# Tree lengths for general $\Lambda$-coalescents and the asymptotic site frequency spectrum around the Bolthausen-Sznitman coalescent 

Christina S. Diehl* and Götz Kersting*

April 18, 2024

#### Abstract

We study tree lengths in $\Lambda$-coalescents without a dust component from a sample of $n$ individuals. For the total lengths of all branches and the total lengths of all external branches we present laws of large numbers in full generality. The other results treat regulary varying coalescents with exponent 1, which cover the Bolthausen-Sznitman coalescent. The theorems contain laws of large numbers for the total lengths of all internal branches and of internal branches of order $a$ (i.e. branches carrying $a$ individuals out of the sample). These results transform immediately to sampling formulas in the infinite sites model. In particular, we obtain the asymptotic site frequency spectrum of the Bolthausen-Sznitman coalescent.

AMS 2010 subject classification: 60J75 (primary), 60F05, 60J27, 92D25
Keywords: $\Lambda$-coalescents, Bolthausen-Sznitman coalescent, law of large numbers, tree length, infinite sites model, sampling formulas, site frequency spectrum

## 1 Introduction and main results

$\Lambda$-coalescents are established models for family trees of a sample of individuals from some large population. Its most prominent representative, the Kingman coalescent [17], is widely used in population genetics. More recently the Bolthausen-Sznitman coalescent [6] gained attention for models including selection. The class of Beta-coalescents with parameter $1<\alpha<2$ has been applied to marine populations [5]. In this paper we investigate branch lengths and sampling formulas in the infinite sites model for the whole class of $\Lambda$-coalescents without a dust component which cover all these special cases.
$\Lambda$-coalescents have been introduced by Pitman [19] and Sagitov [20] as Markov processes whose states are partitions of $\mathbb{N}$ and whose evolution may be imagined as a random tree. In this paper we identify a $\Lambda$-coalescent with an induced sequence of $n$-coalescents, $n \in \mathbb{N}$, by restricting partitions to the subsets $\{1, \ldots, n\}$ of $\mathbb{N}$. These $n$-coalescents are considered to be Markovian models for the family trees of a sample of $n$ individuals. If such a tree contains $b \in\{2, \ldots, n\}$ lineages at the moment $t \geq 0$ backwards in time (representing the ancestors living at that moment), then it is assumed that out of them $k \in\{2, \ldots, b\}$ specified lines merge at rate

$$
\lambda_{b, k}:=\int_{[0,1]} p^{k}(1-p)^{b-k} \frac{\Lambda(d p)}{p^{2}}
$$

[^0]to one line. Here $\Lambda$ denotes any finite, non-vanishing measure on $[0,1]$. The resulting tree consists of $n$ leaves, $\tau_{n}$ merging events, and a root at time $\tilde{\tau}_{n}>0$ representing the MCRA (most recent common ancestor). Its branches have lengths which specify lifetimes. There are external branches ending in leaves on the one hand, and internal branches ending in mergers on the other. For the detailed partition valued picture we refer to the survey [2].

In the sequel we work with the Markovian counting process $N_{n}=\left(N_{n}(t)\right)_{t \geq 0}$, where $N_{n}(t)$ denotes the number of lineages at time $t \geq 0$. Thus $N_{n}(0)=n$ and $N_{n}\left(\tilde{\tau}_{n}\right)=1$. For convenience we set $N_{n}(t):=1$ for $t>\tilde{\tau}_{n}$. Then for $b=2, \ldots, n$ the numbers

$$
\lambda(b)=\sum_{k=2}^{b}\binom{b}{k} \lambda_{b, k}
$$

give the jump rates of the process $N_{n}$, and

$$
\mu(b)=\sum_{k=2}^{b}(k-1)\binom{b}{k} \lambda_{b, k}
$$

its rate of decrease, since merging of $k$ lineages results in a downward jump of the block counting process of size $k-1$. These two sequences can be naturally extended to positive continuous functions $\lambda, \mu:[2, \infty) \rightarrow \mathbb{R}$, see the formulas (3) and (4) below.

In this paper we focus on the class of $\Lambda$-coalescents without a dust component. To put it briefly, in this case the rate, at which within the $n$-coalescents a single lineage merges with some others, diverges as the sample size $n$ tends to infinity. They are characterized by the condition (Pitman [19])

$$
\int_{[0,1]} \frac{\Lambda(d p)}{p}=\infty .
$$

In particular, they cover $\Lambda$-coalescents coming down from infinity. These are the coalescents with the property that the absorbtion times $\tilde{\tau}_{n}$ are bounded in probability uniformly in $n$. They are distinguished by the criterion (Schweinsberg [21])

$$
\int_{2}^{\infty} \frac{d x}{\mu(x)}<\infty
$$

We shall analyze the lengths of the whole $n$-coalescents as well as of different parts. They play an important role in the infinite sites model introduced by Kimura [16]. In this model each mutation effects a different site on the DNA. The mutations are distributed along the branches of the coalescent depending on their appearance in the past. Mathematically they build a homogeneous Poisson point process with rate $\theta>0$. Their total numbers $S(n)$ count the segregating sites in the sample of size $n$ underlying the coalescent, and are thus closely tied to its total lengths $\ell_{n}$. Mutations which are located on an external branch appear only once in the sample, these are the singleton polymorphisms (see Wakeley [23], page 103). Accordingly their number is linked to the total lengths $\widehat{\ell}_{n}$ of all external branches. Likewise the number of mutations visible repeatedly in the sample corresponds to the total internal lengths $\check{\ell}_{n}$.

Notation. For two sequences $A_{n}$ and $B_{n}$ of positive random variables we write $A_{n} \stackrel{1}{\sim} B_{n}$ and $A_{n} \stackrel{P}{\sim} B_{n}$, if the sequence $A_{n} / B_{n}$ converges to 1 in the $L_{1}$-sense or in probability, respectively. The notation $A_{n}=O_{P}\left(B_{n}\right)$ means that the sequence $A_{n} / B_{n}$ is tight, and $A_{n}=o_{P}\left(B_{n}\right)$ that $A_{n} / B_{n}$ converges to 0 in probability.

Now we come to the main results of this paper. As a first notion let

$$
\ell_{n}:=\int_{0}^{\tilde{\tau}_{n}} N_{n}(t) d t, n \geq 1
$$

be the total length of the coalescent tree.

Theorem 1. Assume that the $\Lambda$-coalescent has no dust component. Then as $n \rightarrow \infty$

$$
\begin{equation*}
\ell_{n} \stackrel{1}{\sim} \int_{2}^{n} \frac{x}{\mu(x)} d x . \tag{1}
\end{equation*}
$$

This is an intuitive approximation: if the counting process $N_{n}$ takes the value $x$ then there are currently $x$ lines, and $1 / \mu(x)$, the reciprocal of the rate of decrease, indicates how long on the average $N_{n}$ will stay close to $x$. Observe that the right-hand integral diverges for $n \rightarrow \infty$ : because of Lemma 1 (i) below the function $\mu(x) /(x(x-1))$ is decreasing, thus $\int_{2}^{n} \frac{x}{\mu(x)} d x \geq \frac{2}{\mu(2)} \log (n-1)$. This lower bound is attained by the Kingman coalescent.

Berestycki et al [3] conjectured Theorem 1 and proved it for $\Lambda$-coalescents coming down from infinity in the framework of convergence in probability. For the Kingman coalescent the result was obtained by Watterson [24] and for the Bolthausen-Sznitman coalescent by Drmota et al [10.

In the context of the infinite sites model Theorem 1 may be restated directly in terms of the number $S(n)$ of segregating sites as

$$
S(n) \stackrel{1}{\sim} \theta \int_{2}^{n} \frac{x}{\mu(x)} d x
$$

due to the assumption that mutations appear according to a homogeneous Poisson point process with rate $\theta$.

Next we define the total external length

$$
\widehat{\ell}_{n}:=\int_{0}^{\tilde{\tau}_{n}} \widehat{N}_{n}(t) d t
$$

where $\widehat{N}_{n}(t)$ denotes the number of external branches extant at time $t$. In contrast to the previous theorem the following result contains a statement of convergence in probability.

Theorem 2. Suppose that the $\Lambda$-coalescent has no dust component. Then

$$
\begin{equation*}
\widehat{\ell}_{n} \stackrel{P}{\sim} \frac{n^{2}}{\mu(n)} \tag{2}
\end{equation*}
$$

as $n \rightarrow \infty$.

The sequence $\mu(n) / n^{2}, n \geq 1$, has the limit $\Lambda(\{0\}) / 2$, see formula (7) below. Thus the total external lengths diverge in probability, if and only if $\Lambda(\{0\})=0$. We point out that $x / \mu(x)$ is a decreasing function (see Lemma 1 (i) below), therefore the integral appearing in (1) exceeds the corresponding term in (2). Unfortunately, we cannot deliver any intuitive explanation for Theorem 2, similar to that of Theorem 1. The proof rests on a close relation between the functions $\lambda$ and $\mu$ which seems not to be observed until now. To describe it let us introduce another function $\kappa:[2, \infty) \rightarrow \mathbb{R}$ given by

$$
\kappa(x):=\frac{\mu(x)}{x},
$$

which could be named the rate of decrease per capita. Then we have the approximation

$$
\lambda(x) \sim x^{2} \kappa^{\prime}(x)
$$

as $x \rightarrow \infty$ (see Lemma 1 (ii) below).
In the special case of Beta-coalescents the result follows from [7] and [9]. For $\Lambda$-coalescents with a dust component the picture is rather different. Then $\ell_{n} / n$ as well as $\widehat{\ell}_{n} / n$ converge in distribution to one and the same non-degenerate limit law, see [18]. Fluctuation results on the total lengths or the total external lengths of $\Lambda$-coalescents with no dust component are known only in special cases [10, 13, 14].

Theorem 2 again allows a reformulation in terms of the infinite site model. Letting $M_{1}(n)$ be the number of singletons, we obtain for $\Lambda(\{0\})=0$

$$
M_{1}(n) \stackrel{P}{\sim} \theta \frac{n^{2}}{\mu(n)},
$$

whereas for $\Lambda(\{0\})>0$ it follows that $M_{1}(n)$ is asymptotically Poisson with parameter $2 \theta / \Lambda(\{0\})$.
Remark. From our proofs we will gain further insight in the structure of the coalescents. Let for $0<c<1$

$$
\tilde{\rho}_{n}:=\inf \left\{t \geq 0: N_{n}(t) \leq c n\right\}
$$

be the first moment, when the number of lineages falls below $c n$, and let

$$
\ell_{n}^{*}:=\int_{0}^{\tilde{\rho}_{n}} N_{n}(t) d t, \widehat{\ell}_{n}^{*}:=\int_{0}^{\tilde{\rho}_{n}} \widehat{N}_{n}(t) d t
$$

be the respective lengths up to this moment. Then from 22 and 32 below we have

$$
\ell_{n}^{*} \stackrel{1}{\sim} \int_{c n}^{n} \frac{x}{\mu(x)} d x \text { and } \widehat{\ell}_{n}^{*} \stackrel{P}{\sim}(1-c) \frac{n^{2}}{\mu(n)} .
$$

The picture gives an illustration. $\ell_{n}^{*}$ and $\widehat{\ell_{n}^{*}}$ are the areas of the total grey region and of the lighter part, respectively.

It is tempting to expect an analogous result for the total internal length

$$
\check{\ell}_{n}:=\ell_{n}-\widehat{\ell}_{n}
$$

This is certainly true in cases where the total external length $\widehat{\ell}_{n}$ does not exceed the total internal length $\check{\ell}_{n}$, then we have

$$
\check{\ell}_{n} \stackrel{P}{\sim} \int_{2}^{n} \frac{x}{\mu(x)} d x-\frac{n^{2}}{\mu(n)} \sim \int_{2}^{n}\left(\frac{x}{\mu(x)}-\frac{n}{\mu(n)}\right) d x
$$

To provide some examples let us introduce the following class of coalescents.

Definition. We call the $\Lambda$-coalescent regularly varying with exponent $0 \leq \alpha \leq 2$, if $\Lambda(\{0\})=0$ and if as $y \rightarrow 0$

$$
\int_{(y, 1]} \frac{\Lambda(d p)}{p^{2}} \sim y^{-\alpha} L\left(\frac{1}{y}\right)
$$

with a function $L$ slowly varying at infinity.

This generalizes the notion of Berestycki et al [3] of a strong regularly varying coalescent.

Examples. (i) The Kingman case: If $\Lambda(\{0\})>0$, then $\mu(x) / x^{2} \sim \Lambda(\{0\}) / 2$, thus

$$
\ell_{n} \stackrel{1}{\sim} \frac{2 \log n}{\Lambda(\{0\})} \quad \text { and } \quad \hat{\ell}_{n} \stackrel{P}{\sim} \frac{2}{\Lambda(\{0\})}
$$

as $n \rightarrow \infty$. Here the internal total lengths completely dominates the external ones, and we have

$$
\check{\ell}_{n} \stackrel{1}{\sim} \frac{2 \log n}{\Lambda(\{0\})}
$$

(ii) Regulary varying coalescents with exponent $1<\alpha<2$ come down from infinity as can be easily checked by the above criterion. They fulfil (see Lemma 2 (ii) below)

$$
\mu(x) \sim \frac{\Gamma(2-\alpha)}{\alpha-1} x^{\alpha} L(x)
$$

as $x \rightarrow \infty$. Hence (having in mind how to integrate regulary varying functions, see Thm. 1 (b), Section VIII. 9 in Feller [11])

$$
\ell_{n} \stackrel{1}{\sim} \frac{\alpha-1}{(2-\alpha) \Gamma(2-\alpha)} \frac{n^{2-\alpha}}{L(n)} \text { and } \widehat{\ell}_{n} \stackrel{P}{\sim} \frac{\alpha-1}{\Gamma(2-\alpha)} \frac{n^{2-\alpha}}{L(n)}
$$

and consequently

$$
\check{\ell}_{n} \stackrel{P}{\sim} \frac{(\alpha-1)^{2}}{(2-\alpha) \Gamma(2-\alpha)} \frac{n^{2-\alpha}}{L(n)} \stackrel{P}{\sim} \frac{\alpha-1}{2-\alpha} \widehat{\ell}_{n}
$$

Here the external and the internal lengths are of the same order.
In other cases $\check{\ell}_{n}$ is of smaller order than $\widehat{\ell}_{n}$. Then a large part of internal length will be located close to the coalescent tree's root, where extremely large mergers may take over (which is definitely the case for coalescents not coming down from infinity). Still the internal length may obey the law of large numbers suggested above. The following theorem presents a situation of special interest. Define for a slowly varying function $L$ and for $x \geq 1$

$$
L^{*}(x):=\int_{1}^{x} \frac{L(y)}{y} d y
$$

Theorem 3. Assume that the $\Lambda$-coalescent has no dust component and is regulary varying with exponent $\alpha=1$. Then

$$
\check{\ell}_{n} \stackrel{1}{\sim} \int_{2}^{n}\left(\frac{x}{\mu(x)}-\frac{n}{\mu(n)}\right) d x
$$

and

$$
\int_{2}^{n}\left(\frac{x}{\mu(x)}-\frac{n}{\mu(n)}\right) d x \sim \frac{n L(n)}{L^{*}(n)^{2}}
$$

as $n \rightarrow \infty$.
Below we prove (Lemma 2 (ii)) that the function $L^{*}$ is slowly varying at infinity, too, and that $L(x)=o\left(L^{*}(x)\right)$ as $x \rightarrow \infty$. In comparison with Theorem 2 we see that $\breve{\ell}_{n}=o_{P}\left(\widehat{\ell}_{n}\right)$ for regulary varying coalescents with exponent 1. In particular, for the Bolthausen-Sznitman coalescent Theorems 2 and 3 yield

$$
\widehat{\ell}_{n} \stackrel{P}{\sim} \frac{n}{\log n} \quad \text { and } \quad \check{\ell}_{n} \stackrel{1}{\sim} \frac{n}{\log ^{2} n} .
$$

The latter approximation was already obtained in Kersting et al 15.
Our last object of investigation concerns lengths of higher order. A branch of order $a \geq 2$ is by definition an internal branch carrying a subtree with $a$ leaves out of the original sample. In this context we consider external branches as branches of order 1. Denote the number of branches of order $a \geq 1$ present at time $t \geq 0$ as $\widehat{N}_{n, a}(t)$, notably $\widehat{N}_{n, 1}(t)=\widehat{N}_{n}(t)$. Then the total length of all these branches is given by

$$
\widehat{\ell}_{n, a}=\int_{0}^{\tilde{\tau}_{n}} \widehat{N}_{n, a}(t) d t, a \geq 1
$$

Theorem 4. Suppose that the $\Lambda$-coalescent has no dust component and is regulary varying with exponent $\alpha=1$. Then

$$
\widehat{\ell}_{n, 1} \stackrel{P}{\sim} \frac{n}{L^{*}(n)}
$$

whereas for $a \geq 2$

$$
\widehat{\ell}_{n, a} \stackrel{P}{\sim} \frac{1}{(a-1) a} \frac{n L(n)}{L^{*}(n)^{2}}
$$

as $n \rightarrow \infty$.
These formulas have interesting applications to the site frequency spectrum. It consists of the counts $M_{a}(n), a \geq 1$, specifying the numbers of mutations located on branches of order $a$, which can be distinguished in the various DNAs of the sample. The theorem yields

$$
M_{1}(n) \stackrel{P}{\sim} \theta \frac{n}{L^{*}(n)} \quad \text { and } \quad M_{a}(n) \stackrel{P}{\sim} \frac{\theta}{(a-1) a} \frac{n L(n)}{L^{*}(n)^{2}}, a \geq 2 .
$$

A corresponding result in the so-called infinite allele model was obtained by Basdevant and Goldschmidt [1]. They deal with the allele frequency spectrum and consider the special case of the Bolthausen-Sznitman coalescent. Analogue results for Beta coalescents coming down from infinity were presented by Berestycki, Berestycki and Schweinsberg [4], and more generally for
strongly regular varying coalescents with exponent $1<\alpha<2$ by Berestycki, Berestycki and Limic [3]. We conjecture that these results can be further extended to regular varying coalescents. Computational procedures for the general site frequency spectrum are due to Spence et al [22].

