Abstract

Depending on the interpretation of the type of edges, a chain graph can represent different relations between variables and thereby independence models. Three interpretations, known by the acronyms LWF, MVR, and AMP, are prevalent. Multivariate regression (MVR) chain graphs were introduced by Cox and Wermuth in 1993. We review Markov properties for MVR chain graphs and propose an alternative global and local Markov property for them. Also, we prove equivalence of all proposed Markov properties in the literature for compositional graphoids. We derive a new factorization formula for MVR chain graphs which is more explicit than and different from the proposed factorizations for MVR chain graphs in the literature. Finally, we provide a summary table comparing different features of LWF, AMP, and MVR chain graphs.

Keywords: multivariate regression chain graph; Markov property; graphical Markov models; factorization of probability distributions; conditional independence; marginalization of causal latent variable models; compositional graphoids.

1. Introduction

A probabilistic graphical model is a probabilistic model for which a graph represents the conditional dependence structure between random variables. There are several classes of graphical models; Bayesian networks (BN), Markov networks, chain graphs, and ancestral graphs are commonly used (Lauritzen 1996; Richardson and Spirtes 2002). Chain graphs, which admit both directed and undirected edges, are a type of graphical model in which there are no partially directed cycles. Chain graphs were introduced by Lauritzen, Wermuth and Frydenberg (Frydenberg 1990; Lauritzen and Wermuth 1989) as a generalization of graphical models based on undirected graphs and directed acyclic graphs (DAGs). Later on Andersson, Madigan and Perlman introduced an alternative Markov property for chain graphs (Andersson et al. 1996). In 1993 Cox and Wermuth introduced multivariate regression (MVR) chain graphs as a combination of a (sequence of) multivariate regression graph(s) and covariance graph(s), where a multivariate regression graph is a two-box graph in which all edges are dashed. Edges in both boxes are dashed lines, and between boxes are dashed arrows. Note that if the right-hand box has two lines around it, the distribution of its components have been considered fixed, and a covariance graph is a single box graph in which all edges are undirected dashed lines. The 1993 paper does not provide a (global) Markov property for the newly introduced MVR chain graphs. In 1996, Cox and Wermuth introduced the joint-response chain graphs (Cox and Wermuth 1996) as a graphical model in which the nodes can be arranged in a line of boxes from left to right; each box contains either a single node, or a full-line concentration graph (i.e. a single box graph in which all edges are undirected full lines), or a dashed-line covariance graph. The variables in each box are considered conditionally independent given variables in boxes to the right, in a way that is now going to be specified precisely. Arrows pointing to any one box are either all dashed arrows or all full arrows. Dashed ar-
rows to a node $i$ indicates that regressions of $Y_i$ (the variable corresponding to node $i$; as customary in graphical models, we will not distinguish between nodes and variables) on variables in boxes to the right of $i$ are being considered, whereas full-line arrows mean that the regression is taken both on variables in boxes to the right of $i$ and on the variables in the same box as $i$. For example, see Figure 1 for a simple illustration of the distinctions. Figure 1(a) shows a joint-response chain graph with variables $U$, $V$ as explanatory to $X$, $Y$, $Y$ regressed on $X$, $U$, $V$ and $X$ regressed on $Y$, $U$, $V$. In this graph: $Y \perp \perp U|(X, V)$ and $X \perp \perp V|(Y, U)$. Figure 1(b) shows a joint-response chain graph with $Y$ as a response to $V$ and $X$ as a response to $U$, which implies $Y \perp \perp U|V$ and $X \perp \perp V|U$.

Figure 1: (Cox and Wermuth, 1996, p. 70 and 72) (a) a LWF chain graph, (b) a MVR chain graph

Since the paper appear, the two kinds of chain graphs illustrated in the previous example have received special names; full-edge joint-response chain graphs are known as chain graph under the Lauritzen-Wermuth-Frydenberg (LWF) interpretation, or simply LWF chain graphs, and dashed-edge joint-response chain graphs are known as multivariate regression (MVR) chain graphs.

It is worthwhile to mention that in Cox and Wermuth (1996, p. 43) Cox and Wermuth claim that if we start with any dashed-line joint-response chain graph we can obtain a synthetic directed acyclic graph, i.e. one in which specified nodes represent variables over which marginalization occurs (We prove this claim in Theorem 15). For example, both graphs in Figure 2 and also, both graphs in Figure 3 have the same Markov property. Note that at that time the multivariate regression (MVR) Markov property had not been introduced.

Figure 2: Both graphs specify the same Markov property: $Y \perp \perp U|V$ and $X \perp \perp V|U$.

Furthermore, Cox and Wermuth claim that a directed acyclic graph (DAG) will result, implying the same independencies for the observed nodes unless in the original joint-response chain graph
there is a subgraph with a sink-oriented U-configuration or there is a sink-oriented V-configuration from which a direction-preserving path of arrows leads to nodes joined by an undirected line (Cox and Wermuth, 1996, p. 44). However, we know that there is no (finite) DAG model which, under marginalizing and conditioning, gives the set of conditional independence relations implied by graph $G$ in the Figure 4 (Lauritzen and Richardson, 2002), so the claim is false.

In the first decade of the 21st century, several Markov property (global, pairwise, block recursive, and so on) were introduced by authors and researchers (Richardson and Spirtes, 2002; Wermuth and Cox, 2004; Marchetti and Lupparelli, 2008, 2011; Drton, 2009). Lauritzen, Wermuth, and Sadeghi (Sadeghi and Lauritzen, 2014; Sadeghi and Wermuth, 2016) proved that the global and (four) pairwise Markov properties of a MVR chain graph are equivalent for any independence model that is a compositional graphoid.

In this paper we focus on the class of multivariate regression (MVR) chain graphs and we discuss their definition and their Markov properties. The major contributions of this paper may be summarized as follows:

- Proposed an alternative global and local Markov property for MVR chain graphs, which are equivalent with other Markov properties in the literature for compositional graphoids.

- Compared different proposed Markov properties for MVR chain graphs in the literature and considered conditions under which they are equivalent.
• Derived an alternative explicit factorization criterion for MVR chain graphs based on the proposed factorization criterion for acyclic directed mixed graphs in (Richardson, 2009).

The rest of the paper is organized as follows: Sections 2 review background and related work, and also more definitions and concepts for MVR chain graphs is introduced. In Section 3, we provide an alternative global Markov property for MVR chain graphs and prove that all of proposed Markov properties for MVR chain graphs are equivalent for compositional graphoids. Section 4 presents the proposed an alternative factorization for MVR chain graphs according to the proposed factorization criterion for acyclic directed mixed graphs in (Richardson, 2009). Many properties of the common interpretations of chain graphs are summarized in a table at the end of the paper.

2. Definitions and Concepts

In this section, we introduce some definitions and concepts that we need to review MVR chain graphs.

