Cubical Assemblies and the Independence of the Propositional Resizing Axiom

Taichi Uemura

April 17, 2018

Abstract

We construct a model of cubical type theory with a univalent and impredicative universe in a category of cubical assemblies. We show that the cubical assembly model does not satisfy the propositional resizing axiom.

1 Introduction

Homotopy type theory [Uni13] is an extension of Martin-Löf’s dependent type theory [ML75] with homotopy-theoretic ideas. The most important features are Voevodsky’s univalence axiom and higher inductive types which provide a novel synthetic way of proving theorems of abstract homotopy theory and formalizing mathematics in computer proof assistants [BGL+17].

Ordinary homotopy type theory [Uni13] uses a hierarchy of universes $U_0 : U_1 : U_2 : \ldots$, but there is another choice of universes: one impredicative universe in the style of the Calculus of Constructions [CH88]. Here we say a universe $\mathcal{U}$ is impredicative if it is closed under dependent products along any type family: for any type $A$ and function $B : A \to \mathcal{U}$, the dependent product $\prod_{x : A} B(x)$ belongs to $\mathcal{U}$. An interesting use of such an impredicative universe in homotopy type theory is the impredicative encoding of higher inductive types, proposed by Shulman [Shu11], as well as ordinary inductive types in polymorphic type theory [Has94]. For instance, the unit circle $S^1$ is encoded as $\prod_{X : \mathcal{U}} \prod_{x : X} x = x \to X$ which has a base point and a loop on the point and satisfies the recursion principle in the sense of the HoTT book [Uni13, Chapter 6]. Although the impredicative encoding of a higher inductive type does not satisfy the induction principle in general, some truncated higher inductive types have refinements of the encodings satisfying the induction principle [Spc17, AFS18].

In this paper we construct a model of type theory with a univalent and impredicative universe to prove the consistency of that type theory. As far as the author knows, this is the first model of type theory with a univalent and impredicative universe. Impredicative universes are modeled in the category of assemblies or $\omega$-sets [LM91, Pho06], while univalent universes are modeled in the categories of simplicial sets [KL16] and cubical sets [BCH14]. Therefore, in order to construct a univalent and impredicative universe, it is natural to combine them and construct a model of type theory in the category of internal simplicial or cubical objects in the category of assemblies. One problem is that the category of assemblies does not satisfy the axiom of choice or law of excluded middle, so our choice is the cubical objects in the category of assemblies, which we will call cubical assemblies, because the model in cubical sets [BCH14] is expressed, informally, in a constructive metalogic.

Instead of a model of homotopy type theory itself, we construct a model of a variant of cubical type theory [CCHM15] in which the univalence axiom is provable. Orton and Pitts [OP16] give a sufficient condition for constructing cubical type theory without universes of fibrant types in an elementary topos equipped with an interval object $I$. Although the category of cubical assemblies is not an elementary topos, most of their proofs work in our setting because they use a dependent type theory as an internal language of a topos and the category of cubical assemblies is rich enough to interpret the type theory. For construction of the universe of fibrant types, we can use the right adjoint to the exponential functor $(-)^I$ in the same way as Licata, Orton, Pitts and Spitters [LOPS18].
Voevodsky [Voc12] has proposed the propositional resizing axiom [Uni13 Section 3.5] which asserts that every homotopy proposition is equivalent to some homotopy proposition in the smallest universe. The propositional resizing axiom can be seen as a form of impredicativity for homotopy propositions. Since the universe in the cubical assembly model is impredicative, one might expect that the cubical assembly model satisfies the propositional resizing axiom. Indeed, for a homotopy proposition $A$, there is a natural candidate $A^*$ for propositional resizing defined as

$$A^* := \prod_{X : \text{hProp}} (A \to X) \to X$$

together with a function $\lambda a : X.h.a : A \to A^*$, where $\text{hProp}$ is the universe of homotopy propositions in $U$. However, the propositional resizing axiom fails in the cubical assembly model. We construct a concrete counterexample to propositional resizing.

We begin Section 2 by formulating the axioms for modeling cubical type theory given by Orton and Pitts [OP16, OP17] in a weaker setting. In Section 3 we describe how to construct a model of cubical type theory under those axioms. In Section 4 we give a sufficient condition for presheaf models to satisfy those axioms. As an example of presheaf model we construct a model of cubical type theory in cubical assemblies in Section 5, and show that the cubical assembly model does not satisfy the propositional resizing axiom.

2 The Orton-Pitts Axioms

We will work in a model $\mathcal{E}$ of dependent type theory with

- dependent product types, dependent sum types, extensional identity types, unit type, disjoint finite coproducts and propositional truncation;
- a constant type $\vdash \mathbb{1}$, called an interval, with two constants $\vdash 0 : \mathbb{1}$ and $\vdash 1 : \mathbb{1}$ called end-points and two operators $i,j : \mathbb{I} \vdash i \sqcap j : \mathbb{1}$ and $i,j : \mathbb{I} \vdash i \sqcup j : \mathbb{1}$ called connections;
- a right adjoint $(\cdot)_!$ to the exponential functor $(\cdot)^{\mathbb{1}}$ in the 2-category of models of dependent type theory;
- a propositional universe $\vdash \text{Cof}$ whose inhabitants are called cofibrations;
- an impredicative universe $\vdash U$

satisfying the axioms listed in Figure 1. In the rest of the section we explain these conditions in more detail.

The dependent type theory we use is Martin-Löf’s extensional type theory [ML75]. The notion of model of dependent type theory we have in mind is categories with families [Dyb90] equipped with certain algebraic operators corresponding to the type formers. A category with families $\mathcal{E}$ consists of:

- a category $C^\mathcal{E}$ of contexts;
- a presheaf $F^\mathcal{E} : (C^\mathcal{E})^{\mathbb{1}} \to \text{Set}$ of families;
- a presheaf $T^\mathcal{E} : \text{El}(F^\mathcal{E})^{\mathbb{1}} \to \text{Set}$ of terms, where $\text{El}(P)$ is the category of elements for a presheaf $P$ such that, for any context $\Gamma \in C^\mathcal{E}$ and family $A \in F^\mathcal{E}(\Gamma)$, the presheaf

$$(C^\mathcal{E}/\Gamma)^{\mathbb{1}} \ni (\sigma : A \to \Gamma) \mapsto T^\mathcal{E}(\Delta, A\sigma) \in \text{Set}$$

is representable. We assume that any category with families $\mathcal{E}$ has a choice of a representing object for this presheaf denoted by $\pi_A : \Gamma.A \to \Gamma$ and called the context extension of $A$. A morphism $H : \mathcal{E} \to \mathcal{F}$ of categories with families consists of a functor $H_C : C^\mathcal{E} \to C^\mathcal{F}$ and morphisms of presheaves $H_F : F^\mathcal{E} \to H_F F^\mathcal{F}$ and $H_T : T^\mathcal{E} \to H_T T^\mathcal{F}$ that preserve context extensions: for any family $A \in F^\mathcal{E}(\Gamma)$, the canonical morphism $H_C(\pi_A) \to \pi_{H_F(A)}$ in $C^\mathcal{F}/H_C(\Gamma)$ is an isomorphism. We have a 2-category of models of dependent type theory where the objects are categories with families, the 1-morphisms are morphisms of categories with families and the 2-morphisms $\sigma : H \Rightarrow H'$ are natural transformations $\sigma : H_C \Rightarrow H'_C$. 

1. $\neg(0 = 1)$
2. $\forall i_1 \mid i = i \wedge 0 = 1 \mid i = i \mid 1 = i$
3. $\forall i_1 \mid i = i \mid 0 = 1 \mid i = i \mid 1 = 1$
4. $i : I \vdash i = 0 : \text{Cof}$
5. $i : I \vdash i = 1 : \text{Cof}$
6. $\varphi, \psi : \text{Cof} \vdash \varphi \lor \psi : \text{Cof}$
7. $\varphi : \text{Cof}, \psi : \varphi \rightarrow \text{Cof} \vdash \sum_{\varphi : \varphi} \psi u : \text{Cof}$
8. $\varphi : I \rightarrow \text{Cof} \vdash \forall i : \varphi i : \text{Cof}$
9. $\forall \varphi, \psi : \text{Cof} (\varphi \leftrightarrow \psi) \rightarrow (\varphi = \psi)$
10. $\varphi : \text{Cof}, A : \varphi \rightarrow U, B : U, f : \prod_{\varphi : \varphi} Au \cong B \vdash \text{lift}(\varphi, f) : \sum_{A, d} \{ f : \bar{A} \cong B \mid \forall u : \varphi (Au, fu) = (\bar{A}, \bar{f}) \}$

**Figure 1:** The Orton-Pitts Axioms

Note that there are alternative choices of notions of model of dependent type theory including categories with attributes [Car78] and split full comprehension categories [Jac93]. Whichever model is chosen, we proceed entirely in its internal language.