Theorem 4 illustrates that mutations show mainly up on external branches, whereas the tree structure of the coalescent becomes visible only at branches of higher order. This reflects that for regulary varying coalescents with exponent $\alpha=1$ mergers occur prefentially at a late time and close to the MRCA. Our proof will show that with probability asymptotically equal to 1 any mutation seen in exactly $a \geq 2$ individuals stems from an internal branch of order $a$ arised from one single merger. This is similar to findings of Basdevant and Goldschmidt.

Closing this introduction we briefly discuss our methods of proof, which differ from other approaches in the literature. They rest upon $L_{2}$-considerations and elementary martingale estimates, and they may well find further applications as indicated in two examples below. These methods deal with the time-discrete Markov chain $n=X_{0}>X_{1}>\ldots>X_{\tau_{n}}=1$, imbedded in the Markov process $N_{n}$. Let

$$
\Delta_{i}:=X_{i-1}-X_{i}, i \geq 1
$$

denote its downwards jump size resulting from the $i$-th merger. We shall present different laws of large numbers for expressions of the form $\sum_{i=0}^{\rho_{n}-1} f\left(X_{i}\right)$, with some function $f:[2, \infty) \rightarrow \mathbb{R}$ and with stopping times $\rho_{n}$ of the form

$$
\rho_{n}:=\min \left\{i \geq 0: X_{i} \leq r_{n}\right\},
$$

where $r_{n}, n \geq 1$, is some sequence of positive numbers.
Our approach specifies the following intuition:

$$
\sum_{i=0}^{\rho_{n}-1} f\left(X_{i}\right) \approx \sum_{i=0}^{\rho_{n}-1} f\left(X_{i}\right) \frac{\Delta_{i+1}}{\nu\left(X_{i}\right)} \approx \int_{r_{n}}^{n} f(x) \frac{d x}{\nu(x)}
$$

with

$$
\nu(x):=\frac{\mu(x)}{\lambda(x)}, x \geq 2, \quad \text { thus } \quad \nu(b)=\mathbf{E}\left[\Delta_{i+1} \mid X_{i}=b\right], b \geq 2 .
$$

The rationale behind these approximations is that the differences of both sums are small, because they build a martingale, whereas the second sum may be considered as a Riemann approximation of the right-hand integral. This latter approximation requires that the jump sizes $\Delta_{i+1}$ are small compared to the values $X_{i}$ of the Markov chain, and is only ensured, if the time

$$
\tilde{\rho}_{n}:=\inf \left\{t \geq 0: N_{n}(t)=X_{\rho_{n}}\right\}=\inf \left\{t \geq 0: N_{n}(t) \leq r_{n}\right\}
$$

of entrance into the interval $\left[1, r_{n}\right]$ converges to 0 in probability. Thus we strieve towards small time approximations.

The paper is organized as follows: Section 2 deals in detail with the rate functions. Section 3 contains our general laws of large numbers. Finally, our theorems are proved in Sections 4 to 7.

## 2 Properties of the rate functions

We extent the above sequences $\lambda(b)$ and $\mu(b), b \geq 2$, of rates to positive continuous functions $\lambda, \mu:[2, \infty) \rightarrow \mathbb{R}$ via the definitions

$$
\begin{align*}
& \lambda(x):=\int_{[0,1]}\left(1-(1-p)^{x}-x p(1-p)^{x-1}\right) \frac{\Lambda(d p)}{p^{2}}  \tag{3}\\
& \mu(x):=\int_{[0,1]}\left(x p-1+(1-p)^{x}\right) \frac{\Lambda(d p)}{p^{2}} \tag{4}
\end{align*}
$$

with $x \geq 2$. Note that $\mu(x) \geq \lambda(x)$ for all $x \geq 2$, since the integrands fulfil the corresponding inequality. Recall our notion

$$
\kappa(x):=\frac{\mu(x)}{x}, x \geq 2
$$

Lemma 1. (i) The functions $\lambda(x)$ and $\kappa(x), x \geq 2$, are increasing in $x$, and the functions $\lambda(x) /(x(x-1))$ and $\kappa(x) /(x-1), x \geq 2$, are decreasing.
(ii) For any $0<\chi<1$ as $x \rightarrow \infty$

$$
\lambda(x)=x^{2} \kappa^{\prime}(x)\left(1+O\left(x^{-\chi}\right)\right)
$$

(iii) The coalescent has no dust component, if and only if $\kappa(x) \rightarrow \infty$ as $x \rightarrow \infty$, and then $\kappa(x)=o(\lambda(x))$.

Proof. (i) The function $(1-p)^{x}+x p(1-p)^{x-1}=(1-p)^{x-1}(1+(x-1) p), x \geq 2$, respectively its logarithm has a negative derivative. From (3) we thus obtain monotonicity of $\lambda(x)$. Moreover, a partial integration yields

$$
\begin{equation*}
\frac{\lambda(x)}{x(x-1)}=\frac{\Lambda(\{0\})}{2}+\int_{0}^{1} y(1-y)^{x-2} \int_{(y, 1]} \frac{\Lambda(d p)}{p^{2}} d y \tag{5}
\end{equation*}
$$

implying that $\lambda(x) /(x(x-1))$ is decreasing for $x \geq 2$.
Similarly, from (4) and a partial integration we have

$$
\begin{equation*}
\kappa(x)=\frac{\mu(x)}{x}=\frac{x-1}{2} \Lambda(\{0\})+\int_{0}^{1}\left(1-(1-y)^{x-1}\right) \int_{(y, 1]} \frac{\Lambda(d p)}{p^{2}} d y \tag{6}
\end{equation*}
$$

which is increasing in $x$, and by another partial integration

$$
\begin{equation*}
\frac{\mu(x)}{x(x-1)}=\frac{\Lambda(\{0\})}{2}+\int_{0}^{1}(1-z)^{x-2} \int_{z}^{1} \int_{(y, 1]} \frac{\Lambda(d p)}{p^{2}} d y d z \tag{7}
\end{equation*}
$$

a decreasing function in $x$.
(ii) From (6) we have

$$
\begin{equation*}
\kappa^{\prime}(x)=\frac{\Lambda(\{0\})}{2}+\int_{0}^{1}(1-y)^{x-1} \log \frac{1}{1-y} \int_{(y, 1]} \frac{\Lambda(d p)}{p^{2}} d y \tag{8}
\end{equation*}
$$

From concavity $(1-y) \log \frac{1}{1-y} \leq y$ for $y \in[0,1]$, also $(1-y) \log \frac{1}{1-y} \sim y+O\left(y^{2}\right)$ for $y \rightarrow 0$. Thus, combining (5) and (8), for $0<\chi<1$ and a suitable $c \geq 1$

$$
\begin{aligned}
0 & \leq \frac{\lambda(x)}{x(x-1)}-\kappa^{\prime}(x) \\
& \leq c \int_{0}^{x^{-\chi}} y^{2}(1-y)^{x-2} \int_{(y, 1]} \frac{\Lambda(d p)}{p^{2}} d y+\int_{x^{-x}}^{1} y(1-y)^{x-2} \int_{(y, 1]} \frac{\Lambda(d p)}{p^{2}} d y \\
& \leq c x^{-\chi} \int_{0}^{x^{-\chi}} y(1-y)^{x-2} \int_{y}^{1} \frac{\Lambda(d p)}{p^{2}} d y+\left(1-x^{-\chi}\right)^{x-2} \int_{x^{-\chi}}^{1} y \int_{(y, 1]} \frac{\Lambda(d p)}{p^{2}} d y \\
& \leq c x^{-\chi} \int_{0}^{1} y(1-y)^{x-2} \int_{y}^{1} \frac{\Lambda(d p)}{p^{2}} d y+e^{-x^{-\chi}(x-2)} \int_{0}^{1} y \int_{(y, 1]} \frac{\Lambda(d p)}{p^{2}} d y \\
& \leq c x^{-\chi} \frac{\lambda(x)}{x(x-1)}+e^{2-x^{1-\chi}} \Lambda([0,1]) .
\end{aligned}
$$

Since $\lambda$ is an increasing function, this implies

$$
\kappa^{\prime}(x)=\frac{\lambda(x)}{x^{2}}+O\left(\frac{\lambda(x)}{x^{2+\chi}}\right),
$$

which is equivalent to our claim.
(iii) From (6) it follows by monotone convergence that

$$
\kappa(x) \rightarrow \infty \cdot \Lambda(\{0\})+\int_{0}^{1} \int_{(y, 1]} \frac{\Lambda(d p)}{p^{2}} d y
$$

or

$$
\kappa(x) \rightarrow \int_{[0,1]} \frac{\Lambda(d p)}{p}
$$

This formula implies our first claim. As to the second one, because of the monotonicity statements of part (i) it is sufficient to show $\mu(b)=o(b \lambda(b))$ along natural numbers $b$. For $0<\eta<1$ we define

$$
\mu_{\eta}(b):=\sum_{2 \leq k \leq \eta b}(k-1)\binom{b}{k} \int_{[0,1]} p^{k}(1-p)^{b-k} \frac{\Lambda(d p)}{p^{2}}
$$

Then, in view of the well-known formula for the second factorial moment of binomials,

$$
\begin{aligned}
\mu(b)-\mu_{\eta}(b) & =\sum_{\eta b<k \leq b}(k-1)\binom{b}{k} \int_{[0,1]} p^{k}(1-p)^{b-k} \frac{\Lambda(d p)}{p^{2}} \\
& \leq \frac{1}{\eta b} \int_{[0,1]} \sum_{k=0}^{b} k(k-1)\binom{b}{k} p^{k}(1-p)^{b-k} \frac{\Lambda(d p)}{p^{2}} \\
& =\frac{1}{\eta b} \int_{[0,1]} b(b-1) p^{2} \frac{\Lambda(d p)}{p^{2}}=\frac{(b-1) \Lambda([0,1])}{\eta} .
\end{aligned}
$$

As just shown we have $\mu(b) / b \rightarrow \infty$ in the dustless case, hence we obtain for any $\eta>0$

$$
\begin{equation*}
\frac{\mu_{\eta}(b)}{\mu(b)} \rightarrow 1 \tag{9}
\end{equation*}
$$

as $b \rightarrow \infty$. It follows

$$
\mu(b) \sim \mu_{\eta}(b) \leq \eta b \lambda(b)
$$

for each $\eta>0$. This implies our claim.
First consequences of the previous results are contained in the next lemma.
Lemma 2. Let the coalescent be regulary varying with exponent $\alpha$.
(i) If $0 \leq \alpha<2$, then

$$
\lambda(x) \sim \Gamma(2-\alpha) x^{\alpha} L(x)
$$

as $x \rightarrow \infty$, and for $k \geq 2$

$$
\binom{b}{k} \frac{\lambda_{b, k}}{\lambda(b)} \rightarrow \frac{\alpha}{\Gamma(2-\alpha)} \frac{\Gamma(k-\alpha)}{k!}
$$

as $b \rightarrow \infty$.
(ii) The coalescent has no dust component, if and only if $\int_{1}^{\infty} x^{\alpha-2} L(x) d x=\infty$. Then $\alpha \geq 1$ and we have

$$
\kappa(x) \sim \begin{cases}\frac{\Gamma(2-\alpha)}{\alpha-1} x^{\alpha-1} L(x) & \text { for } 1<\alpha<2 \\ L^{*}(x) & \text { for } \alpha=1\end{cases}
$$

as $x \rightarrow \infty$, with a function $L^{*}$ given by

$$
L^{*}(x):=\int_{1}^{x} \frac{L(y)}{y} d y, x \geq 1
$$

$L^{*}$ is slowly varying at infinity and satisfies $L(x)=o\left(L^{*}(x)\right)$ as $x \rightarrow \infty$.
For $1<\alpha<2$ the convergence result on $\lambda_{b, k}$ has already been obtained by Delmas et al 8]. In this case they also have asymptotic estimates on $\lambda(x)$ and $\mu(x)$ under the assumption that the slowly varying function $L$ is constant.

Proof. (i) Let $1 \leq k \leq b$ be natural numbers. Starting from the identity

$$
1-(1-p)^{b}-b p(1-p)^{b-1}-\cdots-\binom{b}{k} p^{k}(1-p)^{b-k}=\binom{b}{k}(b-k) \int_{0}^{p} y^{k}(1-y)^{b-k-1} d y
$$

we obtain

$$
\begin{aligned}
\lambda(b)-\sum_{j=2}^{k}\binom{b}{j} \lambda_{b, j} & =\binom{b}{k}(b-k) \int_{[0,1]} \int_{0}^{p} y^{k}(1-y)^{b-k-1} d y \frac{\Lambda(d p)}{p^{2}} \\
& =\binom{b}{k}(b-k) \int_{0}^{1} y^{k}(1-y)^{b-k-1} \int_{(y, 1]} \frac{\Lambda(d p)}{p^{2}} d y .
\end{aligned}
$$

Taking account of the definition of regular varying coalescents, it is no loss of generality to specify the function $L$ in such a way that $\int_{(y, 1]} p^{-2} \Lambda(d p)=y^{-\alpha} L(1 / y)$ for $0<y \leq 1$. It follows that

$$
\begin{aligned}
\lambda(b)-\sum_{j=2}^{k}\binom{b}{j} \lambda_{b, j} & =\binom{b}{k}(b-k) \int_{0}^{1} y^{k-\alpha}(1-y)^{b-k-1} L\left(\frac{1}{y}\right) d y \\
& =\binom{b}{k}(b-k) b^{\alpha-k-1} L(b) \int_{0}^{b} z^{k-\alpha}\left(1-\frac{z}{b}\right)^{b-k-1} \frac{L(b / z)}{L(b)} d z,
\end{aligned}
$$

where for $k=1$ we set the value of the left-hand sum equal to 0 .
Since the function $L$ is slowly varying, the right-hand integrand converges pointwise to the limit $z^{k-\alpha} e^{-z}$. Also by the fundamental representation theorem of slowly varying functions (see Feller [11] Section XIII.9, Corollary) we have $L(b) \sim c \exp \left(\int_{0}^{b} \eta(z) z^{-1} d z\right)$ with a constant $c>0$ and a function $\eta(z)=o(z)$ as $z \rightarrow \infty$. This implies that for any $\varepsilon>0$ we have $L(b / z) \leq z^{\varepsilon} L(b)$ for $z \geq 1$ and $L(b / z) \leq z^{-\varepsilon} L(b)$ for $z \leq 1$, if only $b$ is sufficiently large. Hence, for large $b$ we may dominate the above integrand by the function $z^{k-\alpha} \max \left(z^{\varepsilon}, z^{-\varepsilon}\right) e^{-z / 2}$. By the assumption $\alpha<2$ it is integrable for $k \geq 1$, if we choose $\varepsilon$ small enough. Thus by dominated convergence

$$
\lambda(b)-\sum_{j=2}^{k}\binom{b}{j} \lambda_{b, j} \sim \frac{b^{\alpha} L(b)}{k!} \int_{0}^{\infty} z^{k-\alpha} e^{-z} d z=\frac{b^{\alpha} L(b) \Gamma(k-\alpha+1)}{k!}
$$

as $b \rightarrow \infty$, or in other terms

$$
\lambda(b) \sim \Gamma(2-\alpha) b^{\alpha} L(b) \quad \text { and } \quad\binom{b}{k} \lambda_{b, k} \sim \frac{\alpha \Gamma(k-\alpha)}{k!} b^{\alpha} L(b)
$$

for $k \geq 2$. This implies our claim.
(ii) From part (i) and Lemma 1 (ii) we obtain

$$
\kappa^{\prime}(x) \sim \Gamma(2-\alpha) x^{\alpha-2} L(x)
$$

as $x \rightarrow \infty$. In view of Lemma 1 (iii) we are in the dustless case, iff $\kappa(x) \rightarrow \infty$, that is iff the integral $\int_{1}^{\infty} x^{\alpha-2} L(x) d x$ is divergent. This implies $\alpha \geq 1$ and the claimed asymptotic formulas for $\kappa$.

