A NOTE ON NONLINEAR ISOMETRIES BETWEEN VECTOR-VALUED FUNCTION SPACES

ARYA JAMSHIDI AND FERESHTEH SADY

Abstract. Let $X, Y$ be compact Hausdorff spaces and $E, F$ be Banach spaces over $\mathbb{R}$ or $\mathbb{C}$. In this paper, we investigate the general form of surjective (not necessarily linear) isometries $T : A \to B$ between subspaces $A$ and $B$ of $C(X, E)$ and $C(Y, F)$, respectively. In the case that $F$ is strictly convex, it is shown that there exist a subset $Y_0$ of $Y$, a continuous function $\Phi : Y_0 \to X$ onto the set of strong boundary points of $A$ and a family $\{V_y\}_{y \in Y_0}$ of real-linear operators from $E$ to $F$ with $\|V_y\| = 1$ such that

$$Tf(y) - T0(y) = V_y(f(\Phi(y))) \quad (f \in A, y \in Y_0).$$

In particular, we get some generalizations of the vector-valued Banach–Stone theorem and a generalization of Cambern’s result. We also give a similar result in the case that $F$ is not strictly convex, but its unit sphere contains a maximal convex subset which is singleton.

1. Introduction

The study of isometries between subspaces of continuous functions originally dates back to the classical Banach–Stone theorem. The theorem has various generalizations (in scalar valued case) based on different techniques, see for example [6, 9, 12, 13, 16, 15].

For a compact Hausdorff space $X$ and a Banach space $E$, let $C(X, E)$ be the Banach space of continuous $E$-valued functions on $X$ endowed with supremum norm $\| \cdot \|_\infty$. A representation theorem for isometries between $C(X, E)$-spaces was given in [10] by Jerison as follows:

Let $X$ and $Y$ be compact Hausdorff spaces, $E$ be a strictly convex Banach space and let $T : C(X, E) \to C(Y, E)$ be a surjective linear isometry. Then there exist a continuous surjection $\Phi : Y \to X$ and a map $t \to V_t$ which is continuous from $Y$ into the space $B(E)$ of all bounded operators on $E$, endowed with the

Key words and phrases. Isometries, vector-valued continuous functions, strong boundary points, Choquet boundary.
strong operator topology, such that \( T f(t) = V_t(f(\Phi(t))) \) for all \( f \in C(X, E) \) and \( t \in Y \).

This result has been generalized by Cambern [4] for into linear isometries and by Font [8] for certain vector-valued subspaces of continuous functions. In [1] Al-Halees and Fleming relaxed the strict convexity condition on \( E \), and by considering \( T \)-sets in companion with another condition on \( E \), called condition (P), they obtained more general results. We also refer the reader to the nice books [6, 7] including many earlier results.

More recently, surjective isometries between certain subspaces of vector-valued continuous functions have been studied in [3] and [11]. We should note that the method used in these papers is based on extreme point technique. By [3] (see also [2]), for a compact Hausdorff space \( X \) and a reflexive real Banach space \( F \) whose dual is strictly convex, if \( A \) is a subspace of \( C(X, F) \) which separates \( X \) in the sense of [3, Definition 3.1], and \( T : A \rightarrow A \) is a surjective isometry preserving constant functions, then there exist a surjective isometry \( V : F \rightarrow F \) and a homeomorphism \( \tau : X \rightarrow X \) such that

\[
T f(x) = V(f(\tau(x))) \quad (f \in A, x \in X)
\]

This result has been generalized in several directions in [11]. We refer one of them which is related to our results. First we state conditions (S3) and (M) introduced in [11] for a subspace \( A \) of \( C(X, E) \) where \( X \) is a compact Hausdorff space and \( E \) is a Banach space over \( \mathbb{C} \) or \( \mathbb{R} \):

(S3) For each \( x \) in the Choquet boundary \( \text{Ch}(A) \) of \( A \), for each neighborhood \( U \) of \( x \) and for each \( u \in E \) there exists a function \( f \in A \) such that \( \|f\|_\infty = \|u\| \), \( f(x) = u \) and \( f = 0 \) on \( X \setminus U \).

(M) for each \( f \in A \) with \( f(x) = 0 \) and for each \( \epsilon > 0 \), there exist a neighborhood \( U \) of \( x \) and \( f_\epsilon \in A \) such that \( \|f - f_\epsilon\|_\infty < \epsilon \) and \( f_\epsilon = 0 \) on \( U \).