Definition 1 A vertex $\alpha$ is said to be an ancestor of a vertex $\beta$ if either there is a directed path $\alpha \rightarrow \ldots \rightarrow \beta$ from $\alpha$ to $\beta$, or $\alpha = \beta$. A vertex $\alpha$ is said to be anterior to a vertex $\beta$ if there is a path $\mu$ from $\alpha$ to $\beta$ on which every edge is either of the form $\gamma \leftarrow \delta$, or $\gamma \rightarrow \delta$ with $\delta$ between $\gamma$ and $\beta$, or $\alpha = \beta$; that is, there are no edges $\gamma \leftrightarrow \delta$ and there are no edges $\gamma \leftarrow \delta$ pointing toward $\alpha$. Such a path is said to be an anterior path from $\alpha$ to $\beta$. A vertex $\alpha$ is said to be antecedent to a vertex $\beta$ if there is a path $\mu$ from $\alpha$ to $\beta$ on which every edge is either of the form $\gamma \leftrightarrow \delta$, or $\gamma \rightarrow \delta$ with $\delta$ between $\gamma$ and $\beta$, or $\alpha = \beta$; that is, there are no edges of the form $\gamma \leftarrow \delta$. Such a path is said to be an antecedent path from $\alpha$ to $\beta$. We apply these definitions disjunctively to sets:

$\text{an}(X) = \{\alpha | \alpha \text{ is an ancestor of } \beta \text{ for some } \beta \in X\}$;

$\text{ant}(X) = \{\alpha | \alpha \text{ is an anterior of } \beta \text{ for some } \beta \in X\}$;

$\text{antec}(X) = \{\alpha | \alpha \text{ is an antecedent of } \beta \text{ for some } \beta \in X\}$.

The usage of the terms “ancestor” and “anterior” differs from Lauritzen (Lauritzen, 1996), but follows Frydenberg (Frydenberg, 1990).

Definition 2 If $\text{antec}(a) \subseteq A$ for all $a \in A$, we say that $A$ is an antecedental set. The smallest antecedental set containing $A$ is denoted by $\text{Antec}(A)$.

Remark 3 Note that when $a$ is an ancestor of $b$, it can be considered as an anterior or an antecedent of $b$ but not vice versa. Also, note that the notions anterior and antecedent are not comparable in general.

Definition 4 A mixed graph is a graph containing three types of edges, undirected ($-$), directed ($\rightarrow$) and bidirected ($\leftrightarrow$).

Definition 5 An ancestral graph $G$ is a mixed graph in which the following conditions hold for all vertices $\alpha$ in $G$:

(i) if $\alpha$ and $\beta$ are joined by an edge with an arrowhead at $\alpha$, then $\alpha$ is not anterior to $\beta$.

(ii) there are no arrowheads present at a vertex which is an endpoint of an undirected edge.
Condition (i) implies that if $\alpha$ and $\beta$ are joined by an edge with an arrowhead at $\alpha$, then $\alpha$ is not an ancestor of $\beta$. This is the motivation for terming such graphs “ancestral.” Examples of ancestral and nonancestral mixed graphs are shown in Figure 5.

**Definition 6** A nonendpoint vertex $\zeta$ on a path is a **collider** on the path if the edges preceding and succeeding $\zeta$ on the path have an arrowhead at $\zeta$, that is, $\rightarrow \zeta \leftarrow$, or $\leftrightarrow \zeta \leftrightarrow$, or $\leftrightarrow \zeta \leftarrow$, or $\rightarrow \zeta \leftrightarrow$. A nonendpoint vertex $\zeta$ on a path which is not a collider is a noncollider on the path. A path between vertices $\alpha$ and $\beta$ in an ancestral graph $G$ is said to be $m$-connecting given a set $Z$ (possibly empty), with $\alpha, \beta \not\in Z$, if:

(i) every noncollider on the path is not in $Z$, and

(ii) every collider on the path is in $\text{ant}_G(Z)$.

**Definition 7** Let $G_A$ denote the induced subgraph of $G$ on the vertex set $A$, formed by removing from $G$ all vertices that are not in $A$, and all edges that do not have both endpoints in $A$. Two vertices $x$ and $y$ in a MVR chain graph $G$ are said to be collider connected if there is a path from $x$ to $y$ in $G$ on which every non-endpoint vertex is a collider; such a path is called a collider path. (Note that a single edge trivially forms a collider path, so if $x$ and $y$ are adjacent in a MVR chain graph then they are collider connected.) The augmented graph derived from $G$, denoted $(G)^a$, is an undirected graph with the same vertex set as $G$ such that

$$c - d \in (G)^a \iff c \text{ and } d \text{ are collider connected in } G.$$

**Definition 8** Disjoint sets $X, Y,$ and $Z \neq \emptyset$ are said to be $m^*$-separated if $X$ and $Y$ are separated by $Z$ in $(G_{\text{ant}(X \cup Y \cup Z)})^a$. Otherwise $X$ and $Y$ are said to be $m^*$-connected given $Z$. The resulting independence model is denoted by $\mathcal{I}_{m^*}(G)$.

Richardson and Spirtes in [Richardson and Spirtes, 2002, Theorem 3.18.] show that for an ancestral graph $G$, $\mathcal{I}_m(G) = \mathcal{I}_{m^*}(G)$.
**Definition 9** An ancestral graph $G$ is said to be maximal if for every pair of vertices $\alpha, \beta$ if $\alpha$ and $\beta$ are not adjacent in $G$ then there is a set $Z (\alpha, \beta \notin Z)$, such that $\langle \{\alpha\}, \{\beta\}|Z \rangle \in \Im_m(G)$. Thus a graph is maximal if every missing edge corresponds to at least one independence in the corresponding independence model.

A simple example of a nonmaximal ancestral graph is shown in Figure 6: $\gamma$ and $\delta$ are not adjacent, but are $m$-connected given every subset of $\{\alpha, \beta\}$, hence $\Im_m(G) = \emptyset$.

![Figure 6](https://example.com/figure6.png)

**Figure 6:** (Richardson and Spirtes 2002) A nonmaximal ancestral graph.

If $G$ is an undirected graph or a directed acyclic graph, then $G$ is a maximal ancestral graph (Richardson and Spirtes 2002, Proposition 3.19). Richardson and Spirtes (Richardson and Spirtes, 2002) propose the following notation:

**Notation 10** If $\Im$ contains the independence relations present in a distribution $P$, then $\Im|_L$ contains the subset of independence relations remaining after marginalizing out the latent variables in $L$; $\Im|_S$ and constitutes the subset of independencies holding among the remaining variables after conditioning on $S$.

Any chain graph yields a directed acyclic graph $D$ of its chain components having $T$ as a node set and an edge $T_1 \to T_2$ whenever there exists in the chain graph $G$ at least one edge $u \to v$ connecting a node $u$ in $T_1$ with a node $v$ in $T_2$. In this directed graph, we may define for each $T$ the set $pa_D(T)$ as the union of all the chain components that are parents of $T$ in the directed graph $D$. This concept is distinct from the usual notion of the parents $pa_G(A)$ of a set of nodes $A$ in the chain graph, that is, the set of all the nodes $w$ outside $A$ such that $w \to v$ with $v \in A$ (Marchetti and Lupparelli, 2011). For instance, in the graph of Figure 7 for $T = \{1, 2\}$, the set of parent components is $pa_D(T) = \{3, 4, 5, 6\}$, whereas the set of parents of $T$ is $pa_G(T) = \{3, 6\}$.

![Figure 7](https://example.com/figure7.png)

**Figure 7:** (Marchetti and Lupparelli 2011) A MVR chain graph.
Given a chain graph \( G \) with chain components \((T|T \in \mathcal{T})\), we can always define a strict total order \( \prec \) of the chain components that is consistent with the partial order induced by the chain graph, such that if \( T \prec T' \) then \( T \not\in \text{pa}_D(T') \). For instance, in the chain graph of Figure 8 there are four chain components ordered in the graph of Figure 8 as \( \{1,2\} \prec \{3,4\} \prec \{5,6\} \prec \{7,8\} \). Note that the chosen total order of the chain components is in general not unique and that another consistent ordering could be \( \{1,2\} \prec \{5,6\} \prec \{3,4\} \prec \{7,8\} \).

