ON THE WEAK-HASH METRIC
FOR BOUNDEDLY FINITE INTEGER-VALUED MEASURES

Maxime Morariu-Patrichi*

16 October 2018

Abstract

It is known that the space of boundedly finite integer-valued measures on a complete separable metric space becomes itself a complete separable metric space when endowed with the weak-hash metric. It is also known that convergence under this topology can be characterised in a way that is similar to the weak convergence of totally finite measures. However, the original proofs of these two fundamental results assume that a certain term is monotonic, which is not the case as we give a counterexample. We manage to clarify these original proofs by addressing specifically the parts that rely on this assumption and finding alternative arguments.

Keywords: boundedly finite integer-valued measures; weak-hash metric; completeness; separability; Borel sigma-algebra characterisation; convergence characterisation.

2010 Mathematics Subject Classification: primary 28A33, secondary 60G55.

1 Introduction

Let $X$ be a complete separable metric space and $x_0 \in X$ be a fixed origin. We denote by $B_r(x)$ the open ball with radius $r \in \mathbb{R}_{\geq 0}$ and centre $x \in X$. We use the short notation $B_r := B_r(x_0)$ for the open balls centred at $x_0$. For any subset $A \subset X$ and $\varepsilon \in \mathbb{R}_{>0}$, the $\varepsilon$-neighbourhood of $A$ is defined by $A^\varepsilon := \bigcup_{a \in A} B_\varepsilon(a)$, the boundary of $A$ is denoted by $\partial A$ and the closure of $A$ is denoted by $\overline{A}$. For any Borel measure $\xi$ on $X$ and any $r \in \mathbb{R}_{\geq 0}$, we use the notation $\xi^{(r)}$ to refer to the restriction of $\xi$ to the open ball $B_r$, that is $\xi^{(r)}(A) = \xi(A \cap B_r)$ for all $A \in \mathcal{B}(X)$. A Borel measure $\xi$ on $X$ is called totally finite if $\xi(X) < \infty$. We denote by $\mathcal{M}_X$ the space of totally finite measures on $X$ and by $d$ the Prohorov distance on $\mathcal{M}_X$ defined by

$$d : \mathcal{M}_X \times \mathcal{M}_X \to \mathbb{R}_{\geq 0}$$

$$(\mu, \nu) \mapsto d(\mu, \nu) := \inf\{\varepsilon \in \mathbb{R}_{\geq 0} : \mu(A) \leq \nu(A^\varepsilon) + \varepsilon \text{ and } \nu(A) \leq \mu(A^\varepsilon) + \varepsilon,$$

for all closed $A \subset X$.

It is known that $d$ makes $\mathcal{M}_X$ a complete separable metric space, see for example Section A2.5 in Daley and Vere-Jones [1, p. 398–402].

In this paper, we are interested in boundedly finite integer-valued measures. A Borel measure \( \xi \) on \( \mathcal{X} \) is called boundedly finite if \( \xi(A) < \infty \) for all bounded Borel sets \( A \in \mathcal{B}(\mathcal{X}) \). We denote by \( \mathcal{N}_\mathcal{X}^\# \) the space of boundedly finite measures on \( \mathcal{X} \) with values in \( \mathbb{N} \cup \{\infty\} \). Note that such measures are always atomic (i.e., a superposition of Dirac measures), see for example Proposition 9.1.III.(ii) in Daley and Vere-Jones [2, p. 4]. One might ask if the Prohorov distance \( d \) on the space \( \mathcal{M}_\mathcal{X} \) has a counterpart on the space \( \mathcal{N}_\mathcal{X}^\# \). Daley and Vere-Jones [1, p. 403] tackle this question by considering the distance function
\[
d^\# : \mathcal{N}_\mathcal{X}^\# \times \mathcal{N}_\mathcal{X}^\# \to \mathbb{R}_{\geq 0}
\]
\[
(\mu, \nu) \mapsto d^\#(\mu, \nu) := \int_0^\infty e^{-r} \frac{d(\mu(r), \nu(r))}{1 + d(\mu(r), \nu(r))} dr.
\]
The core idea is to use the Prohorov metric on the restrictions to the open balls and compute a weighted average. They name the corresponding topology the \( w^\# \)-topology (“weak-hash”) and refer to \( d^\# \) as the \( w^\# \)-distance. They then obtain the following two fundamental results. The first one is a characterisation of convergence under this metric.

**Theorem 1.1** (Characterisation of convergence). Let \( (\mu_k)_{k \in \mathbb{N}} \) be a sequence in \( \mathcal{N}_\mathcal{X}^\# \) and \( \mu \in \mathcal{N}_\mathcal{X}^\# \). Then, the following statements are equivalent:

(i) \( d^\#(\mu_k, \mu) \to 0 \) as \( k \to \infty \);

(ii) \( \int_X f(x)\mu_k(dx) \to \int_X f(x)\mu(dx) \) as \( k \to \infty \) for all bounded continuous functions \( f \) on \( \mathcal{X} \) vanishing outside a bounded set;

(iii) there exists an increasing sequence \( (r_n)_{n \in \mathbb{N}} \) with \( r_n \to \infty \) as \( n \to \infty \) such that
\[
d(\mu_k(r_n), \mu(r_n)) \to 0 \quad \text{as} \quad k \to \infty \quad \text{for all} \quad n \in \mathbb{N};
\]

(iv) \( \mu_k(A) \to \mu(A) \) as \( k \to \infty \) for all bounded sets \( A \in \mathcal{B}(\mathcal{X}) \) such that \( \mu(\partial A) = 0 \).

The second one confirms that \( d^\# \) is indeed the counterpart of \( d \), that is \( \mathcal{N}_\mathcal{X}^\# \) inherits the completeness and separability properties of \( \mathcal{X} \) under the metric \( d^\# \). This second result also provides us with a characterisation of the Borel \( \sigma \)-algebra \( \mathcal{B}(\mathcal{N}_\mathcal{X}^\#) \).

**Theorem 1.2** (Metric properties of \( \mathcal{N}_\mathcal{X}^\# \)).

(i) The space \( \mathcal{N}_\mathcal{X}^\# \) is a complete separable metric space when it is equipped with the distance function \( d^\# \).