In dependent type theory, a type $\Gamma \vdash \varphi$ is said to be a proposition, written $\Gamma \vdash \varphi \text{Prop}$, if $\Gamma, u_1, u_2 : \varphi \vdash u_1 = u_2$ holds. For a proposition $\Gamma \vdash \varphi$, we say $\varphi$ holds if there exists a (unique) inhabitant of $\varphi$. For a type $\Gamma \vdash A$, its propositional truncation is a proposition $\Gamma \vdash [A]$ equipped with a constructor $\Gamma, a : A \vdash [a] : [A]$ such that, for every proposition $\Gamma \vdash \varphi$, the function $\Gamma \vdash \lambda fa.f([a]) : ([A] \rightarrow \varphi) \rightarrow (A \rightarrow \varphi)$ is an isomorphism. Propositions are closed under empty type, cartesian products and dependent products along arbitrary types, and we write $\bot, \top, \varphi \land \psi, \varphi x : A \varphi(x)$ for $0, 1, \varphi \lor \psi, \prod x : A \varphi(x)$, respectively, when emphasizing that they are propositions. Also the identity type $\text{Id}(A, a_0, a_1)$ is a proposition because it is extensional, and often written $a_0 = a_1$. The other logical operators are defined using propositional truncation as $\varphi \lor \psi := [\varphi + \psi]$ and $\exists x : A \varphi(x) := \| \sum x : A \varphi(x) \|$. One can show that these logical operations satisfy the derivation rules of first-order intuitionistic logic. Moreover, the type theory admits subset comprehension defined as

$$\Gamma \vdash \{ x : A \mid \varphi(x) \} := \sum_{x : A} \varphi(x)$$

for a proposition $\Gamma, x : A \vdash \varphi(x)$.

A finite coproduct $A + B$ is said to be disjoint if the inclusions $\text{inl} : A \rightarrow A + B$ and $\text{inr} : B \rightarrow A + B$ are monic and

$$\forall a, A \forall b, B \text{inl}(a) \neq \text{inr}(b)$$

holds. A proposition $\Gamma \vdash \varphi$ is said to be decidable if $\Gamma \vdash \varphi \lor \neg \varphi$ holds. If the coproduct $2 := 1 + 1$ of two copies of the unit type is disjoint, then it is a decidable subobject classifier: for every decidable proposition $\Gamma \vdash \varphi$, there exists a unique map $\Gamma \vdash b : 2$ such that $\Gamma \vdash \varphi \leftrightarrow (b = 1)$ holds. For readability we identify a boolean value $b : 2$ with the proposition $b = 1$.

For a type $\Gamma \vdash A$, the exponential functor $(-)^A$ can be seen as a morphism of models of type theory. Indeed, for a type $\Gamma \vdash B$, we define a type $\Gamma^A \vdash B^A$ to be

$$p : A \rightarrow \Gamma \vdash \prod_{x : A} B(px).$$

Its right adjoint, written $(-)_A$ if it exists in the 2-category of models of dependent type theory, also acts on types. In particular, for a type $A \rightarrow \Gamma \vdash B$, we have a type $\Gamma \vdash B'$ by reindexing $\langle A \rightarrow \Gamma \rangle_A \vdash B_A$ along the unit $\Gamma \rightarrow (A \rightarrow \Gamma)_A$, and there is a one-to-one correspondence between terms $\Gamma \vdash b' : B'$ and $A \rightarrow \Gamma \vdash b : B$. Having a right adjoint, the exponential functor $(-)^A$ preserves colimits. As a consequence, the interval $1$ is connected

$$\forall \varphi, i : 2 (\forall i : \varphi i) \lor (\forall i : \neg \varphi i),$$
which is postulated in [OP16] as an axiom.

A universe (à la Tarski) is a type \( U \) equipped with a type \( U \vdash \text{el}_U \). We often omit the subscript \( U \) and simply write \( \text{el} \) for \( \text{el}_U \) if the universe is clear from the context. The universe \( U \) is said to be propositional if \( U \vdash \text{el}_U \) is a proposition. An imprevidicative universe is a universe \( U \) equipped with the following operations.

- An element \( A : U, B : \text{el}(A) \rightarrow U \vdash \sum^U (A, B) : U \) equipped with an isomorphism \( A : U, B : \text{el}(A) \rightarrow U \vdash e : \text{el}(\sum^U (A, B)) \cong \sum_{x \in \text{el}(A)} \text{el}(Bx) \).
- An element \( A : U, a_0, a_1 : \text{el}(A) \vdash \text{id}^U (A, a_0, a_1) : U \) equipped with an isomorphism \( A : U, a_0, a_1 : \text{el}(A) \vdash e : \text{el}(\text{id}^U (A, a_0, a_1)) \cong (a_0 = a_1) \).
- For every type \( \Gamma \vdash A \), an element \( \Gamma, B : \text{el}(A) \rightarrow U \vdash \prod^U (A, B) : U \) equipped with an isomorphism \( \Gamma, B : \text{el}(A) \rightarrow U \vdash e : \text{el}(\prod^U (A, B)) \cong \prod_{x : A} \text{el}(Bx) \).

One might want to require that \( \text{el}(\sum^U (A, B)) \) is equal to \( \sum_{x : \text{el}(A)} \text{el}(Bx) \) on the nose rather than up to isomorphism, but in the category of assemblies described in Section 5, the impredicative universe of partial equivalence relations does not satisfy this equation. For this reason, the distinction between elements \( A : U \) and types \( \text{el}(A) \) is necessary, but for readability we often identify an element \( \Gamma \vdash A \) with the type \( \Gamma \vdash \text{el}(A) \). For example, in Axiom 10 some el’s should be inserted formally. Also Axiom 6 formally means that there exists a term \( \varphi, \psi : \text{Cof} \vdash \text{Cof}(\varphi, \psi) : \text{Cof} \) such that \( \varphi, \psi : \text{Cof} \vdash \text{el}(\text{Cof}(\varphi, \psi)) \leftrightarrow (\text{el}(\varphi) \lor \text{el}(\psi)) \) holds.

Almost all the axioms in Figure 1 are direct translations of those in [OP16, OP17]. As already mentioned, the connectedness of the interval I follows from the existence of the right adjoint to the exponential functor \((-)^I\). We need Axiom 11 which asserts the extensionality of the propositional universe Cof, for fibration structures on identity types. This axiom trivially holds in case that Cof is a subobject of the subobject classifier of an elementary topos. We also note that Cof is closed under \( \bot \), \( \top \) and \( \land \) using Axioms 11, 6 and 7.

## 3 Modeling Cubical Type Theory

We describe how to construct a model of a variant of cubical type theory in our setting following Orton and Pitts [OP16]. Throughout the section E will be a model of dependent type theory satisfying the conditions explained in Section 2. Type-theoretic notations in this section are understood in the internal language of E.

Cubical type theory is an extension of dependent type theory with an interval object [CCHM15, Section 3], the face lattice [CCHM15, Section 4.1], systems [CCHM15, Section 4.2], composition operations [CCHM15, Section 4.3] and the gluing operation [CCHM15, Section 6]. It also has several type formers including dependent product types, dependent sum types, path types [CCHM15, Section 3] and, optionally, identity types [CCHM15, Section 9.1]. We make some modifications to the original cubical type theory CCHM15 in the same way as Orton and Pitts [OP16]. Major differences are as follows.

1. In CCHM15 the interval object I is a de Morgan algebra, while we only require that I is a path connection algebra.
2. Due to the lack of de Morgan involution, we need composition operations in both directions “from 0 to 1” and “from 1 to 0”.

In this section we will construct from E a new model of dependent type theory \( E^F \) that supports all operations of cubical type theory.

### 3.1 The Face Lattice and Systems

The face lattice [CCHM15, Section 4.1] is modeled by the propositional universe Cof. Note that in CCHM15 quantification \( \forall_{x} \varphi \) is not a part of syntax and written as a disjunction of irreducible elements, and plays a crucial role for defining composition operation for gluing (Section 5.3). Since Cof need not admit quantifier elimination, we explicitly require Axiom 8.

We use the following operation for modeling systems [CCHM15, Section 4.2] which allows one to amalgamate compatible partial functions.

4
Proposition 3.1. One can derive

\[
\Gamma \vdash \varphi_1 \text{ Prop}
\]
\[
\Gamma, u_1 : \varphi_1 \vdash a_1(u_1) : A \quad \Gamma, u : \varphi_1, u' : \varphi_2 \vdash a_i(u) = a_j(u') \quad (i \text{ and } j \text{ run over } \{1, \ldots, n\})
\]
\[
\Gamma \vdash [(u_1 : \varphi_1) \mapsto a_1(u_1), \ldots, (u_n : \varphi_n) \mapsto a_n(u_n)] : \varphi_1 \vee \cdots \vee \varphi_n \rightarrow A
\]
such that \(\Gamma, v : \varphi_1 \vdash [(u_1) : \varphi_1 \mapsto a_1(u_1), \ldots, (u_n : \varphi_n) \mapsto a_n(u_n)]v = a_i(v)\) for \(i = 1, \ldots, n\).

Proof. Let \(B\) denote the union of images of \(a_i\)'s:

\[
\Gamma \vdash B := \{ a : A \mid (\exists u_1 : \varphi_1, a_1(u_1) = a) \vee \cdots \vee (\exists u_n : \varphi_n, a_n(u_n) = a) \}.
\]

Then \(\Gamma \vdash B\) is a proposition because \(\Gamma, u : \varphi_1, u' : \varphi_2 \vdash a_i(u) = a_j(u')\) for all \(i\) and \(j\). Hence the function \([a_1, \ldots, a_n] : \varphi_1 + \cdots + \varphi_n \rightarrow B\) induces a function \(\|\varphi_1 + \cdots + \varphi_n\| \rightarrow B\).

3.2 Fibrations

We regard the type of Boolean values \(2\) as a subtype of the interval \(\mathbb{I}\) via the end-point inclusion \([0, 1] : 2 \cong 1 + 1 \rightarrow \mathbb{I}\). We define a map \(e : 2 \vdash e : 2\) to be \(0 = 1\) and \(1 = 0\).

