A uniformly accelerated charge and the question of Schott energy-momentum

Ashok K. Singal

(Dated: March 22, 2018)

We show that in the case of a uniformly accelerated charge, in its instantaneous rest frame, there is only a radial electric field as the acceleration fields strangely get cancelled at all distances by a transverse term of the velocity fields. Consequently, no electromagnetic radiation will be detected by any observer, even in the far-off zone, from a uniformly accelerated charge, in agreement with the strong principle of equivalence, where a charge permanently stationary in a gravitational field cannot be radiating indefinitely. We also demonstrate that, contrary to the ideas prevalent in the literature, there is no evidence of any acceleration-dependent Schott energy-momentum within the electromagnetic fields, in the vicinity of a uniformly accelerated charge.

I. INTRODUCTION

According to Larmor’s formula (or its relativistic generalization, Liénard’s formula), electromagnetic power is radiated from an accelerated charge at a rate proportional to square of its acceleration [1–4]. From that one can also infer the rate of momentum carried by the electromagnetic radiation which turns out to be directly proportional to the velocity vector of the charge multiplied by square of its acceleration [3, 2]. The picture here does not seem to be complete however, because if one attempts to compute the consequential rate of energy-momentum loss from the radiating charge, one encounters not only a direct violation of the energy-momentum conservation law but also sees a conflict with the special theory of relativity [7].

Abraham [8, 9] and Lorentz [10, 11] derived for an accelerated charge, a formula for the self-force, widely known as radiation reaction, which gives the rate of loss of momentum of the accelerated charge proportional to its rate of change of acceleration [12–15]. The same formula is also obtained, independently, from momentum conservation law by using the Maxwell stress tensor to calculate the rate of electromagnetic momentum flow across a spherical surface surrounding the neighbourhood of a point charge [16]. A scalar product of the radiation reaction with the velocity of the charge yields the rate of power loss of the accelerated charge. The radiative power loss can also be obtained directly from the Poynting flux in the neighbourhood of a point charge in arbitrary motion, leading exactly to the same formula [17].

The disparity between the two power loss formulas (one proportional to the square of acceleration and the other proportional to the scalar product of the velocity and the rate of change of acceleration of the charge), has remained a nagging puzzle for almost a century. According to the conventional wisdom, the radiative power loss is given correctly by Larmor’s formula, while the rate of loss of momentum is described correctly by the radiation reaction formula. These two apparently conflicting results are reconciled by proposing the presence of an extra term, called Schott term [12], in the fields of an accelerated charge. However, a physical meaning of this acceleration-dependent Schott term is still not clear [6, 18–23] and one does not encounter such an acceleration-dependent energy-momentum term elsewhere in physics.

We shall first get the Schott term in a 4-vector form, from the differences in the two conflicting formulas. The Schott energy-momentum is thought to be present in the electromagnetic fields in the vicinity of an accelerated charge. We shall here examine the case of a uniformly accelerated charge, where the expression for the electromagnetic fields is relatively simple and the Schott term, if present therein, should be tractable mathematically in an exact manner. From a careful scrutiny of the electromagnetic fields of a uniformly accelerated charge, we find that not only is there no evidence whatsoever of the Schott energy-momentum term anywhere in the vicinity of the charge, there is no electromagnetic radiation either, in the far-off regions. As we will explicitly demonstrate, this happens because the transverse acceleration fields get cancelled neatly by a transverse component of velocity fields, for all r. As a result, there is no Poynting flux with a term proportional to the square of acceleration, usually called the radiated power, implying thereby that no electromagnetic radiation takes place from a uniformly accelerated charge.

II. LARMOR’S/LIÉNARD’S RADIATION FORMULA

In Larmor’s/Liénard’s formulation, the rate of energy-momentum loss of an accelerated charge due to radiation damping, expressed in a 4-vector form, is

$$\mathbf{F}_1^\mu = \frac{2e^2}{3c^3} \dot{v}^\alpha \dot{v}_\alpha v^\mu,$$

where in all covariant equations, dot represents a proper time derivative [6].

$$\mathbf{F}_1^\mu$$ is $\gamma \mathbf{P}_1/c$, where

$$\mathbf{P}_1 = \frac{2e^2}{3c^3} \dot{v}^\alpha \dot{v}_\alpha = \frac{2e^2}{3c^3} \left[ \dot{v} \cdot \dot{v} + \frac{\gamma^2 (\ddot{v} \cdot \dot{v})^2}{c^2} \right]$$

