Abstract
Let Ω be an open, possibly unbounded, set in Euclidean space $\mathbb{R}^m$, let $A$ be a measurable subset of $\Omega$ with measure $|A|$, and let $\gamma \in (0, 1)$. We investigate whether the solution $v_{\Omega, A, \gamma}$ of $-\Delta v = \gamma 1_{\Omega \setminus A} - (1 - \gamma) 1_A$, $v \in H^1_0(\Omega)$ changes sign. Bounds are obtained for $|A|$ in terms of geometric characteristics of $\Omega$ (bottom of the spectrum of the Dirichlet Laplacian, torsion, measure, or $R$-smoothness of the boundary) such that $\text{essinf} v_{\Omega, A, \gamma} \geq 0$. We show that $\text{essinf} v_{\Omega, A, \gamma} < 0$ for any measurable set $A$, provided $|A| > \gamma |\Omega|$. This value is sharp. We also study the shape optimisation problem of the optimal location of $A$ (with prescribed measure) which minimises the essential infimum of $v_{\Omega, A, \gamma}$. Surprisingly, if $\Omega$ is a ball, a symmetry breaking phenomenon occurs.

Keywords: Torsion function, Dirichlet boundary condition.
1 Introduction

Let $\Omega$ be an open, possibly unbounded, set in Euclidean space $\mathbb{R}^m$ with boundary $\partial\Omega$, and with, possibly infinite, measure $|\Omega|$. It is well-known [3] that if the bottom of the Dirichlet Laplacian defined by

$$\lambda(\Omega) = \inf_{\varphi \in H_0^1(\Omega) \setminus \{0\}} \frac{\int_{\Omega} |D\varphi|^2}{\int_{\Omega} \varphi^2},$$

is bounded away from 0, then

$$-\Delta v = 1, \quad v = 0 \text{ on } \partial \Omega,$$  \hspace{1cm} (1)

has a unique weak solution denoted by $v_\Omega$, which is non-negative, and which satisfies,

$$\lambda(\Omega)^{-1} \leq \|v_\Omega\|_{L^\infty(\Omega)} \leq (4 + 3m \log 2) \lambda(\Omega)^{-1}. \hspace{1cm} (2)$$

The $m$-dependent constant in the right-hand side of (2) has been improved in [15] and subsequently in [26].

If $|\Omega| < \infty$ then, by the Faber-Krahn inequality, $\lambda(\Omega) > 0$, and by (2), $v_\Omega \in H_0^1(\Omega)$, and $v_\Omega \in L^1(\Omega)$. For an arbitrary open set $\Omega$ we define the torsion, or torsional rigidity, by

$$T(\Omega) = \int_\Omega v_\Omega. \hspace{1cm} (3)$$

Note that, under the assumption $\lambda(\Omega) > 0$, by (2) the solution of an equation like in (1) with a right-hand side $f \in L^\infty(\Omega)$ can be defined by approximation on balls for the positive and negative parts of $f$.

For a measurable subset $A \subset \Omega$, with $\lambda(\Omega) > 0$, and $0 < \gamma < 1$, we denote by $v_{\Omega,A,\gamma}$ the solution of

$$-\Delta v = \gamma 1_{\Omega \setminus A} - (1 - \gamma) 1_A, \quad v = 0 \text{ on } \partial \Omega. \hspace{1cm} (4)$$

These hypotheses on $A$, $\Omega$ and $\gamma$ will not be repeated in the statements of all lemmas and theorems below.

This paper investigates whether the solution of (4) satisfies $\text{essinf } v_{\Omega,A,\gamma} < 0$. Whether this holds depends on the geometry of $\Omega$, and on the size and the location of the set $A \subset \Omega$. This question shows up in a variety of situations. We refer, for instance, to [10], where $v$ is a scalar potential and the right-hand side stands for a magnetic field which changes sign. The influence of the magnetic field on the asymptotic behaviour of the bottom of the spectrum of the Pauli operator is effective provided that the scalar potential has constant sign, i.e. $\text{essinf } v_{\Omega,A,\gamma} = 0$. In fluid mechanics, the function $v$ can be interpreted as a vorticity stream function, for a vorticity taking the values $\gamma$ and $-(1-\gamma)$. If $v_{\Omega,A,\gamma}$ changes sign then there exist at least two stagnation points. More situations where the sign question of the state function is put in relationship with sign changing data can be found in [9], [13], [23] and, in some biological models, [20].
**Definition 1.** For $\gamma \in (0, 1)$, $\Omega \subset \mathbb{R}^m$, with $\lambda(\Omega) > 0$,

\[ \mathcal{C}_-(\Omega, \gamma) = \sup \{ c \geq 0 : \forall A \subset \Omega, A \text{ measurable}, |A| \leq c, \text{ess inf } v_{\Omega, A, \gamma} \geq 0 \}, \]

\[ \mathcal{C}_+(\Omega, \gamma) = \inf \{ c \geq 0 : \forall A \subset \Omega, A \text{ measurable}, |A| > c, \text{ess inf } v_{\Omega, A, \gamma} \leq 0 \}. \]

It follows immediately from the definition that for a homothety $t\Omega$, $t > 0$ of $\Omega$ we have the scaling relations

\[ \mathcal{C}_-(t\Omega, \gamma) = t^m \mathcal{C}_-(\Omega, \gamma), \]

and

\[ \mathcal{C}_+(t\Omega, \gamma) = t^m \mathcal{C}_+(\Omega, \gamma). \]

Furthermore if $\Omega_1, \Omega_2$ are disjoint open sets, then

\[ \mathcal{C}_-(\Omega_1 \cup \Omega_2, \gamma) = \min \{ \mathcal{C}_-(\Omega_1, \gamma), \mathcal{C}_-(\Omega_2, \gamma) \}, \]

\[ \mathcal{C}_+(\Omega_1 \cup \Omega_2, \gamma) = \mathcal{C}_+(\Omega_1, \gamma) + \mathcal{C}_+(\Omega_2, \gamma). \]

This paper concerns the analysis of these quantities and their dependence on $\Omega$. It turns out that $\mathcal{C}_+(\Omega, \gamma) = \gamma |\Omega|$ for arbitrary open sets $\Omega$ with finite measure. On the contrary, $\mathcal{C}_-(\Omega, \gamma)$ is very sensitive to the geometry. We find its main properties, give basic estimates, establish isoperimetric and isotorsional inequalities, and we discuss the shape optimisation problem related to the optimal location of the set $A$ in order to minimise the essential infimum.

**Theorem 1.** For every open set of finite measure $\Omega \subset \mathbb{R}^m$ we have

\[ \mathcal{C}_+(\Omega, \gamma) = \gamma |\Omega|. \]

Below we show that, in general, we have to assume some regularity of $\Omega$ in order to have $\mathcal{C}_-(\Omega, \gamma) > 0$.

**Theorem 2.** $\mathcal{C}_-(\Omega, \gamma) = 0$ in each of the of the following cases:

1. $\Omega = \bigcup_{j \in \mathbb{N}} C_j$, where the sets $C_j, j \in \mathbb{N}$ are non empty, open, disjoint, and $|\Omega| < \infty$.

2. $\Omega \subset \mathbb{R}^2$ is any triangle.

3. $\Omega \subset \mathbb{R}^m$ is an open, unbounded set with $|\Omega| < \infty$.

In Theorem 3 below we show that if $\Omega$ is bounded, and $\partial \Omega$ is of class $C^2$ then $\mathcal{C}_-(\Omega) > 0$. In order to quantify this assertion we introduce some notation. We denote the complement $\mathbb{R}^m \setminus E$ of $E$ by $E^c$, and the closure of $E$ by $\overline{E}$. Furthermore, $B_r(x) := \{ y \in \mathbb{R}^m : |x - y| < r \}$ denotes the open ball centred at $x$ of radius $r$. If $x = 0$, we simply write $B_r$. We set $\omega_m = |B_1|$. For $x \in \overline{\Omega}$ we let $\bar{x} \in \partial \Omega$ be a point such that $|x - \bar{x}| = \min \{|x - z| : z \in \partial \Omega\}$. We recall the following from [2] p.280.

**Definition 2.** An open set $\Omega \subset \mathbb{R}^m$, $m \geq 2$, has $R$-smooth boundary if at any point $x_0 \in \partial \Omega$, there are two open balls $B_R(x_1), B_R(x_2)$ such that $B_R(x_1) \subset \Omega$, $B_R(x_2) \subset \mathbb{R}^m \setminus \Omega$ and $B_R(x_1) \cap B_R(x_2) = \{x_0\}$. 

---

3
We also recall that a bounded $\Omega$ with $C^2$ boundary $\partial\Omega$ is $R$-smooth for some $R > 0$.

**Theorem 3.** If $\Omega$ is an open, bounded set in $\mathbb{R}^m$ with a $C^2$ and $R$-smooth boundary, then

$$C_-(\Omega, \gamma) \geq C_-(B_R, \gamma).$$

Furthermore

$$C_-(B_R, \gamma) \geq \left(\frac{\gamma}{4m}\right)^m \omega_m R^m, \ m = 2, 3, ..., \ (5)$$

$$C_-(B_R, \gamma) \leq \gamma^{m/2} \omega_m R^m, \ m \geq 3, \ (6)$$

and

$$C_-(B_R, \gamma) \leq \left(1 + \log \left(\frac{1}{\gamma^4}\right)\right)^{-1} \gamma \pi R^2, \ m = 2. \ (7)$$

The following isotorsional inequality gives an upper bound for $C_-(\Omega, \gamma)$ in terms of the torsion $T(\Omega)$.

**Theorem 4.** There exists a constant $C(m, \gamma) < \infty$ depending on $m$, and on $\gamma$, such that for every open set $\Omega \subset \mathbb{R}^m$ with finite torsion (possibly with infinite measure),

$$C_-(\Omega, \gamma) \leq C(m, \gamma) T(\Omega) \frac{m}{m+2}. \ (8)$$

The optimal value of $C(m, \gamma)$ is not known. However, the Kohler-Jobin inequality suggests to prove (or disprove) optimality for balls.

We see from Theorems 1 and 3 that $C_-(B_R, \gamma) < C_+(B_R, \gamma)$. The isoperimetric inequality below generalises this to arbitrary open sets with finite measure.

**Theorem 5.**

$$\sup\{\frac{C_-(\Omega, \gamma)}{|\Omega|} : \Omega \subseteq \mathbb{R}^m, \ \Omega \text{ open with } |\Omega| < \infty\} < \gamma. \ (9)$$

The theorem above implies that $C_-(\Omega, \gamma) < C'(m, \gamma)|\Omega|$ for every open set of finite measure, with $C'(m, \gamma) < \gamma$. The proof of Theorem 5 relies on the relaxation of the shape optimisation problem (9) to the larger class of quasi open sets. We shall prove that the supremum is attained at some quasi open set $\Omega^*$ for which $C_-(\Omega^*, \gamma) < \gamma|\Omega^*|$. The optimal value $C'(m, \gamma)$ is not known, nor whether $\Omega^*$ is open. The symmetry breaking phenomenon for balls stated in Theorem 6 below does not support the ball to be a maximiser.