Definition 3.2. For a type \(\Gamma, i : \mathbb{I} \vdash A(i)\), we define a type of composition structures as

\[
\Gamma \vdash \text{Comp}'(A(i)) := \prod_{e : 2} \prod_{\varphi : \text{Cof}} f : \varphi \rightarrow [1 : \exists i : A(i) \mid a : A(c)] \prod_{w : \varphi} f e = a \rightarrow \{ a' : A(e) \mid \forall w : \varphi f \bar{e} = a' \}.
\]

In this notation, the variable \(i\) is considered to be bound.

Definition 3.3. For a type \(\Gamma \vdash A\), we define a type of fibration structures as

\[
\vdash \text{Fib}(A) := \prod_{p : \exists \vdash \Gamma} \text{Comp}'(A(p))
\]

A fibration is a type \(\Gamma \vdash A\) equipped with a global section \(\vdash \alpha : \text{Fib}(A)\).

We get a new model \(\mathcal{E}^F\) of dependent type theory where

- the contexts are those of \(\mathcal{E}\);
- the types over \(\Gamma\) are fibrations over \(\Gamma\);
- the terms of a fibration \(\Gamma \vdash A\) are terms of the underlying type \(\Gamma \vdash A\) in \(\mathcal{E}\).

In the same way as Orton and Pitts [OP16], one can show the following.

Theorem 3.4. The model \(\mathcal{E}^F\) supports composition operations, dependent product types, dependent sum types, path types, identity types, unit type and finite coproducts. If \(\mathcal{E}\) has a natural number object, then so does \(\mathcal{E}^F\).

Therefore, the notion of equivalences is derivable in this model \(\mathcal{E}^F\) as in [CCHM15 Section 5]. For fibrations \(\Gamma \vdash A\) and \(\Gamma \vdash B\), we shall denote by \(\Gamma \vdash A \simeq B\) the type of equivalences from \(A\) to \(B\).

We also introduce a class of objects that automatically carry fibration structures.

Definition 3.5. A type \(\vdash A\) is said to be discrete if \(\forall f : 1 \rightarrow A \forall i : 1 f i = f 0\) holds.

Proposition 3.6. If \(\vdash A\) is a discrete type, then it has a fibration structure.

Proof. Let \(e : 2, \varphi : \text{Cof}, f : \varphi \rightarrow 1 \rightarrow A\) and \(a : A\) such that \(\forall w : \varphi f u e = a\). Then \(a' := a : A\) satisfies \(\forall w : \varphi f \bar{e} = a'\) by the discreteness.
3.3 Gluing

For a proposition \( \Gamma \vdash \varphi \), types \( \Gamma, u : \varphi \vdash A(u) \) and \( \Gamma \vdash B \) and a function \( \Gamma, u : \varphi \vdash f : A(u) \to B \), we define a type \( \text{Glue}(\varphi, f) \) to be

\[
\Gamma \vdash \text{Glue}(\varphi, f) := \sum_{u: \Pi_u \varphi} \{ b : B \mid \forall u, \varphi, f(au) = b \}.
\]

There is a canonical isomorphism \( \Gamma, u : \varphi \vdash \text{unglue}(u) := \lambda(a, b).au : \text{Glue}(\varphi, f) \cong A(u) \) with inverse \( \lambda \alpha. (\lambda v. a)u \).

Proposition 3.7. For \( \Gamma \vdash \varphi : \text{Cof} \), \( \Gamma, u : \varphi \vdash A(u) \), \( \Gamma \vdash B \) and \( \Gamma, u : \varphi \vdash f(u) : A(u) \to B \), if \( A \) and \( B \) are fibrations and \( f \) is an equivalence, then \( \Gamma \vdash \text{Glue}(\varphi, f) \) has a fibration structure preserved by the canonical isomorphism \( \Gamma, u : \varphi \vdash \text{unglue}(u) : \text{Glue}(\varphi, f) \cong A(u) \).

Proof. The construction is similar to \[\text{CCHM15 Section 6.2}\].

Since the universe \( \mathcal{U} \) is closed under type formers used in \( \text{Glue}(\varphi, f) \), one can define a term

\[
\varphi : \text{Cof}, A : \varphi \to \mathcal{U}, B : \mathcal{U}, f : \prod_{u: \varphi} Au \to B \vdash \text{Glue}^\mathcal{U}(\varphi, f) : \mathcal{U}
\]

together with an isomorphism \( e : \text{Glue}^\mathcal{U}(\varphi, f) \cong \text{Glue}(\varphi, f) \). Using Axiom \( \text{UI} \) we have a type \( \text{SGlue}(\varphi, f) : \mathcal{U} \) and an isomorphism \( h : \text{Glue}^\mathcal{U}(\varphi, f) \cong \text{SGlue}(\varphi, f) \) such that \( \forall u, \varphi, (A(u), \text{unglue}(u) \circ c) = (\text{SGlue}(\varphi, f), h) \).

\[
\begin{array}{c}
\Gamma \vdash \text{Glue}^\mathcal{U}(\varphi, f) \\
\downarrow \approx \\
\Gamma, u : \varphi \vdash \text{Glue}^\mathcal{U}(\varphi, f) \xrightarrow{\sim} \text{Glue}(\varphi, f) \xrightarrow{\sim} A(u)
\end{array}
\]

3.4 Universes

For a type \( \Gamma \vdash A \), a fibration structure on \( A \) corresponds to a section \( p : \| \| \to \Gamma \vdash \alpha : \text{Comp}^\mathcal{U}(A(p)) \). Using the right adjoint to \( (-)^\| \), we have a type \( \Gamma \vdash F_\pi A \) and one-to-one correspondence between sections of \( \text{Comp}^\mathcal{U}(A(p)) \) and \( F_\pi A \). Let \( \Gamma, FA = \sum_{i: \Pi_i \varphi} F_\pi A \) and \( \pi_1 : \Gamma, FA \to \Gamma \) be the first projection. By definition a morphism \( \sigma : \Delta \to \Gamma, FA \) corresponds to a pair \( (\sigma_0, \alpha) \) consisting of a morphism \( \sigma_0 : \Delta \to \Gamma \) and a fibration structure \( \alpha : \prod_{i: \Pi_i \alpha} \text{Comp}^\mathcal{U}(A(p)) \).

Using this construction for the universe \( \mathcal{U} \vdash e_\mathcal{U} \), we have a new universe \( \mathcal{U}^F := \mathcal{U}, F(\mathcal{E}) \) together with a fibration \( \mathcal{U} : \mathcal{U}^F \vdash e_{\mathcal{U}^F}(A) := e_{\mathcal{U}}(\pi_1(A)) \). By definition \( \mathcal{U}^F \) classifies fibrations whose underlying types belong to \( \mathcal{U} \). By Proposition 3.7 it has an operation

\[
\varphi : \text{Cof}, A : \varphi \to \mathcal{U}^F, B : \mathcal{U}^F, f : \prod_{u: \varphi} Au \cong B \vdash \text{SGlue}^{\mathcal{U}^F}(\varphi, f) : \mathcal{U}^F
\]

such that \( \forall u, \varphi, Au = \text{SGlue}^{\mathcal{U}^F}(\varphi, f) \) and \( \pi_1(\text{SGlue}^{\mathcal{U}^F}(\varphi, f)) = \text{SGlue}^\mathcal{U}(\varphi, f) \).

Proposition 3.8. \( \vdash \mathcal{U}^F \) has a fibration structure.

Proof. The construction is similar to \[\text{CCHM15 Section 7.1}\].

Theorem 3.9. The model \( \mathcal{E}^F \) has a universe \( \mathcal{U}^F \) which is closed under dependent product types along arbitrary fibrations, dependent sum types and path types and has a gluing operation \( \text{SGlue}^{\mathcal{U}^F} \). If \( \text{Cof} \) belongs to \( \mathcal{U} \), then \( \mathcal{U}^F \) is closed under identity types.

Proof. Proposition 3.8 means that \( \vdash \mathcal{U}^F \) is a type in the model \( \mathcal{E}^F \). To see the closure property of \( \mathcal{U}^F \), it suffices to show that \( \mathcal{U} \) is closed under those type constructors. \( \mathcal{U} \) is closed under dependent product types along arbitrary types and dependent sum types by assumption. Recall \[\text{OPT16 Section 4.3}\] that,
for a type $\Gamma \vdash A$ and elements $\Gamma \vdash a_0 : A$ and $\Gamma \vdash a_1 : A$, the path type $\Gamma \vdash \text{Path}(A, a_0, a_1)$ and identity type $\Gamma \vdash \text{Id}(A, a_0, a_1)$ are defined as

$$\text{Path}(A, a_0, a_1) := \{ p : \| \to A \mid p_0 = a_0 \land p_1 = a_1 \}$$

$$\text{Id}(A, a_0, a_1) := \sum_{p : \text{Path}(A, a_0, a_1)} \{ \varphi : \text{Cof} \mid \varphi \to \forall_{i : \|} pi = a_0 \}.$$ 

Hence $\mathcal{U}$ is closed under path types, and if $\text{Cof}$ belongs to $\mathcal{U}$, then $\mathcal{U}$ is closed under identity types. □

Since the univalence axiom can be derived from the gluing operation [CCHM15 Section 7], we conclude that $\mathcal{U}$ is a univalent and impredicative universe.

### 4 Presheaf Models

In this section we give a sufficient condition for a presheaf category to satisfy the conditions in Section 2. We will work in a model $\mathcal{S}$ of dependent type theory with dependent product types, dependent sum types, extensional identity types, unit type, disjoint finite coproducts and propositional truncation.