(2)
is Liénard's formula (in cgs units) for power being lost by a radiating charge \( \mathbb{E} \), and \( F^i_1 \) is \( \gamma \) times the \( i \)th component, for \( i = 1, 2, 3 \), of the rate of momentum being lost into radiation \( \mathbb{F} \).

\[
F_1 = \frac{P_1}{c^2} v. \quad (3)
\]

The radiative power loss for a charge moving with a non-relativistic velocity \( (v \ll c) \), accordingly, is \( \mathbb{E} \)

\[
P_1 = \frac{2 e^2 \dot{v}^2}{3 c^3}, \quad (4)
\]

while the net rate of momentum loss to radiation by such a charge is nil

\[
P_1 = 0. \quad (5)
\]

This is consistent with the radiation pattern possessing an azimuth symmetry \( (\propto \sin^2 \phi) \) in the case of a non-relativistic motion \( \mathbb{F} \).

### III. ABRAHAM-LORENTZ RADIATION REACTION

Larmor's formula purportedly uses Poynting's theorem of energy conservation to relate Poynting flux through a spherical surface of radius \( r \) at a time \( t \), to the rate of loss of kinetic energy of the radiating charge at a retarded time \( t - r/c \). However, in Poynting's theorem all quantities are supposed to be calculated for the same instant of time \( \mathbb{E} \). A correct application of the Poynting's theorem, using real time values of the charge motion, gives instantaneous power loss of the charge (in a non-relativistic motion) as \( \mathbb{F} \)

\[
P_2 = -\frac{2 e^2 \gamma^4}{3 c^3} \left( \dot{v} \cdot v + \frac{3 \gamma^2 (v \cdot v) \dot{v}}{c^2} \right), \quad (6)
\]

while a relativistic generalization of Eq. (7) is \( \mathbb{E} \)

\[
F_2 = -\frac{2 e^2 \gamma^4}{3 c^3} \left( \dot{v} + \frac{\gamma^2 (v \cdot v) \dot{v}}{c^2} + \frac{3 \gamma^2 (\dot{v} \cdot v) \dot{v}}{c^2} + \frac{3 \gamma^4 (v \cdot v)^2 \dot{v}}{c^4} \right). \quad (7)
\]

IV. SCHOTT ENERGY-MOMENTUM TERM

Power loss by the charge due to radiation reaction (Eq. (4)), is related to the radiated power by Larmor's formula (Eq. (1)), in a non-relativistic case, as

\[
P_2 = \mathbb{P}_1 - \frac{2 e^2 d(\dot{v} \cdot v)}{3 c^3} dt. \quad (12)
\]

The last term on the right hand side in Eq. (12) is known as the Schott term, after Schott \( \mathbb{E} \) first brought it to attention. Schott term is a total derivative and is thought in literature to arise from an acceleration-dependent energy, \(-2 e^2 \dot{v} / 3 c^3\), in electromagnetic fields \( \mathbb{F} \).

We can express Eqs. (8) and (9) in a 4-vector form \( \mathbb{F} \), where

\[
\mathbb{F}^0_2 = \gamma \mathbb{P}_2, \quad \mathbb{F}^i_2 = \gamma \mathbb{F}^i_1, \quad i = 1, 2, 3. \quad (10)
\]

Power loss by the charge due to radiation reaction (Eq. (4)), is related to the radiated power by Larmor's formula (Eq. (1)), in a non-relativistic case, as

\[
P_2 = \mathbb{P}_1 - \frac{2 e^2 d(\dot{v} \cdot v)}{3 c^3} dt. \quad (12)
\]

The last term on the right hand side in Eq. (12) is known as the Schott term, after Schott \( \mathbb{E} \) first brought it to attention. Schott term is a total derivative and is thought in literature to arise from an acceleration-dependent energy, \(-2 e^2 \dot{v} / 3 c^3\), in electromagnetic fields \( \mathbb{F} \).

We can also express \( \mathbb{F}_2 \) in terms of \( \mathbb{F}_1 \) (Eqs. (7) and (5), again in a non-relativistic case) as

\[
\mathbb{F}_2 = \mathbb{F}_1 - \frac{2 e^2}{3 c^3} \dot{\gamma} \mathbb{F}. \quad (13)
\]

The last term on the right hand side, again, is a total derivative, assumedly arising from an acceleration-dependent momentum, \(-2 e^2 \dot{v}^2 / 3 c^3\), apparently in electromagnetic fields.

