ is identified with $\mathcal{O}_{X}$ : it sits inside $\mathrm{J}^{\infty} \mathcal{O}_{X}$ as $p_{2}^{*} \mathcal{O}_{X}$, where $p_{2}: X \times X \rightarrow X$ is the projection to the second copy. This construction trivially extends to the jet bundle $\mathrm{J}^{\infty} A$ of an Azumaya algebra $A$ on $X$ : we complete the sheaf $\mathcal{O}_{X} \otimes A$ on $X \times X$ and push the completion to the first copy of $X$. By the construction, we have a homomorphism of sheaves of algebras with flat connection $\mathrm{J}^{\infty} \mathcal{O}_{X} \rightarrow \mathrm{~J}^{\infty} A$.

Now suppose that $X$ is a symplectic variety that comes with a Hamiltonian action of $G$. We are going to define a pro-coherent sheaf $\mathrm{J}^{\infty} \mathcal{U}_{\hbar, X}$ on $X$ whose fiber at $x \in X$ is the completion of $\mathcal{U}_{\hbar}$ at $\mu(x)$, where $\mu: X \rightarrow \mathfrak{g}^{*}$ is the moment map. Namely, note that we have a $G$-equivariant homomorphism of sheaves $\mathcal{O}_{X} \otimes \mathfrak{g} \rightarrow \mathcal{O}_{X} \otimes \mathbb{C}[X], f \otimes \xi \mapsto f \otimes \mu^{*}(\xi)$. It extends to a homomorphism of sheaves of algebras $\mathcal{O}_{X} \otimes S(\mathfrak{g}) \rightarrow \mathcal{O}_{X} \otimes \mathbb{C}[X]$. The epimorphism $\mathcal{U}_{\hbar} \rightarrow S(\mathfrak{g})$ then gives rise to a homomorphism $\mathcal{O}_{X} \otimes \mathcal{U}_{\hbar} \rightarrow \mathcal{O}_{X} \otimes \mathbb{C}[X]$ of sheaves of algebras on $X$. Inside $\mathcal{O}_{X} \otimes \mathbb{C}[X]$ we have the ideal of the diagonal in $X \times X$, this ideal is generated by $f \otimes 1-1 \otimes f$ for $f \in \mathbb{C}[X]$. Let $\mathcal{I}_{\mu, \Delta} \subset \mathcal{O}_{X} \otimes \mathcal{U}_{\hbar}$ denote the pre-image of the ideal sheaf of the diagonal. We set $\mathrm{J}^{\infty} \mathcal{U}_{\hbar, X}:=\lim _{n \rightarrow \infty} \mathcal{O}_{X} \otimes \mathcal{U}_{\hbar} / \mathcal{I}_{\mu, \Delta}^{n}$. This sheaf again carries a natural flat connection $\nabla$ extended by continuity from the trivial connection on $\mathcal{O}_{X} \otimes \mathcal{U}_{\hbar}$. Note that $\nabla$ satisfies the following identity, where $\xi_{X}$ stands for the velocity vector field induced by $\xi \in \mathfrak{g}$ :

$$
\begin{equation*}
\nabla_{\xi_{X}}=\xi_{\lrcorner \propto \mathcal{U}_{\hbar}}-\frac{1}{\hbar^{2}}[\xi, \bullet] . \tag{2}
\end{equation*}
$$

On the right hand side, the notation is as follows. We write $\xi_{\lrcorner \propto \mathcal{U}_{\hbar}}$ for the derivative of the $G$-equivariant sheaf $J^{\infty} \mathcal{U}_{\hbar}$ induced by $\xi$. In the bracket $\xi$ is viewed as an element of $\mathcal{U}_{\hbar} \hookrightarrow \mathcal{O}_{X} \otimes \mathcal{U}_{\hbar}$. The reason why (22) holds is that it holds on $\mathcal{O}_{X} \otimes \mathcal{U}_{\hbar}$ - there (2) just says that the action of $\mathfrak{g}$ on $\mathcal{O}_{X} \otimes \mathcal{U}_{\hbar}$ is diagonal - and then extends to $J^{\infty} \mathcal{U}_{\hbar}$ by continuity.

Note that we have a homomorphism of sheaves with flat connections $\mathcal{O}_{X} \otimes \mathbb{C}[X]=$ $p_{1 *} \mathcal{O}_{X \times X} \rightarrow \mathrm{~J}^{\infty} \mathcal{O}_{X}$. This gives rise to a homomorphism $\mathcal{O}_{X} \otimes \mathcal{U}_{\hbar} \rightarrow \mathrm{J}^{\infty} \mathcal{O}_{X}$ (that sends $\hbar$ to 0 ). This homomorphism is continuous and is compatible with flat connections. So it lifts to a homomorphism of sheaves of algebras with flat connections $\mathrm{J}^{\infty} \mathcal{U}_{\hbar, X} \rightarrow \mathrm{~J}^{\infty} \mathcal{O}_{X}$. Note
that $J^{\infty} \mathcal{U}_{\hbar, X} \rightarrow J^{\infty} \mathcal{O}_{X}$ when $X$ is a homogeneous $G$-space. This is because the homomorphism $\mathcal{O}_{X} \otimes \mathfrak{g} \rightarrow T_{X}$ induced by the action of $G$ is surjective. We also observe that the fiber of $\mathrm{J}^{\infty} \mathcal{U}_{\hbar}$ at $x \in X$ is the completion $\mathcal{U}_{\hbar}^{{ }^{\mu(x)}}$.