![Figure 8](Marchetti and Lupparelli 2011) One possible consistent ordering of the four chain components: \( \{1,2\} \prec \{5,6\} \prec \{3,4\} \prec \{7,8\} \).

For each \( T \), the set of all components preceding \( T \) is known and we may define the cumulative set \( \text{pre}(T) = \cup_{T \prec T'} T' \) of nodes contained in the predecessors of component \( T \), which we sometimes call the past of \( T \). The set \( \text{pre}(T) \) captures the notion of all the potential explanatory variables of the response variables within \( T \) (Marchetti and Lupparelli 2011).

By definition, as the full ordering of the components is consistent with \( G \), the set of predecessors \( \text{pre}(T) \) of each chain component \( T \) always includes the parent components \( \text{pa}_D(T) \).

** Definition 11 ** Given a chain graph \( G \), the set \( \text{Nb}_G(A) \) is the union of \( A \) itself and the set of nodes \( w \) that are neighbors of \( A \), that is, coupled by a dashed-line (bi-directed edge) to some node \( v \) in \( A \). Moreover, the set of non-descendants \( \text{nd}_D(T) \) of a chain component \( T \), is the union of all components \( T' \) such that there is no directed path from \( T \) to \( T' \) in the directed graph of chain components \( D \).

### 3. Markov Properties for MVR Chain Graphs

In this section, first, we show, formally, that MVR chain graphs are a subclass of the maximal ancestral graphs of Richardson and Spirtes (Richardson and Spirtes 2002).

** Remark 12 ** Sonntag (Sonntag 2014) mentions that unlike the other CGs (Chain Graphs) interpretations, the bidirected [dashed] edge in a MVR CG has a strong intuitive meaning. It can be seen to represent one or more hidden common causes between the variables connected by it. In other words, in a MVR CG any bidirected edge \( X \leftrightarrow Y \) can be replaced by \( X \leftarrow H \rightarrow Y \) to obtain a BN representing the same independence model over the original variables, i.e. excluding the new variables \( H \). These variables are called hidden, or latent, and have been marginalized away in the CG model.
Remark 13 Also, Peña claims that of the three main interpretations of chain graphs (LWF, MVR, and AMP (Andersson et al. [1996]), only MVR chain graphs have a convincing justification. In addition, he claims that since MVR chain graphs are a subset of maximal ancestral graphs without undirected edges, every MVR chain graph represents the independence model represented by a DAG under marginalization (Richardson and Spirtes [2002] Theorem 6.4). That is, every MVR chain graph can be accounted for by a causal model that is partially observed (Peña [2015]).

Remark 14 Sadeghi and Lauritzen in (Sadeghi and Lauritzen [2014]) claim that when the chain components consist entirely of bi-directed edges, the multivariate regression property is identical to the one induced by m-separation.

The following theorem proves Cox and Wermuth’s claim [1], Peña and Sonntag’s claims in Remark [12] and Remark [13] and also Sadeghi and Lauritzen’s claim in Remark [14].

Theorem 15 For every MVR chain graph G there exists a DAG D(G) and a set L such that D(G)[L] = G. In other words, every MVR chain graph has the same independence model as a DAG under marginalization.

Proof First, we show that every MVR chain graph is an ancestral graph. Obviously, every MVR chain graph is a mixed graph without undirected edges. So, it is enough to show that condition (i) in Definition 5 is satisfied. For this purpose, consider that α and β are joined by an edge with an arrowhead at α in MVR chain graph G. Two cases are possible. First, if α ←→ β is an edge in G, by definition of a MVR chain graph, both of them belong to the same chain component. Since all edges on a path between two nodes of a chain component are bidirected, then by definition α cannot be an anterior of β. Second, if α ←− β is an edge in G, by definition of a MVR chain graph, α and β belong to two different components (β is in a box that is in the right side of the box that contains α). We know that all directed edges in a MVR chain graph are arrows pointing from right to left, so there is no path from α to β in G i.e. α cannot be an anterior of β in this case. We have shown that α cannot be an anterior of β in both cases, and therefore condition (i) in Definition 5 is satisfied. In other words, every MVR chain graph is an ancestral graph.

Richardson and Spirtes in (Richardson and Spirtes [2002] Theorem 5.1) prove that if G is an ancestral graph then there exists a unique maximal ancestral graph G’ formed by adding ←→ edges to G such that \( \mathcal{I}_m(G) = \mathcal{I}_m(G’) \).

The result follows directly from (Richardson and Spirtes [2002] Theorem 6.4).
An independence model is a *semi-graphoid* if it satisfies the first four independence properties listed above. If a semi-graphoid further satisfies the intersection property, we say it is a *graphoid*. A *compositional graphoid* further satisfies the composition property [Sadeghi and Wermuth 2016]. If a semi-graphoid further satisfies the composition property, we say it is a *compositional semi-graphoid*.

For a node \( i \) in the connected component \( T \), its *past*, denoted by \( \text{pst}(i) \), consists of all nodes in components having a higher order than \( T \). To define pairwise Markov properties for MVR CGs, we use the following notation for parents, anteriors and the past of node pair \( i, j \):

\[
\begin{align*}
\text{pa}_G(i, j) &= \text{pa}_G(i) \cup \text{pa}_G(j) \setminus \{i, j\}, \\
\text{ant}(i, j) &= \text{ant}(i) \cup \text{ant}(j) \setminus \{i, j\}, \\
\text{pst}(i, j) &= \text{pst}(i) \cup \text{pst}(j) \setminus \{i, j\}.
\end{align*}
\]

The distribution \( \mathcal{P} \) of \((X_n)_{n \in V}\) satisfies a pairwise Markov property \( \mathcal{P}(m) \), for \( m = 1, 2, 3, 4 \), with respect to MVR CG\((G)\) if for every uncoupled nodes \( i, j \):

(P1): \( i \perp \perp j | \text{pst}(i, j) \),
(P2): \( i \perp \perp j | \text{ant}(i, j) \),
(P3): \( i \perp \perp j | \text{pa}_G(i, j) \),
(P4): \( i \perp \perp j | \text{pa}_G(i) \).

Notice that in (P4), \( \text{par}(i) \) may be replaced by \( \text{par}(j) \) whenever the two nodes are in the same connected component. Sadeghi and Wermuth in [Sadeghi and Wermuth 2016] proved that all of above mentioned pairwise Markov properties are equivalent for compositional graphoids. Also, they show that each one of the above listed pairwise Markov properties is equivalent to the global Markov properties in Definitions 6, 8 [Sadeghi and Wermuth 2016, Corollary 1].

**Remark 16** For equivalence of pairwise and global Markov properties, the six compositional graphoid axioms are sufficient. In fact, in general, for the mentioned equivalence, all six axioms are also necessary.

**Remark 17** Two graphical models are Markov equivalent whenever their associated graphs capture the same independence structure, that is, the graphs lead to the same set of implied independence statements. Two MVR chain graphs are Markov equivalent if and only if they have the same skeleton (the skeleton of a graph results by replacing each edge present by a full line) and the same sets of (unshielded) collision \( \vee s \) [Wermuth and Sadeghi 2012, Theorem 1].