**Theorem 1.1.** [11, Theorem 3.4] Let \( X \) and \( Y \) be compact Hausdorff spaces and let \( E \) be a strictly convex reflexive real or complex Banach space. Assume that \( A \) and \( B \) are subspaces of \( C(X, E) \), respectively, containing constant functions and both satisfy conditions (S3) and (M). Let \( T : A \rightarrow B \) be a surjective linear isometry. Then there exist a continuous surjection \( \varphi : \text{Ch}(B) \rightarrow \text{Ch}(A) \) between the Choquet boundaries, and a family \( V_y : E \rightarrow E \), \( y \in \text{Ch}(B) \), of linear operators with \( \|V_y\| = 1 \) such that

\[
T f(y) = V_y(f(\varphi(y))) \quad (f \in A, y \in \text{Ch}(B)).
\]
If, furthermore, the dual space $E^*$ is strictly convex, then $\varphi$ is a homeomorphism and $V_y$ is an isometric isomorphism for each $y \in \text{Ch}(B)$.

The purpose of this paper is to study surjective, not necessarily linear, isometries $T : A \rightarrow B$ between subspaces $A$ and $B$ of $C(X, E)$ and $C(Y, F)$, respectively, where $X, Y$ are compact Hausdorff spaces and $E, F$ are Banach spaces (over $\mathbb{R}$ or $\mathbb{C}$). We first assume that $F$ is strictly convex and give a description of $T$ on appropriate subset $Y_0$ of $Y$. The given description deals with the set of strong boundary points of $A$, which is, in many nice cases, large enough to be a boundary. Then, by imposing some additional assumptions on $A$ and $B$, we give a similar result for certain non strictly convex Banach spaces. We should note that our method is based on studying maximal convex subsets of the unit spheres of $A$ and $B$. This method initially emerged in the works of Eilenberg [5] and Myers [14] and has later been adapted to the scalar valued case by Roberts and Lee [15].

2. Preliminaries

Throughout this paper $\mathbb{K}$ stands for the scalar fields $\mathbb{R}$ or $\mathbb{C}$. For a compact Hausdorff space $X$ and a Banach space $E$ over $\mathbb{K}$, $C(X, E)$ is the Banach space of all continuous $E$-valued functions on $X$ endowed with the supremum norm $\| \cdot \|_\infty$. For each $u \in E$, the constant map $c_u : X \rightarrow E$ is defined by $c_u(x) = u$ for each $x \in X$. We say that a subspace $A$ of $C(X, E)$ is $E$-separating if for any distinct points $x, x' \in X$ and arbitrary $u \in E$ there exists $f \in A$ with $f(x) = 0$, $f(x') = u$ and $\|f\|_\infty = \|u\|$. For every $f \in A$ we put $M(f) = \{ x \in X : \| f(x) \| = \| f \|_\infty \}$.

For a normed space $\mathcal{E}$ we denote the unit sphere of $\mathcal{E}$ by $S(\mathcal{E})$ and we put

$$\tilde{S}(\mathcal{E}) = \{ K : K \text{ is a maximal convex subset of } S(\mathcal{E}) \}.$$  

Clearly $S(\mathcal{E})$ is not convex and each convex subset of $S(\mathcal{E})$ is contained in an element of $\tilde{S}(\mathcal{E})$. We note that if $\mathcal{E}$ is strictly convex, then all maximal convex subsets of $S(\mathcal{E})$ are singleton.

Let $X$ be a compact Hausdorff space and $E$ be a Banach space over $\mathbb{K}$. For a subspace $A$ of $C(X, E)$ the Choquet boundary of $A$ is denoted by $\text{Ch}(A)$. We recall that $\text{Ch}(A)$ consists of all points $x \in X$ such that $\nu^* \circ \delta_x$ is an extreme point of the closed unit ball of $A^*$ for some extreme point $\nu^*$ of the closed unit ball of $E^*$. It is well known that $\text{Ch}(A)$ is a boundary for $A$ in the sense that for each $f \in A$ there exists $x \in \text{Ch}(A)$ such that $\| f(x) \| = \| f \|_\infty$. For $x \in X$ and
$K \subseteq S(E)$ we set

$$V^A_x = \{ f \in S(A) : \|f(x)\| = 1 \}, \quad V^{A}_{x,K} = \{ f \in S(A) : f(x) \in K \}.$$  

**Lemma 2.1.** Let $X$ be a compact Hausdorff space, $E$ be a Banach space over $K$, and $A$ be a $K$-subspace of $C(X, E)$. Then for each convex subset $C$ of $S(A)$ there exist $x \in X$ and $K \in \tilde{S}(E)$ such that $C \subseteq V^{A}_{x,K}$. In particular every maximal convex subset of $S(A)$ is of the form $V^{A}_{x,K}$ for some $x \in X$ and $K \in \tilde{S}(E)$.