We will apply these constructions in the case when $X=G / H$, where $H$ is a finite index subgroup of $Z_{G}(e)$. Here $\mathrm{J}^{\infty} \mathcal{U}_{\hbar}$ is the $G$-homogeneous pro-vector bundle whose fiber at $1 H$ is $\mathcal{U}_{\hbar}^{\wedge x}$.
3.3. Sheaves $\mathfrak{A}_{\hbar}, \mathcal{A}_{\hbar}$. Let us make a remark regarding finite dimensional representations of $\mathcal{W}$. Let $V$ be a finite dimensional $\mathcal{W}$-module that also comes with a projective representation of a finite index subgroup $Q_{V} \subset Q$ whose differential is the linear representation of $\mathfrak{q}$ that comes from restricting the $\mathcal{W}$-action to $\mathfrak{q}$. Let $H$ be the preimage of $Q_{V}$ in $Z_{G}(e)$.

Take the trivial filtration on $V$ and form the Rees $\mathbb{C}[\hbar]$-module $V_{\hbar}$ and its completion $V_{\hbar}^{\wedge_{0}}$. Then $\underline{\mathcal{A}}_{\hbar}^{\wedge_{0}}:=\operatorname{End}_{\mathbb{C}[\hbar \hbar]]}\left(V_{\hbar}^{\wedge_{0}}\right)$ is an algebra that comes with a $Q_{V} \times \mathbb{C}^{\times}$-action by automorphisms and with a $Q_{V} \times \mathbb{C}^{\times}$-equivariant $\mathbb{C}[[\hbar]]$-algebra homomorphism $\mathcal{W}_{\hbar}^{\wedge \chi} \rightarrow \underline{\mathcal{A}}_{\hbar}^{\wedge^{0}}$. Set $\mathcal{A}_{\hbar}^{\wedge \chi}:=\mathbb{A}_{\hbar}^{\wedge_{0}} \widehat{\otimes}_{\mathbb{C}[\hbar]]} \mathcal{A}_{\hbar}^{\wedge_{0}}$. This algebra carries a $Q_{V} \times \mathbb{C}^{\times}$-action by automorphisms and, thanks to (1), comes with a $Q_{V} \times \mathbb{C}^{\times}$-equivariant $\mathbb{C}[[\hbar]]$-algebra homomorphism $\mathcal{U}_{\hbar}^{\wedge \chi} \rightarrow \mathcal{A}_{\hbar}^{\wedge \chi}$. This homomorphism allows to extend a $Q_{V}$-action on $\mathcal{A}_{\hbar}^{\wedge x}$ to an $H$-action because the action of $H$ on $\mathcal{U}_{\hbar}^{\wedge \chi}$ is Hamiltonian.

So we can form a $G$-homogeneous pro-vector bundle $\mathfrak{A}_{\hbar}$ on $G / H$ with fiber $\mathcal{A}_{\hbar}^{\wedge}$. It comes with a flat connection $\nabla$ given by a formula similar to (2), namely:

$$
\begin{equation*}
\nabla_{\xi_{X}}=\xi_{\mathfrak{A}_{\hbar}}-\frac{1}{\hbar^{2}}[\xi, \bullet] . \tag{3}
\end{equation*}
$$

So we get a $G \times \mathbb{C}^{\times}$-equivariant homomorphism of $\mathbb{C}[[\hbar]]$-algebras $\mathrm{J}^{\infty} \mathcal{U}_{\hbar} \rightarrow \mathfrak{A}_{\hbar}$ that intertwines the flat connections.

Now let us describe the bundle $\mathfrak{A}_{\hbar} /(\hbar)$ with a flat connection. Consider the equivariant Azumaya algebra $A:=G \times{ }^{H} \underline{A}$, where $\underline{A}:=\underline{\mathcal{A}}_{\hbar}^{\wedge_{0}} /(\hbar)(=\operatorname{End}(V))$.
Lemma 3.1. The sheaf of algebras $\mathfrak{A}:=\mathfrak{A}_{\hbar} /(\hbar)$ with a flat connection is isomorphic to $J^{\infty} A$.

Proof. We start by obtaining a formula for the connection on $\mathfrak{A}$. Note that we have a bracket map $Z(\mathfrak{A}) \otimes \mathfrak{A} \rightarrow \mathfrak{A}$ thanks to the presence of the deformation $\mathfrak{A}_{\hbar}$. Here we write $Z(\mathfrak{A})$ for the center of $\mathfrak{A}$, of course, this is $J^{\infty} \mathcal{O}_{X}$.

Since we take the trivial filtration on $V$, we see that the algebra homomorphism $\mathbb{C}[S]^{\wedge} \chi \rightarrow$ $\underline{A}$ factors through the residue field of $\mathbb{C}[S]^{\wedge}$. Therefore the image of $J^{\infty} S(\mathfrak{g}) \rightarrow \mathfrak{A}$ lies in the center of $\mathfrak{A}$ and, in particular, the subalgebra of flat sections, $S(\mathfrak{g}) \subset J^{\infty} S(\mathfrak{g})$ lies in $Z(\mathfrak{A})$. Because of this we get the bracket map $\mathfrak{g} \otimes \mathfrak{A} \rightarrow \mathfrak{A}$. Considering (3) modulo $\hbar$, we see that the connection on $\mathfrak{A}$ is also given by

$$
\begin{equation*}
\nabla_{\xi_{X}}=\xi_{\mathfrak{A}}-\{\xi, \bullet\} \tag{4}
\end{equation*}
$$

Set $T:=[\mathfrak{g}, f]$, recall that this is a symplectic vector space. It is identified with the tangent space $T_{1 H}(G / H)$. Now we observe that $\mathfrak{A}$ is the homogeneous sheaf of algebras $G \times{ }^{H}(\mathbb{C}[[T]] \otimes \underline{A})$ on $G / H$, where the action of $H$ on $\mathbb{C}[[T]] \otimes \underline{A}$ is diagonal with the natural action on $\mathbb{C}[[T]]$ coming from the identification $T=T_{1 H}(G / H)$ and the action on $\underline{A}$ that factors through the natural action of the quotient $Q_{V}$ of $H$.