### 3.2 Block-recursive and Multivariate Regression (MR) Markov Properties

According to [Marchetti and Lupparelli 2008], multivariate regression chain graphs represent situations in which the variables can be arranged in an ordered series of groups and all the variables within a group are considered to be on an equal footing, while the relation between two variables in different groups is considered asymmetrically. The associated graph is a special type of chain graph in which the edges between components are arrows and the subgraphs within chain components are covariance graphs.
According to (Marchetti and Lupparelli, 2011), in the general case, the interpretation of the undirected graphs within a chain component is that of a covariance graph, but conditional on all variables in preceding components. For example, the missing edge (a, c) in the graph of Figure 9 is interpreted as the independence statement $X_a \perp \perp X_c | X_d, X_e$, compactly written in terms of nodes as $a \perp \perp c | d, e$.

![Figure 9: A MVR chain graph with chain components: $\mathcal{T} = \{\{a, b, c\}, \{d, e\}\}$.](image)

The interpretation of the directed edges is that of multivariate regression models, with a missing edge denoting a conditional independence of the response on a variable given all the remaining potential explanatory variables. Thus, in the chain graph of Figure 10 the missing arrow (a, d) indicates the independence statement $a \perp \perp d | c$.

![Figure 10: A MVR chain graph with chain components: $\mathcal{T} = \{\{a, b\}, \{c, d\}\}$.](image)

The following definition explains the meaning of the multivariate regression interpretation of a chain graph.

**Definition 18** (multivariate regression (MR) Markov property for MVR CGs) Let $G$ be a chain graph with chain components $(T | T \in \mathcal{T})$ and let $\text{pre}(T) = \cup_{T \prec T'} T'$ be the set of nodes contained in the predecessors of component $T$. A joint distribution $P$ of the random vector $X$ obeys the (local) multivariate regression Markov property for $G$ if it satisfies the following independencies. For all $T \in \mathcal{T}$ and for all $A \subseteq T$:

1. **(MR1)** if $A$ is connected: $A \perp \perp [\text{pre}(T) \setminus \text{pa}_G(A)] | \text{pa}_G(A)$.
2. **(MR2)** if $A$ is disconnected with connected components $A_1, \ldots, A_r$: $A_1 \perp \perp \ldots \perp A_r | \text{pre}(T)$.

Assuming that the distribution $P$ has a density $p$ with respect to a product measure, the definition can be stated by the following two equivalent conditions:

$$P_A | \text{pre}(T) = P_A | \text{pa}_G(A)$$
for all $T$ and for all connected subset $A \subseteq T$.

$$P_{A|\text{pre}(T)} = \prod_j P_{A_j|\text{pre}(T)}$$

for all $T$ and for all disconnected subset $A \subseteq T$ with connected components $A_j, j = 1, \ldots, r$. In other words, for any connected subset $A$ of responses in a component $T$, its conditional distribution given the variables in the past depends only on the parents of $A$. On the other hand, if $A$ is disconnected (i.e., the subgraph $G_A$ is disconnected) the variables in its connected components $A_1, \ldots, A_r$, are jointly independent given the variables in the past (not just the parents).

**Remark 19** (Marchetti and Lupparelli, 2011, Remark 2) One immediate consequence of Definition 18 is that if the probability density $p(x)$ is strictly positive, then it factorizes according to the directed acyclic graph of the chain components:

$$p(x) = \prod_{T \in \mathcal{T}} p(x_T|x_{\text{pa}_D(T)}).$$

**Example 1** In Figure consider that $T = \{a, b, c\}$, so $\text{pre}(T) = \{d, e\}$. Thus, for each connected subset $A \in T$, by (MR1), we have:

$$a \perp \perp e|d; \quad b \perp d, e; \quad c \perp d|e; \quad (a, b) \perp d|e; \quad (b, c) \perp d|e.$$ 

Also, for the disconnected set $A = \{a, c\}$ we obtain by (MR2) the independence $a \perp c|d, e$.

Finally, based on Remark 19 the corresponding factorization for the strictly positive probability density $p(x)$ is: $p = p_{a,b,c|d,e}p_{d,e}$.

Drton discussed four different block-recursive Markov properties for chain graphs, of which we discuss here those with the Markov property of type IV (Drton, 2009).

**Definition 20** (Chain graph Markov property of type IV (Drton, 2009)) Let $G$ be a chain graph with chain components $(T|T \in \mathcal{T})$ and directed acyclic graph $D$ of components. The joint probability distribution of $X$ obeys the block-recursive Markov property of type IV if it satisfies the following independencies:

$(IV0)$ $T \perp \{\text{nd}_D(T) \setminus \text{pa}_D(T)\}|\text{pa}_D(T)$, for all $T \in \mathcal{T}$;

$(IV1)$ $A \perp \{\text{pa}_D(T) \setminus \text{pa}_G(A)\}|\text{pa}_G(A)$, for all $T \in \mathcal{T}$, and for all $A \subseteq T$;

$(IV2)$ $A \perp \{T \setminus \text{Nb}_G(A)\}|\text{pa}_D(T)$, for all $T \in \mathcal{T}$, and for all connected subsets $A \subseteq T$.

**Remark 21** In a multivariate normal distribution, two pairwise marginal independences $v \perp w$ and $v \perp u$ implies that $v \perp \{u, w\}$. However, for the models of type IV a positive discrete distribution that obeys the pairwise Markov property will generally not obey the block-recursive Markov property. This follows from the fact that in almost every positive joint distribution that exhibits $v \perp w$ and $v \perp u$, $v$ is not independent of $\{u, w\}$ (Drton, 2009, Remark 5). In other words, the family of multinomial distributions does not satisfy the composition property in general.
Marchetti and Lupparelli in (Marchetti and Lupparelli, 2011, Theorem 1) claim that for a given chain graph $G$, the multivariate regression Markov property is equivalent to the block-recursive Markov property of type IV. However, the following example shows that independence models, in general, resulting from Definitions 18, 20 are different.

**Example 2** Consider the following MVR chain graph $G$:

For the connected set $A = \{1, 2\}$ the condition (MR1) implies that $1, 2 \indep 6, 7|5$ while the condition (IV2) implies that $1, 2 \indep 6|5$, which is not implied directly by (MR1) and (MR2). Also, the condition (MR2) implies that $1 \indep 3, 4|5, 6, 7$ while the condition (IV2) implies that $1 \indep 3, 4|5, 6$, which is not implied directly by (MR1) and (MR2).

**Theorem 22** Let $G$ be a MVR chain graph. If an independence model $\Im$ over the node set of $G$ is a compositional semi-graphoid, then $\Im$ satisfies the MR Markov property w.r.t. $G$ in Definition 18 if and only if it satisfies the block-recursive Markov property w.r.t. $G$ in Definition 20.