Radiation reaction in the covariant form \( \mathbb{F}_\mu \) yields a 4-vector, \( \mathbb{F}_\mu^\mu \), for the Schott term

\[
\mathbb{F}^\mu_2 = \mathbb{F}^\mu_1 + \mathbb{F}^\mu_2 = \mathbb{F}^\mu_1 - \frac{2 e^2 \dot{v}^\mu}{3 c^3}. \quad (14)
\]

\( \mathbb{F}_\mu^\mu \) is a proper-time derivative of the Schott energy-momentum, \( \mathbb{E}_\mu^\mu = -2 e^2 \dot{v}^\mu / 3 c^3 \). The 4-acceleration \( \dot{v}^\mu \) is obtained from the 4-velocity \( (\gamma c, \gamma v) \) by a differentiation with proper time and the 4-vector \( \mathbb{E}_\mu^\mu \) then is

\[
\mathbb{E}_0 = -\frac{2 e^2 \gamma^4}{3 c^3} \dot{v} \cdot v, \quad (15)
\]

\[
\mathbb{E}_s = -\frac{2 e^2 \gamma^2}{3 c^3} \left( \dot{v} + \frac{2 (v \cdot v) \dot{v}}{c^2} \right), \quad i = 1, 2, 3. \quad (16)
\]
Equation (14) can now be explicitly verified by a proper-time differentiation of $E_p$, in conjunction with Eqs. (2), (3), (5) and (9), to give

$$F^0_s = -\frac{2e^2}{3c^3}v^0 = \gamma (P_2 - P_1)$$

(17)

$$F^i_s = -\frac{2e^2}{3c^3}v^i = \gamma (P^i_2 - P^i_1) \quad i = 1, 2, 3 .$$

(18)

It may be noted that in case of radiation reaction, power and force (Eqs. (5) and (9)) are related by $P_2 = F_2 \cdot v$, implying

$$F^0_s = \frac{F^j_i v_i}{\gamma c},$$

(19)

where $v_i (i = 1, 2, 3)$ stands for $i$th component of the 4-velocity. In contrast, the relation between force and power in case of Larmor’s radiation formula, $F_1 = P_1 v/c^2$ (Eq. (3)), implies

$$F^0_1 \neq \frac{F^j_i v_i}{\gamma c} .$$

(20)

Also

$$F^0_s \neq \frac{F^j_i v_i}{\gamma c},$$

(21)

because

$$v^0 = \frac{(\dot{\gamma} v_i + \dot{v}^i \dot{\gamma}_i)}{\gamma c} .$$

(22)

A pertinent question in Larmor’s radiation loss formula arises in case of an accelerated charge in its instantaneous rest frame. Due to zero velocity of the charge, it could not lose any kinetic energy into radiation. However, Larmor’s formula, according to which the radiated power is proportional to square of acceleration of the charge, yields a finite power loss. Even if the external force causing the acceleration of the charge, were considered to be responsible for the radiative power as well, it could not have done so, because at that instant the rate of work being done by the external force would also be zero as the system has a zero velocity. This uncomfortable question is purportedly resolved by proposing that there is an equivalent decrease in the Schott energy (an acceleration-dependent internal energy!) stored within the electromagnetic fields in the close vicinity of the accelerated charge. According to this argument, even if the Schott energy term may be zero in the instantaneous rest-frame (Eq. (15)), its temporal derivative (Eq. (17)) yields a finite power loss for the instantly stationary charge equal to that expected from Larmor’s formula (Eq. (9)).

However, even if this might seem to resolve the particular energy conservation problem, it gives rise to another awkward question about the presence of momentum for an instantly stationary charge. From Eq. (16) we infer that there is a finite momentum, $-2e^2v/3c^3$, in electromagnetic fields in the vicinity of the charge, even at the instant when the charge is stationary ($v = 0$). Now this apparent momentum, which is directly proportional to the acceleration of the charge, and is strangely independent of the velocity of the charge, at least in the non-relativistic case, raises a vexing question – How come there is supposedly a finite momentum in the fields of a stationary charge when there is no motion of any kind at that instant? We want to examine the case of a uniformly accelerated charge, where it may be possible to tract the question in exact mathematical details whether the electromagnetic fields really harbor the Schott energy-momentum, somewhere in the close vicinity of such a charge, as opined in the literature [20, 21].