Now we observe that the sheaf of algebras with a flat connection $\mathrm{J}^{\infty} A$ has the same description. Namely, $J^{\infty} A$ is the homogeneous vector bundle of algebras with fiber $A^{\wedge_{1 H}}$ at $1 H \in G / H$. This fiber $H$-equivariantly identifies with $\mathbb{C}[[T]] \otimes \underline{A}$ : we have an embedding
$\mathbb{C}[[T]] \hookrightarrow A^{\wedge_{1 H}}$ coming from $\mathrm{J}^{\infty} \mathcal{O}_{X} \hookrightarrow \mathrm{~J}^{\infty} \mathcal{A}$ and also an embedding $\underline{A} \hookrightarrow A^{\wedge_{1 H}}$, together they give rise to the required isomorphism $\mathbb{C}[[T]] \otimes \underline{A} \xrightarrow{\sim} A^{\wedge_{1 H}}$. So we get a $G$-equivariant sheaf of algebras isomorphism

$$
\begin{equation*}
\mathfrak{A} \xrightarrow{\sim} \mathrm{J}^{\infty} A . \tag{5}
\end{equation*}
$$

Now note that, by the construction, the flat connection on $J^{\infty} A$ satisfies

$$
\begin{equation*}
\nabla_{\xi_{X}}=\xi_{\lrcorner \infty_{A}}-\xi_{A} \tag{6}
\end{equation*}
$$

where we write $\xi_{A}$ for the derivation of $J^{\infty} A$ coming from the derivation in the second factor of $\mathcal{O}_{X} \boxtimes A$.

We claim that (5) intertwines the flat connections, which will finish the proof. Since the isomorphism is $G$-equivariant, it is enough to show that it intertwines $\{\xi, \bullet\}$ with $\xi_{A}$. Note that thanks to (4) and (6), both $\{\xi, \bullet\}, \xi_{A}$ are $\mathcal{O}_{G / H}$-linear. Thanks to the $G$-equivariance of both $\{\xi, \bullet\}, \xi_{A}$, it is enough to check that they coincide on the fiber at $1 H$, which is $A^{\wedge_{1 H}}$. On that fiber both maps are the derivatives induced by the $G$-equivariant structure on $A$.

So we see that $\mathfrak{A}_{\hbar}$ is a formal deformation of $\boldsymbol{J}^{\infty} A$. Set $\mathcal{A}_{\hbar}=\mathfrak{A}_{\hbar}^{\nabla}$, the sheaf of flat sections. This is a $G$-equivariant sheaf of $\mathbb{C}[[\hbar]]$-algebras on $G / H$ (but not a sheaf of $\mathcal{O}_{G / H}$-modules).
Proposition 3.2. The sheaf $\mathcal{A}_{\hbar}$ is a formal deformation on $A$.
Proof. Note that $\mathcal{A}_{\hbar}$ is a subsheaf in $\mathfrak{A}_{\hbar}$, hence it is flat over $\mathbb{C}[[\hbar]]$. The subsheaf $\mathcal{A}_{\hbar}$ is closed in the $\hbar$-adic topology. Hence it is complete and separated in the $\hbar$-adic topology. So we only need to check that $\mathcal{A}_{\hbar} /(\hbar)=A$. Note that, since taking the flat sections is a left exact functor, we have $\mathcal{A}_{\hbar} /(\hbar) \hookrightarrow A$.

Note that $\left(\mathcal{A}_{\hbar} /(\hbar)\right)^{\wedge_{1 H}}=\mathcal{A}_{\hbar}^{\wedge_{1 H}} /(\hbar)$. Since $\mathcal{A}_{\hbar}$ is $G$-equivariant, we have that $\mathcal{A}_{\hbar} /(\hbar) \hookrightarrow A$ is an isomorphism if and only if

$$
\begin{equation*}
\mathcal{A}_{\hbar}^{\wedge_{1 H}} /(\hbar) \xrightarrow{\sim} A^{\wedge_{1 H}} . \tag{7}
\end{equation*}
$$

Note that the right hand side is identified with $\mathbb{C}[[T]] \otimes \underline{A}$.
Now note that $\mathcal{U}_{\hbar}$ naturally maps to $\Gamma\left(\mathcal{A}_{\hbar}\right)$. This gives rise to a homomorphism $\mathcal{U}_{\hbar}^{\wedge \chi} \rightarrow$ $\mathcal{A}_{\hbar}^{\wedge_{1 H}}$. In particular, we get a homomorphism $\mathbb{A}_{\hbar}^{\wedge_{0}} \rightarrow \mathcal{A}_{\hbar}^{\wedge_{1 H}}$. It is injective and induces a decomposition $\mathcal{A}_{\hbar}^{\wedge_{1 H}} /(\hbar)=\mathbb{C}[[T]] \otimes \underline{A}^{\prime}$, where $\underline{A}^{\prime}$ is the quotient modulo $\hbar$ of the centralizer of $\mathbb{A}_{\hbar}^{\wedge_{0}}$ in $\mathcal{A}_{\hbar}^{\wedge_{1 H}}$.

Note that (77) is $\mathfrak{g}$-equivariant. The action of $\mathfrak{g}$ induces connections on the $\mathbb{C}[[T]]$-modules $\mathcal{A}_{\hbar}^{\wedge_{1 H}} /(\hbar), A^{\wedge 1 H}$ and (7) intertwines these connections. This reduces the proof of (7) to checking that $\operatorname{dim} \underline{A^{\prime}}=\operatorname{dim} \underline{A}$.