Finally, since $L$ is slowly varying at infinity, we have for $c>1$

$$
\begin{equation*}
L^{*}(c x)-L^{*}(x)=\int_{x}^{c x} \frac{L(y)}{y} d y \sim L(x) \int_{x}^{c x} \frac{1}{y} d y=L(x) \log c \tag{10}
\end{equation*}
$$

as $x \rightarrow \infty$. Because $L^{*}$ is increasing, this implies for any $d>1$ and large $x$

$$
0 \leq \frac{L^{*}(c x)}{L^{*}(x)}-1 \leq \frac{L^{*}(c x)-L^{*}(x)}{L^{*}(x)-L^{*}(x / d)} \sim \frac{\log c}{\log d}
$$

as $x \rightarrow \infty$. Since $d$ may be chosen arbitrarily large, it follows that $L^{*}$ is slowly varying. Consequently, choosing $c=e$ in 10,

$$
\frac{L(x)}{L^{*}(x)} \sim \frac{L^{*}(e x)-L^{*}(x)}{L^{*}(x)}=o(1)
$$

This finishes our proof.
Examples. We consider regulary varying coalescents with exponent $\alpha=1$.
(i) Let $L(x)=(\log x)^{\chi}$ with exponent $\chi>-1$. Then

$$
L^{*}(x)=\int_{0}^{\log x} y^{\chi} d y=\frac{1}{\chi+1}(\log x)^{\chi+1}=\frac{1}{\chi+1} L(x) \log x .
$$

For $-1<\chi \leq 0$ these coalescents neither have a dust component nor come down from infinity, and for $\chi>0$ they come down from infinity. The case $\chi=0$ covers the Bolthausen-Sznitman coalescent.
(ii) Let $L(x)=e^{(\log x)^{\chi}}$ with $0<\chi<1$. Then

$$
L^{*}(x)=\int_{0}^{\log x} e^{y^{\chi}} d y \sim \frac{1}{\chi} e^{(\log x)^{\chi}}(\log x)^{1-\chi}=\frac{1}{\chi} L(x)(\log x)^{1-\chi} .
$$

These coalescents come down from infinity.

## 3 Some general laws of large numbers

The laws of large numbers of this section apply not only to branch lengths of $\Lambda$-coalescents. As explained in the introduction, they concern the discrete-time Markov chains $X=\left(X_{i}\right)_{i \in \mathbb{N}_{0}}$ embedded in the lineage counting processes. For notational ease we do not account here for the dependence of the chains $X$ on $n$. Thus $n=X_{0}>X_{1}>\cdots>X_{\tau_{n}-1}>X_{\tau_{n}}=1$ denote the states which the process $N_{n}$ is successively visiting, and $\tau_{n}:=\min \left\{i \geq 0: X_{i}=1\right\}$ is the respective number of merging events. For convenience we set $X_{i}=1$ for all natural numbers $i>\tau_{n}$. Also let for $i \geq 1$ be $W_{i}$, the waiting times of the process $N_{n}$ in the states $X_{i}$ and

$$
\Delta_{i}:=X_{i-1}-X_{i} .
$$

Recall that

$$
\mathbf{E}\left[\Delta_{i+1} \mid X_{i}=b\right]=\nu(b):=\frac{\mu(b)}{\lambda(b)} .
$$

For sequences $r_{n}, s_{n} \geq 2, n \geq 1$, of positive numbers we set

$$
\rho_{n}:=\min \left\{i \geq 0: X_{i} \leq r_{n}\right\}, \sigma_{n}:=\min \left\{i \geq 0: X_{i} \leq s_{n}\right\}, \tilde{\rho}_{n}:=\inf \left\{t \geq 0: N_{n}(t) \leq r_{n}\right\}
$$

Proposition 1. Assume that the coalescent has no dust component. Let $f:[2, \infty) \rightarrow \mathbb{R}$ be a non-negative function with the property that $x^{\beta} f(x)$ is increasing and $x^{-\beta} f(x)$ is decreasing in $x$ for some $\beta>0$. Let $2 \leq r_{n} \leq s_{n} \leq n, n \geq 1$, be two sequences of numbers fulfilling

$$
\begin{equation*}
r_{n} \leq \gamma s_{n} \tag{11}
\end{equation*}
$$

for all $n \geq 1$ and some $\gamma<1$. Also assume that

$$
\begin{equation*}
\tilde{\rho}_{n} \xrightarrow{P} 0 \tag{12}
\end{equation*}
$$

as $n \rightarrow \infty$. Then, as $n \rightarrow \infty$

$$
\sum_{i=\sigma_{n}}^{\rho_{n}-1} f\left(X_{i}\right) \stackrel{1}{\sim} \int_{r_{n}}^{s_{n}} f(x) \frac{d x}{\nu(x)}
$$

Also, as $n \rightarrow \infty$

$$
\mathbf{E}\left[\sum_{i=\rho_{n}}^{\tau_{n}-1} f\left(X_{i}\right)\right]=O\left(\int_{2}^{r_{n}} f(x) \frac{d x}{\nu(x)}\right) .
$$

Due to the assumption (12) this theorem addresses the coalescent's evolution in only a short initial time interval. This takes double effect: First, as seen from the next lemma, the chain is kept away from the occurence of huge jumps $\Delta_{i}$ being of the same order as the chain's values. Second
the chain $X$ is prevented from taking too small values where larger fluctuations may become obstructive. Note that for any $\Lambda$-coalescent the passage times $\inf \left\{t \geq 0: N_{n}(t) \leq r\right\}$ below some number $r>1$ are bounded away from 0 uniformly in $n \in \mathbb{N}$. Therefore the assumption (12) enforces that

$$
\begin{equation*}
r_{n} \rightarrow \infty \tag{13}
\end{equation*}
$$

as $n \rightarrow \infty$. Actually, boths requirements are equivalent if the coalescent comes down from infinity, otherwise the assumption (12) is the more incisive one.

Example: total number of mergers. If we choose $f \equiv 1$ and $s_{n}=n$, then $\sum_{i=0}^{\rho_{n}-1} f\left(X_{i}\right)$ is equal to the number of mergers up to time $\tilde{\rho}_{n}$. For coalescents coming down from infinity we may consider any divergent sequence $r_{n} \leq \gamma n$. In particular, since $\int_{2}^{\infty} \frac{d x}{\nu(x)}=\infty$, we may choose the $r_{n}$ in such a way that $r_{n}=o\left(\int_{r_{n}}^{n} \frac{d x}{\nu(x)}\right)$. This implies that the number of mergers after the moment $\tilde{\rho}_{n}$ are of negligible order, and that for the total number $\tau_{n}$ of mergers we have

$$
\tau_{n} \stackrel{1}{\sim} \int_{2}^{n} \frac{d x}{\nu(x)} .
$$

Away from coalescents coming down from infinity the scope of this formula is unclear. For the Bolthausen-Sznitman coalescent it is valid (see [12]).

The proof of Proposition 1 is prepared by the next lemma.
Lemma 3. (i) If the coalescent has no dust component and if $\int_{r_{n}}^{n} \mu(x)^{-1} d x \rightarrow 0$, then as $n \rightarrow \infty$

$$
\mathbf{E}\left[\tilde{\rho}_{n}\right] \rightarrow 0 .
$$

(ii) If $\tilde{\rho}_{n} \xrightarrow{P} 0$, then for any $\eta>0$ as $n \rightarrow \infty$

$$
\mathbf{P}\left(\Delta_{i+1}>\eta X_{i} \text { for some } i<\rho_{n}\right) \rightarrow 0 .
$$

Proof. (i) Given $X$ the waiting times $W_{i}$ are exponential with expectation $1 / \lambda\left(X_{i}\right)$. Therefore

$$
\mathbf{E}\left[\tilde{\rho}_{n}\right]=\mathbf{E}\left[\sum_{i=0}^{\rho_{n}-1} W_{i}\right]=\mathbf{E}\left[\sum_{i=0}^{n-1} \frac{1}{\lambda\left(X_{i}\right)} ; X_{i}>r_{n}\right] .
$$

Also $\mathbf{E}\left[\Delta_{i+1} \mid X_{i}\right]=\nu\left(X_{i}\right)$ a.s., thus by the Markov property

$$
\mathbf{E}\left[\tilde{\rho}_{n}\right]=\sum_{i=0}^{n-1} \mathbf{E}\left[\frac{\Delta_{i+1}}{\lambda\left(X_{i}\right) \nu\left(X_{i}\right)} ; X_{i}>r_{n}\right]=\mathbf{E}\left[\sum_{i=0}^{\rho_{n}-1} \frac{\Delta_{i+1}}{\mu\left(X_{i}\right)}\right] .
$$

From Lemma 1 (i) we have that $\mu(x)=x \kappa(x)$ is increasing. Also $\Delta_{i+1} \leq X_{i}$, hence

$$
\mathbf{E}\left[\tilde{\rho}_{n}\right] \leq \mathbf{E}\left[\sum_{i=0}^{\rho_{n}-2} \int_{X_{i+1}}^{X_{i}} \frac{d x}{\mu(x)}+\frac{X_{\rho_{n}-1}}{\mu\left(X_{\rho_{n}-1}\right)}\right]=\mathbf{E}\left[\int_{X_{\rho_{n}-1}}^{n} \frac{d x}{\mu(x)}+\frac{1}{\kappa\left(X_{\rho_{n}-1}\right)}\right],
$$

and since $\kappa$ is an increasing function, we end up with the estimate

$$
\mathbf{E}\left[\tilde{\rho}_{n}\right] \leq \int_{r_{n}}^{n} \frac{d x}{\mu(x)}+\frac{1}{\kappa\left(r_{n}\right)}
$$

Our assumptions imply $r_{n} \rightarrow \infty$. Therefore, since there is no dust component, we have $\kappa\left(r_{n}\right) \rightarrow \infty$ by Lemma 1 (iii). This entails our claim.
(ii) For $b \geq 2 / \eta$ we have

$$
\begin{aligned}
\mathbf{P}\left(\Delta_{i+1}>\eta X_{i} \mid X_{i}=b\right) & =\sum_{k>\eta b} \frac{1}{\lambda(b)} \int_{[0,1]}\binom{b}{k} p^{k}(1-p)^{b-k} \frac{\Lambda(d p)}{p^{2}} \\
& \leq \frac{1}{\lambda(b)} \int_{[0,1]} \sum_{k>\eta b} \frac{2}{\eta^{2}}\binom{b-2}{k-2} p^{k-2}(1-p)^{(b-2)-(k-2)} \Lambda(d p) \\
& \leq \frac{c}{\lambda(b)}
\end{aligned}
$$

with $c:=2 \Lambda([0,1]) / \eta^{2}$.
Let $\chi_{0}:=0$ and $\chi_{i}:=W_{0}+\cdots+W_{i-1}, i \geq 1$, which is the moment of the $i$-th jump. Then

$$
\begin{aligned}
\mathbf{P}\left(\Delta_{i+1}>\eta X_{i}\right. & \text { for some } \left.i<\rho_{n}, \tilde{\rho}_{n} \leq 1\right) \\
& \leq \mathbf{P}\left(\Delta_{i+1}>\eta X_{i}, X_{i}>r_{n}, \chi_{i} \leq 1 \text { for some } i<n\right) \\
& \leq \sum_{i=0}^{n-1} \mathbf{E}\left[\mathbf{P}\left(\Delta_{i+1}>\eta X_{i} \mid X_{i}\right) ; X_{i}>r_{n}, \chi_{i} \leq 1\right] \\
& \leq \sum_{i=0}^{n-1} \mathbf{E}\left[\frac{c}{\lambda\left(X_{i}\right)} ; X_{i}>r_{n}, \chi_{i} \leq 1\right]
\end{aligned}
$$

Also, because $\lambda(x)$ is increasing, for $X_{i} \geq 2$

$$
\mathbf{E}\left[W_{i} I_{\left\{W_{i} \leq 1\right\}} \mid X_{i}\right]=\int_{0}^{1} t \lambda\left(X_{i}\right) e^{-\lambda\left(X_{i}\right) t} d t=\frac{1}{\lambda\left(X_{i}\right)} \int_{0}^{\lambda\left(X_{i}\right)} u e^{-u} d u \geq \frac{d}{\lambda\left(X_{i}\right)}
$$

with $d:=\int_{0}^{\lambda(2)} u e^{-u} d u>0$. This allows for the estimate

$$
\mathbf{P}\left(\Delta_{i+1}>\eta X_{i} \text { for some } i<\rho_{n}, \tilde{\rho}_{n} \leq 1\right)
$$

$$
\begin{aligned}
& =\frac{c}{d} \sum_{i=0}^{n-1} \mathbf{E}\left[W_{i} ; X_{i}>r_{n}, W_{i} \leq 1, W_{0}+\cdots+W_{i-1} \leq 1\right] \\
& \leq \frac{c}{d} \mathbf{E}\left[\sum_{i=0}^{\rho_{n}-1} W_{i} I_{\left\{W_{0}+\cdots+W_{i} \leq 2\right\}}\right] \\
& \leq \frac{c}{d} \mathbf{E}\left[2 \wedge \sum_{i=0}^{\rho_{n}-1} W_{i}\right] \\
& =\frac{c}{d} \mathbf{E}\left[2 \wedge \tilde{\rho}_{n}\right]
\end{aligned}
$$

and consequently

$$
\mathbf{P}\left(\Delta_{i+1}>\eta X_{i} \text { for some } i<\rho_{n}\right) \leq \frac{c}{d} \mathbf{E}\left[\tilde{\rho}_{n} \wedge 2\right]+\mathbf{P}\left(\tilde{\rho}_{n}>1\right) .
$$

Thus by assumption and dominated convergence our claim follows.

Proof of Proposition 1. (i) We start with some preliminary estimates. Since $x^{-\beta} f(x)$ is a decreasing function, we have for $0<\chi<1$ and $0 \leq y \leq \chi z, y \leq z-2$

$$
y f(z) \leq z^{\beta} \int_{z-y}^{z} x^{-\beta} f(x) d x \leq z^{\beta}(z-y)^{-\beta} \int_{z-y}^{z} f(x) d x \leq(1-\chi)^{-\beta} \int_{z-y}^{z} f(x) d x
$$

Similary, using that $x^{\beta} f(x)$ is increasing we obtain a lower bound. Altogether, for $0<\chi<1$, $0 \leq y \leq \chi z$ and $y \leq z-2$

$$
\begin{equation*}
(1-\chi)^{\beta} \int_{z-y}^{z} f(x) d x \leq y f(z) \leq(1-\chi)^{-\beta} \int_{z-y}^{z} f(x) d x \tag{14}
\end{equation*}
$$

Moreover, for any $\varepsilon>0$ there is an $\eta>0$ such that

$$
\begin{equation*}
(1-\varepsilon) \int_{(1-\eta) r_{n}}^{s_{n}} f(x) d x \leq \int_{r_{n}}^{s_{n}} f(x) d x \leq(1+\varepsilon) \int_{r_{n}}^{(1-\eta) s_{n}} f(x) d x \tag{15}
\end{equation*}
$$

for all $n$. We prove the left-hand inequality. By monotonicity of $x^{\beta}$ and $x^{\beta} f(x)$ we have with $\gamma$ as in (11)

$$
\begin{aligned}
\int_{(1-\eta) r_{n}}^{r_{n}} f(x) d x & \leq\left((1-\eta) r_{n}\right)^{-\beta} \int_{(1-\eta) r_{n}}^{r_{n}} f(x) x^{\beta} d x \\
& \leq\left((1-\eta) r_{n}\right)^{-\beta} \frac{\eta}{\eta+\gamma^{-1}-1} \int_{(1-\eta) r_{n}}^{r_{n} / \gamma} f(x) x^{\beta} d x \\
& \leq(\gamma(1-\eta))^{-\beta} \frac{\eta}{\eta+\gamma^{-1}-1} \int_{(1-\eta) r_{n}}^{r_{n} / \gamma} f(x) d x .
\end{aligned}
$$

From condition (11) it follows that

$$
\int_{(1-\eta) r_{n}}^{r_{n}} f(x) d x \leq(\gamma(1-\eta))^{-\beta} \frac{\eta}{\eta+\gamma^{-1}-1} \int_{(1-\eta) r_{n}}^{s_{n}} f(x) d x \leq \varepsilon \int_{(1-\eta) r_{n}}^{s_{n}} f(x) d x
$$

for sufficiently small $\eta>0$. This implies the left-hand inequality of (15). The other one follows similarly, now using the monotonicity of $x^{-\beta} f(x)$.