A *category* in $\mathcal{S}$ consists of:

- a type $\vdash C_0$ of objects;
- a type $c_0, c_1 : C_0 \vdash C_1(c_0, c_1)$ of morphisms;
- a term $c : C_0 \vdash \text{id}_c : C_1(c, c)$ called identity;
- a term $c_0, c_1, c_2 : C_0, g : C_1(c_1, c_2), f : C_1(c_0, c_1) \vdash gf : C_1(c_0, c_2)$ called composition

satisfying the standard axioms of category. We will simply write $C$ and $C(c_0, c_1)$ for $C_0$ and $C_1(c_0, c_1)$ respectively. The notions of functor and natural transformation in $\mathcal{S}$ are defined in the obvious way. For a category $C$ in $\mathcal{S}$, a *presheaf* on $C$ consists of:

- a type $c : C \vdash A(c)$;
- a term $c_0, c_1 : C, \sigma : C(c_0, c_1), a : A(c_1) \vdash a\sigma : A(c_0)$ called (right) $C$-action

satisfying $\text{id} = a$ and $a(\sigma\tau) = (a\sigma)\tau$. For presheaves $A$ and $B$, a *morphism* $f : A \to B$ is a term $c : C, a : A(c) \vdash f(a) : B(c)$ satisfying $c_0, c_1 : C, \sigma : C(c_0, c_1), a : A(c_1) \vdash f(a\sigma) = f(a)\sigma$. For a presheaf $A$, its *category of elements*, written $\text{El}(A)$, is defined as

- $\vdash \text{El}(A)_0 := \sum_{c : C_0} A(c)$;
- $(c_0, a_0), (c_1, a_1) : \text{El}(A)_0 \vdash \text{El}(A)_1((c_0, a_0), (c_1, a_1)) := \{ \sigma : C_1(c_0, c_1) \mid a_1\sigma = a_0 \}$.

There is a projection functor $\pi_A : \text{El}(A) \to C$.

For a category $C$ in $\mathcal{S}$, we describe the presheaf model $\text{PSh}(C)$ of dependent type theory. Contexts are interpreted as presheaves on $C$. For a context $\Gamma$, types on $\Gamma$ are interpreted as presheaves on $\text{El}(\Gamma)$. For a type $\Gamma \vdash A$, terms of $A$ are interpreted as sections of the projection $\pi_A : \text{El}(A) \to \text{El}(\Gamma)$. For a type $\Gamma \vdash A$, the context extension $\Gamma.A$ is interpreted as the presheaf $c : C \vdash \sum_{c : C} A(c, \gamma)$. This construction is also used for dependent sum types. The dependent product for a type $\Gamma.A \vdash B$ is the presheaf

$$(c, \gamma) : \text{El}(\Gamma) \vdash \{ f : \prod_{c' : C} \prod_{\gamma : C(c', c)} B(c', a) \mid \forall_{c, c'} \forall_{\gamma : C(c', c)} (f(c', a)) = f(c', (c') \gamma a) \}.$$ 

Extensional identity types, unit type, disjoint finite coproducts and propositional truncation are pointwise.
4.1 Lifting Universes

We describe the Hofmann-Streicher lifting of a universe \([HS97]\). Let \(C\) be a category in \(S\) and \(U\) a universe in \(S\). We define a universe \([C^{op}, U]\) in \(PSh(C)\) as follows. The universe \(U\) can be seen as a category whose type of objects is \(U\) and type of morphisms is \(A, B : U \vdash \forall V(A \to B)\). For an object \(c : C\), we define \([C^{op}, U](c)\) to be the type of functors from \((C/c)^{op}\) to \(U\). The \(C\)-action on \([C^{op}, U]\) is given by composition. The type \([C^{op}, U] \vdash \forall V([C^{op}, U]) \vdash \forall V([C^{op}, U])(c, A) := \forall V(\lambda(I(d))\).

It is easy to show that, if \(U\) is an impredicative universe, then dependent product types, dependent sum types and extensional identity types in \(U\) can be lifted to those in \([C^{op}, U]\) so that \([C^{op}, U]\) is an impredicative universe in \(PSh(C)\). If \(U\) is a propositional universe in \(S\), then \([C^{op}, U]\) is a propositional universe in \(PSh(C)\).

Proposition 4.1. Let \(U\) be an impredicative universe and \(C\) a propositional universe in \(S\). If they satisfy Axiom [\(\mathbb{A}\) \(\mathbb{B}\) \(\mathbb{C}\) and \(\mathbb{D}\) then so do \([C^{op}, U]\) and \([C^{op}, Cof]\).

Proof. We only check Axiom [\(\mathbb{D}\). The other axioms are easy to verify.

We have to define a term \(\varphi : [C^{op}, Cof], A : \varphi \to [C^{op}, U], B : [C^{op}, U], f : \prod_{u : \varphi} Au \cong B \vdash (D(\varphi, f), g(\varphi, f)) : \prod_{c : C^{op}} A(c, f) \cong B \) in \(PSh(C)\). It corresponds to a natural transformation that takes an object \(c : C\), functors \(\varphi : (C/c)^{op} \to Cof, A : \text{El}(\varphi)^{op} \to U\) and \(B : (C/c)^{op} \to U\) and an isomorphism \(f : A \cong B\) of presheaves on \(\text{El}(\varphi)\) and returns a pair \((D(\varphi, f), g(\varphi, f))\) consisting of a functor \(D(\varphi, f) : (C/c)^{op} \to U\) and an isomorphism \(g(\varphi, f) : A \cong B\) of presheaves on \((C/c)^{op}\) such that \(D(\varphi, f)\varphi = A\) and \(g(\varphi, f)\varphi = f\). Let \(\sigma : (C/c', c)\) be a morphism. Then we have \(\varphi(\sigma) : \text{Cof}, \lambda u. A(\sigma, u) \vdash \varphi(\sigma) \to U, B(\sigma) : U\) and an isomorphism \(\lambda u. f(\sigma, u) : \prod_{u : \varphi(\sigma)} A(\sigma, u) \cong B(\sigma)\). By the isomorphism lifting on \(U\), we have \(D(\varphi, f)(\sigma) : U\) and an isomorphism \(g(\varphi, f)(\sigma) : D(\varphi, f)(\sigma) \cong B(\sigma)\) such that \(\forall u : \varphi(\sigma)(A(\sigma, u), f(\sigma, u)) = (D(\varphi, f)(\sigma), g(\varphi, f)(\sigma))\). For the morphism part of the theory \(D(\varphi, f), f\), let \(\tau : C(c', c)\) be another morphism. Then we define \(\tau^* : D(\varphi, f)(\sigma) \to D(\varphi, f)(\tau)\) to be the composition

\[
\begin{align*}
D(\varphi, f)(\sigma) &\xrightarrow{\gamma(\varphi, f)(\sigma)} B(\sigma) \\
&\xrightarrow{\tau} B(\tau) \\
&\xrightarrow{\gamma(\varphi, f)(\tau)\gamma^{-1}(\tau)} D(\varphi, f)(\tau).
\end{align*}
\]

By definition \(g(\varphi, f)\) becomes a natural isomorphism and \((D(\varphi, f)\varphi, g(\varphi, f)\varphi) = (A, f)\). It is easy to see that \(\forall u : \varphi(\sigma)(A(\sigma, u), f(\sigma, u)) = (D(\varphi, f)(\sigma), g(\varphi, f)(\sigma))\).

4.2 Intervals

Suppose a category \(C\) in \(S\) has finite products. A path connection algebra in \(C\) consists of an object \(I \in C\), morphisms \(\delta_0, \delta_1 : C(I, I)\) called end-points and morphisms \(\mu_0, \mu_1 : C(I \times I, I)\) called connections satisfying \(\mu_0(\delta_0 \times I) = \mu_1(I \times \delta_0) = \delta_0\) and \(\mu_1(\delta_0 \times I) = \mu_0(I \times \delta_0) = \text{id}\) for \(e \in \{0, 1\}\).

For a path connection algebra \(I \in C\), we have a representable presheaf \(yI\) on \(C\). Since the Yoneda embedding is fully faithful and preserves finite products, \(yI\) has end-points and connections satisfying Axiom [\(\mathbb{A}\) and [\(\mathbb{B}\). The interval \(yI\) satisfies Axiom [\(\mathbb{D}\) if and only if \(\forall c, c' \in C, c \neq c'\) holds, where \(!c : C(c, 1)\) is the unique morphism into the terminal object.

Proposition 4.2. Let \(Cof\) be a propositional universe in \(S\) and suppose that, for every pair of objects \(c, c' \in C\), the equality predicate on \(C(c, c')\) belongs to \(Cof\). Then, for every object \(c \in C\), the equality predicate on \(yc\) belongs to \([C^{op}, Cof]\). In particular, \(yc\) and \([C^{op}, Cof]\) in \(PSh(C)\) satisfy Axiom [\(\mathbb{A}\) and [\(\mathbb{B}\).

Proof. Because equality on a presheaf is pointwise.

Proposition 4.3. Suppose that a category \(C\) in \(S\) has finite products. For an object \(c : C\), the exponential functor \((-)^{yc} : PSh(C) \to PSh(C)\) is isomorphic to \((-)\times c^*\). In particular, \((-)^{yc}\) has a right adjoint.

Proof. \(A^{yc}(c') \cong PSh(C)(yc \times yc, A) \cong PSh(C)(yc, c) \cong A(c' \times c)\).