Note that the kernel of $\overline{\mathcal{U}_{\hbar}} \rightarrow \Gamma\left(\mathcal{A}_{\hbar}\right)$ is $\mathcal{J}_{\hbar}$. So the homomorphism $\mathcal{W}_{\hbar}^{\wedge}{ }^{\wedge} \rightarrow \mathcal{A}_{\hbar}^{\wedge_{1 H}}$ factors through $\mathcal{W}_{\hbar}^{\wedge \chi} / \mathcal{J}_{\dagger, \hbar}^{\wedge}$. . The latter is the direct sum of matrix algebras over $\mathbb{C}[[\hbar]]$, each of dimension $\operatorname{dim} \underline{A}$. This implies the equality $\operatorname{dim} \underline{A^{\prime}}=\operatorname{dim} \underline{A}$ and finishes the proof.
3.4. Inequality for Goldie ranks. The following proposition together with Theorem 2.1 prove Theorem 1.2.
Proposition 3.3. We have $\operatorname{Grk}(\mathcal{J}) \leqslant \operatorname{dim} V / \operatorname{ind}(A)$.
Proof. The algebra $\mathcal{U}_{\hbar} / \mathcal{J}_{\hbar}$ is prime and Noetherian, because $\mathcal{U} / \mathcal{J}$ is so. Note that the Goldie ranks of $\mathcal{U} / \mathcal{J}$ and $\mathcal{U}_{\hbar} / \mathcal{J}_{\hbar}$ coincide (because $\left.\left(\mathcal{U}_{\hbar} / \mathcal{J}_{\hbar}\right)\left[\hbar^{-1}\right]=(\mathcal{U} / \mathcal{J})\left[\hbar^{ \pm 1}\right]\right)$. For any affine open subset $U \subset G / H$, we have an inclusion $\mathcal{U}_{\hbar} / \mathcal{J}_{\hbar} \subset \Gamma\left(U, \mathcal{A}_{\hbar}\right)$. Further, $\Gamma\left(U, \mathcal{A}_{\hbar}\right) /(\hbar)=\Gamma(U, A)$. The algebra $\Gamma(U, A)$ is an Azumaya $\mathbb{C}[U]$-algebra hence is Noetherian and prime. The algebra $\Gamma\left(U, \mathcal{A}_{\hbar}\right)$ is a formal deformation of $\Gamma(U, A)$. Since $\Gamma(U, A)$ is a prime Noetherian algebra,
the algebra $\Gamma\left(U, \mathcal{A}_{\hbar}\right)$ is prime and Noetherian as well. Indeed, the usual argument that the algebra of formal power series over a Noetherian ring is Noetherian generalizes to show that $\Gamma\left(U, \mathcal{A}_{\hbar}\right)$ is Noetherian. Further, let $I_{\hbar}, J_{\hbar}$ be two-sided ideals in $\Gamma\left(U, \mathcal{A}_{\hbar}\right)$. Let $I, J$ be their images in $\Gamma(U, A)$. If $I_{\hbar} J_{\hbar}=\{0\}$, then $I J=\{0\}$. So one of $I, J$, say $I$ to be definite, is zero. It follows that $I_{\hbar} \subset \hbar \Gamma\left(U, \mathcal{A}_{\hbar}\right)$. Now we can replace $I_{\hbar}$ with $\hbar^{-1} I_{\hbar}$ and proceed in the same way. This shows $\Gamma\left(U, \mathcal{A}_{\hbar}\right)$ is prime.

By a result of Warfield, [W, Theorem 1], the inclusion $\mathcal{U}_{\hbar} / \mathcal{J}_{\hbar} \subset \Gamma\left(U, \mathcal{A}_{\hbar}\right)$ implies the inequality of Goldie ranks $\operatorname{Grk}\left(\mathcal{U}_{\hbar} / \mathcal{J}_{\hbar}\right) \leqslant \operatorname{Grk}\left(\Gamma\left(U, \mathcal{A}_{\hbar}\right)\right)$. So it remains to show that we can choose $U$ so that $\operatorname{Grk}\left(\Gamma\left(U, \mathcal{A}_{\hbar}\right)\right)=\operatorname{dim} V / \operatorname{ind}(A)$, which is the Goldie rank of $\Gamma(U, A)$.

We claim that we can pick $U$ in such a way that $\Gamma(U, A)=\operatorname{Mat}_{k}\left(D^{\prime}\right)$, where $D^{\prime}$ is a domain, and $k=\operatorname{dim} V / \operatorname{ind}(A)$. Indeed, for an arbitrary affine open subset $U$ we have $\mathbb{C}(U) \otimes_{\mathbb{C}[U]}$ $\Gamma(U, A)=\operatorname{Mat}_{k}(D)$ for a skew-field $D$ over $\mathbb{C}(U)$. The embedding $\operatorname{Mat}_{k}(\mathbb{C}) \hookrightarrow \mathbb{C}(U) \otimes_{\mathbb{C}[U]}$ $\Gamma(U, A)$ is defined over $\mathbb{C}\left[U_{1}\right]$ for some principal open affine subset $U_{1} \subset U$. Let $\epsilon$ denote the primitive idempotent in $\operatorname{Mat}_{k}(\mathbb{C})$. Then $D^{\prime}:=\epsilon \Gamma\left(U_{1}, A\right) \epsilon$ satisfies $\Gamma\left(U_{1}, A\right)=\operatorname{Mat}_{k}\left(D^{\prime}\right)$. Recall that $A$ is a vector bundle. So the natural map $\Gamma\left(U_{1}, A\right) \rightarrow \mathbb{C}\left(U_{1}\right) \otimes_{\mathbb{C}\left[U_{1}\right]} \Gamma\left(U_{1}, A\right)=$ $\operatorname{Mat}_{k}(D)$ is an inclusion. Hence $D^{\prime} \hookrightarrow D$. The latter is an algebra homomorphism, hence $D^{\prime}$ is a domain. It remains to replace $U$ with $U_{1}$.