We note that $(x-1) / x^{2}$ is a decreasing function for $x \geq 2$. Therefore, in view of Lemma 1 the functions $\lambda(x)$ and $\mu(x)$ are increasing and $\lambda(x) / x^{3}$ and $\mu(x) / x^{3}$ are decreasing for $x \geq 2$. Thus the function $f(x) / \nu(x)=f(x) \lambda(x) / \mu(x)$ fulfils the same assumptions as $f(x)$, with $\beta$ replaced by $\beta+3$. Accordingly, we shall use the preceding estimates with $f(x)$ replaced by $f(x) / \nu(x)$ (and $\beta$ replaced by $\beta+3$ ).
(ii) Recall from the previous section for given $\eta>0$ and for $b \geq 2$ the notion

$$
\mu_{\eta}(b):=\sum_{2 \leq k \leq \eta b}(k-1) \int_{[0,1]}\binom{b}{k} p^{k-2}(1-p)^{b-k} \Lambda(d p)
$$

and let for $b \geq 2$

$$
\nu_{\eta}(b):=\frac{\mu_{\eta}(b)}{\lambda(b)}=\mathbf{E}\left[\Delta_{i+1} I_{\left\{\Delta_{i+1} \leq \eta b\right\}} \mid X_{i}=b\right]
$$

Note that $\nu_{\eta}(b)>0$ for $b \geq 2 / \eta$. Therefore, for $0<\eta<1$ and natural numbers $n$ satisfying $r_{n} \geq 2 / \eta$ we may define the random variables

$$
R_{n}=R_{n, \eta}:=\sum_{i=\sigma_{n}}^{\rho_{n}-1} f\left(X_{i}\right) \frac{\Delta_{i+1} I_{\left\{\Delta_{i+1} \leq \eta X_{i}\right\}}}{\nu_{\eta}\left(X_{i}\right)} .
$$

Given $\eta$ these random variables are in view of (13) well-defined up to finitely many $n$. We shall use them below as an intermediate approximation to $\sum_{i=\sigma_{n}}^{\rho_{n}-1} f\left(X_{i}\right)$. We estimate $R_{n}$ from above and below. From (14) with $z=X_{i}, y=\Delta_{i+1}$ and $\chi=\eta$ and with $f(x) / \nu(x)$ replacing $f(x)$ we have on the event that $\Delta_{i+1} \leq \eta X_{i}$

$$
\frac{f\left(X_{i}\right)}{\nu\left(X_{i}\right)} \Delta_{i+1} \leq(1-\eta)^{-\beta-3} \int_{X_{i+1}}^{X_{i}} f(x) \frac{d x}{\nu(x)}
$$

consequently

$$
R_{n} \leq(1-\eta)^{-\beta-3} \sum_{i=\sigma_{n}}^{\rho_{n}-1} \frac{\nu\left(X_{i}\right)}{\nu_{\eta}\left(X_{i}\right)} I_{\left\{\Delta_{i+1} \leq \eta X_{i}\right\}} \int_{X_{i+1}}^{X_{i}} f(x) \frac{d x}{\nu(x)}
$$

and by definition of $\rho_{n}$

$$
\begin{equation*}
R_{n} \leq(1-\eta)^{-\beta-3} \sup _{b \geq r_{n}} \frac{\mu(b)}{\mu_{\eta}(b)} \int_{r_{n}(1-\eta)}^{s_{n}} f(x) \frac{d x}{\nu(x)} \tag{16}
\end{equation*}
$$

Therefore, in view of (9) and (15) and since $r_{n} \rightarrow \infty$, there is for given $\varepsilon>0$ an $\eta>0$ fulfilling

$$
\begin{equation*}
R_{n} \leq(1+\varepsilon) \int_{r_{n}}^{s_{n}} f(x) \frac{d x}{\nu(x)} \tag{17}
\end{equation*}
$$

for all $n$ sufficiently large. Similarly, for given $\varepsilon>0$ there is an $\eta>0$ satisfying for large $n$ the inequality

$$
\begin{equation*}
R_{n} \geq(1-\varepsilon) \int_{r_{n}}^{s_{n}} f(x) \frac{d x}{\nu(x)} \text { on the event }\left\{\Delta_{i+1} \leq \eta X_{i} \text { for all } i<\rho_{n}\right\} \tag{18}
\end{equation*}
$$

(iii) Now observe that the random variables $M_{0}:=0$ and

$$
M_{k}:=\sum_{i=0}^{k \wedge \tau_{n}-1}\left(f\left(X_{i}\right) \frac{\Delta_{i+1} I_{\left\{\Delta_{i+1} \leq \eta X_{i}\right\}}}{\nu_{\eta}\left(X_{i}\right)}-f\left(X_{i}\right)\right), k \geq 1
$$

build a martingale $M=\left(M_{k}\right)_{k \geq 0}$. The optional sampling theorem yields

$$
\begin{aligned}
\mathbf{E}\left[\left(R_{n}-\sum_{i=\sigma_{n}}^{\rho_{n}-1} f\left(X_{i}\right)\right)^{2}\right] & =\mathbf{E}\left[\left(M_{\rho_{n}}-M_{\sigma_{n}}\right)^{2}\right] \\
& \leq \mathbf{E}\left[\sum_{i=\sigma_{n}}^{\rho_{n}-1} \frac{f\left(X_{i}\right)^{2} \Delta_{i+1}^{2}}{\nu_{\eta}\left(X_{i}\right)^{2}} I_{\left\{\Delta_{i+1} \leq \eta X_{i}\right\}}\right] \\
& \leq \eta \mathbf{E}\left[\sum_{i=\sigma_{n}}^{\rho_{n}-1} \frac{f\left(X_{i}\right)^{2} X_{i} \Delta_{i+1}}{\nu_{\eta}\left(X_{i}\right)^{2}} I_{\left\{\Delta_{i+1} \leq \eta X_{i}\right\}}\right] .
\end{aligned}
$$

Letting $x_{n}$ be the point where the function $x f(x) / \nu_{\eta}(x)$ takes its maximal value within the interval $\left[r_{n}, s_{n}\right]$, it follows

$$
\mathbf{E}\left[\left(R_{n}-\sum_{i=\sigma_{n}}^{\rho_{n}-1} f\left(X_{i}\right)\right)^{2}\right] \leq \eta \frac{x_{n} f\left(x_{n}\right)}{\nu_{\eta}\left(x_{n}\right)} \mathbf{E}\left[\sum_{i=\sigma_{n}}^{\rho_{n}-1} \frac{f\left(X_{i}\right) \Delta_{i+1}}{\nu_{\eta}\left(X_{i}\right)} I_{\left\{\Delta_{i+1} \leq \eta X_{i}\right\}}\right]=\eta \frac{x_{n} f\left(x_{n}\right)}{\nu_{\eta}\left(x_{n}\right)} \mathbf{E}\left[R_{n}\right] .
$$

By the assumption (11) it follows that there are numbers $\xi_{n}, n \geq 1$, such that

$$
r_{n} \leq \gamma \xi_{n} \leq x_{n} \leq \xi_{n} \leq s_{n}
$$

Using monotonicity of $x^{\beta+3} f(x) / \nu(x)$ and (14) with $z=\xi_{n}, y=(1-\gamma) \xi_{n}, \chi=1-\gamma$, it follows that

$$
(1-\gamma) \frac{x_{n} f\left(x_{n}\right)}{\nu\left(x_{n}\right)} \leq\left(\frac{\xi_{n}}{x_{n}}\right)^{\beta+2}(1-\gamma) \frac{\xi_{n} f\left(\xi_{n}\right)}{\nu\left(\xi_{n}\right)} \leq \gamma^{-2 \beta-5} \int_{\gamma \xi_{n}}^{\xi_{n}} f(x) \frac{d x}{\nu(x)} \leq \gamma^{-2 \beta-5} \int_{r_{n}}^{s_{n}} f(x) \frac{d x}{\nu(x)}
$$

hence

$$
\mathbf{E}\left[\left(R_{n}-\sum_{i=\sigma_{n}}^{\rho_{n}-1} f\left(X_{i}\right)\right)^{2}\right] \leq \eta \frac{\gamma^{-2 \beta-5}}{1-\gamma} \sup _{x \geq 2 / \eta} \frac{\nu(x)}{\nu_{\eta}(x)} \mathbf{E}\left[R_{n}\right] \int_{r_{n}}^{s_{n}} f(x) \frac{d x}{\nu(x)} .
$$

Finally, the formulas (9) and (17) yield that for any $\varepsilon>0$ there is an $\eta>0$ fulfilling

$$
\begin{equation*}
\mathbf{E}\left[\left(R_{n}-\sum_{i=\sigma_{n}}^{\rho_{n}-1} f\left(X_{i}\right)\right)^{2}\right] \leq \varepsilon\left(\int_{r_{n}}^{s_{n}} f(x) \frac{d x}{\nu(x)}\right)^{2} . \tag{19}
\end{equation*}
$$

(iv) Putting pieces together, we obtain for given $\varepsilon>0$ and $\eta>0$

$$
\begin{aligned}
& \mathbf{P}\left(\left|\sum_{i=\sigma_{n}}^{\rho_{n}-1} f\left(X_{i}\right)-\int_{r_{n}}^{s_{n}} f(x) \frac{d x}{\nu(x)}\right| \geq \varepsilon \int_{r_{n}}^{s_{n}} f(x) \frac{d x}{\nu(x)}\right) \\
& \quad \leq \mathbf{P}\left(\left|R_{n}-\sum_{i=\sigma_{n}}^{\rho_{n}-1} f\left(X_{i}\right)\right| \geq \frac{\varepsilon}{2} \int_{r_{n}}^{s_{n}} f(x) \frac{d x}{\nu(x)}\right) \\
& \quad+\mathbf{P}\left(\left|R_{n}-\int_{r_{n}}^{s_{n}} f(x) \frac{d x}{\nu(x)}\right| \geq \frac{\varepsilon}{2} \int_{r_{n}}^{s_{n}} f(x) \frac{d x}{\nu(x)}, \Delta_{i+1} \leq \eta X_{i} \text { for all } i<\rho_{n}\right) \\
& \quad \quad+\mathbf{P}\left(\Delta_{i+1}>\eta X_{i} \text { for some } i<\rho_{n}\right) .
\end{aligned}
$$

From (19) for suitably chosen $\eta>0$ the first right-hand term becomes smaller than $\varepsilon$ and from (17) and (18) the second one vanishes for large $n$. Consulting also Lemma 3 (ii), we arrive at

$$
\mathbf{P}\left(\left|\sum_{i=\sigma_{n}}^{\rho_{n}-1} f\left(X_{i}\right)-\int_{r_{n}}^{s_{n}} f(x) \frac{d x}{\nu(x)}\right| \geq \varepsilon \int_{r_{n}}^{s_{n}} f(x) \frac{d x}{\nu(x)}\right) \leq \varepsilon
$$

for $n$ large enough. This means that

$$
\sum_{i=\sigma_{n}}^{\rho_{n}-1} f\left(X_{i}\right) \stackrel{P}{\sim} \int_{r_{n}}^{s_{n}} f(x) \frac{d x}{\nu(x)} .
$$

To show $L_{1}$-convergence it is by a convergence criterion due to F. Riesz sufficient to have

$$
\mathbf{E}\left[\sum_{i=\sigma_{n}}^{\rho_{n}-1} f\left(X_{i}\right)\right] \sim \int_{r_{n}}^{s_{n}} f(x) \frac{d x}{\nu(x)}
$$

as $n \rightarrow \infty$. From convergence in probability and Fatou's lemma we have

$$
\liminf _{n \rightarrow \infty} \mathbf{E}\left[\sum_{i=\sigma_{n}}^{\rho_{n}-1} f\left(X_{i}\right)\right] / \int_{r_{n}}^{s_{n}} f(x) \frac{d x}{\nu(x)} \geq 1
$$

On the other hand (17) yields for given $\varepsilon>0$ and suitable $\eta>0$ and large $n$

$$
\mathbf{E}\left[\sum_{i=\sigma_{n}}^{\rho_{n}-1} f\left(X_{i}\right)\right]=\mathbf{E}\left[R_{n}\right] \leq(1+\varepsilon) \int_{r_{n}}^{s_{n}} f(x) \frac{d x}{\nu(x)} .
$$

This gives our first claim.
(v) For the second claim we again use the random variables $R_{n}$, now for some $\eta>0$ (say $\eta=1 / 2)$ with $r_{n}=r:=2 / \eta$. Recall that for this choice the $R_{n}$ are well-defined for all $n$. From inequality (16) we obtain the estimate

$$
R_{n} \leq(1-\eta)^{-\beta-3} \sup _{b \geq 2 / \eta} \frac{\mu(b)}{\mu_{\eta}(b)} \int_{2}^{s_{n}} f(x) \frac{d x}{\nu(x)} .
$$

It follows

$$
\mathbf{E}\left[\sum_{i=\sigma_{n}}^{\tau_{n}-1} f\left(X_{i}\right)\right] \leq \sum_{b<2 / \eta} f(b)+\mathbf{E}\left[\sum_{i=\sigma_{n}}^{\rho_{n}-1} f\left(X_{i}\right)\right]=\sum_{b<2 / \eta} f(b)+\mathbf{E}\left[R_{n}\right] .
$$

Putting both estimates together and then replacing $\sigma_{n}$ by $\rho_{n}$ (which is just a change in notation), we arrive at our second claim.

The next proposition presents a version of Proposition 1 in continuous time. Recall that $\tilde{\tau}_{n}$ denotes the absorbtion time of the process $N_{n}$.

Proposition 2. Under the assumptions of Proposition 1, as $n \rightarrow \infty$

$$
\int_{\tilde{\sigma}_{n}}^{\tilde{\rho}_{n}} f\left(N_{n}(t)\right) d t \stackrel{1}{\sim} \int_{r_{n}}^{s_{n}} f(x) \frac{d x}{\mu(x)} .
$$

Also, as $n \rightarrow \infty$

$$
\mathbf{E}\left[\int_{\tilde{\rho}_{n}}^{\tilde{\tau}_{n}} f\left(N_{n}(t)\right) d t\right]=O\left(\int_{2}^{r_{n}} f(x) \frac{d x}{\mu(x)}\right) .
$$

Example. For $f(x) \equiv 1$ we obtain under the assumptions of Proposition 2

$$
\tilde{\rho}_{n} \stackrel{1}{\sim} \int_{r_{n}}^{n} \frac{d x}{\mu(x)}
$$

as $n \rightarrow \infty$.
Proof of Proposition 2. We have

$$
\int_{\tilde{\sigma}_{n}}^{\tilde{\rho}_{n}} f\left(N_{n}(t)\right) d t=\sum_{i=\sigma_{n}}^{\rho_{n}-1} f\left(X_{i}\right) W_{i}
$$

and

$$
\mathbf{E}\left[\sum_{i=\sigma_{n}}^{\rho_{n}-1} f\left(X_{i}\right) W_{i} \mid X\right]=\sum_{i=\sigma_{n}}^{\rho_{n}-1} \frac{f\left(X_{i}\right)}{\lambda\left(X_{i}\right)} .
$$

Thus for any $\eta>0$ by the Markov property

$$
\mathbf{E}\left[\left(\int_{\tilde{\sigma}_{n}}^{\tilde{\rho}_{n}} f\left(N_{n}(t)\right) d t-\sum_{i=\sigma_{n}}^{\rho_{n}-1} \frac{f\left(X_{i}\right)}{\lambda\left(X_{i}\right)}\right)^{2}\right]=\mathbf{E}\left[\sum_{i=\sigma_{n}}^{\rho_{n}-1} \frac{f\left(X_{i}\right)^{2}}{\lambda\left(X_{i}\right)^{2}}\right]=\mathbf{E}\left[R_{n}\right],
$$

where we now set

$$
R_{n}:=\sum_{i=\sigma_{n}}^{\rho_{n}-1} \frac{f\left(X_{i}\right)^{2}}{\lambda\left(X_{i}\right)^{2}} \frac{\Delta_{i+1} I_{\left\{\Delta_{i+1} \leq \eta X_{i}\right\}}}{\nu_{\eta}\left(X_{i}\right)} .
$$

Using (17) with $\varepsilon=1$, it follows

$$
\mathbf{E}\left[\left(\int_{\tilde{\sigma}_{n}}^{\tilde{\rho}_{n}} f\left(N_{n}(t)\right) d t-\sum_{i=\sigma_{n}}^{\rho_{n}-1} \frac{f\left(X_{i}\right)}{\lambda\left(X_{i}\right)}\right)^{2}\right] \leq 2 \int_{r_{n}}^{s_{n}} \frac{f(x)^{2}}{\lambda(x)^{2} \nu(x)} d x=2 \int_{r_{n}}^{s_{n}} \frac{f(x)^{2}}{\lambda(x) \mu(x)} d x .
$$

Furthermore, since we are in the dustless case, due to Lemma 1 (iii) we have

$$
\mathbf{E}\left[\left(\int_{\tilde{\sigma}_{n}}^{\tilde{\rho}_{n}} f\left(N_{n}(t)\right) d t-\sum_{i=\sigma_{n}}^{\rho_{n}-1} \frac{f\left(X_{i}\right)}{\lambda\left(X_{i}\right)}\right)^{2}\right] \leq o\left(\int_{r_{n}}^{s_{n}} \frac{x f(x)^{2}}{\mu(x)^{2}} d x\right) .
$$

Letting $x_{n}$ be the point, where $x f(x) / \mu(x)$ takes its maximum in the interval $\left[r_{n}, s_{n}\right]$, we obtain in the same manner as in the preceding proof

$$
\mathbf{E}\left[\left(\int_{\tilde{\sigma}_{n}}^{\tilde{\rho}_{n}} f\left(N_{n}(t)\right) d t-\sum_{i=\sigma_{n}}^{\rho_{n}-1} \frac{f\left(X_{i}\right)}{\lambda\left(X_{i}\right)}\right)^{2}\right]=o\left(\frac{x_{n} f\left(x_{n}\right)}{\mu\left(x_{n}\right)} \int_{r_{n}}^{s_{n}} \frac{f(x)}{\mu(x)} d x\right)=o\left(\left(\int_{r_{n}}^{s_{n}} \frac{f(x)}{\mu(x)} d x\right)^{2}\right) .
$$

On the other hand Proposition 1 implies

$$
\sum_{i=\sigma_{n}}^{\rho_{n}-1} \frac{f\left(X_{i}\right)}{\lambda\left(X_{i}\right)} \stackrel{1}{\sim} \int_{r_{n}}^{s_{n}} \frac{f(x)}{\lambda(x)} \frac{d x}{\nu(x)}=\int_{r_{n}}^{s_{n}} \frac{f(x)}{\mu(x)} d x .
$$

These last two formulas imply our first statement. Moreover

$$
\mathbf{E}\left[\int_{\tilde{\rho}_{n}}^{\tilde{\tau}_{n}} f\left(N_{n}(t)\right) d t\right]=\mathbf{E}\left[\sum_{i=\rho_{n}}^{\tau_{n}-1} \frac{f\left(X_{i}\right)}{\lambda\left(X_{i}\right)}\right],
$$

therefore our second claim follows from the second statement of Proposition 1.