V. A UNIFORMLY ACCELERATED CHARGE – NO TRACE OF ANY RADIATED ENERGY-MOMENTUM OR A SCHOTT TERM IN ELECTROMAGNETIC FIELDS

A uniformly accelerated motion is understood to imply a motion with a constant proper acceleration, say, $g$. We shall first show explicitly that in the instantaneous rest frame of a charge with a constant proper acceleration, there are only radial fields as there is a complete cancellation of transverse acceleration fields by a transverse term of the velocity fields at all distances.

The electric field of a charge $e$, moving with a proper acceleration $g = \gamma^3 v$, at time $t$ is given by [2, 4, 26]

$$E = \left[ \frac{e(n - v/c)}{\gamma^2 r^2 (1 - n \cdot v/c)^3} + \frac{e n \times (n - v/c) \times g}{\gamma^2 r^2 (1 - n \cdot v/c)^3} \right]_{\text{ret}},$$

(23)

where the subscript ret indicates that quantities within the square bracket are to be evaluated at the retarded time $t - r/c$.

Now, for a motion with a constant proper acceleration $g$, the velocity $v$ at the retarded time $t - r/c$ is obtained from its present value $v_o$ at time $t$ as

$$\gamma v = \gamma_0 v_0 - gr/c .$$

(24)

Therefore, in the instantaneous rest-frame ($v_o = 0$), the proper acceleration and the retarded value of the velocity are related by $\gamma v = -gr/c$. Basically this happens because for larger $r$, we need to go further back in time to get the time-retarded value of velocity, which is directly proportional to the time interval $r/c$ in the case of a uniform acceleration. Substituting for $g$ in Eq. (23), and after a rearrangement of terms, we get

$$E = \left[ \frac{e(n - v/c - n \times (n \times v/c))}{\gamma^2 r^2 (1 - n \cdot v/c)^3} \right]_{\text{ret}} .$$

(25)

Using the vector identity $n \times (n \times v) = n(n.v) - v$, we get the expression for the electric field in the instantaneous rest-frame of a uniformly accelerated charge as

$$E = \left[ \frac{en}{\gamma^2 r^2 (1 - n \cdot v/c)^2} \right]_{\text{ret}} .$$

(26)
where there is only a radial field term, with the transverse acceleration components in Eq. (23) having got cancelled by transverse component of velocity fields, for all \( r \). There is thus no Poynting flux anywhere and no observer would detect any radiation at whatever distance, in the instantaneous rest frame. Accordingly, we arrive at a conclusion that there is no radiation in such a case. This of course is in agreement with the strong principle of equivalence, where a charge permanently stationary in a gravitational field, which is equivalent to a charge having a constant proper acceleration with respect to a freely falling inertial observer, cannot be continually radiating without any loss of generality, we may assume the one-dimensional motion, i.e., there is no component of velocity perpendicular to the acceleration vector. Now this transverse term, proportional to the present velocity \( \gamma_0 v_0 \), falls rapidly with distance (\( \propto 1/r^2 \)); the Doppler beaming factor \( \delta^3 = 1/\gamma^3(1 - n \cdot v/c)^3 \) merely redistributing the field strength in solid angle without affecting the net Poynting flux at any \( r \). This means a rapidly falling Poynting flux through a spherical surface at large distance (\( r \to \infty \)) and no term proportional to \( \nabla^2 \), independent of \( r \), that is usually defined as the radiated power, implying, consequently, no radiation from a uniformly accelerated charge. This of course is consistent with the absence of radiation for a charge supported in a gravitational field in Eqs. (27), in conformity with the strong principle of equivalence.

Without any loss of generality, we may assume the constant proper acceleration \( \mathbf{a} \) to be along the \( +z \) axis. Let the charge starting along the \( +z \) direction from \( z_e = -\infty \) at time \( t = -\infty \), momentarily comes to rest at time \( t = 0 \) at some point \( z_e = \alpha \) on the \( z \) axis, and then onwards moves with an increasing velocity along the \( +z \) direction.