(ii) The corresponding Borel \( \sigma \)-algebra \( \mathcal{B}(\mathcal{N}_\mathcal{X}^\#) \) is the smallest \( \sigma \)-algebra that makes all mappings \( \Phi_A : \mathcal{N}_\mathcal{X}^\# \to \mathbb{N} \cup \{\infty\}, A \in \mathcal{B}(\mathcal{X}), \) measurable, where \( \Phi_A(\xi) = \xi(A) \).

Theorem 1.1 and Theorem 1.2 in this paper are Proposition A2.6.II and Theorem A2.6.III in Daley and Vere-Jones [1, p. 403–405], respectively.

Regarding the motivation of this article, the metric space \( (\mathcal{N}_\mathcal{X}^\#, d^\#) \) is a stepping stone to the theory of point processes as presented by Daley and Vere-Jones [2], who define a point process as a random element in \( \mathcal{N}_\mathcal{X}^\# \). The present research was in fact triggered by the work of Morariu-Patrichi and Pakkanen [6] who study the existence and uniqueness of marked point processes defined via their intensity. Since the above theorems are crucial in their framework and proofs, the present author examined them carefully, which resulted in this article.
We now turn to the precise purpose of this paper. To argue that the integrand in (1.1) is measurable and prove the above properties of the metric \( d^\# \), Daley and Vere-Jones [1, p. 403–405] assume that \( d(\mu(r), \nu(r)) \) is non-decreasing as a function of \( r \in \mathbb{R}_{\geq 0} \). However, this does not seem true as suggested by the following counterexample.

**Example 1.3.** Set \( \mathcal{X} = \mathbb{R} \), \( x_0 = 0 \), \( \mu = \delta_0 \) and \( \nu = \delta_{0.5} \), where, for any \( x \in \mathcal{X} \), \( \delta_x \) denotes the Dirac measure at \( x \). Then, as long as \( r < 0.5 \), \( d(\mu(r), \nu(r)) = 1 \). However, as soon as \( r > 0.5 \), \( d(\mu(r), \nu(r)) = 0.5 \).

Consequently, our goal is to clarify the original proofs of Theorems 1.1 and 1.2 given in Daley and Vere-Jones [1] by addressing specifically the parts that rely on the assumed monotonicity of \( d(\mu(r), \nu(r)) \). Note that Daley and Vere-Jones [1] consider the larger space \( \mathcal{M}_X^\# \) of boundedly finite measures, i.e., not necessarily integer-valued. The proofs we develop here (except in Section 3) are specialised to the subspace \( \mathcal{N}_X^\# \) and take advantage of the discrete nature of its elements. Besides, we should add that an alternative metrization of \( \mathcal{M}_X^\# \), leading to the same properties, is presented in Kallenberg [4, Section 4.1, p. 111–117]. According to Kallenberg [4, Historical and bibliographical notes, p. 638], this extension from totally finite measures to boundedly finite measures under this alternative metric was first developed by Matthes et al. [5].

The paper is organised as follows. Section 2 gives some preliminary results on the Prohorov metric. Section 3 shows that the distance function in (1.1) is well-defined. Section 4 deals with the proof of Theorem 1.1. Sections 5 and 6 address the proof of Theorem 1.2.

**Remark 1.4.** We would like to stress that this paper focuses on the parts of the original proofs that assume that \( r \mapsto d(\mu(r), \nu(r)) \) is non-decreasing (with the exception of Section 6). Our main objective is to find alternative arguments for these parts specifically. To understand the proofs of Theorems 1.1 and 1.2 in their entirety and the details of the other parts that are not treated here, we refer the reader to the original text [1, p. 403–405].

### 2 Preliminaries on the Prohorov metric

As the Prohorov metric \( d \) is the main building block of the \( w^\# \)-distance \( d^\# \), it is not surprising that we need to study its behaviour. In particular, we will apply the following lemmas.

**Lemma 2.1.** Let \( \mu \in \mathcal{M}_X^\# \) and \( p, r \in \mathbb{R}_{\geq 0} \) such that \( p \leq r \). Then \( d(\mu(p), \mu(r)) \leq \mu(S_r \setminus S_p) \).

*Proof.* Let \( \varepsilon > \mu(S_r \setminus S_p) \). Let \( F \in \mathcal{B}(\mathcal{X}) \) be a closed set. Then, clearly

\[
\mu(p)(F) = \mu(F \cap S_p) \leq \mu(F^c \cap S_r) + \varepsilon = \mu(r)(F^c) + \varepsilon.
\]

Moreover, we have that

\[
\mu(r)(F) = \mu(F \cap S_p) + \mu(F \cap S_r \setminus S_p)
\leq \mu(p)(F) + \mu(S_r \setminus S_p)
\leq \mu(p)(F^c) + \varepsilon.
\]

This means exactly that \( d(\mu(p), \mu(r)) \leq \mu(S_r \setminus S_p) \) by definition of the Prohorov distance \( d \).

**Lemma 2.2.** Let \( \mu, \nu \in \mathcal{N}_X^\# \) such that \( \mu(\mathcal{X}) < \infty \), \( \nu(\mathcal{X}) < \infty \). Let \( \overline{r}, \overline{r}, \varepsilon \in \mathbb{R}_{\geq 0} \) such that \( \overline{r} < \overline{r} \) and \( \varepsilon < (\overline{r} - \overline{r})/2 < 1 \). If \( \mu(B_{\overline{r}} \setminus B_{\overline{r}}) = 0 \) and \( \nu(B_{\overline{r} - \varepsilon} \setminus B_{\overline{r} + \varepsilon}) > 0 \), then \( d(\mu, \nu) \geq \varepsilon \).
Proof. Let $0 \leq \delta < \varepsilon$ and $u \in B_{r-\varepsilon} \setminus B_{r+\varepsilon}$ such that $\nu\{u\} \geq 1$. Then, we have that

$$\nu\{u\} \geq 1 > \delta = \mu\{u\} + \delta,$$

which implies that $d(\mu, \nu) \geq \delta$ by definition of the Prohorov distance. As a consequence, we have that $d(\mu, \nu) \geq \varepsilon$. □

Lemma 2.3. Let $r \in \mathbb{R}_{>0}$ and $\mu, \nu \in \mathcal{N}^d_X$. Then $d(\mu^{(r)}, \nu^{(r)}) \geq |\mu(B_r) - \nu(B_r)|$.