**Proof** Assume that the independence model $\Im$ over the node set of MVR CG(G) is a compositional semi-graphoid, and $\Im$ satisfies the MR Markov property w.r.t. $G$ in Definition 18. We show that $\Im$ satisfies the block-recursive Markov property w.r.t. $G$ in Definition 20 in the three following cases:

Case1 (MR1 $\Rightarrow$ IV0): Let $\tau \in T$. Since $\tau$ is a connected component, by (MR1) we have $\tau \indep \tau \setminus (\text{pre}(\tau) \setminus \text{pa}_G(\tau))|\text{pa}_G(\tau)$. In other words, the joint probability distribution obeys the ordered Markov property relative to the directed acyclic graph $D$ of the chain components. Also, condition (IV0) states that the joint probability distribution obeys the local directed Markov property relative to the directed acyclic graph $D$ of the chain components. Then, using the equivalence of the local and ordered Markov property in directed acyclic graphs (Lauritzen et al., 1990), which holds for semi-graphoids, applied to the directed acyclic graph of the chain components shows that (MR1) implies (IV0).

Case2 (MR1 $\Rightarrow$ IV1): Assume that $\sigma$ is a connected subset of $\tau$. By (MR1) we have $\sigma \indep \sigma \setminus \sigma \setminus \text{pre}(\tau) \setminus \text{pa}_G(\sigma)|\text{pa}_G(\sigma)$. Since $\text{pa}_D(\tau) \setminus \text{pa}_G(\sigma) \subseteq \text{pre}(\tau) \setminus \text{pa}_G(\sigma)$, using the decomposition property implies (IV1): $\sigma \indep \sigma \setminus \sigma \setminus \text{pre}(\tau) | \text{pa}_G(\sigma)$.

Now, consider that $\sigma$ is a disconnected subset of $\tau$ that contains $k$ connected components $\sigma_1, \ldots, \sigma_k$ i.e., $\sigma = \sigma_1 \cup \ldots \cup \sigma_k$. From (MR1) and the weak union property we obtain:

\[
\begin{align*}
\sigma_1 & \indep \text{pre}(\tau) \setminus \text{pa}_G(\sigma_1) | \text{pa}_G(\sigma_1) \quad \Rightarrow \quad \sigma_1 \indep \text{pre}(\tau) \setminus \text{pa}_G(\sigma) | \text{pa}_G(\sigma) \\
\sigma_2 & \indep \text{pre}(\tau) \setminus \text{pa}_G(\sigma_2) | \text{pa}_G(\sigma_2) \quad \Rightarrow \quad \sigma_2 \indep \text{pre}(\tau) \setminus \text{pa}_G(\sigma) | \text{pa}_G(\sigma) \\
\vdots & \quad \vdots \quad \vdots \\
\sigma_k & \indep \text{pre}(\tau) \setminus \text{pa}_G(\sigma_k) | \text{pa}_G(\sigma_k) \quad \Rightarrow \quad \sigma_k \indep \text{pre}(\tau) \setminus \text{pa}_G(\sigma) | \text{pa}_G(\sigma)
\end{align*}
\] (1)
Using the symmetry and composition property gives: \( \sigma \perp (\text{pre}(\tau) \setminus \text{pa}_G(\sigma))|\text{pa}_G(\sigma) \). Now, using the decomposition property implies (IV1): 
\[ \sigma \perp (\text{pa}_D(\tau) \setminus \text{pa}_G(\tau))|\text{pa}_G(\sigma) \]. 

Case 3 (MR1 and MR2 \( \Rightarrow \) IV2): From (MR2) and the composition property, one can obtain:

\[ \sigma \perp \tau \setminus \text{Nb}_G(\sigma)|\text{pre}(\tau) \quad (2) \]

Also, from (MR1) we have \( \sigma \perp (\text{pre}(\tau) \setminus \text{pa}_G(\sigma))|\text{pa}_G(\sigma) \), where \( \sigma \) is a connected subset of \( \tau \). Using the weak union property implies that

\[ \sigma \perp (\text{pre}(\tau) \setminus \text{pa}_D(\tau))|\text{pa}_D(\tau) \quad (3) \]

Applying \( 2 \) and the contraction property gives 
\[ \sigma \perp [(\tau \setminus \text{Nb}_G(\sigma)) \cup (\text{pre}(\tau) \setminus \text{pa}_D(\tau))]|\text{pa}_D(\tau) \].

Now, using the decomposition property leads to (IV2):

\[ \sigma \perp \tau \setminus \text{Nb}_G(\sigma)|\text{pa}_D(\tau) \]

Now, assume that the independence model \( \mathcal{S} \) over the node set of MVR CG(G) is a compositional semi-graphoid, and \( \mathcal{S} \) satisfies the block recursive Markov property w.r.t. \( G \) in Definition 20. We show that \( \mathcal{S} \) satisfies the MR Markov property w.r.t. \( G \) in Definition 18 in the two following cases:

Case 1 (IV0 and IV1 \( \Rightarrow \) MR1): Assume that \( A \) is a connected subset of \( \tau \). From (IV1) we have:

\[ A \perp (\text{pa}_D(\tau) \setminus \text{pa}_G(A))|\text{pa}_G(A) \quad (4) \]

Also, from (IV0) we have \( \tau \perp (\text{nd}_D(\tau) \setminus \text{pa}_D(\tau))|\text{pa}_D(\tau) \), the decomposition property implies that

\[ A \perp (\text{nd}_D(\tau) \setminus \text{pa}_D(\tau))|\text{pa}_D(\tau) \quad (5) \]

Using the contraction property for \( 2 \) and \( 5 \) gives:

\[ A \perp [(\text{nd}_D(\tau) \setminus \text{pa}_G(\tau)) \cup (\text{pa}_D(\tau) \setminus \text{pa}_G(A))]|\text{pa}_G(\tau) \].

Using the decomposition property for this independence relationship gives (MR1): 
\( A \perp (\text{pre}(\tau) \setminus \text{pa}_G(\tau))|\text{pa}_G(\tau) \), because 
\( (\text{pre}(\tau) \setminus \text{pa}_G(\tau)) \subseteq [(\text{nd}_D(\tau) \setminus \text{pa}_G(\tau)) \cup (\text{pa}_D(\tau) \setminus \text{pa}_G(A))]. \)

Case 2 (IV0 and IV2 \( \Rightarrow \) MR2): Consider that \( A \) is a disconnected subset of \( \tau \) that contains \( r \) connected components \( A_1, \ldots, A_r \), i.e., \( A = A_1 \cup \ldots \cup A_r \). From (IV2) we have: 
\[ A_1 \perp \tau \setminus \text{Nb}_G(A_1)|\text{pa}_D(\tau) \]. Using the decomposition property gives:

\[ A_1 \perp A_2|\text{pa}_D(\tau) \quad (6) \]

Also, using decomposition for (IV0) gives: 
\[ A_1 \perp (\text{nd}_D(\tau) \setminus \text{pa}_D(\tau))|\text{pa}_D(\tau) \]. Since 
\( \text{pre}(\tau) \setminus \text{pa}_D(\tau) \subseteq \text{nd}_D(\tau) \setminus \text{pa}_D(\tau) \), using the decomposition property for the last independence relationship implies that 
\( A_1 \perp (\text{pre}(\tau) \setminus \text{pa}_D(\tau))|\text{pa}_D(\tau) \). Using composition for the last independence relationship and \( 5 \) gives: 
\[ A_1 \perp (A_2 \cup (\text{pre}(\tau) \setminus \text{pa}_D(\tau))]|\text{pa}_D(\tau) \]. The weak union implies that 
\( A_1 \perp A_2|(\text{pa}_D(\tau) \cup (\text{pre}(\tau) \setminus \text{pa}_D(\tau)) = \text{pre}(\tau)] \). Similarly, we can prove that for every \( 1 \leq i \neq j \leq r \) we have: 
\[ A_i \perp A_j|\text{pre}(\tau) \].
3.3 An Alternative Global Markov Property for MVR Chain Graphs

In this subsection we formulate an alternative global Markov property for MVR chain graphs. This property is different from the global Markov property resulting from the \( m^* \)-separation criterion proposed in (Richardson 2003; Richardson and Spirtes 2002). We show that this global Markov property implies the block-recursive Markov property of type IV in (Drton 2009; Marchetti and Lupparelli 2008) and MR Markov property in (Marchetti and Lupparelli 2011). Also, we show that they are equivalent for compositional graphoids.