The Schott term \( F^s_s \) for this proper acceleration case is the 4-vector

\[
F^0_s = -\frac{2e^2}{3ct} \gamma \mathbf{v}^2,
\]

\[
F^i_s = -\frac{2e^2}{3ct} \gamma \mathbf{v} \cdot \mathbf{v}^i, \quad i = 1, 2, 3,
\]

while from Eqs. (15) and (16), the Schott energymomentum 4-vector \( \mathcal{E}^\mu_s \) is given by

\[
\mathcal{E}^0_s = -\frac{2e\mathbf{v}}{3c^2} \mathbf{g} \cdot \mathbf{v},
\]

\[
\mathcal{E}^i_s = -\frac{2e\mathbf{v}}{3c^2} \mathbf{g}^i, \quad i = 1, 2, 3.
\]

It is possible to solve the expression for electromagnetic fields of a uniform accelerated charge, not necessarily in terms of motion of the charge at retarded time as in Eqs. (27), instead wholly in terms of the “real-time” motion of the charge [28]. Now, without any loss of generality, we can choose the origin of the coordinate system so that \( \alpha = c^2/\gamma \), then the position and velocity of the charge at a time \( t \) are given by \( z_e = (\alpha^2 + c^2t^2)^{1/2} \) and \( v = c^2t/z_e \). Due to the cylindrical symmetry of the system, it is convenient to employ cylindrical coordinates \((\rho, \phi, z)\). The electromagnetic fields at time \( t \) can then be written as

\[
E_\rho = 8\alpha^2 \rho \mathbf{v} / \xi^3,
\]

\[
E_z = -4\alpha^2 (z_e^2 - \rho^2 + \rho^2 / \xi^2) / \xi^3,
\]

\[
B_\phi = 8\alpha^2 \rho c t / \xi^3,
\]

(32)

where \( \xi = [(z_e^2 - \rho^2)^2 + 4\alpha^2 \rho^2]^{1/2} \). The remaining field components are zero. Our discussion pertains to the region \( z + ct > 0 \) because fields only within this region could have any causal relation with the retarded positions of the charge [29].

The charge happens to be at the same location at times \( t \) and \(-t\), i.e., \( z_e(t) = z_e(-t) \). Then from Eq. (32) it can be seen that the electric field \( E \) (with components \( E_\rho, E_z \)) is an even function of time, i.e., at any given location \((\rho, \phi, z)\), \( E(t) = E(-t) \). On the other hand, the magnetic field \( B \) (with a component \( B_\phi \)) is an odd function of time, i.e., \( B(t) = -B(-t) \), with \( B = 0 \) at \( t = 0 \). Thus there is no Poynting vector, \( \mathcal{S} = (\mathbf{E} \times \mathbf{B})/4\pi \) seen anywhere at \( t = 0 \). Further, at any given location, the Poynting vector at time \( t \) is equal and opposite to its value at time \(-t\).

The absence of radiation is of course very much apparent at \( t = 0 \). Any radiation emitted at, say, \( t = -t_1 \) should be visible at \( t = 0 \) as a Poynting flux through a spherical surface of radius \( r = ct_1 \) around the charge position \( z_e(-t_1) \). But there is actually no Poynting vector, \( \mathcal{S} = 0 \) anywhere at \( t = 0 \), implying absence of any radiation emanating from charge at \(-t_1\) and this is true for all \( t_1 \) values. This is in conformity with our result earlier (Eq. (20)) that no radiation is seen anywhere in the instantaneous rest frame. Incidentally, Pauli [31] exploiting Born’s solutions [28], drew attention to the fact that in the instantaneous rest-frame of a uniformly accelerated charge, \( \mathbf{B} = 0 \) throughout, and from that he inferred that there might be no radiation for such a motion.

It has been said in literature that the radiation emitted by a uniformly accelerated charge goes into regions of space-time inaccessible to a co-accelerating observer [31]. For instance, there is a discontinuous \( \delta \)-field present in the \( z = 0 \) plane at time \( t = 0 \), and it has been suggested that all the radiation emitted by the charge during its uniform acceleration until \( t = 0 \) has gone into the \( \delta \)-field at \( z = 0 \) [32]. However, this \( \delta \)-field could have no causal relation with the charge during this period. At most, the energy in the \( \delta \)-field could be representing the energy loss by the charge due to a rate of change of acceleration (Eq. (5)) at \( t = -\infty \), when the acceleration rose from initial zero value to attain a final constant value, \( \mathbf{g} \) [27].
Let $\Sigma$ be a fixed finite closed surface surrounding the charge at $t_1$. The same surface $\Sigma$ surrounds the charge at $-t_1$ as well. The Poynting vector at any point on the surface $\Sigma$, at time $t_1$ is exactly equal but opposite to its value at time $-t$. Therefore Poynting flux through $\Sigma$ at time $t_1$

$$\int_{\Sigma} d\Sigma \left( n \cdot \hat{S} \right), \quad (33)$$

is equal and opposite to that at $-t_1$. Thus if there is an outgoing Poynting flux through surface $\Sigma$ at time $t_1$, then there was an equal ingoing Poynting flux through surface $\Sigma$ at time $-t_1$. This is not consistent with there being always an outflow of radiation from a surface surrounding an accelerated (or for that matter even a decelerated) charge, as given by standard radiation formulas.