**Proof.** Since $C$ is convex, it follows easily that the family $\{M(f) : f \in C\}$ of compact subsets of $X$ has finite intersection property and consequently $\cap_{f \in C} M(f) \neq \emptyset$. Let $x \in \cap_{f \in C} M(f)$ and put $K_0 = \{ f(x) : f \in C \}$. Then $K_0$ is a convex subset of $S(E)$ and so there exists $K \in \tilde{S}(E)$ such that $K_0 \subseteq K$. This clearly implies that $C \subseteq V^{A}_{x,K}$, as desired. \qed

Let $X$ be a compact Hausdorff space and $A$ be a $K$-subspace of $C(X, E)$. We call a point $x \in X$ a strong boundary point of $A$ if for each neighborhood $U$ of $x$, $\epsilon > 0$, and $u \in S(E)$ there exists a function $f \in A$ such that $\|f\|_{\infty} = 1$, $f(x) = u$ and $\|f(y)\| < \epsilon$ for all $y \in X \setminus U$. We denote the set of all strong boundary points of $A$ by $\Theta(A)$. We also denote the set of points $x \in X$ satisfying the above condition for $\epsilon = 1$ by $\tau(A)$. Hence $\Theta(A) \subseteq \tau(A)$.

### 3. Main results

We begin this section by introducing certain type of points satisfying some maximal convexity conditions.

**Definition 3.1.** Let $X$ be a compact Hausdorff space, $E$ be a Banach space over $K$, and $A$ be a $K$-subspace of $C(X, E)$. We say that a point $x \in X$ is of type one for $A$ if for each $K \in \tilde{S}(E)$, $V^{A}_{x,K}$ is a maximal convex subset of $S(A)$. A point $x \in X$ is of type two for $A$ if for each $K, K' \in \tilde{S}(E)$ and $y \in X$ the inclusion $V^{A}_{x,K} \subseteq V^{A}_{y,K'}$ implies $x = y$.

It is easy to see that if $A$ is $E$-separating or it contains constants, then for any point $x \in X$ of type two, the inclusion $V^{A}_{x,K} \subseteq V^{A}_{y,K'}$, where $K, K' \in \tilde{S}(E)$ and $y \in X$, implies $x = y$ and $K = K'$.

The set of all type one, respectively type two points for $A$ will be denoted by $\eta_1(A)$ and $\eta_2(A)$.

We note that for an arbitrary subspace $A$ of $C(X, E)$ some of the above defined sets may be empty. However, as the next lemma shows, $\eta_1(A)$ and $\eta_2(A)$ contain
the set of strong boundary points of $A$, which is large enough for certain subspaces $A$.

**Lemma 3.2.** Let $X$ be a compact Hausdorff space, $E$ be a Banach space over $\mathbb{K}$ and $A$ be a $\mathbb{K}$-subspace of $C(X,E)$. Then

$$\Theta(A) \subseteq \tau(A) \subseteq \eta_2(A) \cap X_0 \subseteq \eta_1(A),$$

where $X_0 = \{ x \in X : S(E) \subseteq \{ f(x) : f \in S(A) \} \}$. In particular, if $A$ contains constants, then $\eta_2(A) \subseteq \eta_1(A)$. If $A$ is assumed to be $E$-separating, then $\eta_2(A) = X$.

**Proof.** The first inclusion is trivial. Take $x \in \tau(A)$ and assume that $V_{x,K}^A \subseteq V_{y,K'}^A$, where $y \in X \setminus \{x\}$ and $K, K' \in \tilde{S}(E)$. Fixing $u \in K$ we can find an open neighborhood $U$ of $x$ and $f \in A$ such that $y \in X \setminus U$, $\|f\|_\infty = 1$, $f(x) = u$ and $\|f(z)\| < 1$ for all $z \in X \setminus U$. Since $f \in V_{x,K}$ it follows that $f(y) \in K'$ and, in particular, $\|f(y)\| = 1$, a contradiction. This shows that $x \in \eta_2(A)$, that is $\tau(A) \subseteq \eta_2(A)$. Clearly $\tau(A) \subseteq X_0$.

Now suppose that $x \in \eta_2(A) \cap X_0$ and let $K \in \tilde{S}(E)$. Since $V_{x,K}^A$ is a convex subset of $S(A)$, it is contained in a maximal convex subset of $S(A)$. Hence, by Lemma 2.1, there exist $y \in X$ and $K' \in \tilde{S}(E)$ such that $V_{y,K}^A$ is a maximal convex subset of $S(A)$ and $V_{x,K}^A \subseteq V_{y,K'}^A$. Therefore, $y = x$ since $x \in \eta_2(A)$. Hence $V_{x,K}^A \subseteq V_{x,K'}^A$ and, being $x \in X_0$, it follows easily that $K \subseteq K'$. Thus $K = K'$, that is $V_{x,K}^A$ is a maximal convex subset of $S(A)$. This concludes that $\eta_2(A) \cap X_0 \subseteq \eta_1(A)$.

The second part can be easily verified. \hfill $\square$\n
Using a similar argument as in [9, Lemma 3.2] we get the next lemma. We should note that the lemma is similar to the additive Bishop’s Lemma in scalar case, for see instance [16].