Hence the exponential functor \((-)^{yc}\) has a right adjoint. It is easy to extend the right adjoint to a morphism of models of type theory. Proposition [\(\mathbb{A}\)\(\mathbb{B}\) also implies Axiom [\(\mathbb{E}\) for the propositional universe \([C^{op}, Cof]\).

In summary, we have:
Theorem 4.4. Suppose:

- \( S \) is a model of dependent type theory with dependent product types, dependent sum types, extensional identity types, unit types, disjoint finite coproducts and propositional truncation;
- \( \text{Cof} \) is a propositional universe and \( U \) is an impredicative universe satisfying Axiom \([\Pi, \Box, 4]\) and \([\Delta]\);
- \( C \) is a category in \( S \) with finite products and the equality on \( C(c, c') \) belongs to \( \text{Cof} \) for every pair of objects \( c, c' : C \);
- \( \mathbb{I} \) is a path connection algebra in \( C \);
- \( \mathbb{y} \mathbb{I} \) satisfies Axiom \([\Pi]\).

Then the presheaf model \( \text{PSh}(C) \) together with propositional universe \([C^\circ, \text{Cof}]\), impredicative universe \([C^\circ, U]\) and interval \( \mathbb{y} \mathbb{I} \) satisfies all the axioms in Figure \([\Pi]\).

4.3 Decidable Subobject Classifier

An example of the propositional universe \( \text{Cof} \) in Theorem 4.4 is the decidable subobject classifier \( 2 \) which always satisfies Axiom \([\Pi, 4, 7]\) and \([\Pi]\).

Proposition 4.5. Any universe \( U \) satisfies Axiom \([\Pi]\) with respect to the propositional universe \( 2 \).

Proof. Let \( \varphi : 2, A : \varphi \to U, B : U, f : \prod_{a : \varphi} Au \cong B \). We define \( \text{lift}(\varphi, f) \) by case analysis on \( \varphi : 2 \) as \( \text{lift}(0, f) := (B, \text{id}) \) and \( \text{lift}(1, f) := (A \ast, f \ast) \) where \( \ast \) is the unique element of a singleton type. \( \square \)

4.4 Categories of Cubes

We present examples of internal categories \( C \) with a path connection algebra \( \mathbb{I} \) satisfying the hypotheses of Theorem 4.4 with \( \text{Cof} = 2 \). Obvious choices of \( C \) are the category of free de Morgan algebras \([CCHM15] \) and various syntactic categories of the language \( \{0, 1, \land, \lor, \top, \bot\} \) \([BM17]\), but some inductive types and quotient types are required to construct these categories in dependent type theory. Instead, we give simple examples definable only using natural numbers.

Suppose \( S \) is a model of dependent type theory with dependent product types, dependent sum types, extensional identity types, unit type, disjoint finite coproducts, propositional truncation and natural numbers. We define a family of finite types \( n : \mathbb{N} \vdash \text{Fin}_n \) to be \( \text{Fin}_n = \{ k : \mathbb{N} \mid k < n \} \). We define a category \( B \) as follows. Its object of objects is \( \mathbb{N} \). The morphisms \( m \to n \) are functions \( \text{Fin}_m \to 2 \to \text{Fin}_n \to 2 \).

In the category \( B \), the terminal object is \( 0 : \mathbb{N} \) and the product of \( m \) and \( n \) is \( m + n \). One can show, by induction, that every \( B(m, n) \) has decidable equality. \( B \) has a path connected algebra \( 1 : \mathbb{N} \) together with end-points \( 0, 1 : (\text{Fin}_0 \to 2) \to (\text{Fin}_1 \to 2) \) and connections \( \text{min}, \text{max} : (\text{Fin}_1 \to 2) \times (\text{Fin}_1 \to 2) \to (\text{Fin}_0 \to 2) \). One can show that the category \( B \) satisfies the hypotheses of Theorem 4.4. Moreover, any subcategory of \( B \) that has the same finite products and contains the path connection algebra \( 1 \) satisfies the same condition. An example is the wide subcategory \( B_{\text{ord}} \) of \( B \) which are the morphisms are order-preserving functions \( \text{Fin}_m \to 2 \to \text{Fin}_n \to 2 \).

Remark 4.6. In case that \( S = \text{Set} \), the category \( B_{\text{ord}} \) is isomorphic to the canonical cube category \( C_{\text{wec}, \land, \lor} \) in the terminology of \([BM17]\), because any order-preserving function \( f : 2^n \to 2 \) can be written in the language \( \{0, 1, \land, \lor\} \) as

\[
f(x) = \bigvee_{\alpha \in f^{-1}(1)} \bigwedge_{i \in \{0, \ldots, n-1\}} x_i
\]

for \( x = (x_0, \ldots, x_{n-1}) \in 2^n \). As shown in \([BM17]\), \( C_{\text{wec}, \land, \lor} \) is a strict test category in the sense of Grothendieck \([Gro83] \).
4.5 Constant and Codiscrete Presheaves

We show some properties of constant and codiscrete presheaves which will be used in Section 5. Let $S$ be a model of dependent type theory satisfying the hypotheses of Theorem 4.4. For an object $A \in S$, we define the constant presheaf $\Delta A$ to be $\Delta A(c) := A$ with the trivial $C$-action.

Proposition 4.7. Every constant presheaf $\Delta A$ is discrete.

Proof. For every $c : C$, we have $(\Delta A)^{\Phi}(c) \cong \Delta A(c \times 1) = A$ by Proposition 4.3.

For a type $\Gamma \vdash A$ in $S$, we define the codiscrete presheaf $\Delta \Gamma \vdash \nabla A$ to be $\nabla A(c, \gamma) := C(1, c) \to A(\gamma)$ with composition as the $C$-action.

Proposition 4.8. Suppose that $\text{Cof} = 2$. Then for every type $\Gamma \vdash A$ in $S$, the type $\nabla \Gamma \vdash \nabla A$ has a fibration structure.

Proof. Since $\Delta \Gamma$ is discrete, it suffices to show that every fibre of $\nabla A$ has a fibration structure. Thus we may assume that $\Gamma$ is the empty context. We construct a term

$$\alpha : \prod_{c : 2} \prod_{\varphi : (C/c)^{\text{op}}} \prod_{\sigma : (C/c)^{\text{op}}} \prod_{u : \nabla A(a, \nabla A)} \langle \forall_{u, \varphi, f} u e = a \rangle \to \{ \bar{a} : \nabla A | \forall_{u, \varphi, f} u e = \bar{a} \}$$

in $\text{PSh}(C)$. It corresponds to a natural transformation that takes an object $c : C$, an element $e : 2$, a functor $\varphi : (C/c)^{\text{op}} \to 2$, a natural transformation $f : f_{c' \in C}(\sum_{c'} (C/c') (\varphi(c'))) \to \nabla A(c')$ and an element $a : \nabla A(c)$ such that $\forall_{c', \varphi, \sigma, u, e} \nabla A(a) f(\sigma, u, e) = a \sigma$ and returns an element $\alpha(e, \varphi, f, a) : \nabla A(c)$ such that $\forall_{c', \varphi, \sigma, u, e} \nabla A(a) f(\sigma, u, e) = \alpha(e, \varphi, f, a) \sigma$. We define $\alpha(e, \varphi, f, a) : C(1, c) \to A$ as

$$\alpha(e, \varphi, f, a)(\sigma) := \begin{cases} f(\sigma, u, e)(\text{id}_1) & \text{if } u : \varphi(\sigma) \text{ is found} \\ a(\sigma) & \text{otherwise} \end{cases}$$

for $\sigma : C(1, c)$. Then by definition $\forall_{c', \varphi, \sigma, u, e} \nabla A(a) f(\sigma, u, e) = \alpha(e, \varphi, f, a) \sigma$.

Proposition 4.9. Suppose that $C(1, 1)$ only contains 0 and 1, namely $\forall_{\sigma, C(1, 1)} \sigma = 0 \lor \sigma = 1$. Then for every type $\Gamma \vdash A$ in $S$, there exists a term

$$\Delta \Gamma \vdash p : \prod_{a_0, a_1 : \nabla A} \text{Path}(\nabla A, a_0, a_1)$$

in $\text{PSh}(C)$.

Proof. We may assume that $\Gamma$ is the empty context. The term $p$ corresponds to a natural transformation that takes an object $c : C$, elements $a_0, a_1 : \nabla A(c)$ and a morphism $i : C(c, 1)$ and returns an element $p(a_0, a_1, i) : \nabla A(c)$ such that $p(a_0, a_1, 0) = a_0$ and $p(a_0, a_1, 1) = a_1$. We define $p(a_0, a_1, i) : C(1, c) \to A$ as

$$p(a_0, a_1, i)(\sigma) := \begin{cases} a_0(\sigma) & \text{if } i \sigma = 0 \\ a_1(\sigma) & \text{if } i \sigma = 1 \end{cases}$$

for $\sigma : C(1, c)$. Then by definition $p(a_0, a_1, 0) = a_0$ and $p(a_0, a_1, 1) = a_1$.