Now we turn to the special case that $f(x)=1 / x, x \geq 2$, where Proposition 1 can be considerably extended. Here we content ourselves with the case $s_{n}=n$. Observe that the two next statements do not imply each other.

Proposition 3. Assume that the $\Lambda$-coalescent has no dust component. Let $2 \leq r_{n} \leq n, n \geq 1$, be a sequence of numbers fulfilling

$$
r_{n} \leq \gamma n
$$

for all $n \geq 1$ and some $\gamma<1$. Also assume that

$$
\tilde{\rho}_{n} \xrightarrow{P} 0
$$

as $n \rightarrow \infty$. Then

$$
\sum_{i=0}^{\rho_{n}-1} \frac{1}{X_{i}} \stackrel{1}{\sim} \log \frac{\kappa(n)}{\kappa\left(r_{n}\right)}
$$

and

$$
\max _{1 \leq j \leq \rho_{n}}\left|\sum_{i=0}^{j-1} \frac{1}{X_{i}}-\log \frac{\kappa(n)}{\kappa\left(X_{j}\right)}\right|=o_{P}(1)
$$

Proof. (i) The first statement is a special case of Proposition 1: due to Lemma 1 (ii) we have $1 /(x \nu(x))=\lambda(x) /(x \mu(x)) \sim \kappa^{\prime}(x) / \kappa(x)$ as $x \rightarrow \infty$. Therefore

$$
\int_{r_{n}}^{n} \frac{d x}{x \nu(x)} \sim \int_{r_{n}}^{n} \frac{\kappa^{\prime}(x) d x}{\kappa(x)}=\log \frac{\kappa(n)}{\kappa\left(r_{n}\right)}
$$

(ii) For the proof of the second statement we proceed along similar lines as in the proof of Proposition 1. Using the second factorial moment of a binomial distribution, we have as a first estimate

$$
\begin{aligned}
\mathbf{E}\left[\left.\frac{\Delta_{i+1}^{2}}{X_{i}^{2}} \right\rvert\, X_{i}=b\right] & =\frac{1}{b^{2} \lambda(b)} \sum_{k=2}^{b}(k-1)^{2}\binom{b}{k} \int_{[0,1]} p^{k}(1-p)^{b-k} \frac{\Lambda(d p)}{p^{2}} \\
& \leq \frac{1}{b^{2} \lambda(b)} \int_{[0,1]} \sum_{k=0}^{b} k(k-1)\binom{b}{k} p^{k}(1-p)^{b-k} \frac{\Lambda(d p)}{p^{2}} \\
& =\frac{1}{b^{2} \lambda(b)} \int_{[0,1]} p^{2} b(b-1) \frac{\Lambda(d p)}{p^{2}} \\
& \leq \frac{\Lambda([0,1])}{\lambda(b)}
\end{aligned}
$$

This bound yields for large $n$

$$
\begin{aligned}
\mathbf{E}\left[\sum_{i=0}^{\rho_{n}-1} \frac{\Delta_{i+1}^{2}}{X_{i}^{2} \nu\left(X_{i}\right)}\right] & \leq \sum_{i=0}^{n-1} \mathbf{E}\left[\frac{1}{\mu\left(X_{i}\right)} ; X_{i}>r_{n}\right] \Lambda([0,1]) \\
& =\sum_{i=0}^{n-1} \mathbf{E}\left[\frac{\Delta_{i+1}}{\mu\left(X_{i}\right) \nu_{1 / 2}\left(X_{i}\right)} I_{\left\{\Delta_{i+1} \leq X_{i} / 2\right\}} ; X_{i}>r_{n}\right] \Lambda([0,1]) \\
& \leq c \mathbf{E}\left[\sum_{i=0}^{\rho_{n}-1} \frac{\Delta_{i+1}}{\mu\left(X_{i}\right) \nu\left(X_{i}\right)} I_{\left\{\Delta_{i+1} \leq X_{i} / 2\right\}}\right]
\end{aligned}
$$

with $c:=\Lambda([0,1]) \sup _{b \geq 4} \nu(b) / \nu_{1 / 2}(b)<\infty$. In view of Lemma 1 (i) the function

$$
x \mapsto(x-1) \mu(x) \nu(x) / x=\kappa(x)^{2} /(\lambda(x) / x(x-1))
$$

is increasing, which entails $\Delta_{i+1} /\left(\mu\left(X_{i}\right) \nu\left(X_{i}\right)\right) \leq \int_{X_{i+1}}^{X_{i}} x((x-1) \mu(x) \nu(x))^{-1} d x$. By means of Lemma 1 (ii) $\mu(x) \nu(x) \sim \kappa(x)^{2} / \kappa^{\prime}(x)$, therefore

$$
\mathbf{E}\left[\sum_{i=0}^{\rho_{n}-1} \frac{\Delta_{i+1}^{2}}{X_{i}^{2} \nu\left(X_{i}\right)}\right] \leq c \int_{r_{n} / 2}^{n} \frac{x d x}{(x-1) \mu(x) \nu(x)} \sim c \int_{r_{n} / 2}^{n} \frac{\kappa^{\prime}(x)}{\kappa^{2}(x)} d x \leq \frac{c}{\kappa\left(r_{n} / 2\right)},
$$

and consequently, since $\kappa(x) \rightarrow \infty$ in the dustless case,

$$
\mathbf{E}\left[\sum_{i=0}^{\rho_{n}-1} \frac{\Delta_{i+1}^{2}}{X_{i}^{2} \nu\left(X_{i}\right)}\right]=o(1) .
$$

(iii) Now we consider the martingale $M=\left(M_{k}\right)_{k \geq 0}$ given by $M_{0}=0$ a.s. and

$$
M_{k}:=\sum_{i=0}^{k \wedge \tau_{n}-1}\left(\frac{\Delta_{i+1}}{\left(X_{i}-1\right) \nu\left(X_{i}\right)}-\frac{1}{X_{i}-1}\right), k \geq 1
$$

By means of the optional sampling theorem, since $\rho_{n}$ is a stopping time, we have, because $\nu(b) \geq 1$ for all $b \geq 2$,

$$
\mathbf{E}\left[M_{\rho_{n}}^{2}\right] \leq \mathbf{E}\left[\sum_{i=0}^{\rho_{n}-1} \frac{\Delta_{i+1}^{2}}{X_{i}^{2} \nu\left(X_{i}\right)^{2}}\right]=o(1) .
$$

Thus by means of Doob's maximal inequality

$$
\max _{1 \leq j \leq \rho_{n}}\left|\sum_{i=0}^{j-1} \frac{\Delta_{i+1}}{\left(X_{i}-1\right) \nu\left(X_{i}\right)}-\sum_{i=0}^{j-1} \frac{1}{X_{i}-1}\right|=o_{P}(1)
$$

Also for $j \leq \rho_{n}$

$$
0 \leq \sum_{i=0}^{j-1} \frac{1}{X_{j}-1}-\sum_{i=0}^{j-1} \frac{1}{X_{j}} \leq \sum_{m=X_{\rho_{n}-1}}^{\infty}\left(\frac{1}{m-1}-\frac{1}{m}\right)=\frac{1}{X_{\rho_{n}-1}-1} \leq \frac{1}{r_{n}-1}
$$

and consequently

$$
\begin{equation*}
\max _{1 \leq j \leq \rho_{n}}\left|\sum_{i=0}^{j-1} \frac{\Delta_{i+1}}{\left(X_{i}-1\right) \nu\left(X_{i}\right)}-\sum_{i=0}^{j-1} \frac{1}{X_{i}}\right|=o_{P}(1) . \tag{20}
\end{equation*}
$$

(iv) Note that in view of Lemma 1 (i) the function $(x-1) \nu(x)=\kappa(x) /(\lambda(x) / x(x-1))$ is increasing and $\nu(x) /(x-1)^{2}=(x /(x-1)) \cdot(\kappa(x) /(x-1)) / \lambda(x)$ is decreasing. For $X_{i} \geq 2$ this
yields

$$
\begin{aligned}
0 & \leq \frac{1}{\left(X_{i+1}-1\right) \nu\left(X_{i+1}\right)}-\frac{1}{\left(X_{i}-1\right) \nu\left(X_{i}\right)} \\
& =\frac{\left(X_{i+1}-1\right)^{2}}{\nu\left(X_{i+1}\right)} \frac{1}{\left(X_{i+1}-1\right)^{3}}-\frac{\left(X_{i}-1\right)^{2}}{\nu\left(X_{i}\right)} \frac{1}{\left(X_{i}-1\right)^{3}} \\
& \leq \frac{\left(X_{i}-1\right)^{2}}{\nu\left(X_{i}\right)}\left(\frac{1}{\left(X_{i+1}-1\right)^{3}}-\frac{1}{\left(X_{i}-1\right)^{3}}\right) \\
& =\frac{\left(\left(X_{i}-1\right)^{2}+\left(X_{i}-1\right)\left(X_{i+1}-1\right)+\left(X_{i+1}-1\right)^{2}\right) \Delta_{i+1}}{\nu\left(X_{i}\right)\left(X_{i}-1\right)\left(X_{i+1}-1\right)^{3}} \\
& \leq \frac{3\left(X_{i}-1\right)}{\nu\left(X_{i}\right)\left(X_{i+1}-1\right)^{3}} \Delta_{i+1} \\
& \leq \frac{24 X_{i}}{\nu\left(X_{i}\right) X_{i+1}^{3}} \Delta_{i+1} .
\end{aligned}
$$

It follows

$$
\begin{aligned}
& \mathbf{E}\left[\max _{1 \leq j \leq \rho_{n}}\left|\sum_{i=0}^{j-1} \frac{\Delta_{i+1}}{\left(X_{i}-1\right) \nu\left(X_{i}\right)}-\sum_{i=0}^{j-1} \frac{\Delta_{i+1}}{\left(X_{i+1}-1\right) \nu\left(X_{i+1}\right)}\right| ; \Delta_{i+1} \leq X_{i} / 2 \text { for all } i<\rho_{n}\right] \\
& \quad \leq \mathbf{E}\left[\sum_{i=0}^{\rho_{n}-1}\left|\frac{1}{\left(X_{i}-1\right) \nu\left(X_{i}\right)}-\frac{1}{\left(X_{i+1}-1\right) \nu\left(X_{i+1}\right)}\right| \Delta_{i+1} ; \Delta_{i+1} \leq X_{i} / 2 \text { for all } i<\rho_{n}\right] \\
& \quad \leq \mathbf{E}\left[\sum_{i=0}^{\rho_{n}-1} \frac{192}{X_{i}^{2} \nu\left(X_{i}\right)} \Delta_{i+1}^{2}\right]=o(1) .
\end{aligned}
$$

Also, since $(x-1) \nu(x)$ is increasing

$$
\frac{1}{\left(X_{i}-1\right) \nu\left(X_{i}\right)} \Delta_{i+1} \leq \int_{X_{i+1}}^{X_{i}} \frac{d x}{(x-1) \nu(x)} \leq \frac{1}{\left(X_{i+1}-1\right) \nu\left(X_{i+1}\right)} \Delta_{i+1}
$$

and we obtain

$$
\begin{equation*}
\max _{1 \leq j \leq \rho_{n}}\left|\sum_{i=0}^{j-1} \frac{1}{\left(X_{i}-1\right) \nu\left(X_{i}\right)} \Delta_{i+1}-\int_{X_{j}}^{n} \frac{d x}{(x-1) \nu(x)}\right|=o_{P}(1) \tag{21}
\end{equation*}
$$

on the event that $\Delta_{i+1} \leq X_{i} / 2$ for all $i<\rho_{n}$. Lemma 3 (ii) says that the complementary event has an asymptotically vanishing probability.
(v) Finally, by Lemma 1 (ii) with $r_{n} \leq y \leq n$ for $\chi<1$

$$
\begin{aligned}
\int_{y}^{n} \frac{d x}{(x-1) \nu(x)} & =\int_{y}^{n} \frac{\lambda(x) / x^{2}}{\mu(x) / x} d x+\int_{y}^{n} \frac{d x}{x(x-1) \nu(x)} \\
& =\int_{y}^{n} \frac{\kappa^{\prime}(x)}{\kappa(x)} d x+O\left(\int_{r_{n}}^{n} \frac{\kappa^{\prime}(x) d x}{\kappa(x) x^{\chi}}\right)+O\left(r_{n}^{-1}\right)
\end{aligned}
$$

and recalling $r_{n} \rightarrow \infty$

$$
\int_{r_{n}}^{n} \frac{\kappa^{\prime}(x) d x}{\kappa(x) x^{\chi}} \sim \int_{r_{n}}^{n} \frac{d x}{x \nu(x) x^{\chi}} \leq \int_{r_{n}}^{n} \frac{d x}{x^{1+\chi}}=o(1) .
$$

Altogether we obtain

$$
\max _{r_{n} \leq y \leq n}\left|\int_{y}^{n} \frac{d x}{(x-1) \nu(x)}-\log \frac{\kappa(n)}{\kappa(y)}\right|=o(1) .
$$

Combining this formula with (20) and (21) and recalling the definition of $\rho_{n}$, we arrive at

$$
\max _{1 \leq j \leq \rho_{n}}\left|\sum_{i=0}^{j-1} \frac{1}{X_{i}}-\log \frac{\kappa(n)}{\kappa\left(X_{j}\right)}\right|=o_{P}(1) .
$$

This is our claim.

## 4 Proof of Theorem 1

Under the assumptions of Proposition 2 we have

$$
\begin{equation*}
\ell_{n}^{*}:=\int_{0}^{\tilde{\rho}_{n}} N_{n}(t) d t \stackrel{1}{\sim} \int_{r_{n}}^{n} \frac{x}{\mu(x)} d x \tag{22}
\end{equation*}
$$

In particular, this formula holds for $r_{n}:=c n$ with $0<c<1$ as anticipated in the introduction's remark. Here the assumptions of Proposition 2 are satisfied because of Lemma 3 and

$$
\int_{c n}^{n} \frac{d x}{\mu(x)} \leq(1-c) \frac{n}{\mu(c n)}=o(1),
$$

which in turn is valid in view of Lemma 1 (iii).
In order to fill the gap up to $\ell_{n}$, we construct a distinguished sequence of real numbers. We construct the numbers $2 \leq r_{n} \leq n, n \geq 1$, satisfying

$$
\begin{equation*}
\int_{r_{n}}^{n} \frac{d x}{\mu(x)} \rightarrow 0 \quad \text { and } \quad \int_{2}^{r_{n}} \frac{x}{\mu(x)} d x=o\left(\int_{r_{n}}^{n} \frac{x}{\mu(x)} d x\right) \tag{23}
\end{equation*}
$$

as $n \rightarrow \infty$. From Lemma 3 we get that $\tilde{\rho}_{n}=o_{P}(1)$. Also, since by Lemma 1 (i) $x / \mu(x)$ is decreasing

$$
\int_{2}^{r_{n}} \frac{x}{\mu(x)} d x \geq \frac{r_{n}\left(r_{n}-2\right)}{\mu\left(r_{n}\right)} \quad \text { and } \quad \int_{r_{n}}^{n} \frac{x}{\mu(x)} d x \leq \frac{r_{n}\left(n-r_{n}\right)}{\mu\left(r_{n}\right)} .
$$

Therefore the second statement in (23) entails $r_{n}-2=o\left(n-r_{n}\right)$ as $n \rightarrow \infty$ and consequently $r_{n}=o(n)$. Hence the sequence $r_{n}, n \geq 1$, fulfils all requirements of Proposition 2.