Since $\Gamma\left(U, \mathcal{A}_{\hbar}\right)$ is a formal deformation of $\operatorname{Mat}_{k}\left(D^{\prime}\right)$, the inclusion $\operatorname{Mat}_{k}(\mathbb{C}) \hookrightarrow \operatorname{Mat}_{k}\left(D^{\prime}\right)$ lifts to $\operatorname{Mat}_{k}(\mathbb{C}) \hookrightarrow \Gamma\left(U, \mathcal{A}_{\hbar}\right)$. Indeed, we can lift the idempotent $\epsilon \in \Gamma\left(U_{1}, A\right)$ to an idempotent $\epsilon_{\hbar} \in \Gamma\left(U_{1}, \mathcal{A}_{\hbar}\right)$. The right $\epsilon_{\hbar} \Gamma\left(U_{1}, \mathcal{A}_{\hbar}\right) \epsilon_{\hbar}$-module $\Gamma\left(U_{1}, \mathcal{A}_{\hbar}\right) \epsilon_{\hbar}$ is free of rank $k$ because the $\epsilon \Gamma\left(U_{1}, A\right) \epsilon$-module $\Gamma\left(U_{1}, A\right) \epsilon$ is so. Also the algebra homomorphism

$$
\Gamma\left(U_{1}, \mathcal{A}_{\hbar}\right) \rightarrow \operatorname{End}_{\epsilon_{\hbar} \Gamma\left(U_{1}, \mathcal{A}_{\hbar}\right) \epsilon_{\hbar}}\left(\Gamma\left(U_{1}, \mathcal{A}_{\hbar}\right) \epsilon_{\hbar}\right)
$$

is an isomorphism because

$$
\Gamma\left(U_{1}, A\right) \rightarrow \operatorname{End}_{\epsilon \Gamma\left(U_{1}, A\right) \epsilon}\left(\Gamma\left(U_{1}, A\right) \epsilon\right)
$$

is an isomorphism.
The algebra $D_{\hbar}^{\prime}:=\epsilon_{\hbar} \Gamma\left(U, \mathcal{A}_{\hbar}\right) \epsilon_{\hbar}$ is the formal deformation of $D$. So $D_{\hbar}^{\prime}$ is a domain, $\Gamma\left(U, \mathcal{A}_{\hbar}\right)=\operatorname{Mat}_{k}\left(D_{\hbar}^{\prime}\right)$, and the Goldie rank of $\Gamma\left(U, \mathcal{A}_{\hbar}\right)$ equals $k$. This finishes the proof of $\operatorname{Grk}(\mathcal{J}) \leqslant \operatorname{dim} V / \operatorname{ind}(A)$.

## 4. Example of computation

Here we will use Theorem 1.2 to revisit an example of a completely prime primitive ideal in [Pr2] that corresponds to an irreducible representation of $\mathcal{W}$ with large dimension.
4.1. Main result. Let us start by recalling a classical theorem of Duflo.

Let us write $\mathfrak{t}$ for a Cartan subalgebra of $\mathfrak{g}$. For $\lambda \in \mathfrak{t}^{*}$ let $L(\lambda)$ denote the irreducible module in the usual BGG category $\mathcal{O}$ with highest weight $\lambda-\rho$, where $\rho$ is half the sum of the positive roots. Let $\mathcal{J}(\lambda)$ denote the annihilator of $L(\lambda)$ in $\mathcal{U}$. As Duflo proved, the ideals $\mathcal{J}(\lambda)$ exhaust the primitive ideals of $\mathcal{U}$.

Here is the main result of this section.
Let $\mathfrak{g}=\mathfrak{s p}_{2 n}$. We consider the primitive ideal $\mathcal{J}:=\mathcal{J}(\rho / 2)$ in $\mathcal{U}$. It follows from results of McGovern that $\operatorname{Grk}(\mathcal{J})=1$, McG]. By [Pr2, Remark 4.3], the dimension of the corresponding representation of $\mathcal{W}$ is bigger than 1 . We will independently show that the corresponding representation of $\mathcal{W}$ restricts to a spinor representation of $\mathfrak{q}$, hence the inequality in Theorem 1.2 becomes an equality. From here we will deduce the equality $\operatorname{Grk}(\mathcal{J})=1$.

Here is a complete statement.

Proposition 4.1. Let $\mathfrak{g}=\mathfrak{s p}_{2 n}$ with $n>2$. Set $\mathcal{J}=\mathcal{J}(\rho / 2)$. Then the following are true:
(1) For $n=2 m$, the $A$-orbit in $\operatorname{Irr}_{\text {fin }}(\mathcal{W})$ corresponding to $\mathcal{J}$ consists of 2 irreducible representations. Their restrictions to $\mathfrak{q}=\mathfrak{s o}_{n}$ are the (non-isomorphic) half-spinor representations.
(2) For $n=2 m+1$, the $A$-orbit in $\operatorname{Irr}_{\text {fin }}(\mathcal{W})$ corresponding to $\mathcal{J}$ consists a single irreducible representation. Its restriction to $\mathfrak{q}=\mathfrak{s o}_{n}$ is the spinor representation.
(3) $\operatorname{Grk}(\mathcal{J})=1$.
4.2. Category $\mathcal{O}$ for $\mathcal{W}$. Let $T_{Q} \subset Q$ denote the maximal torus and let $\nu: \mathbb{C}^{\times} \rightarrow Q$ be a one-parameter subgroup that is generic in the sense that its centralizer in $\mathfrak{g}$ coincides with the centralizer of $T_{Q}$. The one-parameter subgroup $\nu$ gives rise to the weight decomposition $\mathcal{W}=\bigoplus_{i \in \mathbb{Z}} \mathcal{W}_{i}$. Set $\mathcal{W}_{\geqslant 0}:=\bigoplus_{i \geqslant 0} \mathcal{W}_{i}, \mathcal{W}_{>0}:=\bigoplus_{i>0} \mathcal{W}_{i}, \mathrm{C}_{\nu}(\mathcal{W}):=\mathcal{W}_{\geqslant 0} /\left(\mathcal{W}_{\geqslant 0} \cap \mathcal{W}^{( } \mathcal{W}_{>0}\right)$.