5 Cubical Assemblies and the Independence of the Propositional Resizing Axiom

An assembly, also called an $\omega$-set, is a set $A$ equipped with a non-empty set $E_A(a)$ of natural numbers for every $a \in A$. When $n \in E_A(a)$, we say $n$ is a realizer for $a$ or $n$ realizes $a$. A morphism $f : A \to B$ of assemblies is a function $f : A \to B$ between the underlying sets such that there exists a partial recursive function $e$ such that, for any $a \in A$ and $n \in E_A(a)$, the application $e n$ is defined and belongs to $E_B(f(a))$. In that case we say $f$ is tracked by $e$ or $e$ is a tracker of $f$. We shall denote by $\text{Asm}$ the category of assemblies and morphisms of assemblies. Note that assemblies can be defined in terms of partial combinatory algebras instead of natural numbers and partial recursive functions [Oos08], and that the rest of this section works for assemblies on any non-trivial partial combinatory algebra.
The category $\text{Asm}$ is a model of dependent type theory. Contexts are interpreted as assemblies. Types $\Gamma \vdash A$ are interpreted as families of assemblies $(A(\gamma) \in \text{Asm})_{\gamma \in \Gamma}$ indexed over the underlying set of $\Gamma$. Terms $\Gamma \vdash a : A$ are interpreted as sections $a \in \prod_{\gamma \in \Gamma} A(\gamma)$ such that there exists a partial recursive function $e$ such that, for any $\gamma \in \Gamma$ and $n \in E(\gamma)$, the application $e n$ is defined and belongs to $E_{A(\gamma)}(a(\gamma))$. For a type $\Gamma \vdash A$, the context extension $\Gamma.A$ is interpreted as an assembly $(\sum_{\gamma \in \Gamma} A(\gamma), (\gamma, a) \mapsto \{ (n, m) \mid n \in E(\gamma), m \in E_{A(\gamma)}(a) \})$ where $\langle n, m \rangle$ is a fixed effective encoding of tuples of natural numbers. It is known that $\text{Asm}$ supports dependent product types, dependent sum types, extensional identity types, unit type, disjoint finite coproducts and natural numbers. See, for example, [Oos08, LM91, Jac99]. For a type $\Gamma \vdash A$, the propositional truncation $\Gamma \vdash \| A \|$ is the family

$$[\| A \|](\gamma) = \begin{cases} \ast & \text{if } A(\gamma) \neq \emptyset \\ \emptyset & \text{if } A(\gamma) = \emptyset \end{cases}$$

with realizers $E_{[\| A \|](\gamma)}(\ast) = \bigcup_{a \in A(\gamma)} E_{A(\gamma)}(a)$.

It is also well-known that $\text{Asm}$ has an impredicative universe $\text{PER}$. It is an assembly whose underlying set is the set of partial equivalence relations; namely reflexive and transitive relations, on $\mathbb{N}$ and the set of realizers of $R$ is $E_{\text{PER}}(R) = \{0\}$. The type $\text{PER} \vdash e_{\text{PER}}$ is defined to be $e_{\text{PER}}(R) = \mathbb{N}/R$, the set of equivalence classes on $\{ n \in \mathbb{N} \mid R(n, n) \}$; with realizers $E_{\mathbb{N}/R}(\xi) = \xi$. The universe $\text{PER}$ classifies modest families. An assembly $A$ is said to be modest if $E_A(a)$ and $E_A(a')$ are disjoint for distinct $a, a' \in A$. By definition $\mathbb{N}/R$ is modest for every $R \in \text{PER}$. Conversely, for a modest assembly $A$, one can define a partial equivalence relation $R$ such that $A \cong \mathbb{N}/R$. For the impredicativity of $\text{PER}$, see [Hyb88, LM91, Jac99].

The category $\text{Asm}$ satisfies the hypotheses of Theorem [4.4] with impredicative universe $\text{PER}$, propositional universe 2 and the internal category $\text{Bop}$ defined in Section [4.4]. We will refer to the presheaf model of cubical type theory generated by these structures as the cubical assembly model. In this section we give a counterexample to the propositional resizing axiom in the cubical assembly model.

### 5.1 Propositional Resizing

In cubical type theory, a type family $\Gamma \vdash A$ is a homotopy proposition if the type $\Gamma, a_0, a_1 : A \vdash \text{Path}(A, a_0, a_1)$ has an inhabitant. For a universe $\vdash \mathcal{U}$, we define the universe of homotopy propositions as

$$\vdash \text{hProp} := \sum_{A : \mathcal{U}} \prod_{a_0, a_1 : A} \text{Path}(A, a_0, a_1).$$

Following the HoTT book [Un13], we regard hProp as a subtype of $\mathcal{U}$.

The propositional resizing axiom asserts that, for every homotopy proposition $\Gamma \vdash A$, there exist an element $\Gamma \vdash A^* : \text{hProp}$ and an equivalence $\Gamma \vdash e : A \simeq A^*$. Note that, for homotopy propositions $A$ and $B$, to give an equivalence $A \simeq B$ it suffices to give functions $A \to B$ and $B \to A$. When $\mathcal{U}$ is an impredicative universe, there is a candidate for propositional resizing. For a homotopy proposition $\Gamma \vdash A$, we can define

$$\Gamma \vdash A^* := \prod_{X : \text{hProp}} (A \to X) \to X : \text{hProp}$$

$$\Gamma \vdash \eta := \lambda a. \lambda X f. f a : A \to A^*,$$

because homotopy propositions are closed under dependent product types along arbitrary type families. If $\Gamma \vdash A^* : \text{hProp}$ and $\Gamma \vdash e : A \simeq A^*$ are given, we have a function $\Gamma \vdash f := \lambda x.e^{-1}(\alpha A'e) : A^* \to A$; and thus $\eta$ is an equivalence. Hence, in cubical type theory with an impredicative universe, the propositional resizing axiom is equivalent to the following.

**Axiom 5.1.** For every homotopy proposition $\Gamma \vdash A$, the function $\Gamma \vdash \eta : A \to A^*$ is an equivalence.

### 5.2 Uniform Objects

An assembly $A$ is said to be uniform if $\bigcap_{a \in A} E_A(a)$ is non-empty. An internal presheaf $A$ on an internal category $\mathcal{C}$ is said to be uniform if every $A(c)$ is uniform. An internal presheaf $A$ on $\mathcal{C}$ is said to be well-supported if the unique morphism into the terminal presheaf is regular epi. For an internal presheaf $A$, the following are equivalent:
• $A$ is well-supported;
• $\|A\|$ is the terminal presheaf;
• there exists a partial recursive function $e$ such that, for any $c \in C_0$ and $n \in EC_0(c)$, there exists an $a \in A(c)$ such that $en$ is defined and belongs to $E_A(a)$.

**Proposition 5.2.** Let $C$ be a category in $\text{Asm}$. For a uniform internal presheaf $A$ on $C$ and an internal functor $X : C^{op} \to \text{PER}$, the function

$$i^* : (\|A\| \to X) \to (A \to X)$$

is an isomorphism, where $i : A \to \|A\|$ is the constructor for propositional truncation. In particular, if, in addition, $A$ is well-supported, then the function $\lambda x.a : X \to (A \to X)$ is an isomorphism.

**Proof.** Since $i$ is regular epi, $i^*$ is a monomorphism. Hence it suffices to show that $i^*$ is regular epi. Let $k_c$ denote a common realizer of $A(c)$, namely $k_c \in \bigcap_{a \in A(c)} E(a)$. Let $c \in C_0$ be an object and $x : yc \times \|A\| \to X$ a morphism of presheaves tracked by $e$. We have to show that there exists a morphism $\tilde{x} : yc \times \|A\| \to X$ such that $\tilde{x} \circ (yc \times i) = x$ and that a tracker of $\tilde{x}$ is computable from $e$. For any $\sigma : c' \to c$ and $a', a'' \in A(c')$, we have $\text{ev}_{n,a} \in E(x(\sigma, a)) \cap E(x(\sigma, a'))$ for some $n \in E(\sigma)$. Since $X(c')$ is modest, $x(\sigma, a) = x(\sigma, a')$. Hence $x$ induces a morphism of presheaves $\tilde{x} : yc \times \|A\| \to X$ tracked by $e$ such that $\tilde{x} \circ (yc \times i) = x$.

**Theorem 5.3.** Let $\Gamma \vdash A$ be a type in the cubical assembly model. Suppose that $A$ is uniform and well-supported as an internal presheaf on $\text{El}(\Gamma)$ and does not have a section. Then the function $\Gamma \vdash \eta : A \to A^*$ is not an equivalence.

**Proof.** By Proposition 5.2 we see that $A^* = \prod_{X : A \to \text{Prop}} (A \to X) \to X$ has an inhabitant while $A$ does not have an inhabitant by assumption.

**Theorem 5.4.** Let $\Gamma \vdash A$ be a type in $\text{Asm}$. Suppose that $A$ is uniform and well-supported but does not have a section. Then the function $\Delta \Gamma \vdash \eta : \nabla A \to (\nabla A)^*$ is not an equivalence.

**Proof.** By Theorem 5.3 it suffices to show that the type $\Delta \Gamma \vdash \nabla A$ is uniform and well-supported but does not have a section. For the uniformity, let $k_c$ be a common realizer of $A(\gamma)$ for $\gamma \in \Gamma$. For any object $c \in C$ and element $\gamma \in \Gamma$, the code of the constant function $n \mapsto k_c$ is a common realizer of $\nabla A(c, \gamma) = C(1, c) \to A(\gamma)$.

For the well-supportedness, let $e$ be a partial recursive function such that, for any $\gamma$ and $n \in E_{\Gamma}(\gamma)$, there exists an $a \in A(\gamma)$ such that $en$ is defined and belongs to $E_{A(\gamma)}(a)$. Then the function $f$ mapping $(n, x)$ to the code of the function $y \mapsto ex$ realizes that $\nabla A$ is well-supported. Indeed, for any $c \in C$, $n \in EC(c, \gamma) \in \Gamma$ and $x \in E_{\Gamma}(\gamma)$, the code $f(n, x)$ realizes the constant function $C(1, c) \ni \sigma \mapsto a \in A(\gamma)$ for some $a \in A(\gamma)$ such that $ex \in E_{A(\gamma)}(a)$.