For the construction of the numbers $r_{n}$ recall that

$$
\begin{equation*}
\int_{2}^{\infty} \frac{x}{\mu(x)} d x=\infty \tag{24}
\end{equation*}
$$

which follows from the fact that $\mu(x) /(x(x-1))$ is decreasing in $x$. We distinguish two cases. If $\int_{2}^{\infty} \frac{d x}{\mu(x)}<\infty$, then the required sequence is easily obtained, because the first condition of 23) is fulfilled for any divergent sequence $r_{n} \leq n$ and the second one by reason of (24), if only $r_{n}$ is diverging slowly enough.

Thus let us assume $\int_{2}^{\infty} \frac{d x}{\mu(x)}=\infty$ and let $r_{n, m} \geq 2$ for given $m \in \mathbb{N}$ be the solution of the equation

$$
\int_{r_{n, m}}^{n} \frac{d x}{\mu(x)}=\frac{1}{m},
$$

which exists for $n \geq 3$ and $m \geq 1 / \int_{2}^{3} \frac{d x}{\mu(x)}$. Since $\int_{2}^{\infty} \frac{d x}{\mu(x)}=\infty$ we have $r_{n, m} \rightarrow \infty$ as $n \rightarrow \infty$. It follows

$$
\int_{r_{n, m}}^{n} \frac{x}{\mu(x)} d x \geq r_{n, m} / m \text { and } \int_{2}^{r_{n, m}} \frac{x}{\mu(x)} d x=o\left(r_{n, m}\right)
$$

as $n \rightarrow \infty$ because of $x=o(\mu(x))$ from Lemma 1 (iii). Therefore there are natural numbers $n_{1}<n_{2}<\cdots$ such that

$$
\int_{2}^{r_{n, m}} \frac{x}{\mu(x)} d x \leq \frac{1}{m} \int_{r_{n, r}}^{n} \frac{x}{\mu(x)} d x
$$

for all $n \geq n_{m}$. Now letting $r_{n}:=r_{n, m}$ for $n=n_{m}, \ldots, n_{m+1}-1$ we obtain

$$
\int_{r_{n}}^{n} \frac{d x}{\mu(x)} \leq \frac{1}{m} \quad \text { and } \quad \int_{2}^{r_{n}} \frac{x}{\mu(x)} d x \leq \frac{1}{m} \int_{r_{n}}^{n} \frac{x}{\mu(x)} d x
$$

for all $n \geq n_{m}$. This implies (23).
Applying now Proposition 2 with $f(x)=x$, we obtain from 23

$$
\int_{0}^{\tilde{\rho}_{n}} N_{n}(t) d t \stackrel{1}{\sim} \int_{r_{n}}^{n} \frac{x}{\mu(x)} d x \sim \int_{2}^{n} \frac{x}{\mu(x)} d x
$$

and

$$
\mathbf{E}\left[\int_{\tilde{\rho}_{n}}^{\tilde{\tau}_{n}} N_{n}(t) d t\right]=O\left(\int_{2}^{r_{n}} \frac{x}{\mu(x)} d x\right)=o\left(\int_{2}^{n} \frac{x}{\mu(x)} d x\right)
$$

This implies our claim.

## 5 Proof of Theorem 2

Again, let $r_{n}, n \geq 1$, be any sequence fulfilling the assumptions of Proposition 1 . We investigate the lengths

$$
\begin{equation*}
\widehat{\ell}_{n}^{*}:=\int_{0}^{\tilde{\rho}_{n}} \widehat{N}_{n}(t) d t=\sum_{i=0}^{\rho_{n}-1} W_{i} Y_{i} \tag{25}
\end{equation*}
$$

which are the total lengths of the external branches up to the $\rho_{n}$-th merger. Here $Y_{i}, i \geq 0$, denotes the number of external branches extant after the first $i$ merging events, and $W_{i}$ as above the waiting time at the state $X_{i}$. In the proof we approximate $\widehat{\ell}_{n}^{*}$ by its conditional expectation given the block-counting process $N_{n}$, which in turn can be handled by means of Proposition 2 and 3 . We shall employ the representation

$$
\begin{equation*}
Y_{i}=\sum_{k=1}^{n} I_{\left\{\zeta_{k} \geq i\right\}} \tag{26}
\end{equation*}
$$

where $\zeta_{k}$ denotes the number of coalescent events before the $k$-th external branch (out of $n$ ) merges with some other branches within the coalescent.

Lemma 4. We have for $i, j \geq 0, k, l=1, \ldots, n$

$$
\mathbf{P}\left(\zeta_{k} \geq i \mid N_{n}\right)=\frac{X_{i}-1}{n-1} \prod_{m=0}^{i-1}\left(1-\frac{1}{X_{m}}\right) \text { a.s. }
$$

and for $k \neq l$

$$
\mathbf{P}\left(\zeta_{k} \geq i, \zeta_{l} \geq j \mid N_{n}\right) \leq \mathbf{P}\left(\zeta_{k} \geq i \mid N_{n}\right) \mathbf{P}\left(\zeta_{l} \geq j \mid N_{n}\right) \text { a.s. }
$$

Proof. Let $A$ be a subset of $\{1, \ldots, n\}$ with $a \geq 1$ elements, and let $\xi_{A}$ be the number of mergers before one of the branches ending in $A$ gets involved into a merging event. Given $\Delta_{1}$ the first merger consists of a uniformly random choice of $\Delta_{1}+1$ members out of $X_{0}=n$ elements. Therefore we have

$$
\mathbf{P}\left(\xi_{A} \geq 1 \mid N_{n}\right)=\frac{\binom{X_{0}-a}{\Delta_{1}+1}}{\binom{X_{0}}{\Delta_{1}+1}}=\frac{\left(X_{0}-a\right) \cdots\left(X_{1}-a\right)}{X_{0} \cdots X_{1}}=\frac{\left(X_{1}-1\right) \cdots\left(X_{1}-a\right)}{X_{0} \cdots\left(X_{0}-a+1\right)} \text { a.s. }
$$

or

$$
\begin{equation*}
\mathbf{P}\left(\xi_{A} \geq 1 \mid N_{n}\right)=\frac{\left(X_{1}-1\right) \cdots\left(X_{1}-a\right)}{\left(X_{0}-1\right) \cdots\left(X_{0}-a\right)}\left(1-\frac{a}{X_{0}}\right) \text { a.s. } \tag{27}
\end{equation*}
$$

Because of the Markov property we may iterate this formula yielding

$$
\begin{equation*}
\mathbf{P}\left(\xi_{A} \geq i \mid N_{n}\right)=\frac{\left(X_{i}-1\right) \cdots\left(X_{i}-a\right)}{\left(X_{0}-1\right) \cdots\left(X_{0}-a\right)} \prod_{m=0}^{i-1}\left(1-\frac{a}{X_{m}}\right) \text { a.s. } \tag{28}
\end{equation*}
$$

In particular, with $A=\{k\}$ and $a=1$ our first claim follows.
Similar for $k \neq l$ and $i \leq j$ with $\xi_{\{l\}}^{\prime}:=\xi_{\{l\}}-\xi_{\{k, l\}}$ and $N_{X_{i}}^{\prime}(t):=N_{n}\left(t+W_{0}+\ldots+W_{i-1}\right)$, $t \geq 0$, by means of the Markov property

$$
\begin{aligned}
\mathbf{P}\left(\zeta_{k} \geq i, \zeta_{l} \geq j \mid N_{n}\right) & =\mathbf{P}\left(\xi_{\{k, l\}} \geq i \mid N_{n}\right) \mathbf{P}\left(\xi_{\{l\}}^{\prime} \geq j-i \mid N_{X_{i}}^{\prime}\right) \\
& =\frac{\left(X_{i}-1\right)\left(X_{i}-2\right)}{\left(X_{0}-1\right)\left(X_{0}-2\right)} \prod_{m=0}^{i-1}\left(1-\frac{2}{X_{m}}\right) \times \frac{X_{j}-1}{X_{i}-1} \prod_{m=i}^{j-1}\left(1-\frac{1}{X_{m}}\right) \text { a.s. }
\end{aligned}
$$

Since $X_{i} \leq X_{0}$ and $\left(1-2 / X_{m}\right) \leq\left(1-1 / X_{m}\right)^{2}$ this implies

$$
\begin{aligned}
\mathbf{P}\left(\zeta_{k} \geq i, \zeta_{l} \geq j \mid N_{n}\right) & \leq \frac{\left(X_{i}-1\right)^{2}}{\left(X_{0}-1\right)^{2}} \prod_{m=0}^{i-1}\left(1-\frac{1}{X_{m}}\right)^{2} \times \frac{X_{j}-1}{X_{i}-1} \prod_{m=i}^{j-1}\left(1-\frac{1}{X_{m}}\right) \\
& =\mathbf{P}\left(\zeta_{k} \geq i \mid N_{n}\right) \mathbf{P}\left(\zeta_{l} \geq j \mid N_{n}\right) \text { a.s. }
\end{aligned}
$$

which is our second claim.
Proof of Theorem 2. (i) First we consider $\mathbf{E}\left[\widehat{\ell}_{n}^{*} \mid N_{n}\right]$. Due to (26) and Lemma 4 we have

$$
\begin{align*}
\mathbf{E}\left[\widehat{\ell}_{n}^{*} \mid N_{n}\right] & =\sum_{i=0}^{\rho_{n}-1} \sum_{k=1}^{n} W_{i} \mathbf{P}\left(\zeta_{k} \geq i \mid N_{n}\right) \\
& =\frac{n}{n-1} \sum_{i=0}^{\rho_{n}-1} W_{i}\left(X_{i}-1\right) \prod_{m=0}^{i-1}\left(1-\frac{1}{X_{m}}\right) \text { a.s. } \tag{29}
\end{align*}
$$

Since $\sum_{m=0}^{i-1} X_{m}^{-2} \leq \sum_{a=X_{i-1}}^{\infty} a^{-2} \leq\left(X_{i-1}-1\right)^{-1} \leq\left(r_{n}-1\right)^{-1}$ for $i \leq \rho_{n}$ and in view of Proposition 3

$$
\prod_{m=0}^{i-1}\left(1-\frac{1}{X_{m}}\right)=\exp \left(-\sum_{m=0}^{i-1} \frac{1}{X_{m}}+O\left(r_{n}^{-1}\right)\right)=\frac{\kappa\left(X_{i}\right)}{\kappa(n)} \exp \left(o_{P}(1)\right)
$$

where the $o_{P}(1)$ may be taken uniformly in $i<\rho_{n}$ in the sense of Proposition 3. Thus we obtain

$$
\mathbf{E}\left[\widehat{\ell_{n}^{*}} \mid N_{n}\right] \stackrel{P}{\sim} \frac{1}{\kappa(n)} \sum_{i=0}^{\rho_{n}-1} W_{i}\left(X_{i}-1\right) \kappa\left(X_{i}\right)=\frac{1}{\kappa(n)} \int_{0}^{\tilde{\rho}_{n}} f\left(N_{n}(t)\right) d t
$$

with $f(x):=(x-1) \kappa(x)$. This function satisfies the assumption of Proposition 2. Because of $f(x) \sim \mu(x), r_{n} \rightarrow \infty$ we obtain

$$
\begin{equation*}
\mathbf{E}\left[\widehat{\ell}_{n}^{*} \mid N_{n}\right] \stackrel{P}{\sim} \frac{1}{\kappa(n)} \int_{r_{n}}^{n}(x-1) \kappa(x) \frac{d x}{\mu(x)} \sim \frac{n-r_{n}}{\kappa(n)}=\frac{n\left(n-r_{n}\right)}{\mu(n)} . \tag{30}
\end{equation*}
$$

(ii) Next we have

$$
\begin{aligned}
\mathbf{E}\left[\left(\widehat{\ell}_{n}^{*}\right.\right. & \left.\left.-\mathbf{E}\left[\widehat{\ell}_{n}^{*} \mid N_{n}\right]\right)^{2} \mid N_{n}\right] \\
& =\mathbf{E}\left[\left(\sum_{i=0}^{\rho_{n}-1} \sum_{k=1}^{n}\left(W_{i} I_{\left\{\zeta_{k} \geq i\right\}}-W_{i} \mathbf{P}\left(\zeta_{k} \geq i \mid N_{n}\right)\right)\right)^{2} \mid N_{n}\right] \\
& =\sum_{i, j=0}^{\rho_{n}-1} \sum_{k, l=1}^{n} W_{i} W_{j}\left(\mathbf{P}\left(\zeta_{k} \geq i, \zeta_{l} \geq j \mid N_{n}\right)-\mathbf{P}\left(\zeta_{k} \geq i \mid N_{n}\right) \mathbf{P}\left(\zeta_{l} \geq j \mid N_{n}\right)\right) \text { a.s. }
\end{aligned}
$$

Applying Lemma 4, it follows

$$
\begin{aligned}
\mathbf{E}\left[\left(\widehat{\ell_{n}^{*}}-\mathbf{E}\left[\widehat{\ell}_{n}^{*} \mid N_{n}\right]\right)^{2} \mid N_{n}\right] & \leq \sum_{i, j=0}^{\rho_{n}-1} \sum_{k=1}^{n} W_{i} W_{j} \mathbf{P}\left(\zeta_{k} \geq i \vee j \mid N_{n}\right) \\
& \leq \sum_{i, j=0}^{\rho_{n}-1} W_{i} W_{j} \sum_{k=1}^{n} \mathbf{P}\left(\zeta_{k} \geq i \mid N_{n}\right) \\
& =\mathbf{E}\left[\widehat{\ell_{n}^{*}} \mid X\right] \sum_{j=0}^{\rho_{n}-1} W_{j} \\
& =\tilde{\rho}_{n} \mathbf{E}\left[\widehat{\ell_{n}^{*}} \mid N_{n}\right] \text { a.s. }
\end{aligned}
$$

Since by assumption $\tilde{\rho}_{n}=o_{P}(1)$ and $r_{n} \leq \gamma n$, 30) yields

$$
\mathbf{E}\left[\left(\widehat{\ell}_{n}^{*}-\mathbf{E}\left[\widehat{\ell}_{n}^{*} \mid N_{n}\right]\right)^{2} \mid N_{n}\right]=o_{P}\left(\frac{n\left(n-r_{n}\right)}{\mu(n)}\right)=o_{P}\left(\frac{n^{2}}{\mu(n)}\right) .
$$

Because of Lemma 1 (i) $n(n-1) / \mu(n)$ is increasing, which implies

$$
\begin{equation*}
\widehat{\ell}_{n}^{*}-\mathbf{E}\left[\widehat{\ell}_{n}^{*} \mid N_{n}\right]=o_{P}\left(\frac{n}{\sqrt{\mu(n)}}\right)=o_{P}\left(\frac{n^{2}}{\mu(n)}\right) . \tag{31}
\end{equation*}
$$

and because of 30

$$
\begin{equation*}
\widehat{\ell}_{n}^{*} \stackrel{P}{\sim} \frac{n\left(n-r_{n}\right)}{\mu(n)} . \tag{32}
\end{equation*}
$$

In particular, as discussed in the proof of Theorem 1 and addressed in the introduction, this approximation is valid for the sequence $r_{n}=c n$ with $0<c<1$.
(iii) Finally, let us switch two the numbers $r_{n}, n \geq 1$, constructed in the proof of Theorem 1 and fulfilling (23) as well as $r_{n}=o(n)$. As above

$$
\begin{aligned}
\mathbf{E}\left[\widehat{\ell}_{n}-\widehat{\ell}_{n}^{*} \mid N_{n}\right] & =\frac{n}{n-1} \sum_{i=\rho_{n}}^{\tau_{n}-1} W_{i}\left(X_{i}-1\right) \prod_{m=0}^{i-1}\left(1-\frac{1}{X_{m}}\right) \\
& \leq 2 \exp \left(-\sum_{m=0}^{\rho_{n}-1} \frac{1}{X_{m}}\right) \sum_{i=\rho_{n}}^{\tau_{n}-1} W_{i} X_{i} .
\end{aligned}
$$

From the Markov property and Theorem 1, applied to the coalescent with initial value $X_{\rho_{n}}$, we obtain

$$
\sum_{i=\rho_{n}}^{\tau_{n}-1} W_{i} X_{i} \stackrel{P}{\sim} \int_{2}^{X_{\rho_{n}}} \frac{x}{\mu(x)} d x \leq \int_{2}^{r_{n}} \frac{x}{\mu(x)} d x
$$

By (23) and by monotonicity of $x / \mu(x)$ it follows

$$
\sum_{i=\rho_{n}}^{\tau_{n}-1} W_{i} X_{i}=o_{P}\left(\int_{r_{n}}^{n} \frac{x}{\mu(x)} d x\right)=o_{P}\left(\frac{r_{n}}{\mu\left(r_{n}\right)} n\right) .
$$

Moreover, from Proposition 2

$$
\exp \left(-\sum_{m=0}^{\rho_{n}-1} \frac{1}{X_{m}}\right) \stackrel{P}{\sim} \frac{\mu\left(r_{n}\right)}{r_{n}} \frac{n}{\mu(n)},
$$

and we arrive at

$$
\mathbf{E}\left[\widehat{\ell}_{n}-\widehat{\ell}_{n}^{*} \mid N_{n}\right]=o_{P}\left(\frac{n^{2}}{\mu(n)}\right) .
$$

Hence

$$
\widehat{\ell}_{n}-\widehat{\ell}_{n}^{*}=o_{P}\left(\frac{n^{2}}{\mu(n)}\right) .
$$

This estimate in combination with (30) and (31) proves our theorem.