Given a constant $c \in (C_-(\Omega, \gamma), |\Omega|)$, there exists at least one set $A \subseteq \Omega$, $|A| = c$ such that $\text{essinf } v_{\Omega, A, \gamma} < 0$. A natural question is to find the best location of the set $A$ of measure $c$, which minimises $\text{essinf } v_{\Omega, A, \gamma}$. This question is of particular interest for values of $c$ close to $C_-(\Omega, \gamma)$, as this gives information on where the geometry of $\Omega$ is most sensitive to negative values. We prove the following shape optimisation result for the optimal location.

**Theorem 6.** Let $\gamma \in (0, 1)$ and let $\Omega \subset \mathbb{R}^m$ be an open, bounded and connected set with a smooth boundary $\partial\Omega$. For every $c \in (C_-(\Omega, \gamma), |\Omega|)$, the shape optimisation problem

$$\min\{\text{essinf } v_{\Omega, A, \gamma} : A \subset \Omega, |A| = c\}, \ (10)$$

4
has a solution. Moreover, if $\Omega$ is a ball $B$ then, depending on the value of $c$, the optimal locations may be radial or not.

The existence of an optimal set relies partly on a concavity property of the shape functional $A \mapsto \text{essinf}_{\Omega} v_{\Omega,A,\gamma}$. We point out that the proof relies on both the concavity, and the analysis of optimality conditions in relationship with the PDE (see [11]). If $\Omega$ is a ball $B$ and $c$ is close to $|B|$, then the optimal location is a ball. If $c$ is close to $\mathcal{C}_{-}(B,\gamma)$ then the optimal location is no longer radial. This symmetry breaking phenomenon occurs at a value $c \in (\mathcal{C}_{-}(B,\gamma),\gamma|B|)$, and is supported by analytical, and numerical computations.

Theorem 6 can be interpreted both as a (rather non-standard) shape optimisation problem or as an optimisation problem in a prescribed class of rearrangements, see e.g. [1]. We also refer to the paper of Burton and Toland [10] for models of steady waves with vorticity, where the distribution of the vorticity is prescribed, but we point out that our problem is essentially of different nature since the functional to be minimised is not an energy of the problem.

The proofs of Theorems 1, 2, 3, 4, 5 and 6 are deferred to Sections 2, 3, 4, 5, 6, and 7 below.

2 Proof of Theorem [1]

In order to simplify notation, throughout the paper, if $\Omega$ is an open set and $A \subset \mathbb{R}^m$ is measurable, not necessarily contained in $\Omega$, by $v_{\Omega,A,\gamma}$ we mean $v_{\Omega\cap A,\gamma}$.

Proof. First assume that $\Omega \subset \mathbb{R}^m$ is an open set with finite measure. Assume $A \subset \Omega$ is a measurable set such that $v_{\Omega,A,\gamma} \geq 0$. In a first step, we shall prove that $|A| \leq \gamma|\Omega|$. As a consequence, $\mathcal{C}_{+}(\Omega,\gamma) \leq \gamma|\Omega|$.

Indeed, since $v_{\Omega,A,\gamma} \geq 0$, one can use Talenti’s theorem (see for instance [22, Theorem 3.1.1]) in the following way. We denote by $v^*$ the Schwarz rearrangement of $v_{\Omega,A,\gamma}$, and by $f^*$ the rearrangement of $\gamma1_{\Omega\setminus A} - (1 - \gamma)1_{A}$. There exist two positive values $0 < r_1 < r_2$ such that $f^* = \gamma1_{B_{r_1}} - (1 - \gamma)1_{B_{r_2}\setminus B_{r_1}}$, where $r_1$ is such that $|B_{r_1}| = |\Omega \setminus A|$ and $|B_{r_2}| = |\Omega|$. By Talenti’s theorem, we get

$$0 \leq v^* \leq v_{B_{r_2},B_{r_1},\gamma}.$$ 

By elementary computations, one gets the expression for $v_{B_{r_2},B_{r_1},\gamma}$. Indeed, the solution $v_{B_{r_2},B_{r_1},\gamma}$ is radially symmetric and satisfies the equation

$$-v'' - \frac{m-1}{r}v' = \gamma1_{[0,r_1]} - (1 - \gamma)1_{[r_1,r_2]},$$

with initial condition $v'(0) = 0$, and $v(r_2) = 0$. Moreover, the solution is $C^{1,\alpha}$ regular, for some $\alpha > 0$.

We integrate separately on $[0,r_1]$, and on $[r_1,r_2]$, and write the equality of the left and right derivatives in $r_1$, namely $v'_+(r_1) = v'_-(r_1)$. Hence, we get

$$-\frac{r_1}{m} = \frac{r_2^{m-1}}{r_1^{m-1}}v'(r_2) - (1 - \gamma)\frac{r_2^m}{mr_1^{m-1}} + (1 - \gamma)\frac{r_1}{m}.$$
In general, from the positivity of $v_{B_{r_2}, B_{r_2}, \gamma}$ one gets that $v'(r_2) \leq 0$. Hence,

$$(1 - \gamma) \frac{r_2^m}{m r_1^{m-1}} \leq \frac{r_1}{m},$$

which gives $r_1 \geq (1 - \gamma) \frac{r_2}{r_2}$, or $|B_{r_1}| \geq (1 - \gamma)|B_{r_2}|$. Finally, one gets that $|A| \leq \gamma|\Omega|$. Hence $C_+(\Omega, \gamma) \leq \gamma|\Omega|$.

As a byproduct of the computation, we observe that the constant $\gamma$ in Theorem 1 is sharp, and that equality holds for the ball. As soon as, $r_1 < (1 - \gamma) \frac{r_2}{r_2}$, one gets that $v'(r_2) > 0$. This means that as $v(r_2) = 0$ the solution is not positive near the boundary of the ball.

In order to prove the converse inequality, let us prove that for every $\varepsilon > 0$, there exists a set $A \subseteq \Omega$ of measure $\gamma|\Omega| - \varepsilon$ such that $v_{\Omega, A, \gamma} \geq 0$. This will imply that $C_+(\Omega, \gamma) \geq \gamma|\Omega|$.

The construction is based on the following observation. There exists a finite family of mutually disjoint balls $\bigcup_{i=1}^{k} B_i$ contained in $\Omega$ such that $|\Omega \setminus \bigcup_{i=1}^{k} B_i| < \varepsilon$.

In every ball, we display the set $A_i$ of measure $\gamma|B_i|$ in an annulus centred at the center of $B_i$ and having $\partial B_i$ as external boundary. Hence $v_{B_i, A_i, \gamma} \geq 0$. Moreover, since the sets $B_i$ are mutually disjoint we get that

$v_{\bigcup_i B_i, \bigcup_i A_i, \gamma} \geq 0$.

We have the following.

**Lemma 7.** Let $\Omega_1 \subseteq \Omega_2 \subseteq \mathbb{R}^m$ be open sets with finite measure, $f \in L^2(\Omega_2)$, and let $u_1, u_2$ weak solutions of

$$-\Delta u_i = f \text{ in } \Omega_i, u \in H_0^1(\Omega_i), i = 1, 2.$$

If $u_1 \geq 0$ on $\Omega_1$ and $f \geq 0$ on $\Omega_2 \setminus \Omega_1$ then $u_2 \geq 0$ on $\Omega_2$.

**Proof.** As a consequence of the hypotheses, we get that

$$-\Delta u_1 \leq f \text{ in } \mathcal{D}'(\Omega_2).$$

Hence, by the maximum principle

$$0 \leq u_1 \leq u_2 \text{ on } \Omega_2.$$  

A direct consequence of Lemma 7 is that if $\Omega_1 \subseteq \Omega_2$ then $C_+(\Omega_1, \gamma) \leq C_+(\Omega, \gamma)$. Indeed, for every measurable set $A \subseteq \Omega_1$ such that $v_{\Omega_1, A, \gamma} \geq 0$ we get $v_{\Omega_2, A, \gamma} \geq 0$.

Coming back to the proof of Theorem 1 using the additivity and monotonicity property of $C_+$ we get that

$$C_+(\Omega, \gamma) \geq \gamma|\bigcup_i B_i| \geq \gamma|\Omega| - \gamma\varepsilon.$$  

The theorem follows by letting $\varepsilon \to 0$. 

3 Proof of Theorem 2

We first introduce some basic notation and properties. For a non-empty open set $\Omega \subset \mathbb{R}^m$ we denote by $G_\Omega(x,y)$, $x \in \Omega$, $y \in \Omega$, $x \neq y$, the kernel of the resolvent of the Dirichlet Laplacian acting in $L^2(\Omega)$. This function exists and is well defined for all $x \neq y$, provided $m \geq 3$. It also exists for $m = 2$ for example under the hypothesis that the torsion function $v_\Omega$ defined by approximation on balls, is locally finite. The resolvent kernel is non-negative, symmetric in $x$ and $y$, and is monotone increasing in $\Omega$. That is, if $\Omega_1 \subset \Omega_2$ then,

$$0 \leq G_{\Omega_1}(x,y) \leq G_{\Omega_2}(x,y), \quad x \in \Omega_1, \; y \in \Omega_1, \; x \neq y. \quad (11)$$

If $v_\Omega$ is locally finite then,

$$v_\Omega(x) = \int_\Omega dy G_\Omega(x,y).$$

The monotonicity in (11) implies that both the torsion function $v_\Omega$, and torsion $T(\Omega)$ are monotone increasing in $\Omega$.

We have also that

$$v_{\Omega,A,\gamma}(x) = \int_\Omega dy G_\Omega(x,y)\left(\gamma 1_{\Omega \setminus A}(y) - (1 - \gamma)1_A(y)\right)$$

$$= \int_\Omega dy G_\Omega(x,y)\left(\gamma 1_\Omega(y) - 1_A(y)\right)$$

$$= \gamma v_\Omega(x) - \int_A dy G_\Omega(x,y). \quad (12)$$

Formula (12) implies that

$$-(1 - \gamma)v_\Omega \leq v_{\Omega,A,\gamma} \leq \gamma v_\Omega.$$

Proof of Theorem 2 The proof of these three assertions are independent.

Case 1. Let $c_j = |C_j| > 0$, and let $A = C_j$. Since $\sum_{j \in \mathbb{N}} |C_j| < \infty$, we have that $\lim_{j \to \infty} c_j = 0$, and $\text{essinf } v_{\Omega,A,\gamma} \leq (\gamma - 1)\text{essup } v_{C_j} < 0$. Hence $C_j(\Omega, \gamma) = 0$.