**Definition 23** (Alternative global Markov property for MVR chain graphs) For any triple \((A, B, S)\) of disjoint subsets of \(V\) such that \(S\) separates \(A\) from \(B\) in \((G_{\text{Antec}(A \cup B \cup S)})^a\), in the augmented graph of the smallest antecedental set containing \(A \cup B \cup S\), we have \(A \perp \!\!\!\perp B|S\).

**Proposition 24** The alternative global Markov property in Definition 23 implies the block-recursive Markov property in Definition 20.

**Proof** The proof contains the three following steps:

1. Since \(\tau \cup nd_D(\tau)\) is an antecedental set, and \(pa_D(\tau)\) separates \(\tau\) from \(nd_D(\tau) \setminus pa_D(\tau)\) in \((G_{\text{Ind}(\tau)})^a\); this shows that the global Markov property in Definition 23 implies (IV0) in Definition 20.

2. Assume that \(\sigma \subseteq \tau\), \(\tau \in \mathcal{T}\). Consider that \(A\) is the smallest antecedental set containing \(\sigma\) and \(pa_D(\tau)\). We know that for each vertex \(v \in pa_D(\tau) \setminus pa_G(\sigma)\), \(v \in \text{antec}(\sigma)\) and \(pa_G(\sigma) \subseteq pa_D(\tau)\). Also, we know that there is no directed edge from \(pa_D(\tau) \setminus pa_G(\sigma)\) to elements of \(\sigma\). So, every connecting path that connects \(pa_D(\tau) \setminus pa_G(\sigma)\) to \(\sigma\) in \((G_A)^a\) has intersection with \(pa_G(\sigma)\), which means \(pa_G(\sigma)\) separates \(pa_D(\tau) \setminus pa_G(\sigma)\) from \(\sigma\) in \((G_A)^a\); this shows that the global Markov property in Definition 23 implies (IV1) in Definition 20.

3. Assume that \(\sigma \subsetneq \tau\), \(\tau \in \mathcal{T}\). Also, assume that \(\sigma\) is a connected subset of \(\tau\). Obviously, \(\sigma\) and \(\tau \setminus Nb_G(\sigma)\) are two subsets of \(\tau\) such that there is no connection between their elements. Consider that \(A\) is the smallest antecedental set containing \(\sigma\) and \(\tau \setminus Nb_G(\sigma)\). Clearly, \(pa_D(\tau) \subseteq A\). Since \(\sigma\) and \(\tau \setminus Nb_G(\sigma)\) are disconnected in \(\tau\), any connecting path between them (if it exists) must pass through \(pa_D(\tau)\) in \((G_A)^a\); this shows that the global Markov property in Definition 23 implies (IV2) in Definition 20.

**Proposition 25** The alternative global Markov property in Definition 23 implies the MR Markov property in Definition 18.

**Proof** The proof is very similar to that of Proposition 24 and is omitted.

A special case of Definition 23 is the case in which \(G\) is a DAG. In this case the augmented graph \((G_{\text{Antec}(A \cup B \cup S)})^a\) is the same as moral graph \((G_{\text{An}(A \cup B \cup S)})^m\). In fact, \(A\) and \(B\) are separated by \(S\) if and only if \(A\) and \(B\) are \(d\)-separated by \(S\). Thus we have the following corollary:
Corollary 26 In a DAG D, A is d-separated from B given S if and only if S separates A and B in $(\mathcal{D}_{\text{Antec}(A \cup B \cup S)})^\alpha$.

The following example shows that the proposed alternative global Markov property in Definition 23 is different from the pathwise m-separation criterion and the augmentation separation criterion in [Richardson 2003; Richardson and Spirtes 2002], in general.

Example 3 Consider the MVR chain graph $G$ in Figure 12.

![Figure 12: A MVR chain graph with chain components: $\mathcal{T} = \{\{a, b, c\}, \{d, e, f\}\}$.

According to the pathwise m-separation criterion and the augmentation separation criterion in [Richardson 2003; Richardson and Spirtes 2002], a and f are marginally independent. However, according to Definition 23 a and f are not marginally independent but $a \perp \perp f|d$. Also, according to the pathwise m-separation criterion and the augmentation separation criterion in [Richardson 2003; Richardson and Spirtes 2002], $\{a, b\}$ and f are marginally independent. However, according to Definition 23 we cannot obtain directly that $\{a, b\}$ and f are marginally independent.

Remark 27 Note that the proposed alternative global Markov property in Definition 23 is more general than the block-recursive Markov property of type IV in [Drton 2009]. In other words, the alternative global Markov property in Definition 23 implies the block-recursive Markov property in Definition 20 but not vice versa. For example, in Example 3 the alternative global Markov property implies that $a \perp \perp f|d$ and $a \perp \perp \{e, f\}|d$ while the block-recursive Markov property only implies that $a \perp \perp \{e, f\}|d$.

Remark 28 Note that the proposed alternative global Markov property in Definition 23 is more general than the proposed Markov property in Definition 18. In other words, the alternative global Markov property in Definition 23 implies the Markov property in Definition 18 but not vice versa. For example, in Example 3 the alternative global Markov property implies that $a \perp \perp f|d$ and $a \perp \perp \{e, f\}|d$ while the block-recursive Markov property only implies that $a \perp \perp \{e, f\}|d$.

Theorem 29 Let $G$ be a MVR chain graph. If an independence model $\mathcal{I}$ over the node set of $G$ is a compositional graphoid, then $\mathcal{I}$ satisfies the block-recursive Markov property w.r.t. $G$ in Definition 20 if and only if it satisfies the global Markov property w.r.t. $G$ in Definition 8.

Proof First, we show that the global Markov property w.r.t. $G$ in Definition 8 implies the Markov property w.r.t. $G$ in Definition 20. We have three following cases:
Now, using the decomposition property gives:

\[ \text{Case } 1: \text{ Let } X = \tau \in \mathcal{T}, Y = nd_D(\tau) \setminus pa_D(\tau), \text{ and } Z = pa_D(\tau). \text{ So, } \text{ant}(X \cup Y \cup Z) = \tau \cup nd_D(\tau) \text{ is an anterior set, and } pa_D(\tau) \text{ separates } \tau \text{ from } nd_D(\tau) \setminus pa_D(\tau) \text{ in } (G_{\tau \cup nd_D(\tau)})^a; \text{ this shows that the global Markov property in Definition } 8 \text{ implies (IV0) in Definition } 20. \]