Proof. Without loss of generality, we can assume that $\mu(B_r) > \nu(B_r)$. Let $\varepsilon \in [0, \mu(B_r) - \nu(B_r))$ and let $\delta \in [0, \mu(B_r) - \nu(B_r) - \varepsilon]$. By Proposition A2.2.II in Daley and Vere-Jones [1, p. 386], there exists a closed set $F \subset B_r$ such that $\mu^{(r)}(B_r \setminus F) < \delta$. Then, we have that

$$\mu^{(r)}(F) = \mu^{(r)}(B_r) - \mu^{(r)}(B_r \setminus F) > \mu^{(r)}(B_r) - \delta$$

$$> \mu^{(r)}(B_r) - \varepsilon + \nu(B_r) - \mu(B_r) \geq \nu^{(r)}(F^c) + \varepsilon.$$

Again, this implies that $d(\mu^{(r)}, \nu^{(r)}) \geq |\mu(B_r) - \nu(B_r)|$ by definition of the Prohorov distance. □

3 The metric $d^#$ is well-defined

In this section, we address the proof in Daley and Vere-Jones [1, p. 403] that shows that $d^#$ is indeed a well-defined metric. We have to check that the integral in (1.1) is well-defined and, in particular, that $r \mapsto d(\mu^{(r)}, \nu^{(r)})$ is measurable. To achieve this, it suffices to notice that this function is actually piecewise constant since $\mu$ and $\nu$ are atomic with finitely many atoms in any bounded set. In fact, for any $R \in \mathbb{R}_{>0}$, as $r$ goes from 0 to $R$, the restricted measures $\mu^{(r)}$ and $\nu^{(r)}$ change only a finite number of times and so does $d(\mu^{(r)}, \nu^{(r)})$. The other arguments in Daley and Vere-Jones [1, p. 403] are then enough to obtain that $d^#$ satisfies all the conditions of a distance function.

As a side note, for the general case where $\mu, \nu \in \mathcal{M}^d_X$, we can prove that $r \mapsto d(\mu^{(r)}, \nu^{(r)})$ is measurable by showing that it is of finite variation.

Proposition 3.1. Let $\mu, \nu \in \mathcal{M}^d_X$ and $R \in \mathbb{R}_{>0}$. Then, as a function of $r \in \mathbb{R}_{>0}$, the variation of $d(\mu^{(r)}, \nu^{(r)})$ over $[0, R]$ is bounded by $\mu(S_R) + \nu(S_R)$. In particular, $r \mapsto d(\mu^{(r)}, \nu^{(r)})$ is of bounded variation and, thus, measurable.

Proof. Let $r \in \mathbb{R}_{>0}$ and $\delta > 0$. Applying the triangle inequality to the Prohorov distance, we obtain the following two inequalities:

$$d(\mu^{(r+\delta)}, \nu^{(r+\delta)}) \leq d(\mu^{(r+\delta)}, \mu^{(r)}) + d(\mu^{(r)}, \nu^{(r)}) + d(\nu^{(r)}, \nu^{(r+\delta)}) \leq d(\mu^{(r)}, \nu^{(r)}) + d(\nu^{(r)}, \nu^{(r+\delta)}).$$

This implies that

$$|d(\mu^{(r+\delta)}, \nu^{(r+\delta)}) - d(\mu^{(r)}, \nu^{(r)})| \leq d(\mu^{(r)}, \nu^{(r+\delta)}) + d(\nu^{(r)}, \nu^{(r+\delta)}).$$

Using Lemma 2.1, we can go further and get that

$$|d(\mu^{(r+\delta)}, \nu^{(r+\delta)}) - d(\mu^{(r)}, \nu^{(r)})| \leq \mu(S_{r+\delta}) - \mu(S_r) + \nu(S_{r+\delta}) - \nu(S_r).$$

Since $\mu(S_r)$ and $\nu(S_r)$ are non-decreasing in $r$ and always finite (because $\mu$ and $\nu$ are boundedly finite), they are of bounded variation, which concludes the proof. □
4 Characterisation of convergence in the $w^\#$-topology

In this section, we address the proof of Theorem 1.1, which characterises the convergence of boundedly finite integer-valued measures.

Proof of Theorem 1.1. We only need to show the implication (i) $\implies$ (iii) as this seems to be the only part in Daley and Vere-Jones [1, p. 403] assuming that $d(\mu^{(r)}, \nu^{(r)})$ is non-decreasing in $r \in \mathbb{R}_{\geq 0}$. The rest of the proof of Proposition A2.6.II in Daley and Vere-Jones [1, p. 403-404] can be used to show that (iii) $\implies$ (ii) $\implies$ (iv) $\implies$ (i).

Let $n \in \mathbb{N}$ and $\Sigma_n, \tilde{\Sigma}_n \in \mathbb{R}_{\geq 0}$ such that $n < \Sigma_n < \tilde{\Sigma}_n < n+1$ and $\mu(B_{\tilde{\Sigma}_n} \setminus B_{\Sigma_n}) = 0$. Let $0 < \varepsilon < (\tilde{\Sigma}_n - \Sigma_n)/2$. By contradiction, assume that for any $K \in \mathbb{N}$, there exists $k > K$ such that $\mu_k(B_{\tilde{\Sigma}_n - \varepsilon} \setminus B_{\Sigma_n + \varepsilon}) \geq 1$. Then, by Lemma 2.2, there exists a subsequence $(k_p)_{p \in \mathbb{N}}$ such that $d(\mu^{(r)}_{k_p}, \mu^{(r)}) \geq \varepsilon$ for all $r \geq n+1$, $p \in \mathbb{N}$. Thus, along this subsequence, we must have that

$$d^\#(\mu_{k_p}, \mu) = \int_0^\infty e^{-r} \frac{d(\mu^{(r)}_{k_p}, \mu^{(r)})}{1 + d(\mu^{(r)}_{k_p}, \mu^{(r)})} dr \geq \int_{n+1}^\infty e^{-r} \frac{\varepsilon}{1 + \varepsilon} dr = \frac{\varepsilon}{1 + \varepsilon} e^{-n-1} > 0,$$

which contradicts the assumption that $d^\#(\mu_k, \mu) \to 0$ as $k \to \infty$. As a consequence, there exists a $K \in \mathbb{N}$ such that, for all $k \geq K$, $\mu_k(S_{\tilde{\Sigma}_n - \varepsilon} \setminus S_{\Sigma_n + \varepsilon}) = 0$. This means that, for all $k \geq K$, both $\mu_k$ and $\mu$ do not have atoms in $S_{\tilde{\Sigma}_n - \varepsilon} \setminus S_{\Sigma_n + \varepsilon}$, whence there is some constant $d_k \in \mathbb{R}_{\geq 0}$ such that $d(\mu^{(r)}_{k}, \mu^{(r)}) = d_k$ for all $r \in (\Sigma_n + \varepsilon, \tilde{\Sigma}_n - \varepsilon)$. This implies that, for all $k \geq K$,