**Lemma 3.3.** Let $X$ be a compact Hausdorff space, $E$ be a Banach space and $A$ be a closed $\mathbb{K}$-subspace of $C(X,E)$. Assume that $x \in \Theta(A)$ and $f \in A$ such that $\|f\|_\infty = 1$ and $f(x) = 0$. Then for each $u \in S(E)$ and $0 < r < 1$ there exists $g \in V_{x,u}^A$ such that $rf + g \in V_{x,u}^A$.

We note that, by the above lemma, for each $x \in \Theta(A)$ and $u \in S(E)$ we have

$$\ker(\delta_x) \subseteq s(V_{x,u}) - V_{x,u}$$

where $s > 0$ and $\delta_x : A \rightarrow E$ is defined by $\delta_x(f) = f(x)$, $f \in A$. Motivated by this, we say that a point $x \in X$ is a Bishop point for $A$ if for each $u \in S(E)$ the
above inclusion holds for some \( s > 0 \). We denote the set of such points for \( A \) by \( \Omega(A) \). Hence \( \Theta(A) \subseteq \Omega(A) \).

In what follows we assume that \( X, Y \) are compact Hausdorff spaces, \( E, F \) are Banach spaces over \( \mathbb{K} \) and \( A, B \) are \( \mathbb{K} \)-subspaces of \( C(X, E) \) and \( C(Y, E) \), respectively. Let \( T : A \to B \) be a surjective, not necessarily linear, isometry. Since, by the Mazur-Ulam theorem, \( T - T_0 \) is real-linear, without loss of generality we assume that \( T_0 = 0 \) and \( A \) is closed in \( C(X, E) \). Clearly \( T \) maps each maximal convex subset of \( S(A) \) to a such subset of \( S(B) \). Hence, by Lemma 2.1, for each \( x \in \eta_1(A) \) and \( K \in \tilde{S}(E) \) there exist \( y \in Y \) and \( L \in \tilde{S}(F) \) such that \( T(V^A_{x,K}) = V^B_{y,L} \). In the case that \( F \) is strictly convex, \( L \) is a singleton and so there exists \( v \in S(F) \) such that \( T(V^A_{x,{\{u}\}}) \subseteq V^B_{y,{\{v}\}} \) for each \( u \in K \). Motivated by this, for each \( x \in \eta_1(A) \) we set

\[
H_x = \{ y \in Y : T(V^A_{x,{\{u}\}}) \subseteq V^B_{y,{\{v}\}} \text{ for some } u \in S(E) \text{ and } v \in S(F) \}.
\]

We also put \( Y_0 = \bigcup_{x \in \Theta(A)} H_x \) and \( Y_1 = \bigcup_{x \in \eta_2(A) \cap \Omega(A) \cap X_0} H_x \), where \( X_0 \) is as in Lemma 3.2. We recall that \( X_0 = X \) if \( A \) contains constants and \( \eta_2(A) = X = X_0 \) if \( A \) is \( C \)-separating.

We note that if \( \Theta(A) = X \) and \( \tilde{S}(F) \) contains a singleton \( \{v\} \) (in particular, if \( F \) is strictly convex), then \( Y_0 \supseteq \Theta(B) \). Indeed, for each \( y \in \Theta(B) \), since \( T^{-1} \) is also an isometry, there exist \( x \in X \) and \( K \in \tilde{S}(E) \) such that \( T^{-1}(V^B_{y,{\{v}\}}) = V^A_{x,K} \). This implies that for each \( u \in K \) we have \( T(V^A_{x,{\{u}\}}) \subseteq V^B_{y,{\{v}\}} \), that is \( y \in H_x \). Hence, in this case \( Y_0 \supseteq \Theta(B) \).

**Lemma 3.4.** Let \( x, x' \in X \) be distinct. In either of cases that \( x, x' \in \Theta(A) \) or \( A \) is \( C \)-separating and \( x, x' \in \Omega(A) \) we have \( H_x \cap H_{x'} = \emptyset \).

**Proof.** We first show that for each \( x \in \eta_2(A) \cap \Omega(A) \cap X_0 \) and \( y \in H_x \) if \( f \in A \) such that \( f(x) = 0 \), then \( T f(y) = 0 \). We note that, by the definition of \( H_x \), there are \( u \in S(E) \), \( v \in S(F) \) such that \( T(V^A_{x,{\{u}\}}) \subseteq V^B_{y,{\{v}\}} \). Fixing \( r \in (0, 1) \), by Lemma 3.3, there exists \( g \in V^A_{x,{\{u}\}} \) such that \( r f + g \in V^A_{x,{\{u}\}} \). Therefore \( T(r f + g)(y) = v \) and \( T g(y) = v \) which implies, by the real-linearity of \( T \), \( T f(y) = 0 \).