Case 2. Let $\Omega = \Delta OAB$ be a triangle, with $\alpha := \angle BOA \leq \frac{\pi}{3}$ at the origin, and oriented such that the positive $x$-axis is the bisectrix of that angle. Let $W_\alpha$ be the infinite wedge with vertex at $O$, and edges at angles $\pm \frac{1}{2} \alpha$ with the positive $x$-axis, which contain the two sides $OA$ and $OB$ of $\Omega$. Let $W_{\alpha,c}$ be the radial sector with area $c$ and edges at angles $\pm \frac{1}{2} \alpha$. Then $W_{\alpha,c} \subset \Omega$ for all $c$ sufficiently small. We have by monotonicity that

$$v_{\Omega,W_{\alpha,c},\gamma} = \int_\Omega dy G_\Omega(x,y)(\gamma 1_{\Omega} - 1_{W_{\alpha,c}})(y)$$

$$\leq \gamma \int_{W_{\alpha,c}} dy G_{W_{\alpha,c}}(x,y) - \int_{W_{\alpha,c}} dy G_{W_{\alpha,c}}(x,y)$$

$$= \gamma v_{W_{\alpha,c}}(x) - v_{W_{\alpha,c}}(x). \quad (13)$$

In Cartesian coordinates $x = (x_1, x_2)$ we have that

$$v_{W_{\alpha,c}}(x_1, x_2) = \frac{x_2^2 - s^2 x_1^2}{2(s^2 - 1)} \quad (14)$$
where \( s = \tan(\alpha/2) \). In polar coordinates \( x = (r; \theta) \) we have by p.279 in [24] for the sector with radius \( a = (2c/\alpha)^{1/2} \) that

\[
v_{W_{\alpha,c}}(r; \theta) = \frac{r^2}{4} \left( \frac{\cos(2\theta)}{\cos \alpha} - 1 \right) + \frac{4a^2 \alpha^2}{\pi^3} \sum_{n=1,3,5,\ldots} \frac{(-1)^{(n+1)/2}(r/a)^{n\pi/\alpha} \cos(n\pi \theta/\alpha)}{n \left(n + \frac{2\alpha}{\pi}\right) \left(n - \frac{2\alpha}{\pi}\right)}(15)
\]

We observe that for \( \theta = 0 \) the terms in the series in the right-hand side of (15) are alternating and decreasing in absolute value. Hence

\[
v_{W_{\alpha,c}}(r; 0) = \frac{r^2}{4} \left( \frac{1}{\cos \alpha} - 1 \right) - \frac{4a^2 \alpha^2}{\pi^3} \left( \frac{r}{a} \right)^{\pi/\alpha} \left(1 - \frac{4a^2}{\pi^2}\right)^{-1}. \quad (16)
\]

By (14) \( v_{W_{\alpha,c}}(x_1, 0) = \frac{s^2 x_1^2}{2(1-s^2)} \), and so in polar coordinates,

\[
v_{W_{\alpha}}(r; 0) = \frac{r^2}{4} \left( \frac{1}{\cos \alpha} - 1 \right). \quad (17)
\]

It follows by (13)-(17) that

\[
v_{\Omega_{W_{\alpha,c} \gamma}}(x_1, 0) \leq (\gamma - 1) \frac{s^2 x_1^2}{2(1-s^2)} + O((x_1/a)^{\pi/\alpha}), \quad x_1 \downarrow 0,
\]

which is negative for all \( x_1 \) sufficiently small.

We see from the proof above that we could have chosen any angle of the triangle provided that angle is strictly less than \( \pi/2 \). The proof above also shows that the infinite wedge \( W_{\alpha, \alpha < \pi/2} \) with radial sector \( W_{\alpha,c}, c > 0 \) has a sign changing solution \( v_{W_{\alpha,c} \gamma} \).

**Case 3.** In [9, Lemma 4.6] it was shown that if \( \Omega \) is an open, bounded subset of \( \mathbb{R}^m \) and if \( v \) is the solution of \(-\Delta v = f, v \in H^1_0(\Omega)\)

where \( f : \mathbb{R}^d \to \mathbb{R} \) is measurable with \(-1 \leq f \leq 1 \) and \( \lim_{|x| \to +\infty} f(x) = -1 \) then if the diameter of \( \Omega \) is sufficiently large, the solution \( v \) has to have negative values on points lying beyond some distance from the origin. The proof of the Case 3 relies on a quantitative refinement of this result, stated below.

Let \( R > 0 \) be given, and let \( R_{\gamma} = \left(\frac{1}{1-\gamma}\right)^{\frac{m}{2}} R \). We have the following.

**Lemma 8.** The value \( d(R, m, \gamma) \) given by the first zero larger than or equal to \( R_{\gamma} \) of the equations (with unknown \( x \))

\[
\|v_{B_{R_{\gamma}}, B_{R_{\gamma}}}\|_{\infty} - \frac{R^2}{4} = \frac{x^2}{2} \left( \ln \frac{x}{R} - \frac{1}{2} \right)(1 - \gamma), \quad \text{if } m = 2,
\]

\[
\|v_{B_{R_{\gamma}}, B_{R_{\gamma}}}\|_{\infty} - \frac{R^2}{2m} = (1 - \gamma) \left( \frac{x^m}{m(m-2)} \frac{1}{R^{m-2}} - \frac{x^2}{2(m-2)} \right), \quad \text{if } m \geq 3,
\]

satisfies the following property: for every bounded open set \( \Omega \subset \mathbb{R}^m \) satisfying \( \lambda(\Omega) > 0 \), and every \( x \in \Omega, |x| > d(R, m, \gamma) \), \( v_{\Omega B_{R_{\gamma}}}(x) < 0 \).
Proof. Let us consider a bounded, smooth open set $\Omega \subset \mathbb{R}^m$, such that $\Omega$ contains points “far from the origin”, beyond a certain distance $C$ to be determined, and such that $v$ is positive at some point of $\Omega$ beyond this distance. In fact, without loss of generality, we may assume that $v > 0$ in all of $\Omega$, otherwise, we replace $\Omega$ by the set $v > 0$, for which all the hypotheses above are still satisfied.

As in [9, Appendix A], we introduce the function

$$M(r) = \max_{x \in \partial B_r} v(x). \quad (18)$$

Then $M$ is Lipschitz (since $v$ is Lipschitz), and satisfies

$$M''(r) + \frac{m-1}{r}M'(r) \geq 1 - \gamma,$$

in the viscosity sense on $(R, +\infty)$. Let $d$ be the maximal distance from the origin to a point of $\partial \Omega$.

We introduce the equation

$$\phi''(r) + \frac{m-1}{r}\phi'(r) = 1 - \gamma,$$

on $(R, 0)$. Let $\phi(R) = M(R), \phi(d) = 0$.

By the comparison principle (see for instance [25, Theorem 1.1]) we get that $M \leq \phi$ on $(R, d)$. In particular, this implies that $\phi$ is nonnegative and $\phi'(d) \leq 0$.

Integrating the equation on $(r, d)$, for some $r \in (R, d)$, we get

$$d^{m-1}\phi'(d) - r^{m-1}\phi'(r) = \left(\frac{d^m}{m} - \frac{r^m}{m}\right)(1 - \gamma).$$

From $\phi'(d) \leq 0$, we get

$$-r^{m-1}\phi'(r) \geq \left(\frac{d^m}{m} - \frac{r^m}{m}\right)(1 - \gamma),$$

or

$$-\phi'(r) \geq \left(\frac{d^m}{m} \frac{1}{r^{m-1}} - \frac{r^m}{m}\right)(1 - \gamma).$$

Integrating this inequality from $R$ to $d$, we get that

$$-\phi(d) + \phi(R) \geq \left(\frac{d^m}{m} \int_R^d \frac{1}{s^{m-1}} ds - \frac{d^2}{2m} - R^2\right)(1 - \gamma).$$

Replacing $\phi(d) = 0, \phi(R) = M(R)$, we obtain that

$$M(R) - \frac{R^2}{2m} \geq \left(\frac{d^m}{m} \int_R^d \frac{1}{s^{m-1}} ds - \frac{d^2}{2m} - R^2\right)(1 - \gamma). \quad (19)$$

We first estimate $M(R)$. For this purpose, we use the result of Theorem 1 and the notation introduced in its proof. We start by observing that $M(R) \leq \|v\|_{\infty}$. Since our assumption was that $v \geq 0$, we can use the result of Theorem 1 to get that

$$|\Omega \setminus B_R| \leq \gamma|\Omega|.$$
Hence, there exist some values $0 < r_1 < r_2$ such that $|B_{r_1}| = |\Omega \cap B_{r_2}|$, $|B_{r_2}| = |\Omega|$, and by Talenti’s theorem we get that
\[ v^* \leq v_{B_{r_2},B_{r_1},\gamma}. \]

But $B_{r_1} \subset B_{r_2}$ and $|B_{r_1}| \geq (1 - \gamma)|B_{r_2}|$. A simple computation shows that the maximal $L^\infty$-norm of $v_{B_{r_2},B_{r_1},\gamma}$ is attained for $r_1 = R$, $r_2 = R_{\gamma}$. Finally, equation (19) becomes
\[ \|v_{B_{r_2},B_{r_1},\gamma}\|_\infty \geq \frac{R^2}{2m} \geq \left( \frac{d^m}{m} \int_R^d \frac{1}{s^{m-1}} ds - \frac{d^2}{2m} \right) (1 - \gamma). \]

The assertion in Lemma 8 follows by considering the cases $m = 2$, and $m \geq 3$ in (20) separately.

Coming back to the proof of Case 3, assume $\Omega$ is open, unbounded, and of finite measure. Let $c > 0$. We need to prove that there exists a set $A \subset \Omega$, with $|A| \leq c$, such that $\text{essinf}_{\Omega, A, \gamma} v < 0$. Let $R > 0$ be such that
\[ |\Omega \setminus B_R| \leq \frac{c}{2}. \]

Since $\Omega$ has finite measure, such a value of $c$ exists. We apply Lemma 8 to all sets $\Omega \cap B_n$, for $n \geq d(R, m, \gamma)$ and know that for $x \in \Omega \cap B_n$ at distance larger than $d(R, m, \gamma)$, we have that $v_{\Omega \cap B_n, B_{R_{\gamma}}}(x) < 0$. Passing to the limit we get $v_{\Omega, B_{R_{\gamma}}}(x) \leq 0$ for $x \in \Omega$, $\|x\| \geq d(R, m, \gamma)$.

Replacing $R$ by any $R - \varepsilon$ (for some $\varepsilon > 0$ such that $|\Omega_{R - \varepsilon, \gamma}| < \frac{c}{2}$) we get $v_{\Omega, B_{R - \varepsilon}}(x) < 0$ for $x \in \Omega$, $\|x\| > d(R, m, \gamma)$, so the assertion holds for the set $A = \Omega \setminus B_{R - \varepsilon}$.

4 Proof of Theorem 3.

Proof of Theorem 3. Let us start by observing that the following covering property holds: for every $x \in \Omega$, there exists a ball $B$ of radius $R$ such that $x \in B \subset \Omega$. Indeed, let $x \in \partial \Omega$ be a point which realises the distance to the boundary. Since the boundary of $\Omega$ is of class $C^2$, then $x - \xi$ is normal to the boundary $\partial \Omega$ at $\xi$. If $|x - \xi| \geq R$, then $B_R(x) \subset \Omega$. If $|x_0 - \xi| < R$, then $x$ belongs to the ball of radius $R$ tangent to $\partial \Omega$ at $\xi$.