$$d^\#(\mu_k, \mu) = \int_0^\infty e^{-r} \frac{d(\mu^{(r)}_{k}, \mu^{(r)})}{1 + d(\mu^{(r)}_{k}, \mu^{(r)})} dr \geq \int_{\Sigma_n + \varepsilon}^{\tilde{\Sigma}_n - \varepsilon} e^{-r} \frac{d_k}{1 + d_k} dr \geq \frac{d_k}{1 + d_k} e^{-\Sigma_n - \varepsilon}(1 - e^{-(\tilde{\Sigma}_n - \Sigma_n - 2\varepsilon)}),$$

and, thus, $d_k \to 0$ as $k \to \infty$. If we set $r_n = (\Sigma_n + \tilde{\Sigma}_n)/2$, we finally have that $d(\mu^{(r_n)}_{k}, \mu^{(r_n)}) \to 0$ as $k \to \infty$.

5 Completeness and separability of $\mathcal{N}^\#_{\mathcal{X}}$

In this section, we address the proof of the first part of Theorem 1.2, which states that $\mathcal{N}^\#_{\mathcal{X}}$ is complete and separable when it is endowed with the $w^\#$-metric $d^\#$.

5.1 Completeness

To begin with, we show that if a sequence $(\mu_k)_{k \in \mathbb{N}}$ in $(\mathcal{N}^\#_{\mathcal{X}}, d^\#)$ is Cauchy, then the restrictions along an increasing sequence of balls are also Cauchy for the Prohorov metric $d$.

Proposition 5.1. Let $(\mu_k)_{k \in \mathbb{N}}$ be a Cauchy sequence in $\mathcal{N}^\#_{\mathcal{X}}$ for the $w^\#$-metric $d^\#$. Then, there exists an increasing sequence $(r_n)_{n \in \mathbb{N}}$ in $\mathbb{R}_{\geq 0}$ with $r_n \to \infty$ as $n \to \infty$ such that, for each $n \in \mathbb{N}$, $(\mu^{(r_n)}_{k})_{k \in \mathbb{N}}$ is a Cauchy sequence in $\mathcal{M}_{\mathcal{X}}$ for the Prohorov metric $d$.

Proof. Step 1. We show that $\mu_k(B_r)$ is bounded in $k \in \mathbb{N}$ for all $r \in \mathbb{R}_{\geq 0}$. By contradiction, assume that this is not the case. Then, there exists a subsequence such that $\mu_{k_p}(B_r) \to \infty$. Along this subsequence, for
p large enough and any fixed \( q \in \mathbb{N} \), we have that
\[
\int_{r}^{r+1} e^{-s} \frac{d(\mu_{k_p}^{(s)}, \mu_{k_q}^{(s)})}{1 + d(\mu_{k_p}^{(s)}, \mu_{k_q}^{(s)})} \, ds \geq \int_{r}^{r+1} e^{-s} \frac{|\mu_{k_p}(B_s) - \mu_{k_q}(B_s)|}{1 + |\mu_{k_p}(B_s) - \mu_{k_q}(B_s)|} \, ds \geq \int_{r}^{r+1} e^{-s} \frac{\mu_{k_p}(B_s) - \mu_{k_q}(B_s)}{1 + |\mu_{k_p}(B_s) - \mu_{k_q}(B_s)|} \, ds \to e^{-r}(1 - e^{-1}), \quad p \to \infty,
\]
where we used Lemma 2.3 and the fact that \( \mu_{k_p}(B_s) \) and \( \mu_{k_q}(B_s) \) are non-decreasing in \( s \). But this is incompatible with the Cauchy assumption on \((\mu_k)_{k \in \mathbb{N}}\). Indeed, let \( \varepsilon < e^{-r}(1 - e^{-1}) \). Then, the Cauchy assumption implies that there exists \( K \in \mathbb{N} \) such that, for all \( k, k' \geq K \),
\[
d^\#(\mu_k, \mu_{k'}) = \int_{0}^{\infty} e^{-s} \frac{d(\mu_{k_p}^{(s)}, \mu_{k_q}^{(s)})}{1 + d(\mu_{k_p}^{(s)}, \mu_{k_q}^{(s)})} \, ds \leq \varepsilon.
\]
But then, for \( p, q \in \mathbb{N} \) large enough, we must have that
\[
\varepsilon \geq \int_{0}^{\infty} e^{-s} \frac{d(\mu_{k_p}^{(s)}, \mu_{k_q}^{(s)})}{1 + d(\mu_{k_p}^{(s)}, \mu_{k_q}^{(s)})} \, ds \geq \int_{r}^{r+1} e^{-s} \frac{d(\mu_{k_p}^{(s)}, \mu_{k_q}^{(s)})}{1 + d(\mu_{k_p}^{(s)}, \mu_{k_q}^{(s)})} \, ds > \varepsilon.
\]