\[ \text{Case 2: Let } \tau \in \mathcal{T}, Y = pa_D(\tau) \setminus pa_G(\sigma), \text{ and } Z = pa_G(\sigma). \text{ Consider } W = \text{ant}(X \cup Y \cup Z) = \text{ant}(\sigma \cup pa_D(\tau)). \text{ We know that there is no directed edge from } pa_D(\tau) \setminus pa_G(\sigma) \text{ to } \tau, \text{ and also there is no collider path between nodes of } Y \text{ and } \sigma. \text{ So, every connecting path that connects } pa_D(\tau) \setminus pa_G(\sigma) \text{ to } \sigma \text{ in } (G_W)^a \text{ has intersection with } pa_G(\sigma), \text{ which means } pa_G(\sigma) \text{ separates } pa_D(\tau) \setminus pa_G(\sigma) \text{ from } \sigma \text{ in } (G_W)^a; \text{ this shows that the global Markov property in Definition } 8 \text{ implies (IV1) in Definition } 20. \]

\[ \text{Case 3: Assume that } X = \sigma \nsubseteq \tau \in \mathcal{T} \text{ is a connected subset of } \tau. \text{ Also, assume that } Y = \tau \setminus Nb_G(\sigma), \text{ and } Z = pa_D(\tau). \text{ Obviously, } \sigma \text{ and } \tau \setminus Nb_G(\sigma) \text{ are two subsets of } \tau \text{ such that there is no connection between their elements. Consider that } A \text{ is the anterior set containing } \sigma, \tau \setminus Nb_G(\sigma), \text{ and } pa_D(\tau). \text{ Clearly, } pa_D(\tau) \subseteq A. \text{ Since } \sigma \text{ and } \tau \setminus Nb_G(\sigma) \text{ are disconnected in } \tau, \text{ so any connecting path between them (if it exists) must pass through } pa_D(\tau) \text{ in } (G_A)^a; \text{ this shows that the global Markov property in Definition } 8 \text{ implies (IV2) in Definition } 20. \]

For the "only if" part, since the pairwise Markov property (P4) is equivalent to the global Markov property (Sadeghi and Vemuri, 2016, Corollary 1), it is enough to show that the Markov property w.r.t. \( G \) in Definition 20 implies the pairwise Markov property (P4). We have the two following cases:

\[ \text{Case 1: Let } i, j \in \tau \text{ are two coupled nodes, and } A = \{i\}. \text{ By (IV2) we have } i \perp \perp \tau \setminus Nb_G(i), \text{ using the decomposition property leads to } i \perp \perp j|pa_D(\tau). \text{ From (IV1) we have } i \perp \perp pa_D(\tau) \setminus pa_G(i). \text{ Using the decomposition property leads to } i \perp \perp j|pa_D(\tau) \setminus pa_G(i). \text{ Using the contraction property (let } a = \{i\}, b = \{j\}, c = pa_G(i), \text{ and } d = pa_D(\tau) \setminus pa_G(i)): \text{ if } \perp \perp (j|pa_D(\tau) \setminus pa_G(i)) \text{ is obtained. Now, using the decomposition property gives: } i \perp \perp j|pa_G(i). \]

\[ \text{Case 2: Let } i, j \notin \tau \text{ are two uncoupled nodes. We have two following subcases:} \]

(i): \( i \in \tau, j \in pa_D(\tau). \) By (IV1) we have \( i \perp \perp pa_D(\tau) \setminus pa_G(i)|pa_G(i). \) We know that \( j \in pa_D(\tau) \setminus pa_G(i), \) using the decomposition property leads to \( i \perp \perp j|pa_D(\tau). \) From (IV0) we have \( \tau \perp \perp nd_D(\tau) \setminus pa_D(\tau). \) Using the decomposition property leads to \( i \perp \perp nd_D(\tau) \setminus pa_D(\tau). \) Again, using the decomposition property leads to \( i \perp \perp j|pa_D(\tau), \) because \( j \in nd_D(\tau) \setminus pa_D(\tau). \) From (IV1) we have \( i \perp \perp pa_D(\tau) \setminus pa_G(i)|pa_G(i). \) Using the contraction property (let \( a = \{i\}, b = \{j\}, c = pa_G(i), \) and \( d = pa_D(\tau) \setminus pa_G(i)): \text{ if } \perp \perp (j\cup(pa_D(\tau) \setminus pa_G(i)))|pa_G(i) \text{ is obtained. Now, using the decomposition property gives: } i \perp \perp j|pa_G(i). \]

\[ \text{Theorem 30} \text{ Let } G \text{ be a MVR chain graph. If an independence model } \mathcal{G} \text{ over the node set of } G \text{ is a compositional graphoid, then } \mathcal{G} \text{ satisfies the MR Markov property w.r.t. } G \text{ in Definition } 8 \text{ if and only if it satisfies the global Markov property w.r.t. } G \text{ in Definition } 8. \]

\[ \text{Proof} \text{ The result follows from Theorem } 29 \text{ and Theorem } 22. \]

\[ \text{Theorem 31} \text{ Let } G \text{ be a MVR chain graph. If an independence model } \mathcal{G} \text{ over the node set of } G \text{ is a compositional graphoid, then } \mathcal{G} \text{ satisfies the alternative global Markov property w.r.t. } G \text{ in Definition } 23 \text{ if and only if it satisfies the global Markov property w.r.t. } G \text{ in Definition } 8. \]
ON THE PROPERTIES OF MVR CHAIN GRAPHS

Proof Assume that $S$ separates $A$ from $B$ in $(G_{\text{Antec}(A \cup B \cup S)})$, where $A, B, S$ are disjoint subsets of $V_G$. Since there is no undirected edge in a MVR CG, by definition of anterior and antecedent $\text{ant}(A \cup B \cup S)$ is a subgraph of $\text{Antec}(A \cup B \cup S)$. Therefore, $S$ separates $A$ from $B$ in $(G_{\text{ant}(A \cup B \cup S)})^a$. In other words, the independence model induced by the global Markov property w.r.t. $G$ in Definition 23 is a subset of the independence model induced by the global Markov property w.r.t. $G$ in Definition 8.

The result follows from Proposition 24 and Theorem 29.

3.4 An Alternative Local Markov Property for MVR Chain Graphs

Richardson (Richardson, 2003) describes a local Markov property which is called the ordered local Markov property for a class of graphs (i.e., acyclic directed mixed graphs) that includes all ancestral graphs without undirected edges, and shows that this local Markov property is equivalent to the global Markov property (for semi-graphoids). Since MVR chain graphs are a subclass of ADMGs, this ordered local Markov property can be used as a local Markov property for MVR chain graphs.

In this subsection we formulate an alternative local Markov property for MVR chain graphs. This property is different from the ordered Markov property proposed in (Richardson, 2003). We show that this local Markov property is equivalent to the global and ordered local Markov property for MVR chain graphs (for compositional graphoids).

Definition 32 The local Markov property for a MVR chain graph $G$ with vertex set $V$ holds if, for every $v \in V$:

$v \perp \perp [\text{nd}(v) \setminus \text{bd}(v)]|\text{pa}_G(v)$.

Remark 33 In DAGs, $\text{bd}(v) = \text{pa}_G(v)$, and the local Markov property given above reduces to the directed local Markov property introduced by Lauritzen et al. in (Lauritzen et al., 1990).

Remark 34 In covariance graphs the local Markov property given above reduces to the dual local Markov property introduced by Kauermann in (Kauermann, 1996, Definition 2.1).

The following theorem shows that the set of distributions satisfying the local and global properties are identical for compositional graphoids.