## 6 Proof of Theorem 3

(i) As to the second claim

$$
\int_{2}^{n}\left(\frac{x}{\mu(x)}-\frac{n}{\mu(n)}\right) d x=\int_{2}^{n} \int_{x}^{n} \frac{\kappa(y)^{\prime}}{\kappa(y)^{2}} d y d x=\int_{2}^{n}(y-2) \frac{\kappa^{\prime}(y)}{\kappa(y)^{2}} d y
$$

and by Lemma 1 (ii) and Lemma 2

$$
\int_{2}^{n}\left(\frac{x}{\mu(x)}-\frac{n}{\mu(n)}\right) d x \sim \int_{2}^{n} y \frac{\lambda(y)}{\mu(y)^{2}} d y \sim \int_{2}^{n} \frac{L(y)}{L^{*}(y)^{2}} d y \sim \frac{n L(n)}{L^{*}(n)^{2}}
$$

(ii) Turning to the first claim we now strive for a lower bound for $\check{\ell}_{n}$. We resort to the definitions 22 and 25 and set

$$
\check{\ell}_{n}^{*}:=\ell_{n}^{*}-\widehat{\ell}_{n}^{*}
$$

Again, we first investigate its conditional expectation, given $N_{n}$. Note that $\mathbf{E}\left[\ell_{n}^{*} \mid N_{n}\right]=\ell_{n}^{*}$ a.s., therefore in view of (31)

$$
\check{\ell_{n}^{*}}-\mathbf{E}\left[\check{\ell}_{n}^{*} \mid N_{n}\right]=\mathbf{E}\left[\widehat{\ell}_{n}^{*} \mid N_{n}\right]-\widehat{\ell}_{n}^{*}=o_{P}\left(\frac{n}{\sqrt{\mu(n)}}\right)
$$

Since we deal with a regularly varying coalescent with exponent 1 , we obtain for any $\varepsilon>0$

$$
\begin{equation*}
\check{\ell}_{n}^{*}-\mathbf{E}\left[\check{\ell}_{n}^{*} \mid N_{n}\right]=O_{P}\left(n^{1 / 2+\varepsilon}\right) \tag{33}
\end{equation*}
$$

We like to estimate $\mathbf{E}\left[\ell_{n}^{*} \mid N_{n}\right]$ from below. For this purpose we specify our choice of the numbers $r_{n}$. We fix $h \in \mathbb{N}$, we define stopping times $0=\rho_{n, h} \leq \rho_{n, h-1} \leq \cdots \leq \rho_{n, 1}$ as

$$
\begin{equation*}
\rho_{n, g}:=\min \left\{i \geq 0: X_{i} \leq \frac{g}{h} n\right\}, g=1, \ldots, h \tag{34}
\end{equation*}
$$

and we set $\rho_{n}=\rho_{n, 1}$. As we already argued in the proof of Theorem 1 , we may apply Propositions 2 and 3 to these stopping times. We proceed no in the same manner as in (29). Using $X_{i} \leq n$ respectively $X_{i} \geq n\left(X_{i}-1\right) /(n-1)$ we obtain

$$
\begin{gathered}
\mathbf{E}\left[\sum_{i=\rho_{n, g}}^{\rho_{n, g-1}-1} W_{i}\left(X_{i}-Y_{i}\right) \mid N_{n}\right]=\sum_{i=\rho_{n, g}}^{\rho_{n, g-1}-1} W_{i}\left(X_{i}-\frac{n}{n-1}\left(X_{i}-1\right) \prod_{m=0}^{i-1}\left(1-\frac{1}{X_{m}}\right)\right) \\
\quad \geq \sum_{i=\rho_{n, g}}^{\rho_{n, g-1}-1} W_{i} X_{i}\left(1-\prod_{m=0}^{i-1}\left(1-\frac{1}{X_{m}}\right)\right) \\
\quad \geq\left(1-\prod_{m=0}^{\rho_{n, g}-1}\left(1-\frac{1}{X_{m}}\right)\right) \sum_{i=\rho_{n, g}}^{\rho_{n, g-1}-1} W_{i} X_{i} \\
\quad \geq\left(1-\exp \left(-\sum_{m=0}^{\rho_{n, g}-1} \frac{1}{X_{m}}\right)\right) \int_{\tilde{\rho}_{n, g}}^{\tilde{\rho}_{n, g-1}} N_{n}(t) d t \quad \text { a.s. }
\end{gathered}
$$

Proposition 2 together with Lemma 2 (ii) implies

$$
\int_{\tilde{\rho}_{n, g}}^{\tilde{\rho}_{n, g-1}} N_{n}(t) d t \stackrel{1}{\sim} \int_{(g-1) n / h}^{g n / h} \frac{x}{\mu(x)} d x \sim \frac{n}{h L^{*}(n)}
$$

and Proposition 3 yields

$$
\sum_{m=0}^{\rho_{n, g}-1} \frac{1}{X_{m}} \stackrel{1}{\sim} \log \frac{\kappa(n)}{\kappa(g n / h)} \sim \log \frac{L^{*}(n)}{L^{*}(g n / h)}
$$

Because $L^{*}$ is slowly varying and because of (10) we have

$$
\log \frac{L^{*}(n)}{L^{*}(g n / h)} \sim \frac{L^{*}(n)-L^{*}(g n / h)}{L^{*}(g n / h)} \sim \frac{L(n)}{L^{*}(n)} \log \frac{h}{g},
$$

hence because of Lemma 2 (ii)

$$
\begin{equation*}
\sum_{m=0}^{\rho_{n, g}-1} \frac{1}{X_{m}} \stackrel{1}{\sim} \frac{L(n)}{L^{*}(n)} \log \frac{h}{g}=o_{P}(1) \tag{35}
\end{equation*}
$$

and

$$
1-\exp \left(-\sum_{m=0}^{\rho_{n, g}-1} \frac{1}{X_{m}}\right) \stackrel{P}{\sim} \frac{L(n)}{L^{*}(n)} \log \frac{h}{g}
$$

Altogether

$$
\mathbf{E}\left[\sum_{i=\rho_{n, g}}^{\rho_{n, g-1}-1} W_{i}\left(X_{i}-Y_{i}\right) \mid N_{n}\right] \geq\left(1+o_{P}(1)\right) \frac{n L(n)}{L^{*}(n)^{2}} \frac{1}{h} \log \frac{h}{g}
$$

and consequently

$$
\begin{aligned}
\mathbf{E}\left[\mathscr{\ell}_{n}^{*} \mid N_{n}\right] & =\mathbf{E}\left[\sum_{i=0}^{\rho_{n}-1} W_{i}\left(X_{i}-Y_{i}\right) \mid N_{n}\right] \\
& \geq\left(1+o_{P}(1)\right) \frac{n L(n)}{L^{*}(n)^{2}} \sum_{g=2}^{h} \frac{1}{h} \log \frac{h}{g} \\
& \geq\left(1+o_{P}(1)\right) \frac{n L(n)}{L^{*}(n)^{2}} \int_{2 / h}^{1} \log \frac{1}{z} d z \\
& =\left(1+o_{P}(1)\right) \frac{n L(n)}{L^{*}(n)^{2}}\left(1-\frac{2}{h}-\frac{2}{h} \log \frac{2}{h}\right) .
\end{aligned}
$$

In view of (33) this estimate transferes to $\check{\ell}_{n}^{*}$. We have $\check{\ell}_{n} \geq \check{\ell}_{n}^{*}$, thus letting $h \rightarrow \infty$ we obtain

$$
\begin{equation*}
\check{\ell}_{n} \geq\left(1+o_{P}(1)\right) \frac{n L(n)}{L^{*}(n)^{2}} \tag{36}
\end{equation*}
$$

as $n \rightarrow \infty$.
(iii) Coming to an upper bound, we have in view of $\prod_{m=0}^{i-1}\left(1-1 / X_{m}\right) \geq 1-\sum_{m=0}^{i-1} 1 / X_{m}$

$$
\begin{align*}
\mathbf{E}\left[\check{\ell}_{n}\right] & =\mathbf{E}\left[\mathbf{E}\left[\check{\ell}_{n} \mid N_{n}\right]\right] \\
& =\mathbf{E}\left[\sum_{i=0}^{\tau_{n}-1} W_{i}\left(X_{i}-\frac{n}{n-1}\left(X_{i}-1\right) \prod_{m=0}^{i-1}\left(1-\frac{1}{X_{m}}\right)\right)\right] \\
& \leq \mathbf{E}\left[\sum_{i=0}^{\tau_{n}-1} W_{i}\left(1+\frac{n}{n-1} X_{i} \sum_{m=0}^{i-1} \frac{1}{X_{m}}\right)\right] . \tag{37}
\end{align*}
$$

From Proposition 2 and since $x=o(\mu(x))$ (see Lemma 1 (iii))

$$
\begin{equation*}
\mathbf{E}\left[\sum_{i=0}^{\tau_{n}-1} W_{i}\right]=\mathbf{E}\left[\tilde{\tau}_{n}\right]=O\left(\int_{2}^{n} \frac{d x}{\mu(x)}\right)=o\left(\int_{2}^{n} \frac{d x}{x}\right)=o(\log n) . \tag{38}
\end{equation*}
$$

Furthermore, by means of the Markov property

$$
\begin{aligned}
\mathbf{E}\left[\sum_{i=0}^{\tau_{n}-1} W_{i} X_{i} \sum_{m=0}^{i-1} \frac{1}{X_{m}}\right] & =\sum_{i=0}^{n-1} \mathbf{E}\left[\frac{X_{i}}{\lambda\left(X_{i}\right)} \sum_{m=0}^{i-1} \frac{1}{X_{m}} ; X_{i}>2\right] \\
& =\sum_{i=0}^{n-1} \mathbf{E}\left[\frac{X_{i} \Delta_{i+1}}{\mu\left(X_{i}\right)} \sum_{m=0}^{i-1} \frac{1}{X_{m}} ; X_{i}>2\right] \\
& =\mathbf{E}\left[\sum_{m=0}^{\tau_{n}-1} \frac{1}{X_{m}} \sum_{i=m+1}^{\tau_{n}-1} \frac{X_{i} \Delta_{i+1}}{\mu\left(X_{i}\right)}\right]
\end{aligned}
$$

Since $x / \mu(x)$ is decreasing we have $\sum_{i=m+1}^{\tau_{n}-1} X_{i} \Delta_{i+1} / \mu\left(X_{i}\right) \leq \int_{1}^{X_{m+1}} x / \mu(x) d x$, where we let $x / \mu(x):=2 / \mu(2)$ for $1 \leq x \leq 2$. Thus

$$
\mathbf{E}\left[\sum_{i=0}^{\tau_{n}-1} W_{i} X_{i} \sum_{m=0}^{i-1} \frac{1}{X_{m}}\right] \leq \mathbf{E}\left[\sum_{m=0}^{\tau_{n}-1} \frac{1}{X_{m}} \int_{1}^{X_{m+1}} \frac{x}{\mu(x)} d x\right] .
$$

Invoking the Markov property once again, we obtain

$$
\mathbf{E}\left[\sum_{i=0}^{\tau_{n}-1} W_{i} X_{i} \sum_{m=0}^{i-1} \frac{1}{X_{m}}\right] \leq \mathbf{E}\left[\sum_{m=0}^{\tau_{n}-1} \frac{\Delta_{m+1}}{\left(X_{m}-1\right) \nu\left(X_{m}\right)} \int_{1}^{X_{m+1}} \frac{x}{\mu(x)} d x\right]
$$

and taking now into account that the functions $(x-1) \nu(x)$ and $\int_{1}^{x} z / \mu(z) d z$ are increasing, we end up with

$$
\begin{equation*}
\mathbf{E}\left[\sum_{i=0}^{\tau_{n}-1} W_{i} X_{i} \sum_{m=0}^{i-1} \frac{1}{X_{m}}\right] \leq \int_{1}^{n} \frac{1}{(x-1) \nu(x)} \int_{1}^{x} \frac{z}{\mu(z)} d z d x \tag{39}
\end{equation*}
$$

where we let $(x-1) \nu(x):=\nu(2)$ for $1 \leq x \leq 2$. Using Lemma 2 (ii) it follows

$$
\begin{aligned}
\int_{1}^{n} \frac{1}{(x-1) \nu(x)} \int_{1}^{x} \frac{z}{\mu(z)} d z d x & \sim \int_{2}^{n} \frac{L(x)}{x L^{*}(x)} \int_{2}^{x} \frac{1}{L^{*}(z)} d z d x \\
& \sim \int_{2}^{n} \frac{L(x)}{x L^{*}(x)} \frac{x}{L^{*}(x)} d x \\
& \sim \frac{n L(n)}{L^{*}(n)^{2}}
\end{aligned}
$$

Together with (37), (38) and (39) we obtain all in all

$$
\mathbf{E}\left[\check{\ell}_{n}\right] \leq(1+o(1)) \frac{n L(n)}{L^{*}(n)^{2}}
$$

Combining this result with (36), we get

$$
\check{\ell}_{n} \stackrel{P}{\sim} \frac{n L(n)}{L^{*}(n)^{2}},
$$

and invoking once again the convergence criterion of F. Riesz, also $L_{1}$-convergence follows. This finishes the proof of Theorem 3.

## 7 Proof of Theorem 4

Since the first part is just a special case of Theorem 2, we only have to prove the second claim. We fix $a \geq 2$.
(i) Here we study lengths of the form

$$
\widehat{\ell}_{n, a}^{*}=\int_{\tilde{\sigma}_{n}}^{\tilde{\rho}_{n}} \widehat{N}_{n, a}(t) d t=\sum_{i=\sigma_{n}}^{\rho_{n}-1} W_{i} Y_{i, a},
$$

where $Y_{i, a}$ denotes the number of internal branches of order $a$ present in the coalescent after $i$ merging events. We are going to bound these numbers from below. Let $A$ denote a subset of $\{1, \ldots, n\}$ with $a$ elements. For $1 \leq k \leq i$ let $E_{i, k, A}$ be the event that the external branches ending in $A$ are not involved in the first $k-1$ mergers, next coalesce with the $k$-th merger to one lineage without any other branch participating, and then remain untouched by merging events till the $i$-th merger. These are disjoint events, which all contribute to $Y_{i, a}$, therefore

$$
Y_{i, a} \geq Y_{i, a}^{\prime}:=\sum_{k=1}^{i} \sum_{A} I_{E_{i, k, A}}
$$

where the second sum is taken over all $A \subset\{1, \ldots, n\}$ with $a$ elements.
Lemma 5. Let both $A, A^{\prime} \subset\{1, \ldots, n\}$ have $a \geq 1$ elements. Then for $1 \leq k \leq i$

$$
\mathbf{P}\left(E_{i, k, A} \mid N_{n}\right)=\frac{a!}{\left(X_{0}-1\right) \cdots\left(X_{0}-a\right)} \frac{X_{i}}{X_{k-1}} \prod_{m=0}^{k-2}\left(1-\frac{a}{X_{m}}\right) \prod_{m=k}^{i}\left(1-\frac{1}{X_{m}}\right) 1_{\left\{\Delta_{k}=a-1\right\}} \text { a.s. }
$$

and for $A \neq A^{\prime}$ or $k \neq l$

$$
\mathbf{P}\left(E_{i, k, A} \cap E_{j, l, A^{\prime}} \mid N_{n}\right) \leq\left(1+O\left(X_{k-1}^{-1}\right)+O\left(X_{l-1}^{-1}\right)\right) \mathbf{P}\left(E_{i, k, A} \mid N_{n}\right) \mathbf{P}\left(E_{j, l, A^{\prime}} \mid N_{n}\right) \text { a.s. }
$$

Proof. We proceed similar as in the proof of Lemma 4. From (28) and the Markov property

$$
\begin{aligned}
\mathbf{P}\left(E_{i, k, A} \mid N_{n}\right)= & \frac{\left(X_{k-1}-1\right) \cdots\left(X_{k-1}-a\right)}{\left(X_{0}-1\right) \cdots\left(X_{0}-a\right)} \prod_{m=0}^{k-2}\left(1-\frac{a}{X_{m}}\right) \\
& \times\binom{ X_{k-1}}{a}^{-1} 1_{\left\{\Delta_{k}=a-1\right\}} \times \frac{X_{i}-1}{X_{k}-1} \prod_{m=k}^{i-1}\left(1-\frac{1}{X_{m}}\right) \text { a.s. }
\end{aligned}
$$

Note that $X_{k}-1=X_{k-1}-a$ on the event $\left\{\Delta_{k}=a-1\right\}$. Thus all factors containing $X_{k-1}$ cancel up to the term $X_{k-1}$ in the denominator. Replacing also $X_{i}-1$ by $X_{i}\left(1-1 / X_{i}\right)$, the first statement follows.