**Step 2.** Let \( n \in \mathbb{N} \). We show that for \( k, p \in \mathbb{N} \) large enough, there is a subinterval of \([n, n+1]\) on which the functions \( r \mapsto d((\mu_k(r), \mu_p(r)) \) are constant. Define \( M := \sup_{k \in \mathbb{N}} \mu_k(B_{n+1}) \), which is finite by the first step and can be understood as a bound on the number of points in the ball \( B_{n+1} \) among all measures \( \mu_k \). Let \( \varepsilon_1, \varepsilon_2 \in \mathbb{R}_{>0} \) such that \( \varepsilon_1 < \varepsilon_2 < 1/2(M+1) \) and \( \varepsilon_1 < \varepsilon_2e^{-n-1}/(1 + \varepsilon_2) \). Let \( K \in \mathbb{N} \) such that, for all \( k, k' \geq K \), \( d^\#(\mu_k, \mu_{k'}) \leq \varepsilon_1 \) (Cauchy assumption). Since \( \mu_k(B_{n+1} \setminus B_n) \leq M \), we can find \( \tau_n, \tau_n' \in (n, n+1) \) such that \( \mu_k(B_{\tau_n} \setminus B_{\tau_n'}) = 0 \) and \( \tau_n - \tau_n' \geq 1/(M+1) \). Now, by contradiction, assume that for some \( p > K \), we have \( \mu_p(B_{\tau_n+\varepsilon_2} \setminus B_{\tau_n+\varepsilon_2}) \geq 1 \). Then, using Lemma 2.2, we obtain that
\[
\varepsilon_1 \geq d^\#(\mu_K, \mu_p) = \int_{0}^{\infty} e^{-r} \frac{d(\mu_k^{(r)}, \mu_p^{(r)})}{1 + d(\mu_k^{(r)}, \mu_p^{(r)})} \, dr \geq \int_{n+1}^{\infty} e^{-r} \frac{d(\mu_k^{(r)}, \mu_p^{(r)})}{1 + d(\mu_k^{(r)}, \mu_p^{(r)})} \, dr \geq \frac{\varepsilon_2}{1 + \varepsilon_2} e^{-n-1},
\]
which contradicts the original assumption on \( \varepsilon_1 \) and \( \varepsilon_2 \). As a consequence, for all \( k \geq K \), we have that \( \mu_k(B_{\tau_n-\varepsilon_2} \setminus B_{\tau_n+\varepsilon_2}) = 0 \), which implies that \( r \mapsto d((\mu_p(r), \mu_q(r)) \) is constant on \((\tau_n + \varepsilon_2, \tau_n - \varepsilon_2)\) for all \( p, q \geq K \).

**Step 3.** We finally show that when \( r_n =: (\tau_n + \tau_n)/2, (\mu_k^{(r_n)})_{k \in \mathbb{N}} \) is a Cauchy sequence for the Prohorov metric \( d \). Let \( \delta > 0 \) and set \( \varepsilon := (\tau_n - \tau_n - 2\varepsilon_2)e^{-n-1}/(1 + \varepsilon) \). Let \( J \in \mathbb{N} \) such that, for all \( p, q \geq J \), \( d^\#(\mu_k, \mu_{k'}) \leq \delta \) (Cauchy assumption). Then, for all \( p, q \geq K \cup J \), we must have that
\[
\delta \geq \int_{\tau_n-\varepsilon_2}^{\tau_n+\varepsilon_2} e^{-r} \frac{d_{pq}}{1 + d_{pq}} \, dr \geq \frac{d_{pq}}{1 + d_{pq}} (\tau_n - \tau_n - 2\varepsilon_2)e^{-n-1},
\]
where \( d_{pq} := d((\mu_p^{(r_n)}, \mu_q^{(r_n)}) \), and which implies
\[
d_{pq} \leq \frac{\delta}{(\tau_n - \tau_n - 2\varepsilon_2)e^{-n-1} - \delta} = \frac{1}{\frac{2\varepsilon_2}{\varepsilon} - 1} = \varepsilon.
\]
Proof. Let \((\mu_k^{(r_n)})_{k \in \mathbb{N}}\) be the atoms of \(\mu\) in \(B_R\) where \(N \in \mathbb{N}\) is their total number and let \((w_n)_{n \in \{1, \ldots, N\}}\) be their corresponding weights. Let \(\varepsilon_1 > 0\) such that \(B_{\varepsilon_1}(u_n) \subset B_R\) for all \(n = 1, \ldots, N\). Let \(0 \leq r_1 < \cdots < r_N < R\) be the radii at which the atoms are located where \(N' \in \mathbb{N}\), \(N' \leq N\) \((r_0 = 1\) means that \(x_0 \in (u_n)_{n \in \{1, \ldots, N\}}\)). Define \(\varepsilon_2 := \frac{1}{2} \min_{n < N'}(r_{n+1} - r_n)\) and \(\varepsilon_3 := \varepsilon / 4N'\). Define \(\varepsilon_4 := \varepsilon / (2c - \varepsilon)\), where \(c = 1 - e^{-R}\), and assume that \(\varepsilon < 2c\) (if this is not the case, then the desired inequality already holds no matter \(\tilde{\mu}\)). Finally, set \(\delta := \min(\varepsilon_1, \varepsilon_2, \varepsilon_3, \varepsilon_4)\) and let \((\tilde{u}_n)_{n \in \{1, \ldots, N\}}\) be such that \(\tilde{u}_n \in \mathcal{D}_{X}\), \(\tilde{u}_n \in B_\delta(u_n)\), \(n = 1, \ldots, N\). We will show that \(\tilde{\mu} := \sum_{n=1}^{N} w_n \delta \tilde{u}_n\) satisfies the desired inequality.

Let \(n = 1, \ldots, N' - 1\) and \(r \in (r_n + \delta, r_{n+1} - \delta)\). We can check that \(d(\mu^{(r)}, \tilde{\mu}^{(r)}) \leq \delta\). Indeed, since \(\delta \leq \varepsilon_1\) and \(\delta \leq \varepsilon_2\), we have that \(\tilde{u}_n \in B_r\) if and only if \(\tilde{u}_n \in B_{r_1}\). As a consequence, for any closed set \(A \in \mathcal{B}(X) \cap B_r\), using the fact that \(\tilde{u}_n \in B_{\delta}(u_n)\), we have that

\[
\mu^{(r)}(A) = \mu(A) \leq \tilde{\mu}(A^\delta \cap B_r) = \tilde{\mu}^{(r)}(A^\delta) \quad \text{and} \quad \tilde{\mu}^{(r)}(A) = \tilde{\mu}(A) \leq \mu(A^\delta \cap B_r) = \mu^{(r)}(A^\delta),
\]

which means that \(d(\mu^{(r)}, \tilde{\mu}^{(r)}) \leq \delta\). Similarly, we also have that \(d(\mu^{(r)}, \tilde{\mu}^{(r)}) \leq \delta\) for all \(r \in [0, 0 \vee (r_1 - \delta))\)
and all $r \in (r_{N'}, \delta, R]$. Using this bound on the Prohorov distance between the restrictions, we obtain that

$$
\int_0^R e^{-r} d\left(\mu(r), \tilde{\mu}(r)\right) 1 + d(\mu(r), \tilde{\mu}(r)) dr = \left( \int_0^{r_{N'} \lor 0} + \sum_{n=1}^{N'} \int_{r_n + \delta}^{r_{n+1} \lor 0} + \sum_{n=1}^{N'-1} \int_{r_n + \delta}^{r_{n+1} + \delta} + \int_{r_{N'} + \delta}^R \right) e^{-r} d\left(\mu(r), \tilde{\mu}(r)\right) 1 + d(\mu(r), \tilde{\mu}(r)) dr
$$

$$
\leq \int_0^R e^{-r} \frac{\delta}{1 + \delta} dr + \sum_{n=1}^{N'} \int_{r_n + \delta}^{r_{n+\delta}} e^{-r} d\left(\mu(r), \tilde{\mu}(r)\right) 1 + d(\mu(r), \tilde{\mu}(r)) dr
$$

$$
\leq (1 - e^{-R}) \frac{\delta}{1 + \delta} + 2 \delta N' \leq (1 - e^{-R}) \frac{\varepsilon_4}{1 + \varepsilon_4} + 2 \varepsilon_3 N' = \frac{\varepsilon}{2} + \frac{\varepsilon}{2} = \varepsilon.
$$

\[ \square \]