The electromagnetic field energy in a volume $V$ is given by the volume integral

$$\frac{1}{8\pi} \int_V dV \left( E^2 + B^2 \right). \quad (34)$$

The field energy density, $(E^2 + B^2)/8\pi$, being equal at times $t_1$ and $-t_1$, its volume integral over any chosen $V$, whether in the vicinity of the charge or in some far-off zone, is also equal at times $t_1$ and $-t_1$. Now, the field energy of the charge due to its velocity fields should be the same at $t_1$ and $-t_1$, which is in accordance with what is really seen, but there is no trace of any additional energy in electromagnetic fields corresponding to the energy radiated in the intervening period. Further, the acceleration-dependent Schott energy term, according to Eq. (30), is equal but opposite at $t_1$ and $-t_1$ (because $v = -c^2 t_1 / \gamma c$ at $-t_1$). Thus the Schott energy should be making a positive contribution at $-t_1$ and a negative contribution at $t_1$, which is not consistent with actual field energy, computed from Eq. (34), being identical at $t_1$ and $-t_1$.

One can also compute the electromagnetic field momentum contained within a volume $V$ from

$$\frac{1}{4\pi c} \int_V dV \left( E \times B \right). \quad (35)$$

Since $B = 0$ at $t = 0$ (Eq. 32), there is no momentum in the electromagnetic fields anywhere, whether in the vicinity of the charge or in the far-off regions, in the instantaneous rest frame. Therefore Eq. (31) is clearly violated where the Schott momentum is proportional to $-g$ even at $t = 0$, when the charge is instantly stationary. Further, from Eq. (35) in conjunction with Eq. (32), the electromagnetic field momentum is equal but in opposite directions at times $t_1$ and $-t_1$. Now, the charge occupies the same location but has equal and opposite velocities at $t_1$ and $-t_1$, and should have in any given volume element in its self-fields equal and opposite field momentum contribution, corresponding to its “present” velocities at $t_1$ and $-t_1$, which is in accordance with what is actually seen. However, there is no trace of any additional momentum being carried away by radiation fields which would have different angular distributions at $t_1$ and $-t_1$. Moreover, it is also not in agreement with Eq. (31), where not only the magnitude but also the direction of the Schott momentum should remain the same at times $t_1$ and $-t_1$.

Thus we find no signature of the acceleration-dependent Schott energy-momentum terms that were concurrent with Eqs. (30) and (31). We may add here that the introduction of the Schott energy term to account for the power loss into radiation but without any equivalent rate of decrease of kinetic energy of the radiating charge, say, in the instantaneous rest frame, is akin to the proposal of the loss of internal (rest mass) energy $\frac{\pi}{2}$ without a loss of momentum (c.f. Eqs. 41 and 45), though in the case of Scott energy it is thought to be an acceleration-dependent extraneous kind of energy (neither the rest mass energy nor the kinetic energy, not even some kind of potential energy that may depend upon location in an external field) present in the electromagnetic fields and which does not seem to make an appearance elsewhere in physics. In any case, we see no evidence of the presence of such an energy term in the fields of a uniformly accelerated charge. Actually it has recently been shown that the Schott term is merely a difference in rate of change of energy in self-fields of the charge between retarded and real times $t_1$ and $t_1$, and contrary to the ideas that have been proposed in the literature $[1 \, 18 \, 22]$, there is no acceleration-dependent extra energy term lurking somewhere in the electromagnetic fields.

VI. CONCLUSIONS

We have shown that in the case of a uniformly accelerated charge, in its instantaneous rest frame, there is only a radial electric field as the acceleration fields get cancelled neatly at all distances by a transverse term of the velocity fields, thus no observer anywhere would detect any radiation from such a charge. This way we demonstrated that there is no electromagnetic radiation from a uniformly accelerated charge, in agreement with the strong principle of equivalence, where a charge continually at rest in a gravitational field cannot be radiating indefinitely. We further showed that there is no evidence, whatsoever, of the presence of Schott energy-momentum term in the electromagnetic fields of such a charge.