Assume for contradiction that
\[ \mathcal{C}_-(\Omega, \gamma) < \mathcal{C}_-(B_R, \gamma). \]

For every $\varepsilon > 0$ such that $\mathcal{C}_-(\Omega, \gamma) + \varepsilon < \mathcal{C}_-(B_R, \gamma)$, there exists a set $A_\varepsilon \subset \Omega$ such that $|A_\varepsilon| \leq \mathcal{C}_-(\Omega, \gamma) + \varepsilon$ and
\[ \text{essinf}_{\Omega, A_\varepsilon, \gamma} v < 0, \]
the infimum being attained at $x_\varepsilon$. Taking a sequence $\varepsilon \to 0$, we may assume (up to extracting suitable subsequences) that
\[ 1_{A_\varepsilon} \to g \text{ weakly-$\ast$ in } L^\infty, \quad x_\varepsilon \to x_* \in \overline{\Omega}. \]
Then $\int_\Omega g = \mathcal{C}_-(\Omega, \gamma)$. Denoting $v_{\Omega, g, \gamma}$ the solution of

$$-\Delta v = \gamma(1 - g) - (1 - \gamma)g, \quad v \in H^1_0(\Omega),$$

we get that

$$v_{\Omega, A, \gamma} \rightarrow v_{\Omega, g, \gamma}$$

uniformly on $\overline{\Omega}$. This is a consequence of the elliptic regularity of the solutions, which are uniformly bounded in $C^{1,\alpha}(\overline{\Omega})$ for some $\alpha > 0$. Consequently, $v_{\Omega, g, \gamma} \geq 0$ in $\Omega$. Indeed, for $x^*$ a minimum point of $v_{\Omega, g, \gamma}$ with $v_{\Omega, g, \gamma}(x^*) < 0$, we can modify $g$ slightly to find a new function $\tilde{g}$, such that

$$0 \leq \tilde{g} \leq 1, \quad \int_\Omega \tilde{g} < \mathcal{C}_-(\Omega, \gamma), \quad v_{\Omega, \tilde{g}, \gamma}(x^*) < 0.$$

From the density of the characteristic functions, we can find a sequence of sets $\tilde{A}_\delta$ such that $1_{\tilde{A}_\delta} \rightarrow \tilde{g}$ weakly-* in $L^\infty$, and $|\tilde{A}_\delta| = \int_\Omega \tilde{g}$. In particular, $v_{\Omega, \tilde{A}_\delta, \gamma}(x^*) < 0$. This contradicts the definition of $\mathcal{C}_-(\Omega, \gamma)$.

Consequently, $v_{\Omega, g, \gamma}(x^*) = 0$. There are two possibilities: either $x^* \in \Omega$, or $x^* \in \partial\Omega$. Assume first that $x^* \in \Omega$. As a consequence of the covering property, there exists a ball $B$ of radius $R$ such that $x_0 \in B \subset \Omega$. In particular, this implies that $v_{\Omega, g, \gamma} \geq 0$ on $\partial B$. The maximum principle gives that

$$v_{\Omega, g, \gamma} \geq v_{B, g, \gamma}, \quad \text{on } B.$$

Consequently $v_{B, g, \gamma}(x^*) \leq 0$. Clearly

$$\int_B g \leq \mathcal{C}_-(\Omega, \gamma) < \mathcal{C}_-(B_R, \gamma). \quad (21)$$

**Case 1.** In case $v_{B, g, \gamma}(x^*) < 0$, we immediately get a contradiction since, as above, we can build a sequence of sets $\tilde{A}_\delta \subset B$ such that $1_{\tilde{A}_\delta} \rightarrow \tilde{g} \cdot 1_B$ weakly-* in $L^\infty(B)$, and $|\tilde{A}_\delta| = \int_B \tilde{g}$. By the uniform convergence, we get that $v_{B, \tilde{A}_\delta, \gamma}(x^*) < 0$, so that $\mathcal{C}_-(B_R, \gamma) \leq \int_B \tilde{g}$. This contradicts $(21)$.

**Case 2.** In case $v_{B, g, \gamma}(x^*) = 0$, we claim that either $g$ is itself a characteristic function, or we can find another function $\tilde{g}$ such that

$$0 \leq \tilde{g} \leq 1, \quad \int_B \tilde{g} < \mathcal{C}_-(B_R, \gamma), \quad \text{and } v_{B, \tilde{g}, \gamma}(x^*) < 0.$$

Assume that $g$ is a characteristic function. Then $g = 1_A$. Taking a new set $A \subset \tilde{A} \subset B$, such that $|A| < |\tilde{A}| < \mathcal{C}_-(B_R, \gamma)$ we get by the maximum principle that $v_{B, \tilde{A}, \gamma}(x^*) < 0$, in contradiction with the definition of $\mathcal{C}_-(B_R, \gamma)$.

Assume that $g$ is not a characteristic function on $B$. Then, for some value $\delta > 0$ the set $U_\delta = \{x \in B : \delta \leq g(x) \leq 1 - \delta\}$ has positive Lebesgue measure. We put $\tilde{g} = g + s1_{U_\delta}$, where $s > 0$ is small enough such that $\int_B \tilde{g} < \mathcal{C}_-(B_R, \gamma)$. By the maximum principle, we get $v_{B, \tilde{g}, \gamma}(x^*) < 0$. In this case, we are back to Case 1.

Assume now that $x^* \in \partial\Omega$. Let $n_{x^*}$ be the outward normal vector at $x^*$. Let $\pi_{x^*}$ be the projection on $\partial\Omega$ of $x^*$. Since $\Omega$ is of class $C^2$, we get $\pi_{x^*} \rightarrow x^*$ and that there exists a point $y_\epsilon$ on the segment $[\pi_{x^*}, x^*]$ such that $\nabla v_{\Omega, A, \gamma}(y_\epsilon) \cdot n_{x^*} \geq 0$. Passing to the limit, we get

$$\nabla v_{\Omega, g, \gamma}(x^*) \cdot n_{x^*} \geq 0.$$
Meanwhile, $x^*$ is a minimum point of $v_{\Omega,g,\gamma}$, so that
\[
\frac{\partial v_{\Omega,g,\gamma}}{\partial n}(x^*) \leq 0.
\]
Hence
\[
\frac{\partial v_{\Omega,g,\gamma}}{\partial n}(x^*) = 0.
\]
Using the $R$-smoothness at $x^*$, the ball $B \subset \Omega$ of radius $R$ tangent to $\partial \Omega$ at $x^*$ stays in $\Omega$. Since $v_{\Omega,g,\gamma} \geq 0$, by the maximum principle we get $v_{\Omega,g,\gamma} \geq v_{B,g,\gamma}$. By the Hopf maximum principle, applied to $v_{\Omega,g,\gamma} - v_{B,g,\gamma}$ on $B$ at the minimum point $x^* \in \partial B$, we have either that
\[
\frac{\partial v_{\Omega,g,\gamma}}{\partial n}(x^*) - \frac{\partial v_{B,g,\gamma}}{\partial n}(x^*) < 0,
\]
or that $v_{\Omega,g,\gamma} - v_{B,g,\gamma} = 0$ on $B$. In the first situation,
\[
\frac{\partial v_{B,g,\gamma}}{\partial n}(x^*) < 0,
\]
which means that $v_{B,g,\gamma}$ takes negative values close to $x^*$. Then, we conclude as in Case 1, above. In the second situation, if we find a point $\bar{x} \in \partial B \cap \Omega$, we can conclude as in Case 2 since $v_{B,g,\gamma}(\bar{x}) = 0$. The alternative is that $\partial B \subset \partial \Omega$ so that $\Omega = B$ and we have a contradiction.

To prove (5) we let $m \geq 3$, and let $H$ be an open half-space. Then
\[
G_H(x,y) = c_m \left( |x - y|^{2-m} - |x^* - y|^{2-m} \right),
\]
where $x^*$ is the reflection of $x$ with respect to $\partial H$, and
\[
c_m = \frac{\Gamma((m-2)/2)}{4\pi m/2}.
\]
By (12), and monotonicity we have that
\[
v_{B_R,A,\gamma}(x) \geq \gamma v_{B_R}(x) - \int_A dy G_{B_S}(x, y),
\]
where $H_S$ is the half-space tangent to $B_R$ at $\bar{x} \in \partial B_R$. Note that $|x^* - \bar{x}| = |\bar{x} - x|$. Moreover, $|x - y| \leq |x^* - y|$, $y \in \Omega$. Hence,
\[
0 \leq |x - y|^{2-m} - |x^* - y|^{2-m} \leq (m - 2)|x - x^*||x - y|^{1-m}.
\]
Let
\[
A^*_x = \{ y : |y - x| < r_A \},
\]
where
\[
\omega_m r_A^m = |A|.
\]
By (12), (23), (24), and radial rearrangement of $A$ about $x$, we have that
\[
\int_A dy G_{B_R}(x, y) \leq (m - 2)c_m |x - x^*| \int_{A^*_x} dy |x - y|^{1-m}
\]
\[
\leq (m - 2)c_m |x - x^*| \int_{A^*_x} dy |y - x|^{1-m}
\]
\[
= (m - 2)mc\omega_m r_A |x - x^*|
\]
\[
= 2r_A |x - \bar{x}|.
\]
The following will be used in the proof of (5), and in the proof of (42) and (43) in Remark 6 below.

**Lemma 9.** If $\Omega$ is an open set in $\mathbb{R}^m, m \geq 2$ with $R$-smooth boundary, and if $\lambda(\Omega) > 0$, then

$$v_{\Omega}(x) \geq \frac{|x - \bar{x}|R}{2m}.$$  \hfill (27)

**Proof.** Recall that

$$v_{B_r(c)}(x) = \frac{r^2 - |x - c|^2}{2m}.$$  \hfill (26)

We first consider the case $|x - \bar{x}| > R$. Then, by domain monotonicity of the torsion function, and (26)

$$v_{\Omega}(x) \geq v_{B_R(x - \bar{x})}(x) = \frac{|x - \bar{x}|^2}{2m} \geq \frac{|x - \bar{x}|R}{2m}.$$  \hfill (27)

We next consider the case $|x - \bar{x}| \leq R$. Since $\partial \Omega$ is $R$-smooth, there exists $B_R(c_x) \subset \Omega$ such that $|c_x - \bar{x}| = R$. Hence, by (27),

$$v_{\Omega}(x) \geq v_{B_R(c_x)}(x) = \frac{R^2 - |x - c_x|^2}{2m} \geq \frac{(R - |x - c_x|)R}{2m} = \frac{|x - \bar{x}|R}{2m}.$$  \hfill (27)

In either case we conclude (27).  \hfill \qed

By (26) and (27) we have that

$$v_{B_{rA},\gamma}(x) \geq \gamma \frac{|x - \bar{x}|R}{2m} - 2r_A|x - \bar{x}|.$$  \hfill (28)

The right-hand side of (28) is non-negative for $r_A \leq \gamma R/(4m)$. This is, by (25), equivalent to (5).

Consider the case $m = 2$. Then

$$G_H(x, y) = \frac{1}{2\pi} \log \left( \frac{|x^* - y|}{|x - y|} \right).$$

By the triangle inequality,

$$G_{B_R}(x, y) \leq G_{H_e}(x, y) \leq \frac{1}{2\pi} \log \left( \frac{|x^* - x| + |x - y|}{|x - y|} \right) \leq \frac{|x^* - x|}{2\pi|x - y|}.$$  \hfill (29)

Hence we have that

$$\int_A dy G_{B_R}(x, y) \leq (2\pi)^{-1}|x - x^*| \int_{A^c} dy |x - y|^{-1} = 2r_A|x - \bar{x}|.$$  \hfill (29)

The remaining arguments follow those of the case $m \geq 3$, as the right-hand side above equals the right-hand side of (26).