6 Characterisation of the $\sigma$-algebra $B(N^\#_X)$

This section proves the second part of Theorem 1.2. We show that all mappings $\Phi_A : \xi \mapsto \xi(A), \xi \in N^\#_X, A \in B(X)$, are measurable with respect to the Borel $\sigma$-algebra $B(N^\#_X)$ and that $B(N^\#_X)$ is actually generated by all these mappings. This property is very useful to check the measurability of functionals on $N^\#_X$, like for example Hawkes functionals, as demonstrated in Morariu-Patrichi and Pakkanen [6]. Our proof is different from the original one in Daley and Vere-Jones [1, p. 405] as we identify a convenient basis for the $w^\#$-hash topology (Proposition 6.1). Note however that this last result is directly inspired by Proposition A25.I in Daley and Vere-Jones [1, p. 398], where three different bases for the weak topology on $M_X$ are given. Besides, our proof of Theorem 1.2.(ii) shows explicitly why the mapping $\Phi_A$ is $B(N^\#_X)$-measurable when $A$ is a bounded closed set.

Proposition 6.1. Consider the family of sets

$$
\{ \xi \in N^\#_X : \xi(F_i) < \mu(F_i) + \varepsilon \text{ for } i = 1, \ldots, m, \\
|\xi(\partial B_{r_j}) - \mu(\partial B_{r_j})| < \varepsilon \text{ and } \xi(\partial B_{r_j}) = 0 \text{ for } j = 1, \ldots, n \},
$$

(6.1)

where $\mu \in N^\#_X, \varepsilon \in \mathbb{R}_{>0}, m, n \in \mathbb{N}, F_i, i = 1, \ldots, m$, is a bounded closed set of $X$ and $r_j \in \mathbb{R}_{>0}, j = 1, \ldots, n$, is such that $\mu(\partial B_{r_j}) = 0$. This family forms a basis that generates the $w^\#$-topology.

Proof. Step 1. We check that this family is a basis. Let $\mu, \mu' \in N^\#_X, \varepsilon, \varepsilon' \in \mathbb{R}_{>0},$ let $F_1, \ldots, F_m$ and $F'_1, \ldots, F'_{m'}$ be bounded closed sets and let $r_1, \ldots, r_m, r'_1, \ldots, r'_{m'} > 0$ such that $\mu(\partial B_{r_j}) = 0$ and $\mu'(\partial B_{r'_j}) = 0$. Consider the sets $A$ and $B$ of the form (6.1) generated by these two collections, respectively, and let $\mu'' \in A \cap B$. We will now find a set $C$, again of the form (6.1), such that $\mu'' \in C$ and $C \subset A \cap B$. Set the following parameters:

$$
\delta := \min_{i=1, \ldots, m} \mu(F_i) + \varepsilon - \mu''(F_i),
\delta' := \min_{i=1, \ldots, m} \mu'(F'_i) + \varepsilon' - \mu''(F'_i),
\gamma := \min_{j=1, \ldots, n} \varepsilon - |\mu''(\partial B_{r_j}) - \mu(\partial B_{r_j})|, \gamma' := \min_{j=1, \ldots, n} \varepsilon' - |\mu''(\partial B_{r'_j}) - \mu'(\partial B_{r'_j})|;
$$

and let $\varepsilon'' := \min(\delta, \delta', \gamma, \gamma')$. Now, consider the set

$$
C := \{ \xi \in N^\#_X : \xi(F_i) < \mu''(F_i) + \varepsilon'' \text{ for } i = 1, \ldots, m, \xi(F'_i) < \mu''(F'_i) + \varepsilon'' \text{ for } i = 1, \ldots, m', \xi(\partial B_{r_j}) - \mu''(\partial B_{r_j})| < \varepsilon'' \text{ and } \xi(\partial B_{r_j}) = 0 \text{ for } j = 1, \ldots, n, \xi(\partial B_{r'_j}) - \mu''(\partial B_{r'_j})| < \varepsilon'' \text{ and } \xi(\partial B_{r'_j}) = 0 \text{ for } j = 1, \ldots, n' \}.
$$
Clearly, the set $C$ is of the form (6.1). We now finally check that $C \subset A \cap B$. Let $\xi \in C$. For all $i = 1, \ldots, m$, we have that

$$\xi(F_i) < \mu''(F_i) + \varepsilon'' \leq \mu(F_i) + \varepsilon,$$

because $\varepsilon'' \leq \mu(F_i) + \varepsilon - \mu''(F_i)$. For all $j = 1, \ldots, n$, we have that

$$|\xi(\overline{B}_{r_j}) - \mu(\overline{B}_{r_j})| \leq |\xi(\overline{B}_{r_j}) - \mu''(\overline{B}_{r_j})| + |\mu''(\overline{B}_{r_j}) - \mu(\overline{B}_{r_j})| < \varepsilon,$$

because $\varepsilon'' \leq \varepsilon - |\mu''(\overline{B}_{r_j}) - \mu(\overline{B}_{r_j})|$. Thus, $\xi \in A$. A similar argument yields $\xi \in B$ and so $C \subset A \cap B$.