Theorem 35 Let $G$ be a MVR chain graph. If an independence model $\mathcal{I}$ over the node set of $G$ is a compositional graphoid, then $\mathcal{I}$ satisfies the alternative local Markov property w.r.t. $G$ in Definition 32 if and only if it satisfies the global Markov property w.r.t. $G$ in Definition 8.

Proof (Global $\Rightarrow$ Local): Let $X = \{v\}$, $Y = \text{nd}(v) \setminus \text{bd}(v)$, and $Z = \text{pa}_G(v)$. So, $\text{ant}(X \cup Y \cup \text{S}) = v \cup (\text{nd}(v) \setminus \text{bd}(v)) \cup \text{pa}_G(v)$ is an anterior set, and $\text{pa}_G(v)$ separates $v$ from $\text{nd}(v) \setminus \text{bd}(v)$ in $(G_{v \cup (\text{nd}(v) \setminus \text{bd}(v)) \cup \text{pa}_G(v)})^a$; this shows that the global Markov property in Definition 8 implies local Markov property in Definition 32.

(Local $\Rightarrow$ Pairwise): Consider that $i,j$ are uncoupled nodes and $j \in \text{nd}(i)$. So, $j \notin \text{bd}(i)$ and hence using the decomposition property for the following local Markov property: $i \perp \perp \text{nd}(i) \setminus \text{bd}(i)|\text{pa}_G(i)$ implies that $i \perp j|\text{pa}_G(i)$, which is (P4) in subsection 3.1.

(Pairwise $\Rightarrow$ Global) shown in (Sadeghi and Wermuth, 2016 Corollary 1).
4. An Alternative Factorization for MVR Chain Graphs

Acyclic directed mixed graphs, also known as semi-Markov(ian) (Pearl, 2009) models contain directed (\(\to\)) and bi-directed (\(\leftrightarrow\)) edges subject to the restriction that there are no directed cycles (Richardson, 2009). According to the definition of MVR chain graphs, it is obvious that they are a subset of acyclic directed mixed graphs (ADMGs). In this section, we derive an explicit factorization criterion for MVR chain graphs based on the proposed factorization criterion for acyclic directed mixed graphs in (Richardson, 2009). For this purpose, we need to consider the following definitions and notations:

Definition 36 For a given acyclic directed mixed graph (ADMG) \(G\), the induced bi-directed graph \((G)_{\leftrightarrow}\) is the graph formed by removing all directed edges from \(G\). The district (aka c-component) for a vertex \(x\) in \(G\) is the connected component of \(x\) in \((G)_{\leftrightarrow}\), or equivalently
\[
dis_G(x) = \{y|y \leftrightarrow \ldots \leftrightarrow x\text{ in }G,\text{ or }x = y\}.
\]
As usual we apply the definition disjunctively to sets:
\[
dis_A(B) = \bigcup_{x \in B}dis_A(x).
\]
A set \(C\) is path-connected in \((G)_{\leftrightarrow}\) if every pair of vertices in \(C\) are connected via a path in \((G)_{\leftrightarrow}\); equivalently, every vertex in \(C\) has the same district in \(G\).

Definition 37 In an ADMG, a set \(A\) is said to be ancestrally closed if \(x \rightarrow \ldots \rightarrow a\) in \(G\) with \(a \in A\) implies that \(x \in A\). The set of ancestrally closed sets is defined as follows:
\[
A(G) = \{A|an_G(A) = A\}.
\]

Definition 38 An ordered pair of sets \((H, T)\) form the head and tail of a term associated with an ADMG \(G\) if and only if all of the following hold:
1. \(\forall x \in H : an_G(x) \cap H = \{x\}\).
2. \(H\) forms a path-connected set in \((G_{an(H)})_{\leftrightarrow}\).
3. \(T = \text{tail}(H) = (\text{dis}_{an(H)} \setminus H) \cup \text{pa}(\text{dis}_{an(H)})\).

For a graph \(G\), the set of heads is denoted by \(H(G)\).

Richardson in (Richardson, 2009 Theorem 4) proves that a probability distribution \(P\) obeys the global Markov property for an ADMG(\(G\)) if and only if for every \(A \in A(G)\),
\[
p(X_A) = \prod_{H \in [A]_G} p(X_H|\text{tail}(H)),
\]
where \([A]_G\) denotes a partition of \(A\) into sets \(\{H_1, \ldots, H_k\} \subseteq H(G)\), defined with \(\text{tail}(H)\), as above. The following theorem provides an alternative factorization criterion for MVR chain graphs based on the proposed factorization criterion for acyclic directed mixed graphs in (Richardson, 2009).
Theorem 39 Let $G$ be a MVR chain graph with chain components $(T|T \in T)$. A probability distribution $P$ obeys the global Markov property for $G$ if and only if

$$ p(x) = \prod_{T \in T} p(x_T|x_{pa(T)}). $$

Proof According to Theorem 4 in (Richardson, 2009), since $G \in A(G)$, it is enough to show that $\mathcal{H}(G) = \{T|T \in T\}$ and $\text{tail}(T) = \text{pa}(T)$, where $T \in T$. In other words, it is enough to show that for every $T$ in $T$, $(T, \text{pa}(T))$ satisfies the three conditions in Definition 38.

1. Let $x, y \in T$ and $T \in T$. Then $x$ is not an ancestor of $y$. Also, we know that $x \in an_G(x)$, by definition. Therefore, $\forall x \in T : an_G(x) \cap T = \{x\}$.

2. Let $T \in T$, then from the definitions of a MVR chain graph and induced bi-directed graph, it is obvious that $T$ is a connected component of the forest $(G_{an(T)})_{\leftrightarrow}$. So, $T$ forms a path-connected set in $(G_{an(T)})_{\leftrightarrow}$.

3. $T \subseteq an(T)$ by definition. So, $\forall x \in T : dis_{an(T)}(x) = \{y|y \leftrightarrow \ldots \leftrightarrow x \in an(T), or x = y\} = T$. Therefore, $dis_{an(T)}(T) = T$ and $dis_{an(T)} \setminus T = \emptyset$. In other words, $\text{tail}(T) = \text{pa}(T)$.

The following example shows that the factorization for a MVR chain graph $G$ based on the Theorem 39 is different from the factorization of $G$ in (Drton, 2009; Marchetti and Lupparelli, 2011).

Example 4 Consider the MVR chain graph $G$ in Example 11. Since

$$ [G]_G = \{\{1, 2, 3, 4\}\{5, 6\}\{7\}\} $$

so, $\text{tail}(\{1, 2, 3, 4\}) = \{5\}$, $\text{tail}(\{5, 6\}) = \{7\}$, and $\text{tail}(\{7\}) = \emptyset$. Therefore, based on Theorem 39 we have: $p = p_{1234\{5\}56\{7\}7}$. However, the corresponding factorization of $G$ based on the formula in (Drton, 2009; Marchetti and Lupparelli, 2011) is: $p = p_{1234\{5\}56\{7\}7\{P\}}$.

Conclusion and Summary

Based on the interpretation of the type of edges (directed or dashed-line (bi-directed) edges) in a chain graph, there are different conditional independence structures among random variables in the corresponding probabilistic model. We showed that for MVR chain graphs all Markov properties in the literature are equivalent for compositional graphoids. We proposed an alternative global and local Markov property for MVR chain graphs, and we proved that they are equivalent with other Markov properties for compositional graphoids. Also, we obtained an alternative formula for factorization of a MVR chain graph. Table summarizes some of the most important attributes of different types of common interpretations of chain graphs.