To prove (6) we let $m \geq 3$. By scaling it suffices to prove (6) for $R = 1$. Let $a \in (0,1)$. We obtain an upper bound for $a$ such that $v_{B_{1},B_{a},\gamma}(0) < 0$. Note that

$$G_{B_1}(0, y) = \frac{\Gamma((m - 2)/2)}{4\pi^{m/2}}(|y|^{2-m} - 1).$$
Hence, by (29) we have that

\[ v_{B_1,B_a,\gamma}(0) = \gamma v_{B_1}(0) - \int_{B_a} dy G_{B_1}(0,y) \]

\[ = \frac{\gamma}{2m} - \frac{\Gamma((m-2)/2)}{4\pi^{m/2}} m\omega_m \int_{[0,a]} dr (r - r^{m-1}) \]

\[ \leq \frac{\gamma}{2m} - \frac{a^2}{2m}. \]  

(30)

The right-hand side of (30) is negative for \( a > \gamma^{1/2} \). This implies (6).

To prove (7) we let \( m = 2, a \in (0,1) \), and note that

\[ G_{B_1}(0,y) = -\frac{1}{2\pi} \log |y|. \]

Hence,

\[ v_{B_1,B_a,\gamma}(0) = \frac{\gamma}{4} + \int_{[0,a]} dr r \log r \]

\[ = \frac{\gamma}{4} - \frac{a^2}{4} + \frac{a^2}{4} \log a^2. \]  

(31)

Let

\[ a = \left(1 + \log \left(\frac{1}{\gamma}\right)\right)^{-1/2} \gamma^{1/2}. \]

(32)

Then \( a \in (0,1) \), and by (31) and (32),

\[ v_{B_1,B_a,\gamma}(0) \leq -\frac{\gamma}{4} \log \left(1 + \log \left(\frac{1}{\gamma}\right)\right) < 0. \]

This implies (7). \( \square \)

5 Proof of Theorem 4

Lemma 12 in [4] asserts that if \( P(\Omega) < \infty \) then the spectrum of the Dirichlet Laplacian acting in \( L^2(\Omega) \) is discrete. Hence \( \lambda(\Omega) > 0 \). We proceed with the following.

Lemma 10. If \( \Omega \) is an open set in \( \mathbb{R}^m \), \( m = 1, 2, 3, \ldots \) with \( \lambda(\Omega) > 0 \), then there exists \( C_1(m) \) such that

\[ G_\Omega(x,y) \leq C_1(m)|x-y|^{-m}\lambda(\Omega)^{-1}e^{-|x-y|\sqrt{\lambda(\Omega)/6}}, \quad x \in \Omega, \ y \in \Omega, \]

where the constant \( C_1(m) \) can be read-off from (??) below.

Proof. The proof relies on some basic facts on the connection between the torsion function and the heat kernel which we recall below. These have been exploited elsewhere in the literature. See for example [5]. We recall that (see [12], [16], [17]) the heat equation

\[ \Delta u(x; t) = \frac{\partial u(x; t)}{\partial t}, \quad x \in \Omega, \ t > 0, \]
has a unique, minimal, positive fundamental solution \( p_\Omega(x, y; t) \), where \( x \in \Omega \), \( y \in \Omega \), \( t > 0 \). This solution, the heat kernel for \( \Omega \), is symmetric in \( x, y \), strictly positive, jointly smooth in \( x, y \in \Omega \) and \( t > 0 \), and it satisfies the semigroup property

\[
p_\Omega(x, y; s + t) = \int_\Omega dz \, p_\Omega(x, z; s)p_\Omega(z, y; t),
\]

for all \( x, y \in \Omega \) and \( t, s > 0 \). If \( \Omega_1 \subset \Omega_2 \) are open subsets of \( \mathbb{R}^m \) then, by minimality,

\[
p_\Omega(x, y; t) \leq p_{\Omega_2}(x, y; t), \quad x \in \Omega_1, \ y \in \Omega_1, \ t > 0.
\]

(33)

It is a standard fact that for \( \Omega \) open in \( \mathbb{R}^m \),

\[
G_\Omega(x, y) = \int_{(0, \infty)} dt \, p_\Omega(x, y; t),
\]

whenever the integral with respect to \( t \) converges. We have that

\[
v_\Omega(x) = \int_0^\infty dt \int_\Omega dy \, p_\Omega(x, y; t).
\]

By the heat semigroup property, we have that for \( x \in \Omega, y \in \Omega, t > 0 \),

\[
p_\Omega(x, y; t) = \int_\Omega dr \, p_\Omega(x, r; t/2)p_\Omega(r, y; t/2)
\leq \left( \int_\Omega dr \left( p_\Omega(x, r; t/2) \right)^2 \right)^{1/2} \left( \int_\Omega dr \left( p_\Omega(r, y; t/2) \right)^2 \right)^{1/2}
= \left( p_\Omega(x, x; t)p_\Omega(y, y; t) \right)^{1/2}.
\]

(34)

Furthermore, for all \( s \in (0, t), \)

\[
p_\Omega(z, z; t - s) \leq e^{-s\lambda(\Omega)}p_\Omega(z, z; t - s).
\]

(35)

So choosing \( s = t/2 \) in (35), and subsequently using (34) gives that

\[
p_\Omega(x, y; t) \leq e^{-t\lambda(\Omega)/3}(p_\Omega(x, x; t/2)p_\Omega(y, y; t/2))^{1/3} p_\Omega(x, y; t)^{1/3}.
\]

(36)

Putting \( \Omega_1 = \Omega, \Omega_2 = \mathbb{R}^m \) in (33) gives that both diagonal heat kernels in the right-hand side of (36) are bounded by \((2\pi t)^{-m/2}\), and that \( p_\Omega(x, y; t)^{1/3} \leq (4\pi t)^{-m/6}e^{-|x-y|^2/(12t)}\). Hence by (36),

\[
p_\Omega(x, y; t) \leq 2^{m/3}(4\pi t)^{-m/2}e^{-t\lambda(\Omega)/3-|x-y|^2/(12t)}
\leq 2^{m/3}\sup_{t>0} \left( 4\pi t \right)^{-m/2}e^{-|x-y|^2/(24t)} \sup_{t>0} \left( e^{-t\lambda(\Omega)/6-|x-y|^2/(24t)} \right) e^{-t\lambda(\Omega)/6}
\leq 2^{m/3} \left( \frac{3m}{\pi e} \right)^{m/2} |x-y|^{-m\lambda(\Omega)-1}e^{-|x-y|\sqrt{\lambda(\Omega)/6}}e^{-t\lambda(\Omega)/6}.
\]

(37)

Integrating both sides of (37) with respect to \( t \) over \( [0, \infty) \) gives that

\[
G_\Omega(x, y) \leq 6 \cdot 2^{m/3} \left( \frac{3m}{\pi e} \right)^{m/2} |x-y|^{-m\lambda(\Omega)-1}e^{-|x-y|\sqrt{\lambda(\Omega)/6}}.
\]

\[\square\]
We now prove the following assertion. Let $c_1 > 0$. There exists $c_2 > 0$ depending on $c_1, m$, and on $\gamma$ such that for every $\Omega \subset \mathbb{R}^m$, $P(\Omega) \leq c_2$, there exists $A \subset \Omega$, $|A| \leq c_1$, such that $\text{essinf}_{\Omega \setminus A, \gamma} < 0$. Let $r_1$ be the radius of a ball of volume $\frac{c_1}{2}$ and $r_2 = 2^{\frac{m}{2}}r_1$ be the radius of a ball of volume $c_1$. Following the result of Lieb [21, Theorem 1], there exists a translation $x$ of $B_{r_1}$ such that

$$\lambda(\Omega) + \lambda(B_{r_1}) \geq \lambda(\Omega \cap B_{r_1}(x)).$$

We note that since the torsion of $\Omega$ is finite, the result of Lieb holds for both bounded and unbounded sets $\Omega$.

The Kohler-Jobin inequality asserts that (see for instance [6]) there exists $C_2(m) > 0$ such that for every open set $\Omega$ with finite torsional rigidity,

$$\lambda(\Omega)T(\Omega) \geq C_2(m).$$

This, together with the Lieb inequality, implies that

$$\int_{\Omega \cap B_{r_1}(x)} v_{\Omega \cap B_{r_1}(x)} \geq \left( \frac{C_2(m)}{\lambda(\Omega) + \lambda(B_{r_1})} \right)^{\frac{m+2}{m+1}}.$$

We put $A = B_{r_2}(x) \cap \Omega$ and $A' = B_{r_1}(x) \cap \Omega$.

We estimate the integral of $v_{\Omega, A, \gamma}$ on the set $A'$ as follows.

$$\int_{A'} v_{\Omega, A, \gamma} = \int_{A'} dx \int_{\Omega} dy G_{\Omega}(x, y)(\gamma 1_{\Omega, A}(y) - (1 - \gamma) 1_A(y))$$

$$= \gamma \int_{A'} dx \int_{\Omega \setminus A} dy G_{\Omega}(x, y) - (1 - \gamma) \int_{A'} dx \int_A dy G_{\Omega}(x, y).$$

By monotonicity, we have that

$$(1 - \gamma) \int_{A'} dx \int_A dy G_{\Omega}(x, y) 1_A(y) \geq (1 - \gamma) \int_{A'} v_{A'} = \mathcal{P}(A').$$

For all $x \in A'$, and for all $y \in \Omega \setminus A$ we have that

$$|x - y| \geq \left( \frac{c_1}{\omega_m} \right)^{\frac{1}{m}} \frac{1}{2m}.$$

By Lemma [10] and the preceding inequality,

$$\gamma \int_{A'} dx \int_{\Omega \setminus A} dy G_{\Omega}(x, y)$$

$$\leq C_1(m) \gamma \lambda(\Omega)^{-1} \int_{A'} dx \int_{\Omega \setminus A} dy |x - y|^{m-1} e^{-\left|\frac{\sqrt{\lambda(\Omega)}}{6}(|x - y|/\sqrt{\lambda(\Omega)})^{1/m} \right|$$

$$\leq C_1(m) \gamma \lambda(\Omega)^{-1} |A'| \int_{(c_1/\omega_m)^{1/m}/(2m)}^{\infty} r^{m-1} e^{-\frac{\sqrt{\lambda(\Omega)}}{6} r^{1/m} \omega_m (mr)^{m-1} dr}$$

$$\leq C_1(m) \gamma \lambda(\Omega)^{-1} |A'| \omega_m^{1/m} \int_{(c_1/\omega_m)^{1/m}/(2m)}^{\infty} r^{-1/2} e^{-\left(\frac{\sqrt{\lambda(\Omega)} \omega_m (mr)^{m-1}}{(12m)} \right)}$$

$$\leq 6m^2 \omega_m^{(m+1)/m} C_1(m) c_1^{(m-1)/m} \gamma \lambda(\Omega)^{-3/2} e^{-\left(\frac{\sqrt{\lambda(\Omega)} (c_1/\omega_m)^{1/m}}{(12m)} \right)}.$$
Henceforth,
\[
\int_{A'} v_{\Omega,A,\gamma} \leq 6m^2 \omega_m^{(m+1)/m} C_1(m) c_1^{(m-1)/m} \gamma \lambda(\Omega) \gamma^{3/2} \lambda(\Omega)^{1/2}((c_1/\omega_m)^{1/m})/(12m) 
- (1 - \gamma) \left( \frac{C_2(m)}{\lambda(\Omega) + \lambda(B_{c_1})} \right)^{m+2}.
\]

As \( c_1 \) is fixed, for \( \lambda(\Omega) \) large enough, the quantity on the right-hand side above becomes negative. By the Kohler-Jobin inequality,
\[
\lambda(\Omega)c_2^{m+2} \geq C_2(m),
\]
we find a suitable value of \( c_2 \) depending only on \( c_1, \gamma \) and \( m \) such that \( \int_{A'} v_{\Omega,A,\gamma} < 0 \).