**Step 2.** We check that every element of this basis contains an open ball. Consider first any set $A$ of the form (6.1) but for which $n = 1$ (only one ball). Let $\delta \in (0,1)$ such that $2\delta < \varepsilon$, $\mu(F_i^\delta) = \mu(F_i)$ for all $i = 1, \ldots, m$, and

$$\mu\left(\overline{B}_{r_i} \setminus B_{r_i}^\delta\right) = 0,$$

which means that $\delta$ is chosen small enough such that there are no atoms within a distance $\delta$ of the boundary $\partial B_{r_i}$. Let $R \in \mathbb{R}_{>0}$ such that $F_i^\delta \subset B_R$ for all $i = 1, \ldots, m$ and such that $r_i + 2\delta < R$. Consider now the ball $B := \{\xi \in N_{\mathcal{X}}^\# : d^\#(\mu, \xi) < \gamma\}$ where $\gamma := e^{-R}\delta/(1+\delta)$. Take any $\xi \in B$ and, by contradiction, assume that $\xi(F_i) > \mu(F_i^\delta) + \delta$ for some $i = 1, \ldots, m$. Then, this implies that $d(\xi(r), \mu(r)) \geq \delta$ for all $r \geq R$, which in turn implies that

$$d^\#(\xi, \mu) \geq \int_R^\infty e^{-r} \frac{\delta}{1+\delta} dr = \gamma.$$

This contradicts the fact that $\xi \in B$ and, thus, we must have that

$$\xi(F_i) \leq \mu(F_i^\delta) + \delta = \mu(F_i) + \delta < \mu(F_i) + \varepsilon, \quad i = 1, \ldots, m.$$

The same reasoning holds for the closed sets $\overline{B}_{r_i}$ and $\partial B_{r_i}$, finally implying that

$$\xi(\partial B_{r_i}) = \mu(\partial B_{r_i}) = 0 \quad \text{and} \quad \xi(\overline{B}_{r_i}) - \mu(\overline{B}_{r_i}) \leq \delta < \varepsilon.$$

To obtain that $\xi \in A$, it remains only to show that $\mu(\overline{B}_{r_i}) - \xi(\overline{B}_{r_i}) < \varepsilon$. Using again the previous reasoning, we also have that

$$\xi(\overline{B}_{r_i}^\delta) - \xi(\overline{B}_{r_i}) = \xi(\overline{B}_{r_i}^\delta \setminus B_{r_i}) \leq \xi\left(\overline{B}_{r_i}^\delta \setminus \overline{B}_{r_i}\right) \leq \mu\left(\overline{B}_{r_i}^\delta \setminus \overline{B}_{r_i}\right) + \delta = \delta,$$

and also that $\mu(\overline{B}_{r_i}) \leq \xi(\overline{B}_{r_i}^\delta) + \delta$. This implies the desired inequality

$$\mu(\overline{B}_{r_i}) - \xi(\overline{B}_{r_i}) = \mu(\overline{B}_{r_i}) - \xi(\overline{B}_{r_i}^\delta) + \xi(\overline{B}_{r_i}^\delta) - \xi(\overline{B}_{r_i}) \leq \delta + \delta < \varepsilon,$$

and allows us to conclude that the ball $B$ is included in the neighbourhood $A$. Regarding the general case when the set $A$ is defined by multiple balls (i.e., $n > 1$), simply view it as an intersection of sets $A_j$, where each $A_j$ is defined by one ball (i.e., $m = 1$). As shown above, for each $A_j$, we can find an adequate ball with centre $\mu$ and radius $\gamma_j$. Then, the ball with radius $\gamma = \min \gamma_j$ must be included in $A$.

**Step 3.** We check that every open ball contains an element of this basis. Let $\mu \in N_{\mathcal{X}}^\#$, $\varepsilon \in \mathbb{R}_{>0}$ and consider the ball $B := \{\xi \in N_{\mathcal{X}}^\# : d^\#(\mu, \xi) < \varepsilon\}$. Let $R > 0$ such that $e^{-R} < \frac{1}{2}\varepsilon$. Let $\rho_1 < \ldots < \rho_N$ be all the radii in $(0, R)$ such that $\mu(\partial B_{\rho_j}) > 0$, $j = 1, \ldots, N$. Set also $\rho_0 := 0$ and $\rho_{N+1} := R$. Define $\rho := \frac{1}{2}\min_{j=1,\ldots,N+1} \rho_j - \rho_{j-1}$, let $\gamma < \varepsilon/(8(N+2))$ and set $\delta := \min(\rho, \gamma)$. Define the bounded closed
sets $G_j := \overline{B}_{\rho_j - \delta} \setminus B_{\rho_j - \delta}$ for $j = 1, \ldots, N + 1$ and notice that $\mu(G_j) = 0$. Also, define the radii $r_j := (\rho_j - 1 + \rho_j)/2$, $j = 1, \ldots, N + 1$. For all $r_j$, reusing the last part of the proof of Proposition A2.5.I in Daley and Vere-Jones [1, p. 399], we know that we can find $\bar{\varepsilon}_j \in (0,1)$ and a finite family of closed bounded sets $F_{1,j}, \ldots, F_{m_{j},j}$ such that

$$A_j := \{\xi \in \mathcal{N}_X^# : \xi(F_{i,j}) < \mu(F_{i,j}) + \bar{\varepsilon}_j \text{ for } i = 1, \ldots, m_j, |\xi(\overline{B}_{r_j}) - \mu(\overline{B}_{r_j})| < \bar{\varepsilon}_j\}$$

$$\subset \{\xi \in \mathcal{N}_X^# : d(\nu(r), \xi(r)) < c\},$$

where here we choose $c$ such that $(1 - e^{-R})c/(1 + c) < \varepsilon/4$. Finally, set $\bar{\varepsilon} = \min \bar{\varepsilon}_j$ and consider the set

$$A := \{\xi \in \mathcal{N}_X^# : \xi(F_{i,j}) < \mu(F_{i,j}) + \bar{\varepsilon} \text{ for } i = 1, \ldots, m_j, \xi(G_j) < \mu(G_j) + \bar{\varepsilon},$$

$$|\xi(\overline{B}_{r_j}) - \mu(\overline{B}_{r_j})| < \bar{\varepsilon} \text{ and } \xi(\partial B_{r_j}) = 0, \text{ for } j = 1, \ldots, N + 1\},$$

which is of the form (6.1) and is such that $A \subset A_j$, $j = 1, \ldots, N + 1$. For all $\xi \in A$, this implies that $d(\nu(r), \xi(r)) < c$, $j = 1, \ldots, N + 1$. This also implies that $\xi(G_j) = 0$, and thus $r \mapsto d(\nu(r), \xi(r))$ is constant on each interval $(\rho_{j-1} + \delta, \rho_j - \delta)$, $j = 1, \ldots, N + 1$. Noting that $r_j \in (\rho_{j-1} + \delta, \rho_j - \delta)$, it remains to check that

$$d^#(\mu, \xi) < \int_0^R e^{-r} \frac{d(\nu(r), \xi(r))}{1 + d(\nu(r), \xi(r))}dr + \frac{1}{2}\varepsilon$$

$$< 2\delta(N + 2) + (1 - e^{-R})\frac{c}{1 + c} + \frac{1}{2}\varepsilon < \frac{1}{4}\varepsilon + \frac{1}{4}\varepsilon + \frac{1}{2}\varepsilon = \varepsilon.$$