Following [BGK], define the category $\mathcal{O}_{\nu}(\mathcal{W})$ as the full subcategory in the category of finitely generated $\mathcal{W}$-modules consisting of all modules $M$ such that
(1) $M$ admits a weight decomposition with respect to $\mathfrak{t}_{Q}: M=\bigoplus_{\alpha \in \mathrm{t}^{*}} M_{\alpha}$, where $M_{\alpha}:=$ $\{m \in M \mid x m=\langle\alpha, x\rangle m\}$.
(2) $\mathcal{W}_{>0}$ acts on $M$ locally nilpotently.

In particular, any finite dimensional irreducible $\mathcal{W}$-module lies in $\mathcal{O}$. We remark that, modulo (1), (2) can be shown to be equivalent to the condition that the real numbers $\operatorname{Re}\langle\alpha, \nu\rangle$ are bounded from above.

Note that for $M \in \mathcal{W}$-mod, the annihilator $M^{\mathcal{W}>0}$ is $\mathcal{W}_{\geqslant 0}$-stable and the action of $\mathcal{W}_{\geqslant 0}$ on $M^{\mathcal{W}>0}$ factors through $\mathrm{C}_{\nu}(\mathcal{W})$. It turns out that if $M$ is simple in $\mathcal{O}_{\nu}(\mathcal{W})$, then $M^{\mathrm{C}_{\nu}(\mathcal{W})}$ is a simple $\mathrm{C}_{\nu}(\mathcal{W})$-module. The assignment $M \mapsto M^{\mathcal{W}>0}$ is a bijection between the simples in $\mathcal{O}_{\nu}(\mathcal{W})$ and the simple $\mathrm{C}_{\nu}(\mathcal{W})$-modules. For an irreducible $\mathrm{C}_{\nu}(\mathcal{W})$-module $N$, we write $L_{\nu}(N)$ for the corresponding simple object in $\mathcal{O}_{\nu}(\mathcal{W})$.

The structure of the algebra $\mathrm{C}_{\nu}(\mathcal{W})$ was determined in [BGK], see also [L4]. Let $\mathfrak{g}$ denote the centralizer of $\nu$ in $\mathfrak{g}$, note that $e \in \underline{\mathfrak{g}}$. Let $\underline{\mathcal{U}}$ denote $U(\underline{\mathfrak{g}})$ and $\underline{\mathcal{W}}$ denote the W -algebra for $(\mathfrak{g}, e)$. Then there is an isomorphism $\mathrm{C}_{\nu}(\mathcal{W}) \xrightarrow{\sim} \underline{\mathcal{W}}$, see BGK, Section 4]. This isomorphism is $T_{Q^{-}}$-equivariant but it does not intertwine the quantum comoment maps $\mathfrak{t}_{Q} \rightarrow \mathrm{C}_{\nu}(\mathcal{W}), \underline{\mathcal{W}}$. Rather it induces a shift by a character $\delta$ that we define now. Pick a Cartan subalgebra $\overline{\mathfrak{t}} \subset \mathfrak{g}$ that contains $\mathfrak{t}_{Q}$ and $h$. Let $\Delta \subset \overline{\mathfrak{t}}^{*}$ be the root system. Set $\Delta^{-}:=\{\beta \in \Delta \mid\langle\beta, \nu\rangle<0\}$. We set

$$
\begin{equation*}
\delta=\frac{1}{2} \sum_{\alpha \in \Delta^{-},\langle\alpha, h\rangle=-1} \alpha+\sum_{\alpha \in \Delta^{-},\langle\alpha, h\rangle \leqslant-2} \alpha . \tag{8}
\end{equation*}
$$

Then the isomorphism $\mathrm{C}_{\nu}(\mathcal{W}) \xrightarrow{\sim} \underline{\mathcal{W}}$ restricts to $x \mapsto x-\langle\delta, x\rangle$ on $\mathfrak{t}_{Q}$.
Now pick a finite dimensional irreducible $\mathcal{W}$-module $V$. It lies in $\mathcal{O}_{\nu}(\mathcal{W})$ and so there is a unique finite dimensional irreducible module $\underline{\mathcal{W}}$-module $\underline{V}$ with $V=L_{\nu}(\underline{V})$. Let $\underline{V}$ correspond to the primitive ideal $\underline{\mathcal{J}}(\lambda) \subset \underline{\mathcal{U}}$ (annihilating the irreducible $\underline{\mathfrak{g}}$-module with highest weight $\lambda-\rho)$. It was shown in [L3, Theorem 5.1.1] that the primitive ideal in $\mathcal{U}$ corresponding to $V$ is $\mathcal{J}(\lambda)$.

While we cannot read the Schur multiplier for the $Q_{V}$-action on $V$ from $\underline{V}$, we can recover that for the $Q^{\circ}$-action. Namely, $\mathfrak{t}_{Q}$ embeds into the center of $\underline{\mathcal{W}}$. The action of $\mathfrak{t}_{Q}$ on $\underline{V}$ under this embedding is by $\left.(\lambda-\rho)\right|_{\mathfrak{t}_{Q}}$. Therefore the action of $\mathfrak{t}_{Q}$ on $\underline{V}=V^{\mathcal{W}>0}$ via the embedding $\mathfrak{t}_{Q} \hookrightarrow \mathcal{W}$ is via

$$
\begin{equation*}
\left.(\lambda-\rho-\delta)\right|_{\mathrm{t}_{Q}} . \tag{9}
\end{equation*}
$$

It follows that the weights of $\mathfrak{t}_{Q}$ in $V$ are congruent to $\left.(\lambda-\delta)\right|_{\mathfrak{t}_{Q}}$. This allows to recover the Schur multiplier for the projective action of $Q^{\circ}$ on $V$.
4.3. Proof of Proposition 4.1. Let $\mathfrak{g}=\mathfrak{s p}_{2 n}$. We consider the orbit $\mathbb{O}$ corresponding to the partition $\left(2^{n}\right)$ (where the superscript indicates the multiplicity). The group $Q$ is $\mathrm{O}_{n}$. It is easy to see that the codimension of $\mathbb{O}$ in $\mathfrak{g}$ is $n^{2}$.