In order to finish the proof of Theorem 4, we fix \( c_1 = 1 \) and take the value of \( c_2 \) given above. Let now \( \Omega \subset \mathbb{R}^m \) be some open set with finite torsion. By rescaling, we find \( t > 0 \) such that \( T(t\Omega) = c_2 \). That is
\[
t = \left( \frac{c_2}{T(\Omega)} \right)^{\frac{m+2}{m}}.
\]
We have that
\[
\mathcal{C}_-(t\Omega, \gamma) \leq 1.
\]
By homogeneity, we have that
\[
t^m \mathcal{C}_-(\Omega, \gamma) \leq 1,
\]
or
\[
\mathcal{C}_-(\Omega, \gamma) \leq \frac{1}{t^m} = \left( \frac{T(\Omega)}{c_2} \right)^{\frac{m+2}{m}}.
\]
Hence (8) holds with \( C(m, \gamma) = c_2^{-m/(m+2)} \).

\[\square\]

6 Proof of Theorem 5

The proof of Theorem 5 requires the extension of the constant \( \mathcal{C}_-(\Omega, \gamma) \) to quasi-open sets. A proper introduction to the Laplace equation on quasi-open sets, capacity theory, and gamma convergence can be found in [18] and [8]. We prefer, for expository reasons, to avoid an extensive introduction to this topic, and refer the interested reader to [5, Sections 4.1 and 4.3] where all terminology used below can be found.

The key observation is that the class of quasi-open sets is the largest class of sets where the Dirichlet-Laplacian problem is well defined in the Sobolev space \( H_0^1 \), and satisfies a strong maximum principle (see [14]). Of course any open set is also quasi-open. Although the reader may only be interested in open sets, we are forced to work with quasi-open ones since the crucial step of the proof is the existence of a quasi-open set \( \Omega^* \) which maximises the left-hand side of (9).

The strategy of the proof is as follows. We analyse the shape optimization problem
\[
\sup \left\{ \frac{\mathcal{C}_-(\Omega, \gamma)}{|\Omega|} : \Omega \subset \mathbb{R}^m, \ \Omega \text{ quasi-open with } |\Omega| < \infty \right\}, \quad (38)
\]
and prove in Step 1 below the existence of a maximiser $\Omega^*$. Denoting $C'(m, \gamma) = \mathcal{C}_-(\Omega^*, \gamma)/|\Omega^*|$ we then prove in Step 2 that $C'(m, \gamma) < \gamma$ by a direct estimate on $\Omega^*$.

We start with the following observation. Assume that $(\Omega_n)_n$ is a sequence of quasi-open sets of $\mathbb{R}^m$, $|\Omega_n| \leq 1$, such that $v_{\Omega_n}$ converges strongly in $L^2(\mathbb{R}^m)$, and pointwise a.e. to some function $v$. Let us denote $\Omega := \{v > 0\}$. We then have that

$$\mathcal{C}_-(\Omega, \gamma) \geq \limsup_{n \to +\infty} \mathcal{C}_-(\Omega_n, \gamma). \quad (39)$$

Indeed, in order to prove this assertion let us consider a set $A \subseteq \Omega$ such that $\text{essinf}_{\Omega} v_{\Omega, A, \gamma} < 0$. We have that

$$1_{\Omega}(x) \leq \liminf_{n \to +\infty} 1_{\Omega_n}(x) \text{ a.e. } x \in D, \quad (40)$$

and hence

$$1_{\Omega_n \cap A} \to 1_A \text{ in } L^1(\mathbb{R}^m).$$

Following [8] Lemma 4.3.15, there exists larger sets $\tilde{\Omega}_n \supset \Omega_n$, $|\tilde{\Omega}_n| \leq 2$, such that for a subsequence (still denoted with the same index)

$$\lim_{n \to +\infty} v_{\tilde{\Omega}_n, A \cap \tilde{\Omega}_n, \gamma}(x) = v_{\Omega, A, \gamma}(x), \text{ for a.e. } x \in \mathbb{R}^m.$$ 

Since $\text{essinf}_{\Omega} v_{\Omega, A, \gamma} < 0$, we get for $n$ large enough that $\text{essinf}_{\tilde{\Omega}_n, A \cap \tilde{\Omega}_n, \gamma} < 0$ for $n$ large enough. Lemma [9] (which also holds in the class of quasi-open sets) implies that $\text{essinf}_{\tilde{\Omega}_n, A \cap \tilde{\Omega}_n, \gamma} < 0$, since the right-hand side equals to $\gamma$, $\gamma > 0$ on $\tilde{\Omega}_n \setminus \Omega_n$. Consequently, $\mathcal{C}_-(\tilde{\Omega}_n, \gamma) \leq |\tilde{\Omega}_n \cap A|$. Passing to the limit,

$$\limsup_{n \to +\infty} \mathcal{C}_-(\tilde{\Omega}_n, \gamma) \leq |A|,$$

which implies the assertion follows.

We divide the proof in two steps.

**Step 1.** Let us prove now that the shape optimisation problem (38) has a solution. In order to prove this result, it is enough to consider a maximising sequence $(\Omega_n)$ of quasi-open subsets of $\mathbb{R}^m$, with $|\Omega_n| = 1$. If all $(\Omega_n)$ are subsets of a bounded region $B$ of $\mathbb{R}^m$, the existence result is immediate from the compact embedding of $H^1_0(B) \to L^2(B)$ and the observation above: there exists a subsequence such that $v_{\Omega_n}$ converges strongly in $L^2(\mathbb{R}^m)$ and pointwise a.e. to some function $v$. Taking $\Omega^* := \{v > 0\}$, and using the upper semicontinuity result [10] together with the lower semicontinuity of the Lebesgue measures coming from [40], we conclude that $\Omega^*$ is optimal.

Unfortunately, the sets $\Omega_n$ are not necessarily bounded, so this suggests a concentration-compactness issue (see [7] Theorem 2.1)). Indeed, we shall prove that a maximising sequence is equi-bounded and so we can apply the argument above. After possible translation, we can assume that the origin is density point for $\Omega_n$. We shall prove that the diameters of $\Omega_n$ are uniformly bounded. The arguments below are in the spirit of Theorem [5]. We have the following.

**Lemma 11.** Let $\Omega \subseteq \mathbb{R}^m$ be a quasi-open, quasi-connected set of measure equal to 1, such that $0 \in \Omega$ is a density point. For every $R > 0$, there exists $R' > R$ depending only on $R, m, \gamma$ such that

if $\exists a$ density point $x \in \Omega$, $\|x\| \geq R'$ then $\text{essinf}_{\Omega \cap B_{R'}(x)} v_{\Omega, A, \gamma} < 0.$
The results states that if $\Omega$ is a (quasi) connected set with large diameter containing the origin, then displaying $-1$ on the intersection of $\Omega$ with an annulus with inner radius $R$ and with controlled width, we get negative values. Of course, one does not know how large the measure $|\Omega \cap A_{R,R'}|$ is. Our purpose is to prove that this argument can be achieved for a small measure being able to control in the same time the diameter. The argument to control the measure is the following: as $|\Omega| = 1$, assuming the diameter is large, one can build a series of $k$ annuli

$$A_{R_1,R'_1}, \ldots, A_{R_k,R'_k},$$

with $R_1 = 1, R'_i = R_{i+1}$, and for at least one of the annuli get

$$|\Omega \cap A_{R_i,R'_i}| \leq \frac{1}{k}.$$

Consequently, if the diameter of $\Omega$ is larger than $2R'_k$, applying the result of the Lemma to the annulus $A_{R_i,R'_i}$, we get

$$C(\Omega, \gamma) \leq \frac{1}{k}.$$ In other words, sets with large diameters and fixed measure have a uniformly low $C$-constant, so they are not admissible as maximising sequence. \footnote{This lemma gives also an alternative proof to Theorem\footnote{[15]} with a different displacement of the negative mass.}

Proof of Lemma 14. Assume first that $\Omega$ is open, bounded and smooth and assume that for some $R$ we have

$$v_{\Omega, A_{R,R'}} \cap \Omega, \gamma \geq 0.$$ We follow the same notations as in the proof of Theorem\footnote{[15]} and observe that the function $M$ introduced in (18) is strictly positive on $(R,R)$, Lipschitz, hence differentiable a.e. We introduce the function $\phi$ (depending on $R$) by

$$\phi'' + m - 1 - \frac{1}{r} \phi = 1 - \gamma \text{ on } (R, \bar{R}),$$

$$\phi(R) = M(R), \phi(\bar{R}) = M(\bar{R}).$$

Then $\phi \geq M$ on $(R, \bar{R})$ and, if $\bar{R}$ is a differentiability point for $M$, then $\phi'(\bar{R}) \leq M'(\bar{R})$. Summing the equation on $(r, \bar{R})$ and then on $(R, \bar{R})$, we get as in Theorem\footnote{[15]} that for $m \geq 3$

$$\frac{R^{m-1}}{m-2} \left( \frac{1}{R^{m-2}} - \frac{1}{\bar{R}^{m-2}} \right) \phi'(\bar{R}) =$$

$$= \phi(R) - \phi(\bar{R}) + \frac{(1 - \gamma) R^m}{m(m-2)} \left( \frac{1}{R^{m-2}} - \frac{1}{\bar{R}^{m-2}} \right) - \frac{(1 - \gamma) R^2}{2m}.$$ and for $m = 2$

$$\bar{R} \phi'(\bar{R}) \ln \frac{\bar{R}}{R} = \phi(\bar{R}) - \phi(R) + \frac{1 - 2 - \gamma R^2}{2} \ln \frac{\bar{R}}{R} - \frac{(1 - \gamma) R^2 - \bar{R}^2}{2}.$$ Taking advantage from $|\phi(\bar{R}) - \phi(R)| \leq \|v_\Omega\|_\infty$, the last term being not larger than a dimensional constant, in both cases there exists $R^* > R$, depending on $R, \gamma$ and the dimension of the space such that $\phi'(\bar{R}) \geq 1$ as soon as $\bar{R} > R^*$. \footnote{This lemma gives also an alternative proof to Theorem\footnote{[15]} with a different displacement of the negative mass.}
Let us choose $R^*$ such that $R^* > \|v\|_\infty$. If $\overline{R} > 2R^*$ is a differentiability point for $M$, we get that $\overline{R}_M \geq (\overline{R} - R^*) > R^* > \|v\|_\infty$, in contradiction with $\|M\|_\infty \leq \|v\|_\infty$.

Let us denote $R_1 = 2R^* + 1$. Starting with $R_1$, we reproduce the same argument, computing a second value $R^*_1$ and define $R' = 2R^*_1 + 2$. We claim that $v_{\Omega,\Omega \cap A_{R',R^*+1}}$ is negative on $\Omega \cap A_{R^*+1}^\ast$.