For the second claim note that in the case $A \neq A^{\prime}$ and $A \cap A^{\prime} \neq \emptyset$ or in the case $A=A^{\prime}$ and $k \neq l$ the events $E_{i, k, A}$ and $E_{j, l, A^{\prime}}$ are disjoint, then our claim is obvious. Therefore we may
assume that $A \cap A^{\prime}=\emptyset$. Let us consider the case $k<l<i \leq j$. Then from (28) and the Markov property

$$
\begin{aligned}
\mathbf{P}\left(E_{i, k, A} \cap\right. & \left.E_{j, l, A^{\prime}} \mid N_{n}\right)=\frac{\left(X_{k-1}-1\right) \cdots\left(X_{k-1}-2 a\right)}{\left(X_{0}-1\right) \cdots\left(X_{0}-2 a\right)} \prod_{m=0}^{k-2}\left(1-\frac{2 a}{X_{m}}\right) \\
& \times\binom{ X_{k-1}}{a}^{-1} 1_{\left\{\Delta_{k}=a-1\right\}} \times \frac{\left(X_{l-1}-1\right) \cdots\left(X_{l-1}-a-1\right)}{\left(X_{k}-1\right) \cdots\left(X_{k}-a-1\right)} \prod_{m=k}^{l-2}\left(1-\frac{a+1}{X_{m}}\right) \\
& \times\binom{ X_{l-1}}{a}^{-1} 1_{\left\{\Delta_{l}=a-1\right\}} \times \frac{\left(X_{i}-1\right)\left(X_{i}-2\right)}{\left(X_{l}-1\right)\left(X_{l}-2\right)} \prod_{m=l}^{i-1}\left(1-\frac{2}{X_{m}}\right) \\
& \times \frac{X_{j}-1}{X_{i}-1} \prod_{m=i}^{j-1}\left(1-\frac{1}{X_{m}}\right) \text { a.s. }
\end{aligned}
$$

Here the product $\left(X_{k}-1\right) \cdots\left(X_{k}-a-1\right)=\left(X_{k-1}-a\right) \cdots\left(X_{k-1}-2 a\right)$ cancels out on the event $\left\{\Delta_{k}=a-1\right\}$, and again only the factor $X_{k-1}$ remains. Similarly $X_{l}-2$ and $X_{l-1}-a-1$ cancel. By increasing some other terms we get

$$
\begin{aligned}
& \mathbf{P}\left(E_{i, k, A} \cap\right.\left.E_{j, l, A^{\prime}} \mid N_{n}\right) \leq \frac{a!a!}{\left(X_{0}-1\right) \cdots\left(X_{0}-2 a\right)} \prod_{m=0}^{k-2}\left(1-\frac{a}{X_{m}}\right)^{2} \\
& \quad \times 1_{\left\{\Delta_{k}=a-1\right\}} \frac{1}{X_{k-1}} \prod_{m=k}^{l-2}\left(1-\frac{a}{X_{m}}\right)\left(1-\frac{1}{X_{m}}\right) \\
& \quad \times 1_{\left\{\Delta_{l}=a-1\right\}} \frac{1}{X_{l-1}} \prod_{m=l}^{i-1}\left(1-\frac{1}{X_{m}}\right)\left(1-\frac{1}{X_{m}}\right) \\
& \quad \times\left(X_{i}-1\right)\left(X_{j}-1\right) \prod_{m=i}^{j-1}\left(1-\frac{1}{X_{m}}\right) \text { a.s. }
\end{aligned}
$$

Replacing also $X_{i}-1$ and $X_{j}-1$ as above and comparing with our first formula, we obtain

$$
\begin{aligned}
\mathbf{P}\left(E_{i, k, A}\right. & \left.\cap E_{j, l, A^{\prime}} \mid N_{n}\right) \\
& \leq \frac{\left(X_{0}-1\right) \cdots\left(X_{0}-a\right)}{\left(X_{0}-a-1\right) \cdots\left(X_{0}-2 a\right)}\left(1-\frac{a}{X_{k-1}}\right)^{-1} \mathbf{P}\left(E_{i, k, A} \mid N_{n}\right) \mathbf{P}\left(E_{j, l, A^{\prime}} \mid N_{n}\right) \text { a.s. }
\end{aligned}
$$

This implies our second claim. Other cases like $k<i<l<j$ are treated similarly.
Proof of Theorem 4. (i) Similar as above we first consider conditional expectations given $N_{n}$. Recall from (34) the definition of $\rho_{n, g}$. We have from Lemma 5 for $g \geq 2$

$$
\begin{aligned}
& \mathbf{E}\left[\sum_{i=\rho_{n, g}}^{\rho_{n, g-1}-1} W_{i} Y_{i, a}^{\prime} \mid N_{n}\right]=\sum_{i=\rho_{n, g}}^{\rho_{n, g-1}-1} W_{i} \sum_{k=1}^{i} \sum_{A} \mathbf{P}\left(E_{i, k, A} \mid N_{n}\right) \\
& \quad=\frac{X_{0}}{X_{0}-a} \sum_{i=\rho_{n, g}}^{\rho_{n, g-1}-1} W_{i} \sum_{k=1}^{i} \frac{X_{i}}{X_{k-1}} \prod_{m=0}^{k-2}\left(1-\frac{a}{X_{m}}\right) \prod_{m=k}^{i}\left(1-\frac{1}{X_{m}}\right) 1_{\left\{\Delta_{k}=a-1\right\}} \text { a.s. }
\end{aligned}
$$

The products may be estimated from above by 1 and, by means of Proposition 3 and the bound $(1-z) \geq \exp (-c z)$ for $z \leq 1 / 2$ and a suitable $c>0$, from below uniformly in $i, k$ by

$$
\prod_{m=0}^{\rho_{n, 1}-1}\left(1-\frac{a}{X_{m}}\right) \geq \exp \left(-c a \sum_{m=0}^{\rho_{n, 1}-1} \frac{1}{X_{m}}\right) \stackrel{P}{\sim}\left(\frac{\kappa(n / h)}{\kappa(n)}\right)^{c a} \sim\left(\frac{L^{*}(n / h)}{L^{*}(n)}\right)^{c a} \sim 1
$$

Consequently we may replace the products by 1 and obtain

$$
\begin{equation*}
\mathbf{E}\left[\sum_{i=\rho_{n, g}}^{\rho_{n, g-1}-1} W_{i} Y_{i, a}^{\prime} \mid N_{n}\right] \stackrel{P}{\sim} \sum_{i=\rho_{n, g}}^{\rho_{n, g-1}-1} W_{i} X_{i} \sum_{k=1}^{i} \frac{1}{X_{k-1}} 1_{\left\{\Delta_{k}=a-1\right\}} \tag{40}
\end{equation*}
$$

as $n \rightarrow \infty$.
From Lemma 2 (ii) and (35)

$$
\sum_{m=0}^{\rho_{n, g}-1} \frac{1}{X_{m}} \mathbf{P}\left(\Delta_{m+1}=a-1\right) \stackrel{P}{\sim} \frac{1}{(a-1) a} \sum_{m=0}^{\rho_{n, g}-1} \frac{1}{X_{m}} \stackrel{P}{\sim} \frac{1}{(a-1) a} \frac{L(n)}{L^{*}(n)} \log \frac{h}{g} .
$$

By the Markov property

$$
\begin{aligned}
& \mathbf{E}\left[\left(\sum_{m=0}^{\rho_{n, g}-1} \frac{1}{X_{m}}\left(1_{\left\{\Delta_{m+1}=a-1\right\}}-\mathbf{P}\left(\Delta_{m+1}=a-1\right)\right)\right)^{2}\right] \\
& \quad=\mathbf{E}\left[\sum_{m=0}^{\rho_{n, g}-1} \frac{1}{X_{m}^{2}}\left(1_{\left\{\Delta_{m+1}=a-1\right\}}-\mathbf{P}\left(\Delta_{m+1}=a-1\right)\right)^{2}\right] \\
& \quad \leq \mathbf{E}\left[\frac{1}{X_{\rho_{n, g}-1}-1}\right] \leq \frac{1}{(g n / h)-1} .
\end{aligned}
$$

Therefore

$$
\sum_{m=0}^{\rho_{n, g}-1} \frac{1}{X_{m}} 1_{\left\{\Delta_{m+1}=a-1\right\}} \stackrel{P}{\sim} \frac{1}{a(a-1)} \frac{L(n)}{L^{*}(n)} \log \frac{h}{g},
$$

also once more by Proposition 2 and Lemma 2 (ii)

$$
\sum_{i=\rho_{n, g}}^{\rho_{n, g-1}-1} W_{i} X_{i}=\int_{\tilde{\rho}_{n, g}}^{\tilde{\rho}_{n, g-1}} N_{n}(t) d t \stackrel{1}{\sim} \int_{(g-1) n / h}^{g n / h} \frac{x}{\mu(x)} d x \sim \frac{n}{h L^{*}(n)} .
$$

These formulas yield together with 40) the following lower and upper bounds for $g \geq 2$

$$
\begin{equation*}
\mathbf{E}\left[\sum_{i=\rho_{n, g}}^{\rho_{n, g-1}-1} W_{i} Y_{i, a}^{\prime} \mid N_{n}\right] \geq\left(1+o_{P}(1)\right) \frac{1}{a(a-1)} \frac{n L(n)}{L^{*}(n)^{2}} \frac{1}{h} \log \frac{h}{g} \tag{41}
\end{equation*}
$$

and

$$
\begin{equation*}
\mathbf{E}\left[\sum_{i=\rho_{n, g}}^{\rho_{n, g-1}-1} W_{i} Y_{i, a}^{\prime} \mid N_{n}\right] \leq\left(1+o_{P}(1)\right) \frac{1}{a(a-1)} \frac{n L(n)}{L^{*}(n)^{2}} \frac{1}{h} \log \frac{h}{g-1} . \tag{42}
\end{equation*}
$$

(ii) Now we estimate the difference between $\sum_{i=\rho_{n, g}}^{\rho_{n, g-1}-1} W_{i} Y_{i, a}^{\prime}$ and its conditional expectation given $N_{n}$. We have

$$
\begin{aligned}
\mathbf{E} & {\left[\left(\sum_{i=\rho_{n, g}}^{\rho_{n, g-1}-1} W_{i} Y_{i, a}^{\prime}-\mathbf{E}\left[\sum_{i=\rho_{n, g}}^{\rho_{n, g-1}-1} W_{i} Y_{i, a}^{\prime} \mid N_{n}\right]\right)^{2} \mid N_{n}\right] } \\
& =\mathbf{E}\left[\left(\sum_{i=\rho_{n, g}}^{\rho_{n, g-1}-1} W_{i} \sum_{k=1}^{i} \sum_{A}\left(I_{E_{i, k, A}}-\mathbf{P}\left(E_{i, k, A} \mid N_{n}\right)\right)^{2} \mid N_{n}\right]\right. \\
& =\sum_{i, j=\rho_{n, g}}^{\rho_{n, g-1}-1} W_{i} W_{j} \sum_{k=1}^{i} \sum_{l=1}^{j} \sum_{A, A^{\prime}}\left(\mathbf{P}\left(E_{i, k, A} \cap E_{j, l, A^{\prime}} \mid N_{n}\right)-\mathbf{P}\left(E_{i, k, A} \mid N_{n}\right) \mathbf{P}\left(E_{j, l, A^{\prime}} \mid N_{n}\right)\right) \text { a.s. }
\end{aligned}
$$

For $A=A^{\prime}, k=l$ and $i \leq j$ we obviously have

$$
\mathbf{P}\left(E_{i, k, A} \cap E_{j, k, A} \mid N_{n}\right)=\mathbf{P}\left(E_{j, k, A} \mid N_{n}\right) \leq \mathbf{P}\left(E_{i, k, A} \mid N_{n}\right) \text { a.s. }
$$

Taking also account of Lemma 5, we thus obtain with some $c>0$

$$
\begin{aligned}
& \mathbf{E}\left[\left(\sum_{i=\rho_{n, g}}^{\rho_{n, g-1}-1} W_{i} Y_{i, a}^{\prime}-\mathbf{E}\left[\sum_{i=\rho_{n, g}}^{\rho_{n, g-1}-1} W_{i} Y_{i, a}^{\prime} \mid N_{n}\right]\right)^{2} \mid N_{n}\right] \\
& \leq 2 \sum_{i=\rho_{n, g}}^{\rho_{n, g-1}-1} \sum_{j=i}^{\rho_{n, g-1}-1} \sum_{k=1}^{i} \sum_{A} W_{i} W_{j} \mathbf{P}\left(E_{i, k, A} \mid N_{n}\right) \\
&+c \sum_{i, j=\rho_{n, g}}^{\rho_{n, g-1-1}} \sum_{k=1}^{i} \sum_{l=1}^{j} \sum_{A, A^{\prime}} W_{i} W_{j}\left(\frac{1}{X_{k}}+\frac{1}{X_{l}}\right) \mathbf{P}\left(E_{i, k, A} \mid N_{n}\right) \mathbf{P}\left(E_{j, l, A^{\prime}} \mid N_{n}\right) \\
& \leq 2 \sum_{j=0}^{\rho_{n, g-1}-1} W_{j} \sum_{i=\rho_{n, g}}^{\rho_{n, g-1}-1} \sum_{k=1}^{i} \sum_{A} W_{i} \mathbf{P}\left(E_{i, k, A} \mid N_{n}\right) \\
&+\frac{2 c}{X_{\rho_{n, g-1}-1}}\left(\sum_{i=\rho_{n, g}}^{\rho_{n, g-1}-1} \sum_{k=1}^{i} \sum_{A} W_{i} \mathbf{P}\left(E_{i, k, A} \mid N_{n}\right)\right)^{2} \\
&= 2 \tilde{\rho}_{n, g-1} \mathbf{E}\left[\sum_{i=\rho_{n, g}}^{\rho_{n, g-1}-1} W_{i} Y_{i, a}^{\prime} \mid N_{n}\right]+\frac{2 c h}{n}\left(\mathbf{E}\left[\sum_{i=\rho_{n, g}}^{\rho_{n, g-1}-1} W_{i} Y_{i, a}^{\prime} \mid N_{n}\right]\right)^{2} \text { a.s. }
\end{aligned}
$$

By (42) this implies for $g \geq 2$ and any $\varepsilon>0$

$$
\mathbf{E}\left[\left(\sum_{i=\rho_{n, g}}^{\rho_{n, g-1}-1} W_{i} Y_{i, a}^{\prime}-\mathbf{E}\left[\sum_{i=\rho_{n, g}}^{\rho_{n, g-1}-1} W_{i} Y_{i, a}^{\prime} \mid N_{n}\right]\right)^{2} \mid N_{n}\right]=O\left(n^{1+\varepsilon}\right)
$$

and thus from (41) for $g \geq 2$

$$
\sum_{i=\rho_{n, g}}^{\rho_{n, g-1}-1} W_{i} Y_{i, a}^{\prime} \geq\left(1+o_{P}(1)\right) \frac{1}{a(a-1)} \frac{n L(n)}{L^{*}(n)^{2}} \frac{1}{h} \log \frac{h}{g}
$$

(iii) The last formula implies for $a \geq 2$ that

$$
\begin{aligned}
\widehat{\ell}_{n, a} & =\sum_{i=0}^{\tau_{n}-1} W_{i} Y_{i, a} \geq \sum_{i=\rho_{n, h-1}}^{\rho_{n, 1}-1} W_{i} Y_{i, a}^{\prime} \\
& \geq\left(1+o_{P}(1)\right) \frac{1}{a(a-1)} \frac{n L(n)}{L^{*}(n)^{2}} \sum_{g=2}^{h-1} \frac{1}{h} \log \frac{h}{g} \\
& \geq\left(1+o_{P}(1)\right) \frac{1}{a(a-1)} \frac{n L(n)}{L^{*}(n)^{2}} \int_{2 / h}^{1} \log \frac{1}{z} d z
\end{aligned}
$$

Letting $h \rightarrow \infty$, we obtain the lower estimate

$$
\widehat{\ell}_{n, a} \geq\left(1+o_{P}(1)\right) \frac{1}{a(a-1)} \frac{n L(n)}{L^{*}(n)^{2}} .
$$

For an upper estimate note that $\check{\ell}_{n}=\sum_{a \geq 2} \widehat{\ell}_{n, a}$. This formula and Theorem 3 imply for any natural number $r$

$$
\begin{aligned}
\hat{\ell}_{n, a} & \leq \check{\ell}_{n}-\sum_{2 \leq b \leq r, b \neq a} \widehat{\ell}_{b, n} \\
& \leq\left(1+o_{P}(1)\right) \frac{n L(n)}{L^{*}(n)^{2}}\left(1-\sum_{2 \leq b \leq r, b \neq a} \frac{1}{(b-1) b}\right) \\
& \stackrel{P}{\sim} \frac{n L(n)}{L^{*}(n)^{2}}\left(\frac{1}{r}+\frac{1}{(a-1) a}\right) .
\end{aligned}
$$

Letting $r \rightarrow \infty$, yields the upper estimates. This finishes the proof.