Proof. The proof is in several steps.
Step 1. It is easy to see that $\operatorname{dim} V(\mathcal{J})=\operatorname{dim} \mathbb{O}$. Indeed, the integral Weyl group for $\rho / 2$ has type $B_{\lfloor n / 2\rfloor} \times D_{\lceil n / 2\rceil}$. For the integral root system, $\rho / 2$ is dominant (and, of course, integral). By [J, Corollary 3.5], this implies that $\operatorname{dim} V(\mathcal{J})=\operatorname{dim} \mathfrak{g}-\operatorname{dim} \mathfrak{g}_{\text {int }}^{\vee}$, where $\mathfrak{g}_{\text {int }}^{\vee}$ stands for the integral subalgebra for $\rho / 2$ in $\mathfrak{g}^{\vee}=\mathfrak{s o}_{2 n+1}$. Since $\operatorname{dim} \mathfrak{g}_{\text {int }}^{\vee}=n^{2}$, the claim in the beginning of the paragraph follows.

Step 2. The symplectic form we use to define $\mathfrak{s p}_{2 n}$ is $\omega(u, v)=\sum_{i=1}^{n}\left(u_{i} v_{2 n+1-i}-v_{i} u_{2 n+1-i}\right)$. Identify $\overline{\mathfrak{t}}$ with $\mathbb{C}^{n}$ in a standard way, $\overline{\mathfrak{t}}=\operatorname{diag}\left(x_{1}, \ldots, x_{n},-x_{n}, \ldots,-x_{1}\right)$. When $n=2 m, \mathfrak{t}_{Q}$ is embedded into $\mathfrak{t}$ as

$$
\left\{\left(x_{1}, x_{1}, x_{2}, x_{2}, \ldots, x_{m}, x_{m}\right)\right\}
$$

while for $n=2 m+1$, we get

$$
\mathfrak{t}_{Q}=\left\{\left(x_{1}, x_{1}, \ldots, x_{m}, x_{m}, 0\right)\right\}
$$

We choose $\nu$ corresponding to the vector $\left(x_{1}, \ldots, x_{m}\right) \in \mathbb{Z}^{m}$ with $x_{1}>x_{2}>\ldots>x_{m}>0$, it is dominant for $\mathfrak{g}$.

Step 3. The subalgebra $\underline{\mathfrak{g}}=\mathfrak{z}_{\mathfrak{g}}(\nu)$ is $\mathfrak{s l}_{2}^{n}$ and $e$ is a principal nilpotent element in $\underline{\mathfrak{g}}$. The W-algebra $\underline{\mathcal{W}}$ is, therefore, the center of $\underline{\mathcal{U}}$. Consider the primitive ideal $\underline{\mathcal{J}}(\rho / 2)$ for $\underline{\mathfrak{g}}$. It is minimal, so it gives rise to an irreducible representation of $\underline{\mathcal{W}}$, to be denoted by $\underline{V}$. Set $V=L_{\nu}(\underline{V})$. By [L3, Theorem 5.1.1], $\mathcal{J}(\rho / 2)=\operatorname{Ann}_{\mathcal{W}}(V)^{\dagger}$. It follows that $\mathbb{O} \subset \mathrm{V}(\mathcal{J})$ and, since the codimensions of $\mathbb{O}$ and $\mathrm{V}(\mathcal{J})$ in $\mathfrak{g}$ coincide (both are equal to $n^{2}$ ), we recover the equality $\mathrm{V}(\mathcal{J})=\mathbb{O}$. Equivalently, $V$ is finite dimensional.

Step 4. Let us determine how $\mathfrak{t}_{Q}$ acts on $\underline{V}$. According to (9), the action is by the character $\left.(-\rho / 2-\delta)\right|_{\mathrm{t}_{Q}}$. Below in this step, we will compute this character explicitly.

Note that $e$ is an even nilpotent element so $\delta=\sum_{\alpha \in \Delta^{-}, \alpha(h) \leqslant-2} \alpha$. Note that $\left.\delta\right|_{\mathrm{t}_{Q}}=$ $\left.\frac{1}{2}\left(\sum_{\alpha \in \Delta^{-}, \alpha(h) \neq 0} \alpha\right)\right|_{\mathfrak{t}_{Q}}$ because $\mathfrak{t}_{Q}$ centralizes the $\mathfrak{s l}_{2}$-triple $(e, h, f)$. So $\left.(-\rho / 2-\delta)\right|_{\mathfrak{t}_{Q}}=(\rho / 2-$ $\left.\rho_{0}\right)\left.\right|_{\mathfrak{t}_{Q}}$, where $\rho_{0}$ is $\frac{1}{2} \sum_{\alpha>0 \mid \alpha(h)=0} \alpha$. The element $h \in \mathfrak{t}_{Q}$ equals $(1,-1,1,-1, \ldots)$. The positive roots that vanish on $h$ are of the form $\epsilon_{i}-\epsilon_{j}$, where $i-j$ is even, and $\epsilon_{i}+\epsilon_{j}$, where $i-j$ is odd.