Finally $\nabla A$ does not have a section because $\nabla A(1) \cong A$ and $A$ does not have a section.

### 5.3 The Counterexample

We define an assembly $\Gamma$ to be $(\mathbb{N}, n \mapsto \{m \in \mathbb{N} \mid m > n\})$ and a family of assemblies $A$ on $\Gamma$ to be $A(n) = \{(m \in \mathbb{N} \mid m > n), m \mapsto \{n, m\}\}$. Then $A$ is uniform because every $A(n)$ has a common realization $n$. The identity function realizes that $A$ is well-supported. To see that $A$ does not have a section, suppose that a section $f \in \prod_{n \in \mathbb{N}} A(n)$ is tracked by a partial recursive function $e$. Then for any $m > n$, we have $en \in \{n, f(n)\}$. This implies that $m \leq e(m + 1) \leq f(0)$ for any $m$, a contradiction. Note that this construction of $\Gamma \vdash A$ works for any non-trivial partial combinatory algebra $C$ because natural numbers can be encoded in $C$.

Since $B_{\text{ord}}(1, 1) \cong \mathbb{Z}$ only contains end-points, the type $\Delta \Gamma \vdash \nabla A$ in the cubical assembly model is a fibration and homotopy proposition by Proposition 4.8 and 4.9 while by Theorem 5.3 the function $\Delta \Gamma \vdash \eta : \nabla A \to (\nabla A)^*$ is not an equivalence. Hence the propositional resizing axiom fails in the cubical assembly model.
6 Conclusion and Future Work

We have formulated the axioms for modeling cubical type theory in an elementary topos given by Orton and Pitts [OP16] in a weaker setting and explained how to construct a model of cubical type theory in a category satisfying those axioms. As a striking example, we have constructed a model of cubical type theory with an impredicative and univalent universe in the category of cubical assemblies which is not an elementary topos. It has turned out that this cubical assembly model does not satisfy the propositional resizing axiom.

There is a natural question: can we construct a model of type theory with a univalent and impredicative universe satisfying the propositional resizing axiom? One possible approach to this question is to consider a full subcategory of the category of cubical assemblies in which every homotopy proposition is equivalent to some modest family. Benno van den Berg [Ber18] has constructed a model of a variant of homotopy type theory with a univalent and impredicative universe of 0-types that satisfies the propositional resizing axiom. Roughly speaking he uses a category of degenerate trigroupoids in the category of partitioned assemblies [Oos08], and thus the category of cubical partitioned assemblies is a candidate for such a full subcategory. However, the model given in [Ber18] only supports weaker forms of identity types and dependent product types, and it is unclear whether it can be seen as a model of ordinary homotopy type theory.

The cubical assembly model is a realizability-based model of type theory with higher dimensional structures, but it looks far from what should be called a realizability ∞-topos, a higher dimensional analogue of a realizability topos [Oos08]. One problem is that, in the cubical assembly model, realizers seem to play no role in its internal cubical type theory, because the existence of a realizer of a homotopy proposition does not imply the existence of a section of it. Therefore, we do not expect that the cubical assembly model satisfies interesting principles such as Markov’s Principle and Church’s Thesis which hold in the effective topos [Hyl82].

Our construction of models of cubical type theory is a syntactic one following Orton and Pitts [OP16], but there are semantic and categorical approaches. Frumin and van den Berg [FB18] present a way of constructing a model structure on a full subcategory of an elementary topos with a path connection algebra. Since they make no essential use of subobject classifiers, we conjecture that one can construct a model structure on a full subcategory of a locally cartesian closed category with a path connection algebra. Sattler [Sat17], based on his earlier work with Gambino [GS17], gives a construction of a right proper combinatorial model structure on a suitable category with an interval object. Although Gambino and Sattler use Quillen’s small object argument [Qui67, Hov07, Gar09] which requires the cocompleteness of underlying categories, their construction is expected to work for non-cocomplete categories such as the category of cubical assemblies using Swan’s small object argument in Grothendieck fibrations [Swa18a, Swa18b].

Acknowledgments

I would like to thank Benno van den Berg, Martijn den Besten and Andrew Swan for useful discussions and comments. This work is part of the research programme “The Computational Content of Homotopy Type Theory” with project number 613.001.602, which is financed by the Netherlands Organisation for Scientific Research (NWO).

A Details of Composition for Type Formers

We explain the construction of models of cubical type theory given in Section 3 in more detail.
A.1 Base Changes

Let $\Gamma \vdash A$ be a type and $\sigma : \Delta \to \Gamma$ a morphism. For a fibration structure $\alpha : \text{Fib}(A)$, we define a fibration structure $\sigma^* \alpha : \text{Fib}(\sigma^* A)$ as

$$\sigma^* \alpha = \lambda p.\alpha(\sigma \circ p) : \prod_{p : \Delta} \text{Comp}(A(\sigma(p))).$$

Thus, for a fibration $(A, \alpha)$ on $\Gamma$, we have its base change $(\sigma^* A, \sigma^* \alpha)$ along a morphism $\sigma : \Delta \to \Gamma$. With this base change operation $\mathcal{E}^F$ becomes a category with families.

A.2 Composition Operation

For a fibration $\Gamma, i : \mathbb{I} \vdash A(i)$, one can derive the composition operation

$$\Gamma \vdash e : 2 \quad \Gamma \vdash \varphi : \text{Cof} \quad \Gamma, i : \mathbb{I} \vdash f(i) : \varphi \to A(i) \quad \Gamma \vdash a : A(e) \quad \Gamma, u : \varphi \vdash f(e)u = a$$

such that $\Gamma, u : \varphi \vdash f(e)u = \text{comp}^e(A(i), f(i), a)$. Indeed, for a fibration structure $\alpha : \text{Fib}(A)$, we define

$$\gamma : \Gamma \vdash \text{comp}^e(A(i), f(i), a) := \alpha(\lambda i. (\gamma, i), e, \varphi, \lambda u. f(i)u, a).$$

In the notation $\text{comp}^e(A(i), f(i), a)$, the variable $i$ is considered to be bound. Usually we use the composition operation in the form of

$$\text{comp}^e(A(i), [(u_1 : \varphi_1) \mapsto g_1(u_1, i), \ldots, (u_n : \varphi_n) \mapsto g_n(u_n, i)], a)$$

with a system $[(u_1 : \varphi_1) \mapsto g_1(u_1, i), \ldots, (u_n : \varphi_n) \mapsto g_n(u_n, i)]$.

For a type $\Gamma \vdash A$ and elements $\Gamma \vdash a_0 : A$ and $\Gamma \vdash a_1 : A$, we define the path type $\Gamma \vdash \text{Path}(A, a_0, a_1)$ to be

$$\Gamma \vdash \{ p : \mathbb{I} \to A \mid p0 = a_0 \land p1 = a_1 \}.$$ 

We also define the identity type $\Gamma \vdash \text{Id}(A, a_0, a_1)$ to be

$$\Gamma \vdash \sum_{p : \text{Path}(A, a_0, a_1)} \{ \varphi : \text{Cof} \mid \varphi \to \forall i p i = a_0 \}$$

which is a variant of Swan’s construction [Swa16].

Let $\Gamma, i : \mathbb{I} \vdash A(i)$ and $\Gamma, i : \mathbb{I} \vdash B(i)$ be fibrations. In a similar way to [CCHM15], we have the Kan filling operation

$$\Gamma \vdash e : 2 \quad \Gamma \vdash \varphi : \text{Cof} \quad \Gamma, i : \mathbb{I} \vdash f(i) : \varphi \to A(i) \quad \Gamma \vdash a : A(e) \quad \Gamma, u : \varphi \vdash f(e)u = a$$

such that $\Gamma \vdash \text{fill}^e(A(i), f(i), a)e = a$, $\Gamma \vdash \text{fill}^e(A(i), f(i), a)e = \text{comp}^e(A(i), f(i), a)$ and $\Gamma, u : \varphi, j : \mathbb{I} \vdash f(j)u = \text{fill}^e(A(i), f(i), a)j$. One can also derive the following operation, which means that composition operations are preserved by function application,

$$\Gamma \vdash e : 2 \quad \Gamma \vdash \varphi : \text{Cof} \quad \Gamma, i : \mathbb{I} \vdash f(i) : \varphi \to A(i) \quad \Gamma \vdash a : A(e) \quad \Gamma, u : \varphi \vdash f(e)u = a$$

such that $\Gamma, u : \varphi, j : \mathbb{I} \vdash h(e)(f(e)u) = \text{pres}^e(h(i), f(i), a)j$, where $c_1 = \text{comp}^e(B(i), h(i) \circ f(i), h(e)a)$ and $c_2 = h(e)(\text{comp}^e(A(i), f(i), a))$. 

16
A.3 Dependent Sums and Products

For fibrations $\Gamma \vdash A$ and $\Gamma, x : A \vdash B(x)$, we define fibration structures on $\Gamma \vdash \prod_{x:A} B(x)$ and $\Gamma \vdash \sum_{x:A} B(x)$. To give a fibration structure on $\sum_{x:A} B(x)$, let $p : \emptyset \to \Gamma, e : 2, \varphi : \text{Cof}, f : \varphi \to \prod_{i:1} A(pi), g : \prod_{u : \text{Cof}} \prod_{i:1} B(fui), a : A(pe), b : B(a)$ and suppose $\forall_{u, \varphi} (fue, gue) = (a, b)$. We have to find elements $\bar{a} : A(p\bar{e})$ and $\bar{b} : B(\bar{a})$ such that $\forall_{u, \varphi} (fue, gue) = (\bar{a}, \bar{b})$. Define

$$q : \prod_{i:1} A(pi)$$

$$q := \text{fill}_{\varphi}^i (A(pi), [(\varphi : \varphi) \mapsto fui], a)$$

$$\bar{a} := \bar{q}e$$

$$\bar{b} := \text{comp}_{\varphi}^i (B(qi), [(\varphi : \varphi) \mapsto gui], b).$$

Then, for $u : \varphi$, we have $fue = \bar{a}$ and $gue = \bar{b}$.