Now assume that \( x, x' \in \Theta(A) \) are distinct and assume on the contrary that there exists a point \( y \) in \( H_x \cap H_{x'} \). Since \( \Theta(A) \subseteq \eta_2(A) \cap \Omega(A) \cap X_0 \), it follows from the above argument that \( T f(y) = 0 \) for each \( f \in A \) satisfying either \( f(x) = 0 \) or \( f(x') = 0 \). Let \( u \in S(E) \) and \( v \in S(F) \) be as above. Since \( x \in \Theta(A) \) there exists \( f \in A \) with \( \| f \|_{\infty} = 1 \), \( f(x) = u \) and \( \| f(x') \| < \frac{1}{2} \). Similarly, since \( x' \in \Theta(A) \) we can choose \( h \in A \) satisfying \( h(x') = f(x') \) and \( \| h \|_{\infty} = \| f(x') \| \). Then the
function \( g = f - h \) is an element of \( A \) with \( g(x') = 0 \). Hence \( T(g)(y) = 0 \) and consequently \( v = T(f)(y) = T(h)(y) \). Thus \( 1 = \|v\| = \|T(f)(y)\| = \|T(h)(y)\| \leq \|T(h)\|_\infty = \|h\|_\infty = \|f(x')\| < \frac{1}{2} \), a contradiction.

Consider the case that \( A \) is \( E \)-separating and \( x, x' \in \Omega(A) \). Let \( y \in H_x \cap H_{x'} \) and \( u \) and \( v \) as above. Then, by assumption, there exists \( f \in A \) such that \( \|f\|_\infty = 1 \), \( f(x) = u \) and \( f(x') = 0 \). As before, we get \( T(f)(y) = 0 \) while \( f \in V_{x,\{u\}} \) and \( T(V_{x,\{u\}}) \subseteq V_{y,\{v\}} \), a contradiction. This shows that in both cases we have \( H_x \cap H_{x'} = \emptyset \).

Using the above lemma we can define a map \( \Phi : Y_0 \longrightarrow \Theta(A) \) such that for each \( y \in Y_0 \), \( \Phi(y) \) is the unique point \( x \in \Theta(A) \) with \( y \in H_x \). Clearly \( \Phi \) is a well-defined map which is surjective whenever \( F \) is strictly convex. Similarly we can define a function \( \Phi_1 : Y_1 \longrightarrow \Omega(A) \), whenever \( A \) is \( E \)-separating.

**Theorem 3.5.** Let \( X, Y \) be compact Hausdorff spaces, \( E, F \) be Banach spaces over \( \mathbb{K} \), where \( F \) is strictly convex. Let \( A, B \) be \( \mathbb{K} \)-subspaces of \( C(X,E) \) and \( C(Y,F) \), respectively, and \( T : A \longrightarrow B \) be a surjective (not necessarily linear) isometry. Then there exists a subset \( Y_0 \) of \( Y \), a continuous surjection \( \Phi : Y_0 \longrightarrow \Theta(\overline{A}) \) and a family \( \{V_y\}_{y \in Y_0} \) of real-linear operators from \( E \) to \( F \) with \( \|V_y\| = 1 \) such that

\[
Tf(y) = T0(y) + V_y(f(\Phi(y))) \quad (f \in A, y \in Y_0).
\]

Furthermore,

(i) if \( A \) contains constants, then the map \( Y_0 \longrightarrow B(E,F) \) is continuous with respect to the strong operator topology on \( B(E,F) \);

(ii) if \( A, B \) contain constants and \( T \) maps each constant function to a constant function, then all \( V_y \) are equal to a real-linear isometry \( V : E \longrightarrow F \).