Let us display $-1$ on $A_{R^*+1}^\ast$ and study the function $M$ on $[R^*,2R^*_1 + 1]$. If $M$ is nonnegative on at least one point in $[2R^*,2R^*_1 + 1]$, this point should belong to a connected component of $\{v_{\Omega,\Omega \cap A_n,A_{R^*+1}^\ast} > 0\}$ touching one of the spheres centred at $0$ with radii $R^*$ or $R'$ otherwise, by the maximum principle would be strictly negative. Any of these situations contradicts the choice of $R^*$ and $R'$. Possibly, we can display $-1$ as well on $A_{R^*+1}^\ast \cap \Omega$ and keep the sign negative.

In order to prove the assertion for general quasi-open, quasi-connected, possibly unbounded domains, we apply the preceding result. Take $U_n$ a decreasing sequence of open sets, containing $\Omega$ such that $cap(U_n \setminus \Omega) \to 0$. Inside any $U_n$ consider a bounded, smooth, connected open set $U_n$ such that $\int_{U_n} v_{U_n} - v_{\overline{U}_n} \, dx \leq \frac{1}{n}$.

We display $-1$ on $A_{R^*+1}^\ast$, apply the result to $\overline{U}_n$, and pass to the limit. We get that

$$v_{\Omega,\Omega \cap A_{R^*+1}^\ast} \leq 0 \text{ on } \Omega \cap A_{R^*+1}^\ast.$$ 

If there exists one point such that $v_{\Omega,\Omega \cap A_{R^*+1}^\ast}(x) < 0$, we have finished (possibly, we can display $-1$ as well on $A_{R^*+1}^\ast \cap \Omega$).

Otherwise, $v_{\Omega,\Omega \cap A_{R^*+1}^\ast} > 0$ on $\Omega \cap A_{R^*+1}^\ast$ and $v_{\Omega,\Omega \cap A_{R^*+1}^\ast} \geq 0$ on $\Omega$. We reproduce the same reasoning displaying $-1$ on $\Omega \cap A_{R^*+1}^\ast$. Recalling that $\Omega$ is quasi-connected, $\Omega$ has to intersect $A_{R^*+1}^\ast$, so that the maximum principle (see [1]) we get $v_{\Omega,\Omega \cap A_{R^*+1}^\ast} \leq v_{\Omega,\Omega \cap A_{R^*+1}^\ast}$ on $\Omega$.

Coming back, let us choose $k$ large enough such that $\frac{1}{k} < \mathcal{C}_-(0,1)^4, \gamma)$. We can assume that $0$ is density point of $\Omega_n$ and get that the diameters of $\Omega_n$ are bounded by $2R'_n$, otherwise $\mathcal{C}_-(\Omega_n, \gamma) \leq \frac{1}{k}$, so they are not maximising. This implies that the maximising sequence is equi-bounded and leads to the existence of an optimal set.

**Step 2.** Let $\Omega^*$ be the optimal set found in Step 1. In order to prove that $\mathcal{C}_-(\Omega^*, \gamma) < \gamma|\Omega^*|$, we just notice that if we display the $-1$ value on a level set $L_c = \{v_{\Omega^*} > c\}$ of measure equal to $\gamma|\Omega^*|$, we have that

$$\int_{\Omega^*} v_{L_c,\gamma} \, dx < 0,$$

so that essinf$v_{L_c,\gamma} < 0$ and hence $\mathcal{C}_-(\Omega^*, \gamma) < \gamma|\Omega^*|$. This is a consequence of the following equality

$$\int_{\Omega^*} v_{\Omega^*,L_c,\gamma} \, dx = \gamma \int_{\Omega^*} v_{\Omega^*,L_c} \, dx = \int_{\Omega^*} v_{\Omega^*,L_c} \, dx = \gamma \int_{\Omega^*} v_{\Omega^*} \, dx = \gamma \int_{\Omega^* \setminus L_c} v_{\Omega^*} \, dx = (1 - \gamma) \int_{L_c} v_{\Omega^*} \, dx < \gamma(1 - \gamma)|\Omega^*|c - (1 - \gamma)\gamma|\Omega^*|c < 0.$$
7 Proof of Theorem 6 and further remarks

Proof of Theorem 6 For a measurable set \( A \subset \Omega \), we denote
\[
m(A) := \text{essinf } v_{\Omega, A, \gamma}.
\]
Note that the smoothness of \( \partial \Omega \) implies that \( v_{\Omega, A, \gamma} \in C^{1,\gamma}(\Omega) \).

First we extend the shape functional \( m \), on the closure of the convex hull of
\[
\{ \gamma 1_{\Omega \setminus A} + (1 - \gamma) 1_A : A \subset \Omega, |A| = c \}.
\]
Denote by
\[
\mathcal{F} := \{ f \in L^\infty(\Omega) : -(1 - \gamma) \leq f \leq \gamma, \int_\Omega f = \gamma |\Omega| - c \}.
\]
One naturally extends the functional \( m \) to the set \( \mathcal{F} \) by defining \( v_{\Omega, f, \gamma} \) as the solution of \(-\Delta v = f \) in \( H^1_0(\Omega) \). We shall prove in the sequel that the relaxation of the shape optimisation problem (10) on the set \( \mathcal{F} \) has a solution in \( \mathcal{F} \).

Precisely, we solve
\[
\min \{ m(f) : f \in \mathcal{F} \}. \tag{41}
\]
Clearly, \( \mathcal{F} \) is compact for the weak-* \( L^\infty \)-topology, so that we can assume that \((f_n)_n\) is a minimising sequence which converges in weak-* \( L^\infty \) to \( f \). We know, by the Calderon-Zygmund inequality, that \((v_{n, f_n, \gamma})_n\) are uniformly bounded in \( W^{2,p}(\Omega) \), for every \( p < \infty \). In particular, for \( p \) large enough, this implies that \( v_{\Omega, f_n, \gamma} \) converges uniformly to \( v_{\Omega, f, \gamma} \). Consequently, this implies that \( m(f_n) \) converges to \( m(f) \) so that \( f \) is a solution to the optimisation problem (41).

Secondly we prove that there exists some set \( A \) such that \( f = \gamma 1_{\Omega \setminus A} + (1 - \gamma) 1_A \). To prove this we exploit both the concavity property of the map \( f \mapsto m(f) \), and the structure of the PDE. Assume for contradiction that the set \( A_\varepsilon := \{ x \in \Omega, -(1 - \gamma) + \varepsilon \leq f(x) \leq \gamma - \varepsilon \} \) has non-zero measure, for some \( \varepsilon > 0 \). Let \( A_1, A_2 \subset A_\varepsilon \) be two disjoint sets, such that \( |A_1| = |A_2| \). We consider the functions \( f_1 = f + t_1 A_1 - t_1 A_2 \), and \( f_2 = f - t_1 A_1 + t_1 A_2 \), for \( t \in (-\varepsilon, \varepsilon) \). Then, \( f_1, f_2 \in \mathcal{F} \), and by linearity we have
\[
v_{\Omega, f, \gamma} = \frac{1}{2} v_{\Omega, f_1, \gamma} + \frac{1}{2} v_{\Omega, f_2, \gamma}.
\]
Consequently,
\[
m(f) \geq \frac{1}{2} m(f_1) + \frac{1}{2} m(f_2),
\]
with strict inequality if the point \( x^* \) where \( v_{\Omega, f, \gamma} \) is minimised also minimises \( v_{\Omega, f_1, \gamma} \) and \( v_{\Omega, f_2, \gamma} \). Moreover, we have \( v_{\Omega, f, \gamma}(x_*) = v_{\Omega, f_1, \gamma}(x_*) = v_{\Omega, f_2, \gamma}(x_*) \). We distinguish between two situations: \( v_{\Omega, f, \gamma}(x_*) = 0 \), and \( v_{\Omega, f, \gamma}(x_*) < 0 \). If we are in the first situation, then \( x^* \) could belong to \( \partial \Omega \). In this case, for all admissible sets \( A \) we have \( v_{\Omega, A, \gamma} \geq 0 \), the minimal value, which is 0 being attained on \( \partial \Omega \). In this case, every admissible set \( A \) is a solution to the shape optimisation problem.

If we are in the second situation, then necessarily \( x^* \in \Omega \). By linearity, from \( v_{\Omega, f, \gamma}(x_*) = v_{\Omega, f_1, \gamma}(x_*) \) we get
\[
v_{\Omega, 1_{A_1}, 0}(x_*) = v_{\Omega, 1_{A_2}, 0}(x_*),
\]

In particular, for every pair of points \( x, y \in A \setminus \{x^*\} \) with density 1 in \( A \), we get
\[
G_\Omega(x^*, x) = G_\Omega(x^*, y).
\]
Since \( G_\Omega \) is harmonic on \( \Omega \setminus \{x^*\} \), we get that \( G_\Omega \) is constant in \( \Omega \setminus \{x^*\} \), in contradiction with the fact that it is a fundamental solution.

Finally, this implies that \( |A_\varepsilon| = 0 \) for every \( \varepsilon > 0 \). Hence \( f \) is a characteristic function.

**Remark 1.** Clearly, the solution of the shape optimisation problem above is, in general, not unique. If the minimal value is 0, then any admissible set \( A \) is a solution. If the minimal value is strictly negative, then there are geometries with non-uniqueness. For example if \( \Omega \) is the union of two disjoint balls with the same radius. Then \( A \) is a subset of one of the two balls.

**Remark 2.** Assume \( \Omega = B_R \), and \(|B_R| > c \geq \gamma |B_R|\). The solution to the shape optimisation problem (10) is given by the (concentric) ball \( B^c \), of mass \( c \), \( c = |B_c| \). Indeed, there are two possibilities. In the case that \( A \subset B_R \) has measure \( c \) and \( v_{B_R, A, \gamma} \leq 0 \), we can use directly Talenti’s theorem to conclude (applied to \(-v_{B_R, A, \gamma}\)).

Assume now that \( v_{B_R, A, \gamma} \) changes sign on \( B_R \). We define the sets \( \Omega^+ = \{v_{B_R, A, \gamma} > 0\} \) and \( \Omega^- = \{v_{B_R, A, \gamma} < 0\} \). In view of Theorem [1], we have that \( |\Omega^+| \leq \gamma |\Omega^+| \) and \( |\Omega^-| \geq \gamma |\Omega^-| \). We use Talenti’s theorem on \( \Omega^- \), and get that the essential infimum of the function \( v_{B_R', B_r', \gamma} \) is not larger than the infimum of \( v_{B_R, A, \gamma} \), where \( B_{R'}, B_r' \) are the balls centred at the origin of measures \( |\Omega^-|, |\Omega^- \cap A| \), respectively. We claim that \( v_{B_{R'}, B_r', \gamma} \leq v_{B_{R'}, B_r', \gamma} \). Indeed, making a suitable rescaling by a factor \( t \geq 1 \) such that \(|t(\Omega^- \cap A)| = c \geq \gamma |B_R|\), the function \( v_{tB_{R'}, tB_r', \gamma} \) has an essential infimum lower than that of \( v_{B_{R'}, B_r', \gamma} \).

We finally notice that \( v_{B_{R'}, B_r', \gamma} \leq v_{B_{R'}, B_{r'}, \gamma} \). Indeed, this is a consequence of the fact that \( v_{tB_{R'}, tB_r', \gamma} \) is equal to \( \min \{ -\delta, v_{B_{R'}, B_r', \gamma} \} + \delta \), for a suitable \( \delta > 0 \).