To give a fibration structure on $\prod_{x:A} B(x)$, let $p : \emptyset \to \Gamma, e : 2, \varphi : \text{Cof}, h : \varphi \to \prod_{i:1} \prod_{x:A(pi)} B(x), f : \prod_{x:A(pe)} B(x)$ and suppose $\forall_{u, \varphi} hue = f$. We have to find an element $\bar{f} : \prod_{x:A(pe)} B(x)$ such that $\forall_{u, \varphi} hue = \bar{f}$. Define

$$q : \prod_{a : A(pe)} \prod_{i:1} A(pi)$$

$$qa := \text{fill}_{\varphi}^i (A(pi), [], a)$$

$$\bar{f}a := \text{comp}_{\varphi}^i (B(qai), [(\varphi : \varphi) \mapsto huai], f(qae)).$$

Then, for $u : \varphi$ and $a : A(p\bar{e})$, we have $huca = hu(eqa) = \bar{f}a$.

A.4 Path and Identity Types

Suppose that $\Gamma \vdash A$ is a fibration and let $\Gamma \vdash a_0 : A$ and $\Gamma \vdash a_1 : A$ be elements. To give a fibration structure on $\Gamma \vdash \text{Path}(A, a_0, a_1)$, let $p : \emptyset \to \Gamma, e : 2, \varphi : \text{Cof}, f : \varphi \to \prod_{i:1} \text{Path}(A(pi), a_0(pi), a_1(pi)), b : \text{Path}(A(pe), a_0(pe), a_1(pe))$ and suppose $\forall_{u, \varphi} fuc = b$. Define

$$\bar{b} : \emptyset \to A(p\bar{e})$$

$$\bar{b}j := \text{comp}_{\varphi}^i (A(pi), [(\varphi : \varphi) \mapsto fuij], (j = 0) \mapsto a_0(pi), (j = 1) \mapsto a_1(pi), bj).$$

Then $\bar{b}0 = a_0(p\bar{e})$ and $\bar{b}1 = a_1(p\bar{e})$, and thus $\bar{b} : \text{Path}(A(p\bar{e}), a_0(p\bar{e}), a_1(p\bar{e}))$. Moreover, for $u : \varphi$ and $j : I$, we have $fuej = \bar{b}j$.

To give a fibration structure on $\text{Id}(A, a_0, a_1)$, it suffices to show that $\Gamma, p : \text{Path}(A, a_0, a_1) \vdash \{ \varphi : \text{Cof} \mid \varphi \vdash \forall_{i:1} pi = a_0 \}$ has a fibration structure. Let $p : \emptyset \to \Gamma, q : \prod_{i:1} \text{Path}(A(pi), a_0(pi), a_1(pi)), e : 2, \varphi : \text{Cof}, f : \varphi \to \emptyset \to \text{Cof}, \psi : \text{Cof}$ and suppose $\forall_{u, \varphi} \forall_{i:1} fui \to \forall_{j:1} qij = a_0(pi), \psi \to \forall_{j:1} qej = a_0(pe)$ and $\forall_{u, \varphi} fuc = \psi$. By Axiom $[\ref{axiom}]$ we can define $\psi := \sum_{u, \varphi} fue : \text{Cof}$. Then $\psi \to \forall_{j:1} qej = a_0(pe)$ and $\forall_{u, \varphi} fue \leftrightarrow \psi$. By Axiom $[\ref{axiom}]$ we have $\forall_{u, \varphi} fue = \psi$.

A.5 Finite Coproducts

Let $\Gamma \vdash A$ and $\Gamma \vdash B$ be fibrations. To give a fibration structure on $\Gamma \vdash A + B$, let $p : \emptyset \to \Gamma, e : 2, \varphi : \text{Cof}, h : \varphi \to \prod_{i:1} A(pi) + B(pi), c : A(pe) + B(pe)$ and suppose $\forall_{u, \varphi} hue = c$. Let $\text{inl} : A \to A + B$ and $\text{inr} : B \to A + B$ denote the constructors of $A + B$. Without loss of generality we assume $c = \text{inl}(a)$ for some $a : A(pe)$. Since the exponential functor $(-)^1$ preserves colimits and $hue = \text{inl}(a)$ for $u : \varphi$, we may assume that $h$ is of the form $\lambda u. \text{inl}(fui)$ for some $f : \varphi \to \prod_{i:1} A(pi)$. Define $\bar{c} := \text{inl}(\text{comp}_{\varphi}^i (A(pi), [(\varphi : \varphi) \mapsto fui], a)) : A(p\bar{e}) + B(p\bar{e})$. Then we have $\forall_{u, \varphi} hue = \bar{c}$. 
A.6 Equivalences

In the same way as [CCHM15 Section 5], for fibration $\Gamma \vdash A$ and $\Gamma \vdash B$, one can derive an operation

$$\Gamma \vdash f : A \simeq B \quad \Gamma \vdash e : 2 \quad \Gamma \vdash \varphi : \text{Cof} \quad \Gamma \vdash b : B \quad \Gamma \vdash p : \varphi \to \sum_{a : A} \text{Path}(B, b, fa)$$

such that $\Gamma, u : \varphi \vdash pu = \text{equiv}(f, p, b)$.

For a fibration $\Gamma, i : I \vdash A(i)$, we define a function $\Gamma, e : 2 \vdash \text{tp}^i(A(i)) : A(e) \to A(\bar{e})$ to be $\text{tp}^i(A(i))u = \text{comp}^i(A(i), [\cdot], u)$. In the same way as [CCHM15 Section 7.1] we see that $\text{tp}^i(A(i))$ is an equivalence.

A.7 Gluing

Proof of Proposition 3.4. Let $p : I \to \Gamma, e : 2, \varphi : \text{Cof}, g : \psi : \prod_{i : I} \prod_{w : \psi(p(i))} A(u(i)), h : \psi : \prod_{i : I} B(p(i)), a : \prod_{w : \varphi(p(e))} A(u)$ and $b : B(p(e))$, and suppose $\forall_{w : \psi} \forall_{i : \psi} ; \forall_{w : \varphi(p(i))} f(u)(gvi) = hv\psi, \forall_{w : \varphi(p(e))} f(u)(au) = b$ and $\forall_{w : \psi} gve = a \land hv\psi = b$. We have to find elements $\bar{a} : \prod_{w : \varphi(p(e))} A(u)$ and $\bar{b} : B(p(e))$ such that $\forall_{w : \varphi(p(e))} f(u)(\bar{a}u) = \bar{b}$ and $\forall_{w : \psi} gve = \bar{a} \land hv\psi = \bar{b}$. We define

\[\bar{b}_1 := \text{comp}^i_B(B(p(i)), [(v : \psi) \mapsto hv\psi], b) : B(p(e))\]
\[\bar{\delta} := \forall_{i : \psi} ; \forall_{w : \psi} \psi(p(i)) : \text{Cof}\]
\[\bar{a}_1 := \lambda w . \text{comp}^i_A(A(w), [(v : \psi) \mapsto gvi(w)], a(we)) : \prod_{w : \delta} A(we)\]
\[q : \prod_{w : \delta} \text{Path}(\bar{b}_1, f(w\psi)(\bar{a}_1 w))\]
\[qw := \text{pres}^i_A(f(w), [(v : \psi) \mapsto gvi(w)], a(we))\]
\[\bar{a} := \prod_{w : \varphi(p(e))} A(u)\]
\[q_2 := \prod_{w : \varphi(p(e))} \text{Path}(\bar{b}_1, f(u)(\bar{a}u))\]

Then one can derive that $\bar{b} = q_2u1 = f(u)(\bar{a}u)$ for $u : \varphi(p(e))$ and that $\bar{a} = gve\psi$ and $\bar{b} = hv\psi$ for $v : \psi$. Moreover, for every $w : \prod_{i : I} \varphi(p(i))$, we have $\bar{a}(we) = \bar{a}_1 w = \text{comp}^i_A(A(w), [(v : \psi) \mapsto gvi(w)], a(we))$ which means the preservation of fibration structure by the function $\Gamma, u : \varphi \vdash \lambda(a, b). au : \text{Glue}(\varphi, f) \to A(u)$.

A.8 Universes

Proof of Proposition 3.5. Let $e : 2, \varphi : \text{Cof}, f : \varphi \to I \to \mathcal{U}^F$ and $B : \mathcal{U}^F$ such that $\forall_{w : \varphi} f u e = B$. We have to find a $\bar{B} : \mathcal{U}^F$ such that $\forall_{w : \varphi} f u \bar{e} = \bar{B}$. Let $A := \lambda u . f u e : \varphi \to \mathcal{U}^F$. We have an equivalence $g := \lambda u . \text{tp}^i_A(f u i) : \prod_{w : \varphi} A u \simeq B$. Let $\bar{B} := \text{Sglue}(\varphi, g) : \mathcal{U}^F$, then $\forall_{w : \varphi} f u \bar{e} = Au = B$.