**Proof.** As we noted before, we can assume that \( T \) is real-linear and \( A \) is closed in \( C(X,E) \). Let \( Y_0 \subseteq Y \) and \( \Phi : Y_0 \longrightarrow \Theta(A) \) be defined as above. For each \( y \in Y_0 \), let \( V_y : E \longrightarrow F \) be defined by \( V_y(u) = T(f_0)(y) \), where \( f_0 \in A \) satisfies \( f_0(\Phi(y)) = u \). We note that there exists a function \( f_0 \in A \) satisfying this property, since \( \Phi(y) \in \Theta(A) \). Note also that \( V_y \) is well defined. Indeed, for \( u \in E \) if \( f_0, f_1 \in A \) such that \( f_0(\Phi(y)) = u = f_1(\Phi(y)) \), then \( (f_0 - f_1)(\Phi(y)) = 0 \) and it follows from real-linearity of \( T \) and the argument given in Lemma 3.4 that \( T(f_0)(y) = T(f_1)(y) \). It is easy to see that \( V_y \) is a real-linear operator and since \( f_0 \in A \) with \( f_0(\Phi(y)) = u \) can be chosen such that \( \|f_0\|_\infty = \|u\| \) we have \( \|V_y\| \leq 1 \). Clearly \( Tf(y) = V_y(f(\Phi(y))) \) holds for all \( f \in A \) and \( y \in Y_0 \).
The strict convexity of $F$ shows that for each $x \in \Theta(A)$, $H_x$ is nonempty. Hence $\Phi$ is surjective. To show that $\Phi$ is continuous, let $y_0 \in Y_0$ and $U$ be a neighborhood of $\Phi(y_0)$ in $\Theta(A)$. Choose an open neighborhood $\tilde{U}$ in $X$ with $U = \tilde{U} \cap \Theta(A)$. By the definition of $\Phi$, there exist $u \in S(E)$ and $v \in S(F)$ such that $T(V_{\Phi(y_0)},u) \subseteq V_{\Phi(y_0)}^B$. Since $\Phi(y_0) \in \Theta(A)$, we can find $f \in V_{\Phi(y_0),u}$ such that $\|f(z)\| \leq \frac{1}{2}$ on $X \setminus \tilde{U}$. Then $W = \{y \in Y_0 : \|Tf(y)\| > \frac{1}{2}\}$ is a neighborhood of $y_0$ in $Y_0$ and for each $y \in W$, $\|f(\Phi(y))\| \geq \|V_y(f(\Phi(y)))\| = \|Tf(y)\| > \frac{1}{2}$, that is $\Phi(W) \subseteq \tilde{U} \cap \Theta(A)$ and so $\Phi$ is continuous.

We now show that for each $y \in Y_0$, $\|V_y\| = 1$. Let $y_0 \in Y_0$ and choose $u \in S(E)$ and $v \in S(F)$ as above. Let $f_0 \in A$ such that $f_0(\Phi(y_0)) = u$ and $\|f_0\|_\infty = 1$. Then $V_{y_0}(u) = T(f_0)(y_0)$ and since $f_0 \in V_{\Phi(y_0),u}$ we have $T(f_0)(y_0) = v$. Hence $\|V_{y_0}(u)\| = \|T(f_0)(y_0)\| = 1 = \|u\|$ and consequently $\|V_{y_0}\| = 1$.

To prove (i) assume that $A$ contains constants. Then for each $y \in Y_0$ and $u \in E$ we have $V_y(u) = T(c_u)(y)$. Hence for each net $\{y_0\}$ in $Y_0$ converging to a point $y \in Y_0$, it follows from continuity of $T(c_u)$ that $V_{y_0}(u) \to V_y(u)$, as desired.

Finally to prove (ii) assume that $A, B$ contain constants and $T$ maps constants to constants. For each $u \in S(E)$ we have $\|V_y(u)\| = \|T(c_u)(y)\| = \|v\| = 1$ where $v \in S(F)$ such that $c_v = T(c_u)$. Hence all $V_y$’s are real-isometries and equal. □

**Remark 3.6.** (i) In the above theorem, if $\mathbb{K} = \mathbb{C}$ and $T$ is assumed to be complex linear, then each $V_y$ is also complex-linear.

(ii) If $A$ is assumed to be $E$-separating, then the same argument can be applied to get a similar description of $T$ for all points $y \in Y_1$ and the previously defined map $\Phi_1 : Y_1 \to \Omega(A)$.

(iii) If $T$ maps constants onto constants, then it is easy to see that the real-linear isometry $V : E \to F$ is surjective.

For the application of the results we give next corollaries.

As we noted before, the following (S3) condition has been considered in [11] in some results.

(S3) For each $x \in \text{Ch}(A)$, for each neighborhood $U$ of $x$ and for each $u \in E$ there exists a $f \in A$ such that $\|f\|_\infty = \|u\|$, $f(x) = u$ and $f = 0$ on $X \setminus U$.

Clearly if (S3) holds for $A$, then we have $\text{Ch}(A) \subseteq \Theta(A)$ and consequently $\Theta(A)$ is a boundary for $A$. Now in the next corollary we consider this later condition. Hence this corollary may be compared with Theorem 1.1.

**Corollary 3.7.** Let $X, Y$ be compact Hausdorff spaces, $E, F$ be Banach spaces over $\mathbb{K}$, where $F$ is strictly convex. Let $A$ and $B$ be $\mathbb{K}$-subspaces of $C(X, E)$ and
\( C(Y, F) \) such that \( \text{Ch}(A) \subseteq \Theta(A) \). Then for any surjective isometry \( T : A \to B \) there exist a subset \( Z \) of \( Y \), a continuous surjection \( \phi : Z \to \text{Ch}(A) \) and a family \( \{ V_y \}_y \in Z \) of real-linear operators from \( E \) to \( F \) with \( \| V_y \| = 1 \) such that
\[
T f(y) = T_0(y) + V_y(f(\phi(y))) \quad (f \in A, y \in Z).
\]
Moreover, in the case that \( A, B \) contain constants, and \( T \) maps constants to constants, all \( V_y \)'s are equal to a real-linear isometry \( V : E \to F \) and \( Z \) is a boundary for \( B \).