As a consequence, we have indeed that $A \subset B$, which concludes the proof.

\[\square\]

**Proof of Theorem 1.2.(ii).** **Step 1.** We first show that $\Phi_A$ is $\mathcal{B}(\mathcal{N}_X^#)$-measurable for all bounded closed set $A$. Let $n \in \mathbb{N}$. We prove that $I := \{\xi \in \mathcal{N}_X^# : \xi(A) \leq n\}$ is an open set of $\mathcal{N}_X^#$, implying that $\Phi_A$ is indeed $\mathcal{B}(\mathcal{N}_X^#)$-measurable. If $A = \emptyset$, then $I = \mathcal{N}_X^#$, which is open. From now on, we assume that $A \neq \emptyset$. Let $\mu \in I$ ($I$ is clearly not empty). Let $\delta \in (0,1)$ such that $\mu(A) = \mu(A^\delta)$ (this is always possible since $\mu$ has a finite number of atoms in $A^\gamma \setminus A$, with $\gamma = 1$, say). Let $R > 0$ such that $A^\delta \subset B_R$. Consider the open ball $J := \{\nu \in \mathcal{N}_X^# : d^#(\mu, \nu) < \varepsilon\}$ with $\varepsilon = e^{-R}\delta/(1 + \delta)$. We then have that $J \subset I$, which implies that $I$ is open. Indeed, let $\nu \in J$ and, by contradiction, assume that $\nu(A) > \mu(A^\delta) + \delta$. Then, for all $r \geq R$, this implies that

$$\nu^{(r)}(A) = \nu(A) > \mu(A^\delta) + \delta = \mu^{(r)}(A^\delta) + \delta,$$

which means that $d(\mu^{(r)}, \nu^{(r)}) \geq \delta$. Hence,

$$d^#(\mu, \nu) \geq \int_R^\infty e^{-r} \frac{\delta}{1 + \delta}dr = \varepsilon,$$

which contradicts the assumption that $\nu \in J$. As a consequence, we must have that $\nu(A) \leq \mu(A^\delta) + \delta = \mu(A) + \delta$. Since, $\nu(A) \in \mathbb{N}$, $\mu(A) \in \mathbb{N}$ and $\delta < 1$, this implies that $\nu(A) \leq \mu(A) \leq n$, and thus $\nu \in I$.

**Step 2.** Consider the class $\mathcal{C}$ of sets $\mathcal{C} := \{A \in \mathcal{B}(X) : \Phi_A \text{ is } \mathcal{B}(\mathcal{N}_X^#) \text{-measurable}\}$. By the continuity of measures [3, Lemma 1.14 p. 8], we have that $\Phi_{A_n} \uparrow \Phi_A$ for any sequence $A_n \uparrow A$, and since the limit of measurable functions is measurable [3, Lemma 1.9 p. 6], we have that $\mathcal{C}$ is closed under increasing limits. In other words, $\mathcal{C}$ forms a monotone class. Moreover, consider the class $\mathcal{R}$ of sets of the form $\bigcup_{i=1}^n A_i \setminus B_i$ where $n \in \mathbb{N}$ and $A_i, B_i \in \mathcal{B}(X)$ are bounded closed sets such that $(A_i \setminus B_i) \cap (A_j \setminus B_j) = \emptyset$ as soon as $i \neq j$ (i.e., we consider finite disjoint unions of differences of bounded closed sets). One can check that $\mathcal{R}$
is stable by finite intersections and symmetric differences (perhaps the most difficult is to see that, for any bounded closed sets $A_1, A_2, B_1, B_2$, the difference $(A_1 \setminus B_1) \setminus (A_2 \setminus B_2)$ can be written as a disjoint union of differences of bounded closed sets). This means that $\mathcal{R}$ forms a ring. Besides, for any bounded closed sets $A, B \in \mathcal{X}$, since $\xi(A) < \infty$ for all $\xi \in \mathcal{N}_\mathcal{X}^\#$, we have that $\Phi_{A \setminus B} = \Phi_{A \setminus (A \cap B)} = \Phi_A - \Phi_{A \cap B}$. As $A \cap B$ is still a bounded closed set, by applying the first part of the proof, we obtain that $\Phi_{A \setminus B}$ is measurable. By the countable additivity of measures, this implies that $\Phi_A$ is measurable for any set $A \in \mathcal{R}$, and thus $\mathcal{R} \subset \mathcal{C}$.

By the monotone class theorem [1, p. 369], we then have that $\sigma(\mathcal{R}) \subset \mathcal{C}$. But $\mathcal{R}$ contains all the bounded closed balls and any open set in $\mathcal{X}$ is a countable union of those since $\mathcal{X}$ is separable. As a consequence, we must have that $\mathcal{B}(\mathcal{X}) = \sigma(\mathcal{R}) \subset \mathcal{C}$, meaning that $\Phi_A$ is measurable for all $A \in \mathcal{B}(\mathcal{X})$.

**Step 3.** To show that $\mathcal{B}(\mathcal{N}_\mathcal{X}^\#)$ is actually generated by all mappings $\Phi_A, A \in \mathcal{B}(\mathcal{X})$, consider any $\sigma$-algebra $\mathcal{R}$ on $\mathcal{N}_\mathcal{X}^\#$ such that all mappings $\Phi_A$ are measurable. Then, all the sets of the form (6.1) should belong to $\mathcal{R}$ and, by Proposition 6.1, these sets form a basis for the $w^\#$-topology. Since $\mathcal{N}_\mathcal{X}^\#$ is separable, any open set of the $w^\#$-topology can be represented as a countable union of these sets and, thus, $\mathcal{B}(\mathcal{N}_\mathcal{X}^\#) \subset \mathcal{R}$.