**Remark 3.** Assume \( \Omega = B_R \), and \( c > \mathcal{E}_*(\Omega, \gamma) \). We observe that among all radial sets \( A \) of volume \( c \), the one giving the lowest essential infimum is \( B_c \), the ball with the same center as \( B_R \) and of volume \( c \). Indeed, let us denote for simplicity \( v = v_{B_R, A, \gamma} \) and \( v_c = v_{B_R, B_c, \gamma} \). Using the fact that both \( v \) and \( v_c \) are radial, we get that
\[
-r^{m-1} v'(r) = \int_0^r s^{m-1} (\gamma 1_{B_R \setminus A} - (1 - \gamma) 1_A) ds
= \frac{1}{\omega_{m-1}} \int_{B_c} (\gamma 1_{B_R \setminus A} - (1 - \gamma) 1_A),
\]
and
\[
-r^{m-1} v'_c(r) = \int_0^r s^{m-1} (\gamma 1_{B_R \setminus B_c} - (1 - \gamma) 1_{B_c}) ds
= \frac{1}{\omega_{m-1}} \int_{B_c} (\gamma 1_{B_R \setminus B_c} - (1 - \gamma) 1_{B_c}),
\]
where, for a radial set \( E \subseteq B_R \), we define (with abuse of notation), \( 1_E(r) \) being the value of \( 1_E \) on the sphere of radius \( r \).

Since for all \( r \in (0, R) \),
\[
\int_{B_r} (\gamma 1_{B_R \setminus A} - (1 - \gamma) 1_A) \geq \int_{B_r} (\gamma 1_{B_R \setminus B_c} - (1 - \gamma) 1_{B_c}),
\]
22
we get that for all \( r \in (0, R) \)
\[-r^{m-1} v'(r) \geq -r^{m-1} v'_c(r).\]
Hence
\[\int_{r}^{1} v'_c(s) ds \geq \int_{r}^{1} v'(s) ds,\]
and
\[-v_c(r) \geq -v(r).\]
This concludes the proof. Moreover, the infimum value is attained either at 0 or at \( R \), as \( v'_c \) is increasing.

For \( \gamma = \frac{1}{2} \), we can compute the value of \( c \) such that \( v_c(0) = v_c(R) = 0 \). Indeed, in \( \mathbb{R}^2 \), the corresponding value \( r_c \) is the solution of
\[\frac{r^2}{2} - \frac{1}{4} - r^2 \ln r = 0.\]
An estimate of the solution is \( r_c \approx 0.432067 \).

**Remark 4.** Assume \( \Omega = B_R \), and \( \mathcal{C}_-(B_R, \gamma) < c < \gamma |B_R| \). The solution of the shape optimisation problem is non-trivial in this case. While we do not know the general solution, we can observe a symmetry breaking phenomenon: the solution is not radially symmetric for small values of \( c \).

Let \( \gamma = \frac{1}{2}, r_c = 0.432 \) just below the value computed in the previous remark. Then, for every radial set \( A \), the essential infimum of \( v_{B_R, A, \frac{1}{2}} \) is equal to 0. Meanwhile, there exists a non-radial set \( A \) which gives a lower essential infimum. This fact is observed numerically, if for instance the set \( A \) is a disc, centred at \((0.52, 0)\) of radius \( r_c = 0.432 \). Of course, the fact that in this case the essential infimum is strictly negative can be directly deduced from estimates of the Poisson formula. In Figures 1 and 2 below, we display the (rescaled) numerical solutions computed with MATLAB.

![Figure 1](image1.png)

Figure 1: Negative mass displayed in the disc centred at 0 of radius \( r = 0.432 \): the essential infimum is 0.

If \( c \) is less than the critical value, the infimum is equal to 0, and is attained for an infinite number of solutions to the shape optimisation problem.

**Remark 5.** The solutions of the following shape optimisation problems
\[
\max \left\{ \int_{\Omega} v_{\Omega, A, \gamma} : A \subset \Omega, |A| = c \right\},
\]
and
\[
\min \left\{ \int_{\Omega} v_{\Omega, A, \gamma} : A \subset \Omega, |A| = c \right\}.
\]
are immediate. Indeed, we observe that
\[
\int_{\Omega} v_{\Omega,A,\gamma} = \gamma \int_{\Omega} v_{\Omega} - \int_{A} v_{\Omega}.
\]
Hence, the position of the set \(A\) is a suitable lower/upper level set of \(v_{\Omega}\).

**Remark 6.** If \(|A| \leq C_{-}(B_{R},\gamma)\) then \(v_{\Omega,A,\gamma} \geq 0\), and \(\int_{\Omega} v_{\Omega,A,\gamma} \geq 0\). Below we improve the bound \(|A| \leq C_{-}(B_{R},\gamma)\) for \(\int_{\Omega} v_{\Omega,A,\gamma} \geq 0\) to hold.

Let \(\Omega \subset \mathbb{R}^{m}, m \geq 2\), be an open set with finite measure and a \(C^{2}, R\)-smooth boundary. Let \(\gamma > 0\) and let \(v_{\Omega,A,\gamma}\) be the solution of (4). If either \(m \geq 3\), and
\[
|A| \leq \frac{m}{6(m-1)} \gamma \omega_{m} R^{m},
\]
(42)
or \(m = 2\), and
\[
|A| \leq \frac{10 + 7\sqrt{7}}{324} \gamma \pi R^{2},
\]
(43)
then \(\int_{\Omega} v_{\Omega,A,\gamma} \geq 0\).

**Proof.** First consider the case \(m \geq 3\). By Lemma [5] and the coarea formula, we have for \(a > 0\) that,
\[
\int_{\Omega} v_{\Omega} \geq \int_{\{x \in \Omega: |x - \bar{x}| < a\}} dx \frac{|x - \bar{x}| R}{2m} \geq \int_{[0,a]} d\theta \frac{R\theta}{2m} \mathcal{H}^{m-1}(\partial \Omega_{\theta}),
\]
(44)
where \(\mathcal{H}^{m-1}(\partial \Omega_{\theta})\) denotes the \((m-1)\)-dimensional Hausdorff measure of the parallel set \(\{x \in \Omega: |x - \bar{x}| = \theta\}\). It was shown in Lemma 5 in [2] that for an open, bounded set \(\Omega\) with a \(C^{2}, R\)-smooth boundary,
\[
\mathcal{H}^{m-1}(\partial \Omega_{\theta}) \geq \left(1 - \frac{(m-1)\theta}{R}\right) \mathcal{H}^{m-1}(\partial \Omega), \ \theta \geq 0.
\]
(45)
By (44) and (45) we obtain that
\[
\int_{\Omega} v_{\Omega} \geq \frac{R}{2m} \left(\frac{a^{2}}{2} - \frac{(m-1)a^{2}}{3R}\right) \mathcal{H}^{m-1}(\partial \Omega).
\]
Optimising over $a$ yields,
\[ \int_{\Omega} v_{\Omega} \geq \frac{R^3}{12(m-1)^2} \mathcal{H}^{m-1}(\partial \Omega). \] (46)

By the isoperimetric inequality, we have that,
\[ \mathcal{H}^{m-1}(\partial \Omega) \geq m \omega_m^{(m-1)/m}. \] (47)

Since $\Omega$ contains a ball of radius $R$, $|\Omega| \geq \omega_m R^m$. Hence, by (46) and (47),
\[ \mathcal{H}^{m-1}(\partial \Omega) \geq m \omega_m^{(m-2)/m} R^{m-3} |\Omega|^{2/m}. \]

This, together with (46), yields that
\[ \int_{\Omega} v_{\Omega} \geq \frac{\omega_m^{(m-2)/m}}{12(m-1)^2} R^m |\Omega|^{2/m}. \] (48)

By Talenti’s theorem,
\[ \int_{A} v_{\Omega} \leq \int_{A^*} v_{\Omega^*} \]
\[ = 2^{-1} \omega_m \int_{[0,\alpha R]} dr (R^2_\Omega - r^2)^{m-1} \]
\[ \leq (2m)^{-1} \omega_m R^2 \Omega^* A^m \]
\[ = (2m)^{-1} \omega_m^{(m-2)/m} |\Omega|^{2/m} |A|. \] (49)

By (4), (48), and (49) we have that
\[ \int_{\Omega} v_{\Omega,A,\gamma} = \gamma \int_{\Omega} v_{\Omega} - \int_{A} v_{\Omega} \]
\[ \geq \frac{\omega_m^{(m-2)/m}}{12(m-1)^2} \gamma R^m |\Omega|^{2/m} - (2m)^{-1} \omega_m^{(m-2)/m} |\Omega|^{2/m} |A|. \] (50)

This implies that $\int_{\Omega} v_{\Omega,A,\gamma} \geq 0$ for all measurable $A \subset \Omega$ satisfying (42).

Next consider the planar case. By Lemma 9, we have for any $\alpha \in (0,1)$ that
\[ \int_{\{x \in \Omega : |x - \bar{x}| \geq \alpha R\}} v_{\Omega} \geq \frac{\alpha R^2}{4} |\{x \in \Omega : |x - \bar{x}| \geq \alpha R\}|. \] (51)

By the coarea formula, Lemma 9 and (45), we find that
\[ \int_{\{x \in \Omega : |x - \bar{x}| < \alpha R\}} v_{\Omega} \geq \frac{R^3}{4} \left( \frac{\alpha^2}{2} - \frac{\alpha^3}{3} \right) \mathcal{H}^1(\partial \Omega). \] (52)

By Lemma 5 in [2],
\[ \mathcal{H}^1(\partial \Omega_\theta) \leq \frac{R}{R - \theta} \mathcal{H}^1(\partial \Omega), \ 0 \leq \theta < R. \] (53)

By the coarea formula, and (53), we find that
\[ |\{x \in \Omega : |x - \bar{x}| \leq \alpha R\}| \leq \mathcal{H}^1(\partial \Omega) \int_{[0,\alpha R]} \frac{d\theta}{R - \theta} \]
\[ \leq \alpha(1 - \alpha)^{-1} \mathcal{H}^1(\partial \Omega) R. \] (54)
Putting (51), (52), and (54) together gives that
\[
\int_{\Omega} v_{\Omega} \geq \frac{\alpha R^2}{4} |\{ x \in \Omega : |x - \bar{x}| \geq \alpha R \}|
+ \frac{1}{24} \alpha (1 - \alpha)(3 - 2\alpha) R^2 |\{ x \in \Omega : |x - \bar{x}| \leq \alpha R \}|
\geq \min \left\{ \frac{\alpha}{4}, \frac{1}{24} \alpha (1 - \alpha)(3 - 2\alpha) \right\} R^2 |\Omega|
= \frac{1}{24} \alpha (1 - \alpha)(3 - 2\alpha) R^2 |\Omega|.
\]

We choose \( \alpha = \frac{1}{6} (5 - \sqrt{7}) \) so as to maximise the above right-hand side, and obtain that
\[
\int_{\Omega} v_{\Omega} \geq \frac{10 + 7\sqrt{7}}{1296} R^2 |\Omega|.
\] (55)

Formula (49) for \( m = 2 \), (55), and the first equality in (50) yield,
\[
\int_{\Omega} v_{\Omega,A,\gamma} \geq \left( \frac{10 + 7\sqrt{7}}{1296} \gamma R^2 - \frac{1}{4\pi} |A| \right) |\Omega|.
\]
The above right-hand side is non-negative for all measurable \( A \subset \Omega \) satisfying (43).