Proof. The first part is immediate from Theorem 3.5. It suffices to consider \( Z = \Phi^{-1}(\text{Ch}(A)) \) and \( \phi = \Phi \mid Z \). For the second part, assume that \( A, B \) contain constants and \( T \) sends constants to constants. By the above theorem, there exists a real-linear isometry \( V : E \to F \) such that \( V_y = V \) for all \( y \in Y_0 \). To show that \( Z \) is a boundary for \( B \), let \( g \in B \) and \( f \in A \) such that \( T f - T_0 = g \). Since \( \phi : Z \to \text{Ch}(A) \) is surjective and \( \text{Ch}(A) \) is a boundary for \( A \), there exists a point \( y_0 \in Z \) such that \( \sup_{y \in Z} \| f(\phi(y)) \| = \| f(\phi(y_0)) \| = \| f \|_\infty \). Thus
\[
\| f \|_\infty = \| g \|_\infty \geq \| g(y_0) \| = \| V(f(\phi(y_0))) \|
= \| f(\phi(y_0)) \| = \| f \|_\infty.
\]
Therefore, \( \| g \|_\infty = \| g(y_0) \| \), that is \( Z \) is a boundary for \( B \). \( \square \)

We recall that a subspace \( A \) of \( C(X, E) \) is called completely regular if for each \( x \in X \), \( u \in S(E) \) and closed subset \( F \) of \( X \) not containing \( x \), there exists \( f \in A \) with \( f(x) = u \), \( \| f \|_\infty = 1 \) and \( f(z) = 0 \) for each \( z \in F \). Obviously for such subspaces we have \( \Theta(A) = X \). So we get the following generalization of Cambern’s result [4], which is also a generalization of [8, Theorem 1] for not necessarily linear isometries.

**Corollary 3.8.** Let \( X, Y \) be compact Hausdorff spaces and \( E, F \) be Banach spaces over \( \mathbb{K} \), where \( F \) is strictly convex. Let \( A \) be a completely regular \( \mathbb{K} \)-subspace of \( C(X, E) \) and \( B \) be a \( \mathbb{K} \)-subspace of \( C(Y, F) \). Then for any surjective isometry \( T : A \to B \) there exist a subset \( Y_0 \) of \( Y \), a continuous surjection \( \Phi : Y_0 \to X \) and a collection \( \{ V_y \}_{y \in Y_0} \) of real-linear operators from \( E \) to \( F \) with \( \| V_y \| = 1 \) such that
\[
T f(y) = V_y(f(\Phi(y))) \quad (f \in A, y \in Y_0).
\]

In the next theorem we give a similar result for surjective isometries, in not necessarily strictly convex case. We consider the case that \( F \) is a Banach space
whose unit sphere \( S(F) \) has at least a point \( v \) such that \( \{v\} \) is a maximal convex subset of \( S(F) \). Before stating our result we give an example of such (non strictly convex) Banach spaces.

**Example 3.9.** Let \( n \in \mathbb{N} \) and \( K \) be a compact symmetric convex subset of \( \mathbb{R}^n \) with nonempty interior. Then we set \( \|0\| = 0 \) and for each nonzero point \( x \in \mathbb{R}^n \) we define \( \|x\| = \frac{1}{\max\{\|tx\| : t \in K\}} \). Then \( \|\cdot\| \) defines a norm on \( \mathbb{R}^n \) whose closed unit ball is \( K \). In particular, consider the following subset of \( \mathbb{R}^2 \):

\[
K = \{(\sec(\theta), \theta) : \theta \in (0, \frac{\pi}{4}) \cup \left(\frac{7\pi}{4}, 2\pi\right)\} \cup \{(\sqrt{2}, \theta) : \theta \in \left(\frac{\pi}{4}, \frac{3\pi}{4}\right) \cup \left(\frac{7\pi}{4}, \frac{5\pi}{4}\right)\} \\
\cup \{(-\sec(\theta), \theta) : \theta \in \left(\frac{3\pi}{4}, \frac{5\pi}{4}\right)\}.
\]

Then \( K \) satisfies the above mentioned properties and so \( (\mathbb{R}^2, \|\cdot\|) \) is a Banach space with closed unit ball \( K \). It is clear that this Banach space is not strictly convex, and there are infinitely many points in \( K \) which are maximal convex subsets of \( K \).