It is easy to see that $\rho=n \epsilon_{1}+(n-1) \epsilon_{2}+\ldots+\epsilon_{n}$. Let $\eta_{i}$ denote the $i$ th coordinate function on $\mathfrak{t}_{Q} \cong \mathbb{C}^{m}$.

Consider the case of $n=2 m$ first. Here

$$
\left.\rho\right|_{\mathfrak{t}_{Q}}=(4 m-1) \eta_{1}+(4 m-5) \eta_{2}+\ldots+3 \eta_{m}
$$

We get

$$
\begin{aligned}
& 2 \rho_{0}=(m-1)\left(\epsilon_{1}+\epsilon_{2}\right)+(m-3)\left(\epsilon_{3}+\epsilon_{4}\right)+\ldots+(1-m)\left(\epsilon_{2 m-1}+\epsilon_{2 m}\right)+m\left(\epsilon_{1}+\ldots+\epsilon_{2 m}\right) \\
& =(2 m-1)\left(\epsilon_{1}+\epsilon_{2}\right)+(2 m-3)\left(\epsilon_{3}+\epsilon_{4}\right)+\ldots+\left(\epsilon_{2 m-1}+\epsilon_{2 m}\right)
\end{aligned}
$$

Hence $\left.2 \rho_{0}\right|_{\mathfrak{t}_{Q}}=(4 m-2) \eta_{1}+\ldots+2 \eta_{m}$. We conclude that $\left.\left(\rho / 2-\rho_{0}\right)\right|_{\mathfrak{t}_{Q}}=\left(\eta_{1}+\ldots+\eta_{m}\right) / 2$. This is the highest weight of a half-spinor representation.

Now consider the case of $n=2 m+1$. Here

$$
\left.\rho\right|_{\mathfrak{t}_{Q}}=(4 m+1) \eta_{1}+(4 m-3) \eta_{2}+\ldots+5 \eta_{m} .
$$

We get

$$
\begin{aligned}
& 2 \rho_{0}=m \epsilon_{1}+(m-2) \epsilon_{3}+\ldots-m \epsilon_{2 m+1}+(m-1) \epsilon_{2}+(m-3) \epsilon_{4}+\ldots+(1-m) \epsilon_{m-1}+ \\
& +m\left(\epsilon_{1}+\epsilon_{3}+\ldots \epsilon_{2 m+1}\right)+(m+1)\left(\epsilon_{2}+\ldots+\epsilon_{2 m}\right)= \\
& =2 m\left(\epsilon_{1}+\epsilon_{2}\right)+(2 m-2)\left(\epsilon_{3}+\epsilon_{4}\right)+\ldots+2\left(\epsilon_{2 m-1}+\epsilon_{2 m}\right) .
\end{aligned}
$$

So $\left.2 \rho_{0}\right|_{\mathfrak{t}_{Q}}=4 m \eta_{1}+4(m-1) \eta_{2}+\ldots+4 \eta_{m}$. It follows that $\left.\left(\rho / 2-\rho_{0}\right)\right|_{\mathfrak{t}_{Q}}=\left(\eta_{1}+\ldots+\eta_{m}\right) / 2$, the highest weight of the spinor representation.

Step 5. It remains to prove that $V$ is irreducible over $\mathfrak{q}$. Consider a more general situation. Let $\nu$ be as in Section 4.2, let $\underline{V}$ be an irreducible $\underline{\mathcal{W}}$-module such that $V=L_{\nu}(\underline{V})$ is finite dimensional. Assume that
(i) $\operatorname{dim} \underline{V}=1$ (this always holds when $e$ is principal in $\underline{\mathfrak{g}}$, which is true in the case of interest for us),
(ii) The algebra $\mathfrak{q}$ is semisimple.
(iii) The action of $\mathfrak{t}_{Q}$ on $\underline{V}$ via $\mathfrak{t}_{Q} \hookrightarrow \mathrm{C}_{\nu}(\mathcal{W})$ is by a minuscule weight, say $\omega$.

We claim that in this case $V$ is irreducible over $\mathfrak{q}$ (with highest weight $\omega$ ). This partially generalizes [L3, Theorem 5.2.1]. The proof is similar but we provide it for readers convenience.

Note that all $\mathfrak{t}_{Q}$-weights $\beta$ in $V$ are congruent to $\omega$ modulo the root lattice of $\mathfrak{q}$ and also $\langle\beta, \nu\rangle \leqslant\langle\omega, \nu\rangle$ with equality if and only if $\beta$ is a weight of $\underline{V}$. If $V$ is not irreducible over $\mathfrak{q}$, then there is another highest weight, say $\omega^{\prime}$. Since $\omega$ is minuscule, we have $\omega^{\prime} \geqslant \omega$ (meaning that $\omega^{\prime}-\omega$ is the sum of positive roots). This contradicts the inequality $\left\langle\omega^{\prime}, \nu\right\rangle \leqslant\langle\omega, \nu\rangle$ and proves the irreducibility of $V$ over $\mathfrak{q}$.

Step 6. Let us now complete the proof. By Step 4, $V$ satisfies condition (iii) of Step 5, while conditions (i),(ii) were established above in the proof. So $V$ is the spinor representation of $\mathfrak{s o}_{2 m+1}$ when $n=2 m+1$ and one of the half-spinor representations of $\mathfrak{s o}_{2 m}$ in the case when $n=2 m$. In the former case, $V$ is $Q$-stable because $\underline{V}$ is stable under $N_{Q}\left(\mathfrak{t}_{Q}\right)$. In the latter case, $V$ is not stable because of an outer automorphism in $Q$ that permutes the half-spinor representations. This proves (1),(2) of the proposition. (3) now follows from Theorem 1.2 and Examples 2.7 (the case of $n=2 m+1$ ) and 2.8 (the case of $n=2 m$ ).