**Theorem 3.10.** Let \( X, Y \) be compact Hausdorff spaces, \( E, F \) be Banach spaces such that \( \tilde{S}(F) \) contains at least one singleton and let \( A, B \) be \( \mathbb{K} \)-subspaces of \( C(X, E) \) and \( C(Y, F) \) with \( \Theta(A) = X \) and \( \theta(B) = Y \). Then for any surjective isometry \( T : A \to B \), there exist a continuous map \( \Phi : Y \to X \), a family \( \{V_y\}_{y \in Y} \) of linear operators from \( E \) to \( F \) with \( \|V_y\| \leq 1 \), for all \( y \in Y \) such that

\[
T f(y) = T0(y) + V_y(f(\Phi(y))) \quad (f \in A, y \in Y).
\]

If, in addition, \( \tilde{S}(E) \) also contains a singleton, then \( \Phi \) is a homeomorphism and all \( V_y \) are isometries.

**Proof.** As before we may assume that \( T \) is real-linear. By hypothesis, there exists \( v \in S(F) \), such that \( \{v\} \) is a maximal convex subset of \( S(F) \). For each \( y \in Y \), since \( Y = \Theta(B) \), it follows from Lemma 3.2 that \( V_{y,\{v\}} \) is a maximal convex subset of \( S(B) \). Being \( T^{-1} \) an isometry, there exists \( x \in X \) and \( K \in \tilde{S}(E) \) such that \( T^{-1}(V_{y,\{v\}}) = V_{x,K} \), that is \( T(V_{x,K}) = V_{y,\{v\}} \). We note that the point \( x \in X \) satisfying the above equality for some \( K \in \tilde{S}(E) \) is unique. Indeed, if \( V_{x,K} = V_{z,L} \) where \( z \in X \) is distinct from \( x \) and \( L \in \tilde{S}(E) \), then since \( x \) and \( z \) are strong boundary points for \( A \) we can find easily a function \( f \in V_{x,K} \) with \( \|f(z)\| < \frac{1}{2} \), a contradiction. The same argument as in Lemma 3.4 shows that for all \( f \in A \), \( f(x) = 0 \) implies \( T f(y) = 0 \) and consequently for each \( f, h \in A \) with \( f(x) = h(x) \) we have \( T f(y) = Th(y) \). Thus we can define a real linear operator \( V_y : E \to F \)
by \( V_y(e) = Tf(y) \) where \( f \in A \) such that \( f(x) = e \). Since \( X = \Theta(A) \), the above function \( f \in A \) can be chosen such that \( \|f\|_\infty = \|e\| \) and \( f(x) = e \). This shows that \( \|V_y\| \leq 1 \). Clearly \( Tf(y) = V_y(f(x)) \) holds for all \( f \in A \). By the above argument we can define a map \( \Phi : Y \to X \) and a family of real linear operators \( \{V_y\}_{y \in Y} \) such that

\[
Tf(y) = V_y(f(\Phi(y))) \quad (f \in A, y \in Y).
\]

As in Theorem 3.5 we see that \( \Phi : Y \to X \) is continuous.

For the second part, assume that \( \tilde{S}(E) \) also contains a singleton. Then using the above discussion for \( T^{-1} \) we can define a continuous map \( \Psi : X \to Y \) and a family \( \{W_x\}_{x \in X} \) of real-linear operators from \( F \) to \( E \) such that \( \|W_x\| \leq 1 \) and

\[
T^{-1}(g)(x) = W_x(g(\Psi(x))) \quad (g \in B, x \in X).
\]

Thus, for each \( f \in A \) and \( x \in X \) we have

\[
f(x) = W_x(Tf(\Psi(x))) = W_x(V_{\Psi(x)}(f(\Phi(\Psi(x)))))
\]

If \( x \in X \) and \( \Phi(\Psi(x)) \neq x \), then there exists \( f \in A \) with \( \|f(x)\| = 1 \) and \( \|f(\Phi(\Psi(x)))\| \leq \frac{1}{2} \). Hence

\[
1 = \|f(x)\| = \|W_x(V_x(f(\Phi(\Psi(x)))))\| \leq \|f(\Phi(\Psi(x)))\| \leq \frac{1}{2}
\]

which is a impossible. Therefore, \( \Phi(\Psi(x)) = x \) for all \( x \in X \). Similar argument shows that \( \Psi(\Phi(y)) = y \) for all \( y \in Y \), that is \( \Psi = \Phi^{-1} \), in particular, \( \Phi \) is a homeomorphism. By the above argument we have

\[
f(x) = W_x(V_{\Psi(x)}(f(x)) \quad (f \in A, x \in X).
\]

Since for each \( x \in X \) and \( e \in E \) we can choose \( f \in A \) with \( f(x) = e \), it follows from the above equality that \( W_x(V_{\Phi(x)}(e)) = e \) for all \( e \in E \). Similarly, \( V_y(W_{\Phi(y)}(e')) = e' \) for all \( e' \in F \). Hence \( V_y = W_{\Phi(y)}^{-1} \) and \( \|V_y\| = \|W_{\Phi(y)}\| = 1 \), that is each \( V_y \) is an isometry, as desired.
